Results of hypothesis tests
To test the hypotheses proposed in this research framework, structural equation modelling (SEM) was used to assess the model fit with the data. The path coefficients
for the SEM model were shown in Table 3. The fit indices for the model were $\chi^2 = 495.035$, df = 293, normed = 1.690, CFI = 0.926, IFI = 0.927, RMSEA = 0.076, indicating that the model was of good fit.

The results of the hypothesis tests were shown in Table 3. The path coefficient was 0.34 and was statistically significant at the level of 0.001, which supports Hypothesis 1. This result showed that incentive alignment was significant and positively related with CCR-SC. Hypothesis 2 was also supported with a path coefficient of 0.64, which was statistically significant at the level of 0.001. The finding indicated that goal congruence was positively related to incentive alignment. Hypotheses 3, 4 and 5 were also supported.

**Conclusion and limitation**

The present study provides an empirical analysis of the antecedents and consequences of incentive alignment in the setting of CCR-SC, a topic that has been under-researched in previous studies. It verifies the enabling role of incentive alignment to CCR-SC and its antecedent, namely, goal congruence. The resulting CCR-SC can however affect environmental and financial performance. From a research perspective, this study advances empirical investigation in the research areas of low-carbon SCM and supply chain collaboration. From a practical perspective, this study is of interest to managers involved in initiating CCR-SC. As shown by the empirical analysis, managers should collaborate with their supply chain partners, developing common goals and designing aligned incentives, in order to ensure that CCR-SC has a positive effect.

While the research has made significant contributions to the existing literature, there are still limitations that need to be avoided in future study. First, because of the difficulty of data collection, the sample size used in this paper was relatively small. Future research could increase the sample size in order to improve the effectiveness of reliability and validity. Furthermore, this research is based on questionnaire data, which means that the conclusion might reflect the current status of firms, although environmental management practices are dynamic under sustainable development. Future research should consider using a longitudinal study in order to incorporate the changing dynamics of CCR-SC.

Abstract

Profit is the primary objective that every company aims to achieve but, in pursuing it, a company can no longer afford to overlook two aspects, i.e., social and environmental, closely connected to the economic dimension. Scholars are trying to understand what link exists among these three aspects. However, to date researchers have achieved inconsistent results regarding the impact of Corporate Social Responsibility (CSR) on Corporate Financial Performance (CFP). This article aims to explore, through a quantitative analysis, the CSR-CFP relationship, namely, to analyze how CSR actions influence a company's profitability and if the industry is a relevant contingency to consider.

Keywords: Sustainability, Corporate Social Responsibility, Sustainability reporting

Introduction

Corporate social responsibility (CSR) intrinsically entails to take actions towards the simultaneous achievement of the three pillars of sustainability, or, in other words, of the triple bottom line (Elkington, 1998). In fact, CSR has been defined as “context-specific organizational actions and policies that take into account stakeholders’ expectations and the triple bottom line of economic, social, and environmental performance” (Aguinis, 2011). Over the years, multiple attempts have been done in order to test the actual relationships existing among the pillars. As an example, Aupperle et al. (1985) summarize various efforts made between 70s and 80s to examine the relationship between CSR and profitability. Moreover, the authors found evidence of a negative relationship between the economic component of sustainability and non-economic ones, as well as, the companies tendency to consider the non-economic components altogether (Aupperle et al., 1985). Other authors focused their studies on the relationship between CSR and financial performance, finding inconsistent results (McWilliams & Siegel, 2000). Although, Orlitzky et al. (2003), by integrating previous researches through a meta-analysis that allowed to compare studies in an objective way, concluded that a positive association between Corporate Social Performance (CSP) and financial ones exists. In this context, a big challenge is linked to how to measure CSP. Chatterji et al. (2009) found
evidence that environmental and social ratings might not reflect the actual companies’ behavior, when it comes to environmental and social practices. Companies themselves are struggling in measuring their environmental and social performance. Even if some standards to measure environmental (e.g. ISO 14000, ISO 140001, ISO 14031) and social (e.g. SA8000, ISO 26000) performance exist, none of them provide benchmarks about acceptable performance (Hubbard, 2009). To complicate this picture, also multiple CSR reporting standards have been developed, all using different measures and practices. Some examples are Global Reporting Initiative (GRI), UN Global Compact and AccountAbility’s AA1000 standard (Chen & Bouvain, 2009). Consequently, the analysis of the relationships among the three pillars becomes challenging, making it extremely important to clearly define context of analysis, as well as to triangulate information from multiple sources.

Related literature
Over the decades, the topic of CSR has been a central research topic for many scholars and authors that have contributed to creating a real scientific, business-economic debate not only at national level but also an international one. This interest has continued to grow in importance and significance (Carroll & Shabana, 2010). The basic tenet of corporate social responsibility is that society and business are tightly interwoven but scholars are still trying to understand the precise mechanisms behind this link (Wood, 2010).

Nowadays companies have high pressure to be greener. An increasing number of shareholders, analysts, regulators, activists, labor unions, employees, community organizations, and news media are asking companies to be accountable for an everchanging set of CSR issues (McWilliams et al., 2000).

Regarding the definition and measurement of CFP, no significant problems are found in the literature. The indicators used to measure financial performance in studies investigating the relationship between CFP and CSP are generally of two type: accounting-based indicators (indicators derived from accounting data, such as ROE, ROA, ROI) (Aupperle et al., 1985; Margolis, Elfenbein, & Walsh, 2009; Tsoutsoura, 2004) and market-based measures (market indicators, such as the share price) (Moskowitz, 1972).

Instead, Wood (1991, p. 691) defines the CSP as “the configuration in the business organization of principles of social responsibility, processes of response to social requirements, and policies, programs and tangible results that reflect the company's relations with society”.

Indeed, CSP is a very complex system, and therefore its measurement requires equally complex tools, and despite three decades of research, there are no consistent metrics for measuring CSP (Mitnick, 2000; Peloza, 2009). In the literature, there are dozens of metrics that manager and researchers used to analyze CSP. Many scholars have used those indicators that embrace more than one dimension of CSP, for which, therefore, it is not possible to accurately identify principles, processes, and results (e.g. McWilliams & Siegel, 2000; Tsoutsoura, 2004). In addition, despite social and environmental rating agencies seek to make corporations’ environmental data more transparent (Peloza, 2009), many companies are still skeptical in publishing sensitive data and relevant information. Nevertheless, we must emphasize how new sources are becoming increasingly available for researchers including standards and data (Wood, 2010).

Academia has so far focused on the relationship between CSP and CFP to have empirical results able to demonstrate whether socially responsible behaviors are recommended (i.e., improve financial performance) or not. CSR supporters intend to prove that CSR has positive impacts for the company that is reflected directly on the
bottom line (Ambec & Lanoie, 2008; Flammer, 2015; Margolis et al., 2009; Surroca, Tribó, & Waddock, 2010). Opponents, on the other hand, want to show that CSR is expensive and goes beyond the legitimate interests of the company unless there is a direct and studied strategic connection between responsible behavior and profits (Barnett & Salomon, 2006; Bromiley & Marcus, 1989; Frooman, 1997). According to Wood (2010), this inconclusiveness is primarily due to difficulty on the measurement on how the social policies examined directly influence firms’ bottom lines (Russo & Fouts, 1997).

In conclusion, we can say that there is no convincing evidence that the CSR is too expensive; the majority of the evidence leads to the opposite: for companies, it is costly to be socially irresponsible (Wood, 2010). In fact, analyzing the results of the literature, it appears that the most recent studies are showing that there is a positive correlation between the CSR-CSP (Ambec & Lanoie, 2008; Flammer, 2015; Margolis et al., 2009; Surroca et al., 2010). This recent result could be connected to the fact that companies today are called to be more transparent about social and environmental aspects.

**Literature gaps and research questions**

The relationship between CSP and CFP is a thorny topic much debated in the literature. Besides, the analysis of the literature has shown that it has not been identified yet whether there is a relationship between the CSR and CFP and the direction of this relationship. Researchers have tried to understand how the CSR initiatives influence the economic indicator, but also how financial performance has consequences on CSR. The relationship between CSR and profitability could be seen as a two-way association. In this context, gaining a better understanding over the causal relationship between CSP and CFP and its direction is an urgent gap to fill.

Therefore, this article seeks to address the following dual research question:

- **RQ1a**: Do CSR’s activities (environmental and social) have an impact on the company’s CFP?
- **RQ1b**: Do CFP has an impact on the company’s CSR’s activities (environmental and social)?

In addition, we believe industry to be a relevant contingent variable when it comes to assessing the relationship between CSR and CFP. In fact, many articles dealing with the topic of sustainability build on a multi-industry approach and find in the industry a relevant contingent factor to base the discussion of results on (Ciliberti, De Haan, De Groot, & Pontrandolfo, 2011; Formentini & Taticchi, 2016; Schneider, Marcus Wallenburg, & Fabel, 2014). As a consequence, in this article we aim to explore a second research question:

- **RQ2**: Does industry is a relevant contingent variable to consider when studying the CSR-CFP relationship?

Figure 1 displays the model framing the research.
Methodology

Sample

Within the international and national scenario, various forms of social reporting have been developed, thanks to the work of institutions and companies, trying to standardize the reporting formula, in order to avoid falling into self-referentiality (Chen & Bouvain, 2009). Among the various initiatives that aim to define the guidelines for a reporting tool that also includes sustainability issues, the one considered most relevant has been promoted by the multi-stakeholder process of the Global Reporting Initiative (GRI) (Global Reporting Initiative, 2019). Consequently, the sample of firms for this study was drawn from the Global Reporting Initiative (GRI)’s list of corporations. Firms that have published their social report respecting the guidelines developed by the GRI in the time frame from 2010 to 2016 were selected. This choice of this time frame is due to the fact that some data presented in the sustainability reports were not clearly shown in previous years when the theme of sustainability was still not widespread within companies. Moreover, for greater consistency of data, the dataset include data ranging from 2010 to 2016, so that the trend effect over time is taken into account.

According to the numbers of available companies, three industries were selected in order to explore the second research question: automotive, hardware technologies, and telecommunication. The final sample include 64 large (with more than 500 employees) companies with data along the selected timeframe. Table 1 report a summary of the sample.

Measures

Corporate financial performance

From the study of the literature, the most used indicators to correlate the relationship between CSR and CFP are: Return on Equity (ROE), Share Price, Return on Asset (ROA) and Return on Investment (ROI). CFP data were retrieved from Thomson Reuters’s EIKON Database (Financial performance) and Orbis Bureau Van Dijk’s Database (Balance sheet data).

Table 1 reports the detail of the four variables in terms of mean and standard deviation across industries. In order to have normal distributions all the variables were log-transformed.

Environmental performance
The measures of environmental performance were obtained through a content analysis of the reports published by the companies along the analysed timeframe. Content analysis is a method of codifying written text into various groups or categories, so as to be able to compare texts (Krippendorff, 2018; Unerman, 2000). For that reason, the collection of such data was a part of a long process because companies, despite the directives published by the GRI, released different indicators with different units of measurement.

Therefore, in order to obtain more homogeneous and comparable data for each sector, we decided to use four measures for environmental performance derived from the reports and one measure derived from Environmental, Social and Governance (ESG) module accessible in Thomson Reuters’s EIKON Database. Table 2 reports the summary statistics of the variables by industry. The four variables derived from the report (CO2, Waste, Water and Energy) were normalized with respect to the net sales of the companies, thus assuming that emissions and consumptions are proportional to the amount of output produced by a company. Instead the variable derived from EIKON (Environmental) was measured as a total environmental performance as the sum of the single indicators reported in EIKON (Resource use, emissions and innovation). For all the variables high values indicate worst environmental performance. To reach a better shape of the distributions all the variables were log-transformed.

Social performance
Regarding the social performance, we realized that the content analysis of the social reports was not suitable in order to retrieve comparable information about the companies. The measures of social performance were thus obtained from the EIKON database. In particular, both the elementary indicators (Workforce, Human Rights, Community and Product Responsibility) and the sum of the scores (Social) were used in the analysis. Table 3 reports the summary statistics of the variables by industry. For all the variables high values indicate worst social performance. The elementary indicators were not transformed in the analysis, since they were already showing a normal shape, instead the summary score was log-transformed.

Analysis

To answer to the research questions time-series cross-sectional data regression analyses were carried out. First, the non-stationarity of the time series was checked with the Dickey-Fuller test (Dickey & Fuller, 1979). Moreover, the Hausman test to check the suitability of a model with fixed effects against a model with random effects was performed (Hausman, 1978); the more consistent model with fixed effects was selected for all the analyses. The analysis of correlograms allowed us to select a one-year lag as the most suitable to explain the data. Finally, we relaxed the hypothesis of identically distributed errors by clustering the observations according to the company they belong to. In order to capture the variables direct effect, we adopted a hierarchical linear regression model, by adding variables in subsequent models. Moreover, the analyses were replicated in the three industries analysed, in order to assess the industry effect.

Results

The structure of the data allowed us to test causality among the variables. Particularly, we tested both directions of the relationships, as reported in Figure 1. Table 4 reports the results of the models with CFP as dependent variables, and environmental and social performance as independent variables. In all the models, we added the logarithm of the number of employees as control variable and run separate analyses for each industry.

Generally, the results highlight a significant relationship between the environmental performance and CFP. The relationship is different depending on the environmental indicator considered. For some indicators (e.g., environmental in case of automotive, water in case of hardware technologist) the results show that an increase of the environmental indicators, that corresponds to a worse environmental performance, imply an increase in CFP. Instead, other indicators (e.g. waste in case of hardware technologies, water and energy in case of telecommunication) are characterized by the opposite relationship: better environmental performance means better CFP.

Concerning the social indicators, few results are significant and generally better social performance means worst CFP (e.g. in case of automotive).

In order to assess the direction of the relationship between CSP and CFP we performed the analyses also in the other direction. Table 5 and 6 report the results of the models with environmental and social performance as dependent variables, and CFP as independent variables. In all the models, we added the logarithm of the number of employees as control variable.

3741
Concerning the environmental indicators, the results interestingly show that, in general, a negative relationship exists among CFP and environmental indicators. This result is stronger when considering CFP measured at the same time as the environmental indicators for the telecommunication industry. Instead, it is stronger when considering CFP measured with one-year lag with respect to the environmental indicators for the automotive industry. The hardware technology industry instead shows mixed results.

Concerning the social indicators, few significant results are present. The telecommunication industry seems to benefit the most from better CFP, when deciding to invest on social sustainability.

Having conducted the analysis on three different industry allows to answer to the second research questions, by concluding that the results about the previously analysed relationship are context dependent.

Concerning the social indicators, few significant results are present. The telecommunication industry seems to benefit the most from better CFP, when deciding to invest on social sustainability.

Having conducted the analysis on three different industry allows to answer to the second research questions, by concluding that the results about the previously analysed relationship are context dependent.
Discussion and conclusions
The relationship between CSR and CFP has been extensively explored in literature. Even if the latest research defines that a positive relationship exists (Flammer, 2015; Margolis et al., 2009; Surroca et al., 2010), the review of the literature showed that the analysis conducted by the scholars engendered varying and mixed results (Wood, 2010).

The results of the analyses allowed to answer to the three research questions of this study. First, through the analysis of time-series cross-sectional data we were able to test causality between CSP and CFP. Concerning environmental performance, we found significant causal relationships in all the industries, but with different environmental indicators being significant and with different signs according to the industry under analysis. By looking at the relationship in the opposite direction, usually different environmental indicators, with respect to the ones identified in the previous direction, are significantly affected by CFP. The most interesting result is that the relationships from CFP to environmental performance are usually negative, meaning that companies with better CFP are more prone to invest also in environmental sustainability, even if it may not pay. Concerning social performance, we found few significant causal relationships, with most of them being from the automotive industry. This industry is generally characterized by the association between better social performance and worst CFP. By looking the relationship in the opposite direction, the casual relationship between CFP and social performance seems to exist only in the telecommunication industry, in which better CFP supports a reduction in the community and product responsibility indicators, but a worsening of the workforce indicator. In summary, the results support the bidirectionality of the relationship between CSP and CFP identified in literature, but this study takes a step further by highlighting that the relationship is beneficial when developed from CFP to CSP (negative relationships), while the opposite is not always true (positive relationships). This represent a major implication for companies, that have better to become first solid from a financial point of view and then start investing on CSR, in order to enlarge the company strategy to embrace also the environmental and social dimensions. In addition, from the analyses it has emerged that the relationships differ among the industries chosen and analyzed, thus answering to the second research question. This generates a warning for companies aiming to move towards full sustainability, given that the context in which they operate strongly affect the benefits they can obtain. Joint efforts should be carried out by companies within industries with similar characteristics in order to accelerate the path towards complete sustainability. Policy makers will play a critical role in supporting this kind of efforts.

In conclusion, this research contributes to bring evidence about the relationships among CSP and CFP, by relying on multiple data sources from which information was retrieved about companies’ effort towards sustainability. In addition, both qualitative and quantitative indicators to measure sustainability are defined in this study, thus leading the way for future analyses in different contexts and on a wider scale, allowing to overcome the main limitations of this study.

Abstract

Sustainability in supply chains around the world have an increased importance due to the complex systems involved in different geographical regions. Sustainable supply chain management (SSCM) literature was reviewed along with the Base of Pyramid (BoP) and Triple Bottom Line (TBL) approaches. It is noticed that several factors remain understudied when it comes to Latin America, as the agricultural practices and traditions, cultural influence, geographical and climatic aspects, and institutional considerations. Two cases in the cocoa production industry in Ecuador were compared analysing their drivers and challenges for sustainability and, their strategies used for sustainable supply chain management.

Keywords: sustainable supply chain, Latin America, cocoa production

Introduction

Sustainable Supply Chain Management (SSCM) research in the bottom of the pyramid markets (Prahalad, 2012) had been developed in few developing countries. Authors have claimed that Latin America as a region is an important contributor to the global economy and thus deserves more scholarly attention because its rich potential source of data for research (Martínez and Kalliny, 2012).

Sustainable supply chain management in Latin America should be studied beyond the triple bottom line (Fritz and Silva, 2018) because of various reasons that limit companies to develop stronger business models and supply chains, e.g., the lack of infrastructure, poverty and security issues, local conditions, routines and institutions (Blanco and Paiva, 2014; Fritz and Silva, 2018). In particular, the study of SSCM in Latin America, and specifically in the Andean Region, is relevant given its cultural background that involves traditions influenced by climate conditions, history and social interactions and routines (Fritz and Silva, 2018). According to Fritz and Silva (2018), in Latin America the main motives for SSCM are innovation, risk management, trust, power, working conditions, traditions and culture, among others, which are overall similar for developed countries except for how to manage trust and power, traditions and culture. Considering that Ecuador, counts with up to 98% of micro and small companies (INEC, 2016), their approach for sustainability is expected to differ to the traditional view.

The study analyzes the cocoa production and transformation in Ecuador considering companies that produces chocolate bars in different configurations, with certified or non-
certified cocoa, and address different consumption markets. Hence, the aims in this study are i) to identify the main sustainability issues, challenges and competitive advantages for applying SSCM in the cocoa production in Ecuador, and ii) to identify the possible SSCM strategies that companies apply in this sector, in this country. The paper is organized as follows: the research background is set around sustainability and supply chain management, in particular in Latin America and the bottom of the pyramid sectors. Afterwards, the research questions and methodology are presented, followed by the cases description and analysis; finally, the discussion and conclusions.

**Research Background**

**Sustainability and SDGS**

A big start to develop the sustainability subject was the World Committee in Environment and Development in 1987 where the Brundtland report was published and the urge to consider sustainable ways of production and consumption to preserve natural resources for next generations was proposed (WCED, 1987). The 2030 Agenda for Sustainable Development provides the Sustainable Development Goals (SDGs), which are a call for action by all countries to contribute in a global partnership to tackle climate change through strategies that spur economic growth and reduce inequality (UN, 2015). In relation with our study, the SDGs that are considered in cocoa production are 1. No poverty, 2. Zero hunger, 8. Decent work and economic growth, 9. Industry, innovation and infrastructure, 12. Responsible consumption and production, 16. Peace, Justice and Strong Institutions, and finally number 17. Partnerships for the goals.

The Brundtland report brought into consideration corporative strategies such as Corporate Social Responsibility policies (CSR) and the Triple Bottom Line (TBL). In one hand CSR is defined by the World Business Council for Sustainable Development (WBCSD) as the “continuing commitment by business to contribute to economic development while improving the quality of life of the workforce and their families as well as of the community and society at large” (WBCSD, 1998). In particular, the food and beverage manufacturing sector face similar challenges concerning sustainability, food security, ethical sourcing of raw material, and increasing demand for healthier products. Firms in the food-manufacturing sector also face issues within CSR like responsible use of natural resources, responsible usage of energy and water, as well as labor standards and supply chain management (Puggioni and Stefanou, 2019). The shared view about economic strategies in business recommend that sustainable development approaches and CSR should be considered to ensure a balance between natural resources reserves, economic growth and social progress (Pirnea et al., 2011).

In the other hand, the Triple Bottom Line (TBL) considers the economic, environmental and social factors explored to obtain sustainability in business. When it comes to sustainable business practices, the economic factor is always important, the environmental factor is generally important, and the social factor is important at some extend. The TBL framework helps firms as a guide to plan, implement and follow-up corporate considerations (priority and importance) of the longitudinal aspects of sustainable business practices (Høgevold et al., 2019).

Furthermore, new concepts and methodologies have arisen regarding sustainability implementation. According to Visser (2015), system change is a multiplayer game that includes issues such as Safety and Social issues (S2), Quality issues (Qu), Environmental, Economic and Ethical issues (E3), Labour issues (L), Carbon or Climate issues (C), and finally Health and Human rights issues (H2) called by the author as SQuELCH issues. Creating integrated value (CIV) aims to help a company to integrate governance practices and value chain linkages applying life-cycle thinking.
Sustainability and SCM studies
Sustainable Supply Chain Management (SSCM) was defined by Seuring and Müller (2008) as, “the management of materials, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social into account which are derived from customer and stakeholder requirements. In sustainable supply chains, environmental and social criteria need to be fulfilled by the members of the networks to remain within the supply chain, while it is expected that competitiveness would be maintained through meeting customer needs and related economic criteria” (Seuring and Müller, 2008, p.1700). These processes of innovation in SSCM are, however, important due to the considerable impact showed as sustainable practices and because of the complex intra-firm challenges (Koster et al., 2017). In the other hand, poverty alleviation is still a main subject to tackle through rural development. The environmental and social crisis can be addressed by community engagement with their skills in managing resources, larger farmers dominate the best agricultural land and small farmers take control of more fragile lands.

Sustainability change agents from developing and developed countries seek to contribute to sustainable development; however, most of the studies are Eurocentric when it comes to sustainable practices according to Demssie et al. (2019). Nonetheless, a base of the pyramid context (BoP) refers to socioeconomic characteristics of mainly developing countries including some common characteristics as rural population, limited infrastructure and low per capita income (Demssie et al., 2019) remain understudied.

Following some literature review from the base of the pyramid (BoP), Prahalad (2012) refer to it as the bottom tier of the world income pyramid where most of the people live in moderate and extreme poverty. Furthermore, Hahn (2009) suggests a holistic view that embraces poor communities as a main part of international supply chains and productive processes. Consequently, Gold et al. (2013) analysed food projects in the BoP as an option to achieve sustainable supply chain management (SSCM) and as a path to TBL approaches for organizations worldwide. Authors exemplified that multinationals like Danone, BASF and Nestlé provided cooperation through education, technical assistance, implementation of Good Agricultural Practices, and, training to conduct quality checks. These initiatives resulted in a combination of SSCM and BoP focused on the double bottom line (social and economic) and it could be transferred to other regions of the world or business fields (Gold et al., 2013).

Sustainability studies in Latin America
According to Jabbour and Jabbour (2014) when it comes to address sustainable development it is important to consider the region of study and the social and environmental aspects involved to understand the possible opportunities and restrictions in management. The authors propose a wide opportunity of research in Latin America since it has similar problems as other regions in the world such as the role of government, CO₂ emissions control, generation of clean energy, institutional economic, social and environmental issues and changes.

The authors Blanco and Paiva (2014) mention how the Latin American region is underrepresented in SCS research and therefore the opportunity of addressing relevant issues in the region. Latin America is considered a diverse place due to the geographical aspects, different cultures, highly urbanised populations and climates. Even though Latin America is a potential market to develop, the search for sustainable supply chain management must include businesses and academics in the region willing to leverage the
future growth of Latin America (Blanco and Paiva, 2014). The two additional elements to study in sustainable supply chains, according to Fritz and Silva (2018) are cultural and institutional. The former refers to local traditions that could influence the meaning of sustainability in the region. The latter implies the political environment that could foster or prevent sustainable practices in the region.

Hence, the need for further information in Latin America, since most of the literature about sustainability in the supply chain, about cocoa production refers to regions in Africa, Asia, and mainly in Brazil, as part of South America, call for research in the region. For instance, other producing countries as Ecuador, that is in the top 10 world cacao producers according to FAO statistics (FAO, 2019), have specific characteristics that could determine its approach to sustainability. Agricultural practices, land use for agricultural production, dependence on agriculture as main income for economic and social development, smallholders’ size, sustainable management of natural resources, population growth, and access to technology, among others are features that could shape the strategies that companies deploy for growth and sustainability.

**Research questions and method**

In line with Fritz and Silva (2018), our study intends to contribute to supply chain sustainability (SCS) theory and practice by including local characteristics in the analysis of sustainability in food industry beyond the triple bottom line. Hence, our study aims at understanding how sustainability is approached in this industry in Ecuador, given the special production characteristics, challenges and opportunities, and identifying the benefits and challenges of implementing sustainability –beyond the triple bottom line-. Moreover, considering that regional specificities draw the SCS strategies in Latin America, according to Fritz and Silva (2018), our study aims at identifying the strategies that companies in Ecuador, in the cocoa production and transformation, are applying for managing their supply chains while considering sustainability as part of it. Thus, the research questions in this study are:

*RQ1. What are the main sustainability issues and challenges in the SSCM in the cocoa production in Ecuador, and how they contrast with the traditional SSCM view?*

*RQ2. What are the possible strategies of sustainable SCM in the in the cocoa production in Ecuador?*

**Research Methodology**

Considering the most recent academic research developed in Latin America (Jabbour and Jabbour, 2014, Fritz and Silva, 2018) in the topic of sustainability in supply chains, we identified the main areas, methodologies, objectives and industries covered in previous contributions. Following, our study analyzes two cases dealing with cocoa transformation and production in Ecuador, a country in the Andean Region. As Martínez and Kalliny (2012) mentioned, the case study methodology represents a complementary perspective for research in Latin America. The authors explain how case studies could address complex phenomena and provide in-depth and inductive understanding in the region (Eisenhardt, 1989; Eisenhardt and Graebner, 2007; as cited in Martínez and Kalliny, 2012). The analysis is performed first within case and then cross-case with the goal of finding commonalities and differences that shape each one’s strategy for sustainability.

**Findings**

*Cocoa production, transformation and trade*

Cocoa chains are globalized and complex and their concern for sustainability extends from the producing regions or origin to the consumption stages. Africa is the main
producer, accounting for around 65% of the bean's world production, while the European Union is the world’s leading grinder (ICCO, 2018a). Approximately 2/3 of world production is exported in the form of beans, with almost 1/3 being exported in the form of cocoa products (liquor, butter, cake or powder) (ICCO, 2018b). Farmers with an average of 3 Ha, and average production of 350 Kg /Ha mostly produce cocoa. Around 14 million workers in the world depend on cocoa production (FAO, 2010; Vorley and Fox, 2004). Cocoa tree varieties produce two bean categories: fine of flavour, and bulk. The ICCO defines fine or flavour cocoa as the category coming from tree varieties with specific genetic and morphological characteristics that produces beans with especial aroma and flavour (ICCO, 2017). From all the cocoa world production, 5% is fine cocoa (ICCO, 2017). The bulky or ordinary is the most produced cocoa bean in the world (ICCO, 2018a; ICCO, 2018b).

Once harvested, the cocoa beans go through two main processes: fermentation and drying, and, bagging and delivery. Quality control or grading is applied to a random sample before shipping, and after delivery. Cocoa trade associations and national authorities establish the type of test to be performed. Trading and shipping can happen in two kind of markets, physical and futures (ICCO, 2018a; ICCO, 2018b). Cocoa market liberalization resulted in new market structures: increase dominance of national trade networks by multinationals (intra-firm trade), and, few opportunities have emerged for smallholders to upgrade to higher value ‘buyer-driven’ cocoa chains (ICCO, 2018b; Vorley and Fox, 2004).

Hence, the cocoa supply chain is wide and complex due to the structure and characteristics of the main agricultural producers in Africa, Asia and the Americas, combined with the features of the cocoa manufacturers in Europe and Northern America (ICCO, 2018b; ICCO, 2016). In the upstream, cocoa bean production represents an important income for developing countries around South America, Asia and Oceania, according to the FAO (FAO, 2019). The World Cocoa Foundation announced that more than 90% of the world’s production of cocoa comes from small producers and it generates dependence on crop production for their livelihood of approximately 50 million people (World Cocoa Foundation, 2013). In the downstream, SSCM strategies had been applied in North America and Europe, where 70% of the top 10 chocolatiers belong to these regions according to the ICCO (2016).

**Cocoa industry in Ecuador**

Ecuador is said to be the largest fine or flavoured cocoa producer and exporter in the world (Ecuador and chocolate, s.d) and is in the top 10 world cacao producers according to FAO statistics (FAO, 2019). Cocoa production in Ecuador is dedicated up to 75% production to the fine or flavour category (ICCO, 2017; Anecacao, 2015). Its geographical location and biological resources favour fine cocoa production with its high level of purity and special flavour and aroma.

The cocoa production and export have been fundamental in the country’s economic development since before the Europeans arrived and colonized the continent, representing today up to 700 million dollars industry (Anecacao, s.d; Ecuador and chocolate, s.d). In the 16th century, as Spanish colony, the cocoa production in Ecuador flourished and was recognized for its quality and aromas. In the late 19th century, Ecuador becomes the first exporter in terms of volumes thanks to its soil and temperatures that favoured especially the ‘National’ variety. Pest and diseases at the beginning of the 20th century gravely reduced production to the lowest levels in history. Moreover, lack of transport means and international market difficulties due to the World War I, caused the Ecuadorian economy crisis and instability (Anecacao, s.d.)
In the National Development Plan of Ecuador (2017) for the year 2021, the aim is to shift from being a country that mainly extracts resources to be a local producer of finished goods, in this case, cocoa that becomes chocolate. According to the National Secretary of Development and Planning of Ecuador (SENPLADES, 2017), sustainable practices are mainly supported due to the objective of managing natural resources in a responsible way, creation of win-win situations, and increased value through alliances with local suppliers to achieve local development. The increasing demand for fine chocolate beans means there is a potential chance for growth, thus, cocoa provides an alternative production for small-scale farmers threatened by food insecurity and climate change (FAO, 2018). Hence, in the last years, the industry is moving toward an adding value strategy and several local brands have focused on producing with ‘fine or flavour’ cocoa and exporting chocolate bars to the main North American and European markets (Ecuador and chocolate, s.d).

**Case 1: Chocolate manufacturer**

This company is a non-profit organization producing mainly food (but also small handcrafted objects) founded in the 70’s. Today the company merges 60 cooperatives and associations and it is based in a small town located in the Ecuadorian Andes. Profits are reinvested in public works as roads, building improvements and infrastructures. These positive actions have reduced the migration phenomenon and led to a balanced social and economic growth in the respect of the environment.

Case 1 produces mainly food products using Ecuadorian raw material as cocoa, nougat or cheese. Cocoa is only a segment of their production (5-8% of sales) but focusing on that, the key partners are the cocoa cooperative in Esmeraldas province producing the cocoa and the logistics provider for the export, even if most of the customers are domestic. About export, the company has few relationships, in France and Japan, and these customers share the commitment to fair trade. The plant is also organic certified for the European standards. They work mainly in a make-to-order configuration with both national and international customers. Key activities in cocoa processing are the chocolate manufacturing and commercialization, managed by their ‘export centre’ that manages also the customers’ relationships. Distribution channels are mainly focus in national markets, while in export are the customers that resell the products. Case 1 produces high quality organic products.

The company complies with all the regulations and requirements of the organic certification by keeping records and visiting the farms. For Case 1, law, regulations, and transparency are the main drivers for traceability. The company is also devoted to highlight the quality of the product and the commitment to the promotion of local Ecuadorian products. Instead, barriers for traceability are the setup costs and documentation associated to the organic certification that requires dedicated processing in the production line other than long cleaning and preparation. Besides, the cost of the certification itself that is very expensive for the business it represents.

Specifically, about sustainability, the company’s commitment to social development is its main axe of action. First, the company buys cocoa beans at a higher price than the stocks, in order to guarantee supply and safeguard the environment, but also for helping better quality of life in the communities. Additionally, the company supports the local community through helping senior and handicapped citizens, collaborating with the social welfare ministry, supporting education and provides housing and food. Case 1 is also a religious foundation and they support to develop new leaders in the community. The foundation works also with women associations for the handicrafts and textile industries, working to help them organize and define a line of production. In this way, women can
identify and develop their products, giving them the possibility of an income that is also a way of emancipation.

These company values and top management commitment is the basis of Case 1’s business strategy, for which to continue the social work, the products selling, and export are to be developed. Instead, the barriers are the costs, complexity and effort, because of the multitude of projects absorb many resources and time to be implemented as well as the cost certification, and low domestic demand for certified products.

Case 2: Coffee roaster and chocolate manufacturer
This company was created by the merge of two family businesses. The main operations in the company are chocolate manufacturing and coffee roasting. The company is based in Quito and is completely committed to high quality Ecuadorian chocolate (Nacional) and specialty coffee, all organic certified. With cocoa, they process the green beans brought up to the production plant into different varieties of chocolate bars. The brands are growing in visibility, in the local and international markets. For export, the company got the organic certification for the European and US markets. The only own point of sale is in Quito for smaller or private customers buying directly. Larger customers, as supermarket chains, require direct delivery. The company have their own small fleet for that. On-line sales are the third channel.

About traceability, the company controls every shipment and makes sure all the documentation regarding certification and origin is compiled. This documental traceability system allows the company to demonstrate the “from bean to bar” philosophy. Traceability for Case 2 is complex because ensuring organic origin for all the ingredients is challenging and costly. This is also a limitation for product innovation and new product development, and only the compliant ingredients are blended in exported products. Therefore, drivers for traceability are law and regulation compliance, quality. Barriers are instead the cost of the certification, most of the time not attractive for farmers, and documentation and formalities.

The company values are grounded in sustainability and collaboration and are supported by top management commitment. For the upstream chain, the company pays higher prices than the price stated by the government. For Case 2, it is not a matter of beating competition, but of loyalty and trust. In addition, it is a strategic choice because the company does not have the competencies to work the land; therefore, it needs to create strong, close and loyal relationships with suppliers. This, however, entails some challenges as higher costs, and a complexity and effort in managing numerous close supplier relationship, and the effort to motivate suppliers to be certified. This is accompanied by low domestic demand for certified products that create a strong barrier for the company.

Discussion
Sustainability drivers and barriers in the cases studied
For answering the first research question, the coding for the cases' analysis was based on the constructs proposed in previous literature regarding the drivers for sustainability. Regulations and stakeholder pressures, company’ social and environmental concern (company values), green image and reputation and top management commitment, economic benefits and collaboration (Walker et al. 2008; León-Bravo et al. 2018; Bloemhof et al. 2015) are commonly cited. From the cross-case analysis, it was noticed that the cases shared some reasoning when developing sustainability initiatives or projects. Similarly, both cases reported commonalities that restrain their sustainability adoption, as cost, complexity for implementing sustainability and adopting certifications,
difficulty to locate the product in the market expecting premium prices, e.g. low domestic demand for certified products (FAO, 2010, León-Bravo et al. 2018, Bloemhof et al. 2015, Fritz and Silva, 2018).

Although the drivers and barriers for sustainability observed in the Ecuadorian cases are somewhat aligned with previous literature (Walker et al. 2008; Bloemhof et al. 2015), they also provide some insights pointing at a wider consideration of sustainability in the cocoa production and transformation in Ecuador. Drivers as “export potential” and “collaboration” delve into the need for understanding first, the probability of achieving business opportunities abroad if sustainability is part of their activities. Such probability depends as well on the current institutional structure that may or may not facilitate expanding operations to a more adding value manufacturing strategy, facilitate access to exporting procedures and actually perceive economic gains from exporting. Second, collaboration in our cases meant to build closer relationships mainly with suppliers, either for ensuring quality and quantity of supply, or for being a part of the social and economic development in the cocoa growing areas. In turn, this could enhance the brand image in the local and international markets.

Similarly, the barriers for sustainability observed in our cases are in line with previous literature (Walker et al. 2008; FAO, 2010; FAO, 2018), they also reflect the specific cultural, social and geographical characteristics of the cocoa production in Ecuador. For instance, being the local market small and the international difficult to access, sustainability results costly to implement and indeed not worthy. Even though the cocoa quality is renowned, companies feel compelled to adopt certifications in order to access markets that could appreciate the effort and pay higher prices.

Strategies for SSCM in the cases studied
Building on Fritz and Silva (2018) framework that called for including the regional specificities in sustainable supply chain research, the cases analyzed here suggest the adoption of different SCS strategies than the traditional triple bottom line. Case 1 prioritizes its attention to the social problems and institutional complexities affecting the communities when deciding its business strategies and sustainability activities. Moreover, the focus on the local market preferences, the company opted for engaging the community, highlight the cultural and social value of its product, empowering and integrating the community. On the other hand, Case 2, being a for-profit company, prioritize its economic development leveraging on the institutional needs for farmers to count with a structured buying scheme that keep prices constant and appreciate the beans quality. In addition, Case 2 differentiates the product for national and international markets considering consumer preferences including local ingredients connected with the national traditions, which in turn as in Case 1 promote local development.

Therefore, the initiatives, projects and practices implemented in these Ecuadorian cases as their SSCM strategies can be shaped within the Fritz and Silva (2018) five-star framework. Case 1 considers the institutional, social and cultural angles as priorities for sustainability; while Case 2 takes into account the economic, cultural and institutional ones (See Figure 1). The SSCM strategies in these Ecuadorian cases are also in line with the double bottom line, i.e., economic and social, that should be prioritized in bottom of the pyramid markets as Gold et al. (2013) explained.

Conclusion
This study intends to contribute to literature on two main streams. On one side to sustainability management in developing countries, given the scarce research in the Latin America, specifically in the Andean region. This study provides empirical evidence about
the particularities, drivers and barriers that characterize sustainability understanding and implementation in the cocoa production and transformation industry in Ecuador. On the other side, this study investigates how cocoa producers in Ecuador deal with stakeholder expectations for sustainability in the local and international markets and shape their strategies according to the specific context characteristics (Figure 1). Similarly, findings in this study could be interesting for practitioners to identify the possible strategies of sustainable SCM in the Andean region, in the cocoa production industry. As pointed in literature and evidenced in the cases in our study, sustainability in Latin American companies encompasses institutional and cultural aspects along with the traditional triple bottom line and are still understudied. Hence, future research in this topic could also study intermediate actors in the chain as traders and logistic carriers, or enlarge the sample with buying companies in other geographies that have an established sustainability strategy that could contrast the ones in the supplying markets, to include companies dealing with non-certified crops. Other avenues of research could also involve the access to technological and financial tools for developing sustainability in the region.

Abstract
Traceability can serve multiple goals in the food industry. This study focuses on the coffee supply chain, which is globally dispersed and in which different traceability solutions respond to the need of mandatory and voluntary quality standards, certifications of origin, but they also create the ground to report on sustainability related practices and performance. By analyzing 10 case studies at different stages of the coffee supply chain, this study provides a taxonomy of the traceability systems and investigates how these systems are implemented, i.e. technological solutions, information width and depth, as well as the relationship with sustainable value creation.

Keywords: traceability, sustainability, coffee industry

Introduction
Consumers around the world increasingly demand for food that is not only safe but also ethical, organic, generates low carbon footprint, etc., which in turn calls for better and more efficient traceability systems (Dabbene et al., 2014). Nonetheless, traceability requires substantial investments in technology and processes aimed at tracking goods along the supply chain. Cost is still proving to be a difficult barrier to overcome (Norton et al., 2014; Kuit and Waarts, 2014; International Trade Centre, 2015), especially in the first production phases (Dabbene et al., 2014; International Trade Centre, 2015). On the other hand, the benefits of traceability could be spread along food supply chains (Dabbene et al., 2014): for managing risks, keeping consistency and market specific product features, efficient recall procedures, keeping a chain of custody (Norton et al., 2014; International Trade Centre, 2015; Karlsen et al. 2013). Traceability helps to achieve operational efficiencies, cost reductions, increased productivity and reputational benefits (Norton et al., 2014; Karlsen et al. 2013; Stranieri et al. 2017). In particular, traceability for sustainability in food chains can be a tool to guarantee products features, e.g., origin, quality, respect for people and environment, all along the supply chain (Norton et al., 2014; Kuit and Waarts, 2014).
In this vein, traceability can represent an interesting mean to “reduce the information distance”, typical of a global supply chain. Coffee supply chain represents an interesting and challenging context in these regards. Coffee industry employs millions of farmers throughout the tropical and subtropical regions of the globe (DeFries et al, 2017). As means to gain control of the more remote activities in their value chains, different traceability solutions are emerging in this context. In addition to the standard voluntary certification schemes developed in the industry (i.e. Fairtrade, UTZ and Rainforest Alliance), some well-known coffee roasters in the western economies have developed their private certification initiatives (Alvarez et al., 2010; Longoni and Luzzini, 2016). Current debate in the literature questions whether these forms of traceability systems are driven by quality or sustainability needs and goals (Garcia-Torres et al., 2019). Moreover, other technological options could serve the same scope, allowing also to shorten the information distance in a supply chain that typically expands globally.

In light of these considerations, the objectives in this study are i) to identify the traceability systems implemented by different actors along the coffee supply chain, and, ii) to analyse how traceability systems are related with the achievement of sustainability goals in the coffee industry. This study analyses multiple cases covering different stages in the coffee supply chain. Companies are located in different geographical areas, allowing for a broader view of traceability and sustainability implications.

The paper is organized as follows: in the next section, the research goal and design are reported; then the methodology is described. Following, it illustrates the main findings of the cross-case analysis and then conclusions end the paper.

**Conceptual Background**

**Traceability in commodity chains**

Food quality and safety are expected from food supply chains and they could be ensured through traceability (Dabbene et al., 2014; Karlsen et al. 2013). Several definitions of traceability are proposed. For instance, the Food and Agriculture Organization (FAO) defines traceability as “the ability to follow the movement of a food through specified stage(s) of production, processing and distribution” (Codex Alimentarius, 2006). In Europe, a definition of traceability in agri-food supply chains is stated as “the ability to trace and follow a food, feed, food producing animal or substance intended to be, or expected to be incorporated into a food or feed, through all the stages of production, processing and distribution” (European Commission, 2002). Other organizations as the International Trade Centre, the International Organization for Standardization also offer their definitions considering identification, tracing and tracking.

Traceability systems (TS) provide information on the components, parts, and materials as well as information on product transformations throughout the value chain. TS ensure the accuracy of information, such as product quality, safety and labelling (Norton et al. 2014). According to the International Trade Centre (2015), the key components of traceability systems are the identification of units, the registration of information and the system linking and sharing information. In addition, according to McEntire at al. (2010) and as cited by Stranieri et al. (2017), four elements characterize the level of traceability: breath (number of attributes), depth (how far upstream or downstream in the supply chain), precision (how accurately is the attribute characterized) and access (how fast a supply chain member can visualize the tracking and traced information).

The information gathered through traceability systems has huge potentials in efficiency gains (Costa, et al., 2013), food process control and, quality and identity preservation (Dabbene et al., 2014; Smith, 2018). In particular, traceability for sustainability in food supply chains addresses diverse challenges due to company
capabilities, skills, interest and willingness and, multiple requirements are needed for implementation (International Trade Centre, 2015). Indeed, only a very small percentage of food commodities are traceable on sustainability attributes (Norton et al., 2014; Kuit and Waarts, 2014), maybe because of its barriers: often suppliers are dispersed in the world, language, legal or technology barriers exists (Norton et al., 2014).

Certification schemes became popular as traceability systems addressing a wide range of attributes, among which sustainability. Certifications on agri-food commodities have become particularly important given an increased stakeholder pressure (Rajeev et al., 2017; Kolk, 2012; Reinecke et al., 2012) among which also governments have progressively increased their attention (Vermeulen and Kok, 2012). DeFries et al. (2017) identified four main reasons why commodities, as coffee, are focused of certification schemes. These reasons are: low state-level governance opening the development of certification standards by private sector and NGOs, poverty in the producing regions where farmers deal with low prices and climate change issues, the need for habitat conservation, and the effects on trade in global supply chains (DeFries et al., 2017; United Nations, 2015). The authors also highlight the recognition of premium prices, as consumers “will only be willing to pay more if they trust the certifying entity to achieve positive impacts” (DeFries et al., 2017)

Coffee certification schemes as traceability systems for sustainability are varied in their scope, premium prices paid and requirements. The most known certification schemes in this industry are Fairtrade that focuses on social elements; Rainforest Alliance that fosters ecosystem and biodiversity preservation; the Organic certification; UTZ certification that is specialized in coffee and cocoa, and focuses on traceability. Currently, UTZ and Rainforest Alliance are merging and they announced a completion of a single standard by the end of 2019 (Utz, s.d.).

Sustainability in the coffee industry
Latin America is the main coffee producer region, particularly Brazil. Two main species are recognized, Arabica and Robusta (ICO, 2017). The quality criteria is related to the altitude/region, rain feed or irrigation, species or varieties, processing method (wet or dry), bean size, density, shape and colour, number of imperfections, roast and appearance (ICO, 2017). Half of the world's coffee supply comes from small farms with less than 5Ha (ICO, 2017; Vorley and Fox, 2004).

Commodity chains, as coffee, are said to be important contributors to global greenhouse gas (GHG) emissions, from food production (and its inputs) through food processing, food distribution and consumption, to the disposal of waste (FAO, 2010). Processing, trading, transport, roasting, packaging, retailing, brewing, serving, etc., have also important contribution to emissions, communities’ well-being and employment (FAO, 2010; ICO, 2017).

Particularly the upstream actors face sustainability challenges as they deal with several constraints and restrictions. For instance, regarding economic development: price volatility, lack of long-term contracts and spot transactions that create a huge uncertainty for farmers and cooperatives, limited access to credits or financial aid, side selling for solving short-term liquidity problems (Ortiz-Miranda et al., 2015; Luna and Wilson, 2015). Instead, in the environmental side, farmers struggle with pest and diseases and the need of using pesticides and fertilizers (Ntiamoah and Afrane, 2008), climate change i.e., rising temperatures and rainfall variability, decrease yield, reduce quality as well (Ovalle-Rivera et al., 2015). These economic and environmental challenges are in turn closely related to the social development in the producing regions (Vorley and Fox, 2004; Pay, 2009; Winston et al., 2005).
Coffee industry employs millions of farmers from whose sales often represent a significant portion of export. Coffee prices are determined in the futures markets. Selling far ahead is considerably risky (Pay, 2009). Low prices are driving poverty, ill health, unemployment, lack of education and forced migration, and a risk of increasing crop diversification (Pay, 2009; Winston et al., 2005). Besides, farmers in producing regions face lack of technical competences for specialty or organic production that require specific agronomic knowledge to improve yields and quality (Ovalle-Rivera et al., 2015).

On the buying side the demand is strong in many countries, particularly in North America, Europe and Japan; but the biggest potential is in emerging markets and coffee exporting countries, e.g., Brazil, Indonesia, India and Mexico (ICO, 2019; Pay, 2009). Mature markets as Europe and North America observe a higher preference for specialty coffee (ICO, 2019; Pay, 2009; Reinecke et al., 2012) for which buyers pay premium prices. In the downstream, buyers are motivated to deploy sustainability initiatives mainly by external drivers i.e., to face competition, due to legal requirement and policies, because of stakeholder expectations as NGOs, important suppliers or local communities (Emamisaleh et al., 2017; Karlsen et al. 2013).

Research questions
As explained by Karlsen et al. (2013), in the supply chain management field, traceability is an issue when dealing with risk management, supplier management, logistics and distribution. In consequence, implementation of traceability systems is increasingly appealing for companies in search of efficiencies, consistency, differentiation, and for ensuring customers the product features they expect (Norton et al., 2014; International Trade Centre, 2015; Karlsen et al. 2013). Furthermore, in many companies, traceability is implemented as a tool to assure and verify sustainability on commodity chains; however, only a very small percentage of commodities are traceable on sustainability attributes (Kuit and Waarts, 2014; Norton et al., 2014).

Specifically, traceability for sustainability, as defined by Garcia-Torres et al. (2019) is the “ability to combine SC information sharing and visibility […] for operational reasons and to ensure the reliability of sustainability claims”. The authors stress the need for managing capabilities that enhance better performance in SCs and allow sustainability goals to be implemented and evaluated (Garcia-Torres et al. 2019). Companies that invest on increased transparency and traceability could have a competitive advantage and reputational benefits through traceability systems that demonstrate a commitment to sustainability (Norton et al. 2014; International Trade Centre, 2015). However, the implementation of traceability systems along multiple tiers of the supply chain is still to be studied in commodity’s industry where actors are spread around the world, have different capabilities and interests for sustainability. Hence, the research questions addressed in this study are the following:

**RQ1:** What are the traceability systems implemented in the coffee industry?

**RQ2:** How are traceability and sustainability related in the coffee industry?

4. Methodology
This study is based on multiple exploratory case studies selected standing on their overall strategy for sustainability reflected in their mission, vision, communication, awards winning, etc. Furthermore, the set of cases are companies of different sizes, belong to different supply chain stages in different geographical locations. In addition, a certification entity is included as well (See Table 1). Multiple cases are chosen per supply chain tier aiming at more robust findings following a replication logic (Yin, 2009) and for grasping the heterogeneous behaviours along the chain.
Data collection and analysis
Data is collected by means of semi-structured interviews, visits to production plants and from secondary sources, ensuring validity and reliability (Yin, 2009). Interviews lasted between 60 and 120 minutes, with follow-ups via email or by phone when needed. Multiple researchers performed the interviews outlined in three parts:

- General business aspects: company characteristics (size, product lines, markets), business model and relationships with other supply chain actors
- Sustainability: sustainability practices implemented, drivers and barriers, the role of certification, if available
- Traceability: traceability systems in use, drivers and barriers, and future perspective toward new traceability systems

The coding was performed for all the companies interviewed, then the cross-case analysis per SC tier and finally at supply chain level.

5. Findings
In light of the primary evidences collected from the cases, we were able to identify and describe different traceability systems adopted by different actors along the coffee supply chain. Traceability systems can be distinguished on the basis of three key dimensions. In the following subsection we present first, the three type traceability solutions detected from our case studies, considering the systems adopted for tracing the information as well as the technological solutions adopted for transmitting the traced information to the customers (e.g. a QR code positioned on the packaging). Following, we present the different ways of implementing the traceability systems. Finally, we describe the relationship between sustainability and traceability.

Traceability systems
Option 1 - Simple documental traceability: in this scenario, the product along the supply chain is tracked thanks to the registration of transportation documents and invoices at the different tiers of the coffee supply chain. This kind of essential information is then reported on the product packaging. For instance, Case H (roaster) relies on HACCP standard for the internal traceability and on the documentation released by suppliers, i.e. transportation documents and invoices.

Option 2 - Advanced documental traceability: these types of solutions rely on private database systems. This is the case of companies (e.g., Case G, Case I) that relied on
certified purchases guaranteed by the certification entities (e.g. Organic, Fairtrade, Rainforest Alliance, Utz). Thus, along with the simple documental traceability, the goods are tracked and monitored also in the ledger of certification entities that authorize the use of the label. The information is transmitted to the end customer through the packaging, including not only mandatory information but also the certification labels. This is complemented by extensive information reported on the website and about processing methods and sustainability initiatives, if present. Case I (trader) and case G (retailer) demand traceability to the certification entities that are in control of the certified product in their ledgers. Case C is a certification entity itself and adopts a system that enable certified companies to connect and communicate with each other, report and verify certified volumes.

Option 3 - Integrated platform: this system allows the different actors in the supply chain tiers to register and upload information on the traced product. The administrator of the platform regulates information visibility to the other actors and controls how information is managed. The only case in the sample which adopts this type of system, i.e. Blockchain system, is Case A. This technological option allows to have complete set of information through a QR code that reaches the end customer. In Case A, by reading the QR code, consumers are directed to the company website in which the “journey” of the product as well as additional information about certifications and sustainability practices is available.

Implementing different traceability systems
Traceability systems adopted by the companies in the sample can be distinguished also on the basis of the information width and depth. Information width refers to different types of information that are traced. In addition to some mandatory information of product origin, ingredients and nutritional value, the traced data include quality and safety certifications as well as sustainability practices. Information depth refers instead to: how much upstream the supply chain the different traceability solutions allowed tracing, and at which granularity level. This is, traceability is possible at country, region, cooperative (i.e. organized group of farmers) or individual farmer level. In terms of granularity, traceability systems can be applied to all products (all the different product variants that are offered by the company) or to just some variants. Table 2 shows the 10 case studies classified according to the abovementioned dimensions.

Relationship between traceability and sustainability
The companies under investigation explained that they do not necessarily look at traceability and sustainability together. Sustainability and traceability are considered important but they are usually managed separately. Traceability is mainly required by law and regulations compliance. Whereas, sustainability is driven by company values and commitment. It was interesting to note that no company in our study considered sustainability as traceability driver, or vice versa.

Nevertheless, there are cases which leverage on forms of Advanced documental traceability (Option 2) as the certifications, to implement sustainability practices in the coffee countries of origin. Sustainability practices are required to third parties, i.e. the certification entities, who guarantee not only origin but also sustainability. The three mostly adopted certifications in the coffee industry and which have dedicated traceability solutions are: Fairtrade system (managed by FLOCERT) and the so-called “Chain of Custody” for Rainforest Alliance and Utz. The respective third-parties (i.e. Fairtrade, Rainforest Alliance, and Utz) guarantee that sustainable practices are carried out with
certified producers. In the cases of our sample adopting these type of certifications (i.e. Case G and I) traceability coincides with sustainability.

Case A instead adopts an integrated platform (i.e. Option 3) as the main traceability solution. This technology, which brings information depth at its utmost, enables Case A to report to consumers also the different sustainability practices implemented in the origin countries.

Interestingly, Case F is the only company within the sample that holds no certifications. This is a precise choice made by Case F managers who believe that the certification schemes available for the coffee industry are too much focused on quality. Thus, the company develops its own certification scheme, validated by a neutral international accredited registrar and classification society. The proprietary certification scheme is grounded on four main pillars: ethic, social sustainability, economic sustainability and environmental sustainability. Upstream in the supply chain, in origin countries this certification entails a path to quality and sustainability merged together. The main practices include direct purchases (or as much direct as possible, depending on...
the geographical region), growers’ selection, training and motivation, right price for high
cache, and the creation of sound relationships with producers that are developing
as high-quality coffee. Therefore, this means: investment plans for local grower’s
communities (e.g. schooling facilities, sanitation), investments to sustain integrated
sustainable agriculture (and not organic or conventional agriculture) that offers benefits
both for people and environment. All these practices are structured in the proprietary
certification scheme, which represent a pivotal condition for the implementation of
sustainability practices in Case F.

In these three cases (Case G and I, Case A, Case F), traceability appears therefore to
be synergistic with sustainability.

The approach adopted by Case J is different. The company purchases from traders a
share of organic certified coffee, but at the same time develops sustainability activities in
almost all the countries where the traders source from, adopting a multiple stakeholders
approach collaborating with NGOs, other roasters, local communities and traders as well.
However, the company is not able to link its efforts on sustainability with traceability: no
initiative is able to provide enough coffee to make a distinct product line and thus to make
any specific sustainability claim over a product. Committed to sustainability, Case J
prefers to carry out these initiatives without linking it with direct purchases, counting on
spill-over effects in the local realities that over time will spread best practices within the
country. In this specific case in our sample, traceability appears to be disconnected with
traceability.

6. Discussion and conclusion

Observing Table 2, findings in this study suggest that the most common traceability
system implemented in the coffee supply chain is the advanced documental traceability
that traces the most complete information width, from origin and quality to sustainability
practices (Cases B, C, I, E, F). Moreover, regardless of the supply chain tier, these
companies prefer to invest in a traceability system that go as much in depth as possible,
i.e., up producer or cooperative if possible, to all products. The white rows in Table 2
refer to this type of strategy. Nonetheless, other companies, shaded in dark grey in Table
2, are interested in tracing only origin and quality, but not sustainability. Hence, they
adopt either a simple documental traceability system or an advanced documental one.
The lack of interest on tracing sustainability practices in these cases (Cases D, G, J, H)
could also be determined by the supply chain tier, type of product or even company size.
Finally, it can be observed that the only one case that opted an integrated traceability
system, covering all the information width possible, is in turn not focused on information
depth or granularity, allegedly because of the difficulty to apply the technology to a highly
fragmented supply base, as is the specialty coffee chain. Traceability at region level is
common in specialty coffee sourced from poor countries where higher detail is impossible
to get but the specific quality requires keeping trace at least up to the region to be
categorized as specialty.

Therefore, the implementation of traceability systems along the coffee supply chain
could be influenced by the type of information width and information depth that the
company is interested in, along with the supply chain tier, country of origin or company
 technological capabilities.

On the other hand, from our findings we could observe that the relationship between
traceability and sustainability for coffee roasters might be influenced by two main
contingencies: volumes purchased and product type. The largest company in our sample,
that purchases up to four million bags (Case J) depicts a disconnected relationship
between traceability and sustainability, because the complexities of tracing back upstream
to many producers spread around the world. This company deals with coffee in bulk. Alternatively, smaller companies dealing with specialty coffee are able to deploy systems that trace at a higher level of detail up to the cooperative or even to the single producers where sustainability practices are carried out. These companies show a more *synergistic* relation between traceability and sustainability. Moreover, according to Case C, if we enlarge the view to consider also other commodities, as cocoa, in addition to the two approaches detected, we can retrieve an additional case, which refers to traceability and sustainability in *trade-off*. This is for example the case of specific certified cocoa for which the certification entity adopts a mass-balance approach.

In conclusion, our study is in line with previous literature stating that traceability systems are a tool in the supply chains in order to ensure that responsible social and environmental practices are used (Norton et al. 2014). Moreover, with the present work we contribute to literature by identifying three types of traceability systems adopted in the coffee supply chain, along with the information width and depth. In addition, we contribute to the debate around the relationship between traceability and sustainability (e.g., Garcia-Torres et al., 2019) by characterizing two types of relationships, disconnected and synergistic, that are influenced by the volume and product types purchased.

Findings in our study could be of interest for practitioners as well for identifying the needs for traceability according to their technological capabilities and the product type they deal with. Similarly, managers could adopt a certain strategy relating sustainability and traceability according to their needs and interests. Further research in this topic could extend the study to a larger sample, to involve other commodities and other industries or to delve into the contingency variables that determine the adoption of certain traceability system and its relationship with sustainability.

Designing Inclusive Supply Chains for Sustainability: Empirical Insights from the Bottom of the Global Economic Pyramid

Abstract

Integration of the population at the Bottom of the Pyramid (BOP) within company operations was identified as pivotal for realizing both value for companies operating in these challenging markets, as well as for harnessing the full potential of the BOP proposition in fostering value for individuals living in them. However, research on the topic remains predominantly simplistic, with nuanced and empiric based argumentation relatively scarce. In this paper we address this gap and provide a clear overview of how companies integrate BOP individuals in the different stages of their supply-chain, and how this integration facilitates different levels of sustainability depth.

Keywords: Base of the Pyramid, Sustainable Development, Co-creation

Introduction

The importance of a supply chain (SC) focus when addressing sustainability concerns is widely established in research on developed economies. The discourse on sustainable supply chain (SSC) practices in these contexts focuses on environmental issues, aiming at altering companies’ existing operations to conserve resources and reduce environmental damage (Seuring and Muller, 2008). Research on SSC practices carries additional urgency in Bottom of the Pyramid (BOP) markets. BOP markets span geographic borders and their population ranges from farmers, to day-labourers and even bonded-labour, with a daily income as low as 1 United States Dollars (USD; Rangan et al., 2011). The widespread farmer suicides in India are a sobering example for what these figures mean in practice for people living in poverty. Carleton (2017) found that a one-degree Celsius increase in temperature leads to 70 more farmer suicides, annually. This characteristic vulnerability of the BOP to fluctuations in external conditions makes it crucial for companies in these markets to not stop at reducing the “un-sustainability” of their SC practices, but also to actively design them for creating sustainable value.
Integration of the BOP population within company operations was identified as pivotal for realizing the full potential of companies in fostering sustainability (Nahi, 2016). However, despite many researchers echoing this sentiment, there is still a stark lack of scrutiny and specific, empirical-based understanding of how this integration takes place and how it facilitates sustainable poverty alleviation. In this paper we address this gap, aiming to shed clarity on the topic by providing a more nuanced, empiric based understanding on how BOP integration at various stages in companies’ supply chains can contribute to different depths of sustainable value.

**State of the Art**

**Supply Chain Challenges at the BOP**

The phrase “Bottom of the Pyramid” was coined by Prahalad and colleagues (Prahalad and Hart, 2002), and refers to the population at the bottom of the world’s economic pyramid, originally defined by Prahalad as those whose annual purchasing power parity (PPP) is less than 1500 USDs annually. This original definition has since been expanded upon (see for example Rangan et al., 2011) to incorporate a more nuanced and arguably more appropriate segmentation of people in BOP markets, who have a vastly diverse geographic, class and religious background (Webb et al., 2010), in addition to their various levels of (limited) financial means (Rangan et al, 2011). The full spectrum can range from people who earn 1 USD or less daily and live in extreme poverty, to people earning up to 5 USD a day, living on a relatively regular, albeit low, income (Rangan et al, 2011). In management disciplines, the interest in the BOP market had been first and foremost for economic benefit to companies, particularly multinational corporations (MNCs; London and Hart, 2004), who sought growth opportunities abroad following the increased saturation and stagnation in industrialized markets (London and Hart, 2004).

Despite the great potential, companies wishing to succeed in BOP markets must overcome several key issues, two of which are its informal economy and gaps in the supply chain. First, the informal economy prevalent in BOP markets essentially means that transactions are primarily grounded on social and not legal contracts (Kolk et al., 2013) and are not regulated by formal bodies. The lack of competent formal institutions in place to mitigate the issues resulting from companies transacting with parties outside their own social network can be a great deterrence for companies thinking to enter the market, as they could result in lack of dispute resolution mechanisms, and issues such as corruption and property rights. Secondly, the often poorly developed educational, legal, political and business systems at the BOP (Webb et al., 2010) cause significant gaps in companies’ value chains. Services such as electricity, water supply and support activities like financing distribution or information infrastructure (Wheeler et al., 2005) are lacking or missing altogether. This means that companies operating at the BOP must find innovative solutions to overcome these gaps and their effect on the various SC stages.

**The Need for Co-Creation in General and BOP Integration in Particular**

The challenges companies face often prove too difficult to be overcome by a single stakeholder; “No firm can do this [succeed in BOP markets] alone […]” (Prahalad and Hart, 2002, pp.6). By working together, the various stakeholders at the BOP can achieve a solution that is greater than the sum of its parts, as different organization types or stakeholders bring different degrees of technical know-how, local understanding, production capacities, financial resources, sales and marketing insights and connections to their respective industry (Ravn, 2010; Wheeler et al., 2005). This notion of working
together with various, also non-traditional stakeholders such as non-governmental organization or the BOP population itself, is often dubbed “co-creation” and “[...] has become a central tenet of second generation BOP strategies that seek to create a fortune with rather than at the BOP.” (Nahi, 2016, pp. 416).

In research, co-creation is an umbrella-term used by different papers to refer to companies working together with different proposed actors and for different purposes (Nahi, 2016). The purpose of engaging in co-creation and the consequent sustainable value in it differs, and can range from shallow, business driven ties aimed at company legitimation within the local market and increased operational efficiency, to deeper, empowerment-driven integration. In the scale proposed by Nahi (2016), the purpose of co-creation, also known as its “sustainability depth” (see Nahi, 2016; pp. 294) ranges from co-creation for the purpose of creating legitimacy for the company, co-creation for efficiency, co-creation for sustainability, ensuring environmental and social value, and lastly, co-creation for empowerment of the low-income population itself. The participants of co-creation range from least-inclusive, i.e. companies co-creating with either own-company employees, or other business partners, to more inclusive, i.e. companies co-creating with non-business partners, or the BOP population itself. Of these potential stakeholders, engaging with individuals at the BOP is considered the most inclusive category of co-creation, as its sustainability depth ranges across the entire spectrum, from creation of legitimacy for the company, to empowerment of individuals (Nahi, 2016; Kolk et al., 2013). Indeed, whilst BOP research initially supported a “consumer oriented” perspective of selling to the individuals at the BOP (Khalid et al., 2015), it has since transitioned to considering them as an integral and active stakeholder in companies’ success, rather than passive consumers. “[...] consumers are seen as key co-creators.” (Nahi, 2016; pp. 421) or more specifically; “[...] firms have found mutually beneficial ways of engaging the people at the BOP not just as consumers but as co-creators of value – as suppliers, distributors, partners and employees” (Gollakota et al, 2010; pp. 365). Therefore, in this paper we do not consider all possible configurations of co-creation, i.e. with all the different possible stakeholder, but rather focus specifically on co-creation as the integration of BOP individuals as active participants within company processes and the consequent potential value incurred for all parties involved.

One crucial recommendation for research in this field noted by Khalid et al., (2015; pp. 692) is that “BoP-related research often takes a too simplistic and positive turn on related corporate activities, and thus a more detailed analysis of such integration activities [of BOP individuals within the SC] would be required. This would be an opportunity for SCM [supply-chain management] researchers to address this gap in research and thereby contribute to SSCM-related [sustainable supply-chain management] research, which is rarely based on empirical data from BoP-related research.”. The purpose of this paper is to address this critical void and provide a nuanced, specific and empiric-based exploration of BOP integration within different SC stages at the BOP. More specifically we aim to answer: how do companies integrate BOP individuals in various stages of their supply-chain and how does this facilitate different levels of sustainability depth?

Methodology

Data Collection
To answer this question, we draw on insights from integration practices of over 100 small and medium sized ventures operating in BOP markets, across countries and industries. Our aim was not to assess the prevalence of companies practicing integration in BOP markets, but rather the scope and depth of integration in companies that do so, and do so well. Therefore, we decided for a best-practice oriented case-selection. An initial list of 213 cases was composed, of initiatives that have already been proven successful by winning the prestigious “SEED” award, jointly founded by several prominent institutes to identify outstanding ventures that actively target sustainability concerns at the BOP, such as provision of clean electricity, safe drinking water, sanitation and accessible healthcare. Publically available data from the award website was compiled using a self-developed web-crawler. Descriptive data on each venture, such as year founded, product offering, geographic market and industry was aggregated systematically and automatically. The data was cleaned, standardized and inputted into a robust case-study protocol in Excel.

Extensive manual secondary data collection was then carried out by two coders on the processes each venture employs at each stage of its SC (Procurement, Production, Distribution, Return). This included extensive and meticulous, manual data collection of supply-chain practices from a wide-range of secondary sources, with multiple sources per venture as well as different data types, both video and text. For most ventures, sources included a diverse combination of financial reports, news articles, official social-media presence, as well as videos of interviews by founders or key employees in each company in reputable news sources or from the ventures’ own (official) online outlets, thus ensuring the highest levels of data triangulation (Yin, 2014). At this stage, due to a stark lack of publically available information, “Return” processes were removed from the study. The coders also documented the level of technology sophistication of each venture’s key value offerings (very low, low, medium, (very) high) to ensure an adequate spectrum is covered. Very low technology sophistication refers to ventures where almost no additional processing into a final product is carried out (for example, ventures in the agriculture industry that sell their aggregated and packed produce). Low refers to little or some additional processing into a final product (such as bio-pellets for clean cooking), medium refers to more robustly developed products (such as solar lamps) and (very) high refers to advanced products and services or complex offerings more heavily entwined with technology (such as home systems or off-grid energy providers). Additionally, at this stage, ventures for which an insufficient amount of information could be found on SC practices were excluded. For each remaining venture, the coders marked a binary yes / no for whether integration of BOP individuals takes place at each of the SC stages. Ventures for which proof of integration practices could not be found in at least one stage were removed from the study. This process resulted in a final database of 135 front-running ventures that were included for subsequent analysis.

Data Analysis
The subsequent qualitative data analysis explored the purpose of BOP integration in ventures (“Integration: for what purpose?”; see table 2) based on the scale of integration “sustainability depth” proposed by Nahi (2016). We also explored the specific patterns of integration used across the SC to achieve this depth (“Integration: how?”; see Table 2). Bottom-up thematic pattern derivation of integration activities was conducted, deriving codes iteratively as needed from the ventures and aggregating into second-order patterns. The patterns were then assigned to the relevant first order categories for purpose of integration by Nahi (2016). For the detailed thematic categorization and example codes, refer to Table 2.

Lastly, a quantitative, exploratory analysis was carried out on the relationship between the depth of integration at various stages in the SC, as well as the relationship of the technology sophistication level of a venture’s key product as a moderating factor for integration depth. First, we explored the purpose of BOP integration by cumulating all instances of specific patterns according the categories legitimation, efficiency, sustainability and empowerment (see Table 2). For example, we were interested in understanding how many of the ventures that integrate BOP individuals in their distribution did so with the purpose of legitimation? How many did so and led to the individuals’ empowerment? Alternatively, how many of the ventures that integrate the BOP in production do so with the purpose of legitimation or efficiency? How many result in empowerment? The relative frequency of each integration purpose at each of the three SC stages was used to generate the heat-map shown in Figure 1. Then, we expanded our exploration with regard to the technological sophistication of each venture, thus allowing

the comparison of the relative frequencies of the purpose of BOP integration in each of the three SC stages with respect to technological sophistication, as shown in Figure 2.

Findings

In this section, we discuss the key findings distilled from the previously elaborated upon research design. In particular, this section will outline at which SC stages companies integrate the BOP and in particular the resulting sustainability depth; i.e. business-oriented integration for the purpose of creating legitimation or efficiency, or more empowerment-oriented integration, for the purpose of also building agency for the BOP locals integrated (see Figure 1). We also shed light on the characteristic patterns of how integration at each SC stage takes place, thus providing a nuanced understanding on how integration at different stages of the SC can lead to different depths of sustainable depths. Lastly, we explore the relationship between the technology-sophistication of the venture’s key product offering to where in the SC they integrate the BOP and for what purpose.

The findings show that ventures integrating BOP individuals in their SC do so within their upstream processes; with 64% of all ventures integrating the BOP in their procurement processes and 61% in their production. Integration is also done in ventures’ distribution, though to a lesser degree (42%). Ventures tend to focus on either upstream or downstream processes, with only 17% of ventures integrating BOP individuals in all SC stages. When we assess the correlation with the purpose of integration at the different SC stages of ventures (see Figure 1), the overwhelming majority of BOP integration results in business-level sustainability depth, i.e. efficiency or legitimation, across both upstream and downstream SC stages. The business-oriented integration is carried out across all ventures, by those with very low product technology sophistication, as well as high (Figure 2), thus empirically supporting the claim that integration of the local population is at least perceived as useful if not necessary for businesses operating in these markets. However, here we note a difference between the different SC stages. Integration practices in distribution processes in particular tend to “stop” at business-oriented integration, whilst upstream processes incorporate to a larger degree also sustainability and empowerment characteristics.
**BOP Integration Patterns and Purpose in Downstream SC Processes**

BOP integration predominantly in downstream processes tends to be lower in depth and business-driven, and characterized by employment of a very large number of locals for door-to-door sales and maintenance jobs for increased efficiency and creation of accessibility in ventures’ sales and after-sales networks. Integration of the BOP in downstream processes contributes to ventures’ legitimation (in 79% of cases, see Figure 1) and efficiency (74%) but to a significantly lesser extent to sustainability (26%) or empowerment (26%) of the BOP individuals involved. One reason for the halt at business-oriented integration depth, is due to the fact that in distribution processes in particular the BOP are often integrated into the supply chain on a commission-basis as opposed to full time, formal employees; "[...]in addition to these direct jobs [of full-time, official staff], several hundred indirect jobs are created in the distribution chain." (Lagazel, 2019, pp. 6). The decision to separate the large employee pool stems from practical reasons of working hours and localization; "For practical reasons, Kumudzi Kuwale has decided to assign charging station operators as agents and not employees. The agents are to a large extent choosing their own working hours, using their own home as a base for Kumudzi Kuwale activities, which often is combined with other business." (Kumudzi Kuwale Annual Report, 2017; pp. 38). Alternatively, motivation was noted for the commission-based configuration of integration; “The agents get a fixed percentage of their earnings to keep for themselves, instead of a salary [...] as a fair way to reward agents that perform well." (Kumudzi Kuwale Annual Report, 2017; pp. 38). Lastly, financial reasons stemming from the exponential costs often associated with a large employee-pool were noted; "being a small entrepreneur everything is about your cash flow [...] you don’t actually need employees, you can buy services and get somebody to render a service for you without you putting out and paying a monthly salary and monthly taxes for employing somebody.” (Malherbe, 2019).
BOP Integration Patterns and Purpose in Upstream SC Processes

In contrast to integration in distribution, BoP integration within upstream processes addresses business-oriented purposes, but also deeper outcomes such as sustainability and empowerment. Typically, ventures’ upstream chain is highly localized and aimed at company-legitimation; in procurement, this is often achieved by ventures utilizing locally available material or waste as inputs or develop local smallholder farmers, and in production through utilization of local knowledge and skills, with value adding steps characterized by “traditional”, “artisan” or “time-honoured techniques”. In addition to business-oriented outcomes, we see that particularly production at the BOP and with the BOP is key for empowerment outcomes. Value-adding processes in production at the BOP are human-intensive and ventures extensively train and fully-employ people, often specifically targeting marginalized actors in local communities, such as refugees, single-mothers and youth. Consequently, they heavily contribute to empowerment of local populations, with integration in production processes contributing more than any other SC stage to empowerment purposes. 80% of ventures who integrate the BOP in production result in empowerment outcomes, as opposed to 42% of integration in procurement and 26% in distribution (Figure 1). This is achieved primarily through formalization of work conditions, wages and contracts (in 65% of ventures), a focus on inclusion of marginalized members of local communities (26%) and additional creation of ownership and agency (17%).

Figure 2 – Technology Sophistication as a Moderating Factor for Integration Purpose

Concluding Remarks

Previous research focused on showing that integration of BOP individuals within the SC of companies, rather than only as consumers, could be a key mechanism for sustainable value creation, as these individuals are “[...] experts in their own needs and capabilities, as well as masters in manoeuvring their operating environment”. (Nahi,
2016, pp. 421). This paper has addressed existing calls to delve deeper, and concretely and systematically show where and how ventures integrate local populations in their SC to achieve different sustainability depths. To the best of our knowledge, this is the largest empirical investigation scrutinizing how and where in the SC integration is carried out, and its sustainability depth. This is crucial for advancing our understanding of sustainability, and particularly SSCs, in BOP contexts. Based on the abovementioned findings, we note the prevalence and perceived necessity of business-oriented BOP integration across all stages of the SC, but also the stark discrepancy in the ability to achieve more empowerment-oriented integration, which takes place primarily within production processes. These nuanced insights on highlight the importance of several future avenues of research. In particular, the distinct importance of production at the BOP and with the BOP is shown, despite the current focus of BOP research on marketing and modification of products. BOP integration in production contributes more than any other stage of the SC to empowerment of individuals through formalization of work-contracts and conditions, creation of ownership and agency, and a focus on integrating fringe stakeholders in local communities, as opposed to more prominent members.

Abstract

Supply chains have become more 'customer-centric' requiring more agility. Previous research focuses on economic benefits of lean and agile operations and overlooks its impact on environmental sustainability despite its emergence as a core business need. Though some studies have hinted a link between lean and environmental sustainability, little is known on the effect of agile operations. This research resolves some inconsistencies in the literature and shows how sustainability outcomes could be affected by lean and agility within the furniture manufacturing industry. An in-depth case study is used to illustrate how the leagile strategy could be a more environmentally sustainable option.

Keywords: Lean, Agility, Sustainability
Introduction
Sustainability management is increasingly a normative behaviour expected of supply chain managers. Though not yet a universal order winner for supply chains, there is no denying its significance as a market qualifier (Potter et al., 2015). Environmental sustainability is an even more critical issue as supply chains become more 'customer-centric' with increased customer involvement. Meanwhile, lean and agility have remained relevant best practices for gaining competitive advantage and addressing customer needs as is evidenced by their continued presence in the supply chain literature (Chatha & Butt, 2015). Research has shown that lean operations could be positively linked with environmental sustainability (King & Lenox, 2001). However, much of the previous research into lean and agile focuses on economic benefits and overlooks the environmental impact of supply chain management despite its emergence as a core business need (Pagell & Shevchenko, 2014). This paper does not question the benefits of operations management but seeks to understand the nature of its relationship with environmental sustainability as supply chains become more agile. The paper contends that lean and agile paradigms share common practices that positively affect environmental sustainability and that with innovative technologies, the environmental impact of lean and agile operations is not significantly different in the furniture manufacturing industry. However, lean tends to address environmental impacts in the production processes, while agile impact is significant around design, procurement, and distribution.

This research highlights some inconsistencies in lean and agile operations literature and shows how sustainability outcomes could be affected by lean and agile operations within the furniture manufacturing industry. An in-depth case study is used to understand how lean and agile practices affect environmental sustainability outcomes and what specific initiatives can be taken to mitigate any negative effects.

Sustainability
Sustainability broadly means development that meets the needs of the present without compromising the ability of future generations to meet their own needs (WCED, 1987). Environmental sustainability (hereafter referred to as green) entails recognising the finite limits of the earth as a source of resource and sink for waste (Borland et al., 2016). To be green, society should strive to create a closed loop system that can support itself in perpetuity without external inputs. In supply chain management, green focuses on reducing the generation of pollutants and waste in production processes (Alves & Alves, 2015). Supply chains need to reduce the environmental impact from production, raw materials, energy use, emissions from transformation, and recycling of products post-consumption to be truly sustainable (Piercy & Rich, 2015). However, the adoption of green management should be complementary with the organisation’s operations and cooperate level strategy (Siegel, 2009). There must be an alignment of business operations and green management to achieve truly sustainable supply chains (Pagell & Shevchenko, 2014).

Lean, agile and leagile operations
The lean, agile and leagile debate has continued for two decades since the influential paper by Naylor et al. (1999). Confusion arises when authors entangle ‘what’ the underlying values and principles are, with ‘how’ they should be implemented (Purvis et
Narasimhan et al. (2006) references to these two main levels of analysis as paradigmatic and pragmatic. Paradigmatic studies treat lean and agile as systems of practices guided by philosophical and cultural elements. Lean aims for excellent quality at low cost and is therefore explicitly focused on removal of waste (non-value adding activities or Muda) (Shah & Ward, 2003). By contrast, agility represents the ability of a manufacturer to thrive in the face of continuous change in market demand, technology, customer requirements and social factors (Sharifi & Zhang, 2001). It seeks rapid and adaptive response to variable customer requirements (Yusuf et al., 1999). This adaptive response to uncertainty is generally perceived as flexibility. Qamar et al. (2018) categorises flexibility as product mix, process flexibility and volume flexibility. Mix flexibility refers to the ability of the firm to change the range of products made within a given time period, while maintaining the same aggregated output. Process flexibility is the ability to reconfigure the process without significantly increasing cost, and volume flexibility means the ability to change the level of aggregated output.

Research has consistently distinguished lean and agile based on the emphasis on cost and flexibility (Hallgren & Olhager, 2009; Naim & Gosling, 2011; Qamar et al., 2018). Cost and flexibility emerge as key order winners for lean and agile respectively. Naylor et al. (1999) argue that the most important differentiator of lean and agile is flexibility. They argue that while it may be desirable to have some flexibility in a lean system, flexibility is not a prerequisite for lean as it is more focused on standardisation. However agile manufacturing calls for a high level of rapid reconfiguration and will eliminate as much waste as possible but does not emphasise the elimination of all waste as a prerequisite. Hallgren et al. (2011) suggests that flexibility and cost efficiency are developed in parallel and not sequentially. This means that flexibility does not build upon cost efficiency, and cost efficiency does not build upon flexibility. Instead, a balanced approach is necessary for these two capabilities, such that the decision on one of these capabilities cannot be taken in isolation, without considering the other one. This interrelatedness of the lean and agile paradigms makes their distinction murky, mainly because both paradigms share common practices targeted at minimal waste, flexible response and short lead-times (Martin & Towill, 2000).

Earlier research is inconsistent on what practices characterise each paradigm, thus diluting the unique attributes (Purvis et al., 2014). For example, Just in Time (JIT) is often considered as a lean practice (Shah & Ward, 2003), yet others argue that it is an agile practice or even both (Qamar & Hall, 2018). Several studies use quality management, supplier management, and JIT flow, as identifiable practices of lean firms (for examples see Cherrafi et al., 2018; Garza-Reyes et al., 2018; Longoni et al., 2015). In contrast, Narasimhan et al. (2006) found these practices had significantly higher emphasis in agile firms than lean firms. A possible explanation for these inconsistencies could be that lean is more conceptually developed than agility, thus most of the efficiency focused practices are attributed to lean (Purvis et al., 2014). These inconsistencies have important implications when trying to understand lean and agile impact on environmental sustainability.

The identifiable lean and agile attributes tend to occur regularly at a pragmatic level (Purvis et al., 2014). At this level, disentangling lean and agility focuses on ‘how’ they are implemented. It is necessary here to clarify exactly what is meant by lean and agile. According to Narasimhan et al. (2006) production can loosely be considered lean if it is
accomplished with minimal waste from unneeded operations, inefficient operations, or excessive buffering in operations. On the other hand, production can be considered agile if it efficiently changes operating states in response to uncertain and changing demands placed upon it. Thus, lean firms develop performance capabilities to compete on costs while agile performers exhibit performance capabilities that reflect ‘service’ to increase availability and flexibility (Narasimhan et al., 2006). Fisher (1997) classified products into two types, functional products characterized by stable demand, long life cycles, low profit margins and low variety, and innovative products with volatile demand, short life cycles, high profit margins and high variety. He argued that Lean supply is suitable for functional products, and responsive supply is suitable for innovative products. However, lean and agile concepts are not mutually exclusive in practice but can co-exist in a supply chain.

Previous research suggests ways of marrying lean and agile to present a more robust supply chain design that benefits from both strategies. Figure 1 shows how lean and agile can be combined in three ways but never in the same space at the same time (Towill & Christopher, 2002).

</tr>
</tbody>
</table>

*Figure 1: Leagile Time/Space Matrix (adapted from Christopher and Towill 2002)*

In figure 1, using lean and agile at the same time in different space requires having separate processes operating in parallel, differentiating ‘base’ from ‘surge’ demand. This may mean separating standard components from more bespoke products which would require agility. To have them in the same space at different times requires changing your supply according to seasons. Stock is built at low cost through lean during the quiet period in anticipation for demand during the busy period which is satisfied through agile supply. De-coupling strategies postpone the assembly of the final product in order to handle demand uncertainties efficiently. Naylor et al. (1999) coined the term leagility to represent this kind of integration of lean and agile in different space at different times. A decoupling point acts as a buffer between the variable demand for a wide variety of products and the level production schedule for a smaller variety of components, allowing for leaness upstream and agility downstream. In this way, the supply chain combines lean and agile through ‘postponement’ of final assembly to benefit from both philosophies.

**Operations management and environmental sustainability**

Early research hinted at the accidental environmental benefits of lean methods (Florida, 1996; King & Lenox, 2001). Subsequent studies suggest that lean and green practices result in synergetic outcomes regardless of whether managers implementing such practices fully understood or simply dismissed potential synergies (Campos & Vazquez-
A recurring argument is that practices that support lean manufacturing are aligned in focus as those that support environmental performance (Garza-Reyes et al., 2018; Simpson & Power, 2005). For example, cultural elements such as kaizen (continuous improvement), cross-functional teams, employee empowerment have been found to facilitate higher environmental sustainability performance through an integrated system of management (Alves & Alves, 2015). While these practices have a positive impact on environmental sustainability, they are not exclusive to Lean. JIT, TQM (continuous improvement) and cellular manufacturing are not strong differentiators of leaness (Narasimhan et al., 2006). These form vital foundational capabilities for agility. One possible implication of this is that agility could positively contribute to environmental sustainability. The true impact of individual lean and agile manufacturing on environmental sustainability needs further investigation (Sarkis & Zhu, 2017). This is what this paper seeks to address.

**Methodology**

In this study, a theory-driven inductive approach is adopted largely due to the exploratory nature of the subject. A case study based qualitative research method is appropriate for generating deep insights and causal explanations for a complex system within a real-life context. This paper adopts a critical realist position that combines the ontological strengths of realism with the epistemological value of both positivism and constructivism. A systematic review of literature was conducted to develop the research question and identify critical initial theory to form the basis for possible explanations of the causal powers of lean and agile. To guard against bias while ensuring external validity, multiple data sources where used. Data collection involved semi-structured interviews with managers, site visits, and analysing company documents. Interviews were transcribed and coded for thematic analysis. The case was selected based on its ability to illustrate how lean and agility impact green performance.

The furniture manufacturing industry was selected as the context for the study for several reasons. First, companies in the furniture industry are less likely to implement green practices except those required by law. There is a relationship between the type of product sold by a firm and its inclination to engage in green management. McWilliams and Siegel (2001) makes a specific distinction between experience goods and search goods. Experience goods must be used or consumed before their true value to the consumer can be determined. Examples of experience goods are automobiles, and appliances. Firms supplying experience goods will stress their reputation for high quality in advertising. On the other hand, search goods and services are readily evaluated prior to purchase, and most advertising will involve information about product availability and price. Examples of search goods include clothing and furniture. They argue that a firm selling an experience good is more likely to engage in green management than a firm producing a search good. Therefore, the furniture manufacturing industry presented a good context for understanding the effect of lean and agile on green since firms selling furniture, a search good, are less likely to engage in green management. Secondly, several key processes are common to many other manufacturing industries (e.g. coating processes using solvent-based paints, solid waste, paper packaging). Lastly, several of the key processes have significant environmental implications and faces primarily the same legislative initiatives faced by many manufacturing sectors.
Findings from case study
FurnCo (pseudonym) is a UK based medium sized coffin manufacturer offering coffins and veneered boards supplied to funeral directors and coffin manufacturers respectively. Its product offering can be regarded as low volume high variety. A customer can choose from over 28 coffin types, 6 colour indexes, 10 moulds and 40 different sizes resulting in over a thousand different combination of the final product. Waste sources includes wood waste, paper and packaging. Figure 2 shows the supply chain for FurnCo.

The company implemented lean initiatives to reduce cost and waste from the production process. Table 1 shows a comparison of the green impact from literature and the case study.

Table 1: Evidence of impact from case and literature

<tr>
<td>TQM - Quality contributes to green performance through perfect process yields without scrap and defects (King &amp; Lenox, 2001)</td>
<td>FurnCo compressive quality program ensures that products are ‘right the first time.’ The company does not currently have waste from defects or scrap.</td>
</tr>
</tbody>
</table>

**Agile practices**

In a make to order system, the variety in product offerings could negatively affect waste generated, especially if the products come from a few raw materials.

Product flexibility could necessitate excess capacity which consumes resources (Ciccullo et al., 2018).

**Leagile practices**

Early customisation (i.e if first part to be produced is customisable) reduces flexible movement of customer de-coupling point and creates storage problems (Akinc & Meredith, 2015).

FurnCo faced a storage problem because of early customisation of the product. The coffin lids and bottoms needed to be veneered and cut early in the production process, thereby making make-to-forecast not feasible with the current storage space.
Lean impact on environmental sustainability
Findings suggest that lean practices contribute to reducing environmental impact by tackling internal wastes and pollution. At FurnCo, practices such as quality management (TQM), employee empowerment and Total Preventive Maintenance (TPM) had positive effects on green. Fixing production defects before they happen significantly reduced environmental risks related to rework. As stated by the Operations Director, whether in the agile or lean side of production, FurnCo implemented some ‘input and output’ criteria between different stages of production. The defects are caught early when they are cheapest to fix, reducing the need for full product re-work. Here is an example of quality management’s positive impact on both the lean and agile sections of production. Similarly, TPM ensured that production equipment ran at optimum conditions to process materials efficiently and used less energy. FurnCo empowered its employees to own the process quality and identify areas of improvement. All these benefits were reinforce by cultural transformation of the company, similar to the findings by Alves and Alves (2015). However, Lean did not address all environmental concerns (e.g. formaldehyde and toxins in glues) thus there is a need to integrate lean and green practices (Inman & Green, 2018). Nevertheless, lean’s positive contribution to and synergy with green is undeniable, despite its limitations in addressing all environmental concerns.

Some lean practices led to unsustainable outcomes. For instance, firms could place emphasis on more efficient processes rather than less polluting initiatives (Pagell & Shevchenko, 2014). A waste reduction programme undertaken by the company showed that waste could be significantly reduced if the size of the purchased chipboard is changed. Besides a reduction in cost of other materials (i.e. veneer and paper), this improvement could reduce annual waste by 10%. However, when the supplier was asked to supply the desired size, it declined because its standard size. By so doing, the mills pushed waste material downstream even when they were better able to handle the waste through recycling. This is a case where lean results in waste generation downstream. Of course, there are other factors that contributed in this case for example, the buyer-supplier power differences and the nature of the material. FurnCo’s Operations Director stated that, "We can sometimes be arm strung by our suppliers as well as our customers. Sometimes the customers will want a lower price but still want the agility in specifications. Then, our suppliers come along, and they want the lean in the specification and the flexibility to increase the price. So, we end up sitting at some sort of halfway towards both". However, though better placed to handle the waste through recycling, the supplier preferred to maintain the standard sized chipboard to have greater efficiency.

Agile impact on environmental sustainability
Research suggests that agile firms address environmental concerns at design, procurement and distribution stages but rarely at production (Kumar & Rodrigues, 2018). According FurnCo’s Managing Director, “Agile is about responding to change but it also places high value on people versus process. Verbal human interaction is important in the design and development stage where higher quality designs can be achieved through successful prototyping and close communication with the people who will have to produce the product.” However, the product offering at FurnCo did not require frequent new product development but only occasional adjustment to the product features. Thus, little evidence was found to support the argument that organisations operating in agile
environment tend to address sustainability at the design stage (Kumar & Rodrigues, 2018).

Procurement was an important aspect of agility that contributed to sustainability. Product flexibility may require purchase of a wide variety of raw materials resulting in increased waste generation. At FurnCo, wide variety of product offered affected waste generation. An initiative to reduce product variety showed that a variety reduction would allow the purchase of two chipboard sizes, which would be cheaper and reduce waste. In this case, high variety of products affected green because the raw materials bought were discrete and standard. By contrast, for flexible products such as rolls of fabric, it wouldn’t matter how many sizes are offered, as the waste is at the end of the roll. The variety did not affect the moulds which were bought as rolls because the offcut is the last cutting and not at every cut that is made. Therefore, if flexible alternative material can be sourced, it could reduce the waste.

JIT practices can reduce energy consumption by having lower inventory levels. However, carbon emissions could increase from transportation, packaging, and handling of the materials. This could be seen in downstream of FurnCo in its supply chain. FurnCo’s customers demanded a JIT delivery due to lack of storage space at their premises. To reduce the number of trips and ensure full truckloads, customers were grouped into zones to consolidate delivery. Customer demand outside these zones was satisfied through outsourcing to third party transporters. FurnCo planned its production based on delivery schedule and location of customers. Although, delivery-led production created unevenness in the production processes especially at the assembly point, this distribution strategy resulted in less costs and CO₂ emissions from transportation. Therefore, though JIT can have both negative and positive impact on environment, the negative impact can be mitigated in distribution. This is more likely to be the case in agile which is people focused than in lean which is process focused.

**Leagile and environmental sustainability**

FurnCo adopted the leagile approach to draw on the strengths of lean and agile to improve sustainability performance by separating the part of the supply chain that directly responds to the customer needs. FurnCo implemented separate production lines based on the components of the products. A ‘veneer production line’ dedicated to producing sides and ends of the coffins which were standardised for all coffins, and a ‘Coffin line’ for the lids and bottom of the product. Whereas standardised operations in veneer line enabled efficient production of few variances with minimal waste, wide variety on the coffin line, made it challenging for FurnCo to apply lean production. Early customisation of production reduced flexible movement of the customer order de-coupling point and created storage problems on the coffin line (Akinc & Meredith, 2015). Nonetheless, technology played an important role to reduce the impact of variety on the environmental impact by addressing both efficiency of the processes and energy consumption (Sarkis & Zhu, 2017). FurnCo invested in a CNC machine capable of nesting the various sizes onto a standard chipboard in the most efficient and cost-effective manner. Nesting resulted in 30% reduction in waste generated from offcuts whilst allowing the company to offer a wide variety of sizes.
Conclusion
This paper makes a key contribution by exploring the impact of agile and lean operations on various environmental outcomes. Past research has focused almost exclusively on synergies and alignment of just lean and green. This paper attempts to conceptualize the role and impact of agile operations on environmental sustainability. It demonstrates how Leagile could be extended to be a more sustainable strategy. This theoretical contribution has important implications for managers as it informs how agile related capabilities can also increase environmental performance. Without a clear understanding of the environmental outcomes associated with agility, supply chain managers have little guidance on what results to expect from the implementation of agility-focused practices.

Prompting the diffusion of supplier codes of conduct: The role of content

Johannes Heller (Johannes.Heller@uni-bayreuth.de)
University of Bayreuth, Faculty of Law and Economics, 95440 Bayreuth, Germany

Abstract
Supplier codes of conduct are an important tool for establishing sustainability in supply chains. They can serve to simultaneously govern multiple direct relations with suppliers. However, companies are also expected to ensure sustainability at lower-tier suppliers, which they have no direct relation with. Consequently, codes have to diffuse, which refers to their spread amongst the members of a supply chain who adopt them. Based on diffusion of innovations theory, we highlight the crucial role that their contents play in prompting this process and compile a framework for future scientific inquiry.

Keywords: Supplier Code of Conduct, Diffusion of Innovations, Sustainability

Introduction
Sustainability has become one of the central topics in both business research and practice. Companies have answered the pressure executed on them by both customers and governments by increasing internal efforts to establish sustainable behaviour. However, it is far from enough for companies to assume responsibility within their boundaries. Much rather, their performance in regard to sustainability is judged on the behaviour of their affiliated companies who are located upstream in the supply chain, as well. They consequently have to ensure compliance with both environmental and social standards by their suppliers (Porteous et al., 2015).

Codes of conduct (CoCs) have been implemented to foster sustainable or ethical behaviour for almost a century. Codes of conduct typically comprise a set of rules that constitute which behaviour, especially regarding situations that show some sort of critical relation towards environmental and/or social issues, is considered to be acceptable (Kaptein, 2004). These were found to take a primary role in achieving the aforementioned change towards more sustainable or ethical behaviour (Kaptein, 2011). Consequently, companies have picked up on their experiences with CoCs and designed supplier codes of conduct (SCoCs), which have become the most commonly applied practice to implement particularly social sustainability in supply chains (Yawar and Seuring, 2017). Both research on and practice of SCoCs has focused on their establishment in close dyadic relationships between focal companies and a small number of suppliers. In this sense, SCoCs can serve as a means to effectively and simultaneously govern multiple dyadic relations with suppliers and to prevent misconduct (Schleper and Busse, 2013).

However, when companies have to deal with large numbers of suppliers, it becomes impossible to govern the SCoCs in dyadic relationships, even if it can be done simultaneously to some extent. This problem weights even heavier when considering suppliers that are located on lower tiers and are not in direct contact with the focal company, but who
are nonetheless expected to comply with the requirements set out in the SCoC. Reaching a larger amount of suppliers is unfortunately not as easy as dictating that the SCoC has to be followed by all of them (Awaysheh and Klassen, 2010). Instead, the SCoC has to diffuse. Diffusion refers to the process that leads towards a spread of the SCoC from members of the supply chain towards other members who adopt them (Meqdadi et al., 2018).

Research on codes of conduct has provided indications that their contents are a factor that determines their effectiveness in influencing behaviour (Kaptein, 2011). The contents of a SCoC are particularly important in the described situations, where suppliers solely have to rely on them. So far, research has widely neglected the connection between contents of SCoCs and their effectiveness. We argue that the effectiveness of a SCoC is highly related to its described ability to diffuse, as a prerequisite for its implementation, and that consequently, their contents play a crucial role in this process. We thus propose the following research question:

How does the content of a supplier code of conduct affect its diffusion?

In order to approach an answer to the proposed research question, we first review content-oriented research for both CoCs and SCoCs. Thereafter, diffusion of innovation theory (DOIT), as established by Rogers (2010), is introduced in order to identify factors that can affect diffusion. As the last step, a framework which combines research on both CoCs and SCoCs with DOIT is compiled. We aim to theoretically derive the role that the contents of a SCoC play for its diffusion and propose a new path for future research.

**State of research**

According to Kaptein (2004) a code of conduct defines the responsibilities of the corporation towards its stakeholders and the conduct it expects of employees. Supplier codes of conduct serve the same purpose with the key difference being, that the target corporations are suppliers.

Research on the content of CoCs can be categorized into two main streams. First, research regarding which actual contents (e.g. labour laws or waste management) are included. Second, research which examines code content on a structural level and attempts to unveil guidelines or quality criteria (Garegnani et al., 2015) regarding their complexity (e.g. in form of wording) and the presentation of contents. Both research streams have highlighted that the content of a CoC is one decisive component for determining their effectiveness in influencing behaviour (Kaptein, 2011). Since our goal is to identify generalizable insights regarding the relevance of SCoC content for influencing suppliers’ behaviour, we focus on the latter research stream.

As shown in table 1, Schwartz (2004) examined five criteria that can be used to evaluate the contents of a code of conduct and guide its creation. The author conducted 75 interviews in four large Canadian corporations to determine their value. All of the identified aspects were assessed as important by the interviewees. Surprisingly, justification received the lowest importance compared to the other included criteria.

Erwin (2011) used the characteristics depicted in table 1 to determine the relationship between code quality and ethical performance within rankings on ethical corporate behaviour. He found that code quality is related to CSR performance on both a meso- and macro-level and hence concludes that high quality codes of conducts are more effective in establishing a responsible organizational culture and guide employee behaviour.

Research regarding whether or not the quality of supplier codes of conduct affects their effectiveness is not available to the best of our knowledge. Although creating a SCoC is not as easily done as simply including the word supplier in the title of an existing CoC, we argue that the overall findings from research on CoCs can be transferred to SCoCs and used as a ground for conducting research into this matter.
The aim of increasing the quality of CoCs is that employees intuitively know what to do and understand what is expected of them to be able to act accordingly (Kaptein, 2011) and are motivated to do so. Most of the highlighted quality criteria aim at promoting this notion. The underlying assumption is, that it is impossible to directly govern the behaviour of employees in the variety of critical situation that they might face and thus rather provide them with a basis for acting in an appropriate manner on their own. This is exactly what the goal of supplier codes of conduct is as well (Andersen and Skjoett-Larsen, 2009), since, as we highlighted before, the large numbers of suppliers do not allow for governing their behaviour in dyadic relationships. Especially lower tier suppliers have to be able to transfer the requirements into actions on their own.

### Diffusion of Innovations Theory

One of the most influential works in the field of innovation diffusion research was conducted by Everett M. Rogers in the early 1960s. Rogers defines diffusion as “[…] the process in which an (1) innovation is (2) communicated through certain channels (3) over time (4) among the members of the social system.” Five main variables determine the rate of adoption: The perceived attributes of an innovation, the type of innovation-decision, communication channels, the nature of the social system and the extent of change agent´s efforts. The first element of Rogers´ definition is the innovation itself, which he views as “[…] an idea, practice or object that is perceived as new by an individual or other unit of adoption” (Rogers, 2010, p. 12).

Newness is not necessarily expressed by a lack of knowledge of an innovation. Much rather, it describes that a subject may have had knowledge of an innovation for some time, but is yet to develop an opinion, either positive or negative, towards it and has hence not yet decided whether to adopt or reject it. This decision can also be related to the continuous application of an innovation after the decision to adopt was made and efforts related to do so. The five attributes that influence a subject’s opinion regarding the adoption of an innovation are its perceived relative advantage, compatibility, complexity, trialability and observability. These have been found to explain between 49 and 87 per cent in the variance of the rate of adoption in earlier studies (Rogers, 2010).

A plethora of additional attributes has been applied throughout the history of innovation diffusion research. Tornatzky and Klein (1982) were able to identify 25 additional attributes. However, the authors found that relative advantage, compatibility and complexity provide the most consistent results in terms of their effects. Given the fact that this finding has been confirmed afterward (Kaur Kapoor et al., 2014), we limit our research to those three attributes.

Relative advantage describes the extent to which an innovation is recognized as better than the current state. Its degree is often expressed through economic profit or social status. Incentives can be used to increase the relative advantage of an innovation.

Compatibility expresses a similarity regarding the existing situation. The decisive factors for similarity are most commonly related to sociocultural values and beliefs, already existing ideas and needs for the innovation. The first is very hard to anticipate since they are deeply rooted within a society’s intangible norms. The second factor takes into account that existing ideas, which are applied in similar situations as the new innovation is supposed to, are the basis which possible adopters use to judge the value of the new innovation. The third factor expresses that a subjects motivation to adopt is higher if the innovation meets a so far unsatisfied need.

Complexity describes whether or not the innovation is difficult to understand and apply. One way of decreasing complexity is to provide possible adopters with knowledge regarding how to apply an innovation, instead of merely making them aware of their existence.

While most of the studies on the diffusion of innovations take individuals as their focal point, it is also possible to examine groups such as communities or organizations. It is utterly important to note that, while key differences regarding the diffusion of innovations among organizations exist, research has found no significant difference regarding the role of the attributes of innovations (Rogers, 2010).

**Conceptual Framework**

Research on SCoCs has picked up on diffusion of innovations theory in the past, without explicitly stating to do so. Mamic (2005) proposed a collaborative process between focal companies and suppliers which postulates a move from authority towards collective decisions and thus change the type of innovation-decision. Roberts (2003) highlights that the diffuseness of a supply chain and the power between members are decisive factors, which is in line with how Rogers conceptualizes the influence of the social system. Por teous et al. (2015) highlight the significance of incentives and penalties issued by the focal company, which corresponds to efforts of the change agent in DOIT. However, research has so far neglected the role of the innovation and its perceived attributes.

As we highlighted, an innovation is defined as “an idea, practice or object that is perceived as new by an individual or other unit of adoption” (Rogers, 2010, p. 12). The innovations that we examine are SCoCs, which arguably fit all three different aspects or characteristics that Rogers defined. A SCoC can be viewed as an idea since it transmits
an image (or idea) of how a company (the supplier) should deal with issues related to sustainability. A SCoC can also be considered as a practice, given that they contain precise guidelines for how business is to be conducted by suppliers. Lastly, SCoCs in their written form as a document are an object as well, which the suppliers are passed on to and which they are expected to pass on to their suppliers. Thus, a SCoC can clearly be considered as an innovation in the sense of Rogers’ definition. Furthermore, an innovation in a supply chain can be characterized as “[…] a change within the supply chain processes that takes place in a company or the supply chain as a whole, which aims at the creation of new value for stakeholders” (Arlbjørn et al., 2011, p. 8), which additionally underlines this fit. When considering SCoCs as the innovation we want to examine, the perception of Rogers’ attributes of innovations by suppliers is influenced by the contents of a SCoC. Especially in situations where lower-tier suppliers are not in direct contact with focal companies and thus heavily rely on the SCoC’s contents, as we described before. Of course, this perception can also be influenced by other measures, such as communication activities by the focal company. However, we argue that the contents play an important role in influencing the supplier’s perception, without stating that they are solely responsible for doing so.

The idea, that SCoCs are subject to diffusion has been picked up by research before. Meqdadi et al. (2018) analyse the influence of different forms of power on the diffusion of sustainability practices, which includes codes of conduct, from focal company to suppliers. However, the authors do not consider the actual contents in their research. Kaptein and Schwartz (2007) note that this has been a gap in many research approaches in the past. Schleper and Busse (2013) follow a similar train of thought as proposed within this article in order to create a universal supplier code of conduct, which they argue could be applied throughout various industries. The authors connect the content of their proposed artefact to relative advantage and compatibility.

The importance of relative advantage, compatibility and complexity have been highlighted by past research on SCoCs as well. Grimm et al. (2014) identify perceived value, which is similar to relative advantage, by suppliers and sub-suppliers as the most important factor in adopting SCoCs. Andersen and Skjoett-Larsen (2009) argue that a key pre-requisite for SCoC success is that suppliers understand what is expected from them, which we consider as code complexity. Additionally, the authors found that the supplier’s corporate history and available assets are key determinants, which is related to how we conceptualize compatibility. We aim to explore the role that the contents of a code play in promoting these perceptions by suppliers, since it was again not considered in these past studies.

Since no framework or scale for the assessment of the role of SCoC content, especially as perceived by the suppliers, exists, new constructs have to be defined. The constructs are derived from a combination of Rogers’ attributes of innovations and research on CoCs and SCoCs. The constructs aim to assess how the contents of a SCoC influence a suppliers perception. We do not explicitly consider which actual contents in terms of e.g. the triple bottom line are mentioned within the SCoCs, but rather focus on the established quality criteria. For every construct, we highlight how they are expected to influence the suppliers’ perception and their relation to SCoC content. Additional sources, that highlight their relevance, and which were not explicitly referred to within the course of this paper, are also provided.

In line with Rogers, we expect the influence or relative advantage on diffusion to be positive. The SCoC has to explicitly outline the relative advantage that suppliers can achieve through its adoption to increase its diffusion. The corresponding constructs and their relation to SCoC content are outlined in table 2.
Table 2 – Relative Advantage of SCoCs

</tr>
</tbody>
</table>

First, the construct tone from the top expresses that the focal company’s top management declares its commitment to the SCoC. Second, relative advantage can be promoted through pointing out rewards (in the sense of e.g. increased order volumes) and benefits (such as e.g. decreased operational costs) that can be achieved through adopting the SCoC. Third, relative advantage can also be increased by avoiding negative consequences such as sanctions. The supplier should be made aware of those consequences in the SCoC. Fourth, we included the possibility to report misbehaviour for the supplier as a construct that constitutes relative advantage. There is a broad consent that the ability to report wrongdoing is a key determinant for the effectiveness and perceived value of CoCs. It presents a relative advantage to the supplier by giving him the impression that his activities are important to the issuing company. Since SCoCs are a kind of preventive innovations (Rogers, 2010), we expect the effect of relative advantage to be particularly high. We formulate the following hypothesis regarding the influence of relative advantage:

H1: Relative Advantage is positively related to the diffusion of SCoCs.

Compatibility expresses that the SCoC has to be specific to its target audience. Its constructs are defined in table 3. First, the requirements of the SCoC have to be compatible with the values and strategy of the supplier. Additionally, compatibility is also expected to increase if the requirements from the SCoC are compatible with other SCoCs that the supplier has to comply with. A high degree of compatibility between those SCoCs could dramatically decrease the supplier’s efforts to implement the necessary measures.
Lastly, the compatibility between the requirements of the SCoC and the supplier’s internal capabilities plays a major role as well. If the supplier does not possess the knowledge or financial resources to implement the requirements from the SCoC, its adoption and diffusion are less likely, since it can appear like an overwhelming task. However, their relation to overall code content is hard to generalize. Compatibility serves as a proxy for covering the actual contents of the SCoCs in terms of its requirements and statements, which was suggested as an important factor as we highlighted before as well. We thus do not explicitly outline the relation to code content for these constructs as we do for relative advantage and complexity, but rather highlight that it is an important aspect that has to be included in future research. If compatibility were to be found as the most important factor for the adoption and diffusion of SCoCs, then e.g. companies would have to consider creating different SCoCs for different suppliers in varying cultural settings. We expect compatibility’s effect to be positive, and thus formulate the second hypothesis:

H2: Compatibility is positively related to the diffusion of SCoCs

</tbody>
</table>

The last construct, complexity, is related to the presentation of the SCoC and its accessibility in terms of e.g. language and scope. Its constructs are depicted in Table 4. We aim to assess whether or not suppliers actually comprehend the contents of SCoCs and which particularities of their presentation and style have an impact on this. As discussed, the length of the document can play a crucial role. A SCoC should neither be too short, since in this case, it probably will not cover all relevant aspects, nor too long, since this could appear dissuasive for the supplier. Comprehension aides such as examples and case studies can be used to increase the understandability of the SCoC and thus reduce complexity. The overall readability and tone relate to aspects such as the style of writing (e.g. long explanations vs. bullet points) and how principles are stated (e.g. negative or positive). Lastly, complexity can also be decreased if the SCoC includes clear guidelines regarding management systems and processes that have to be implemented in order to ensure its governance. The last two variables also aim at assessing whether or not the SCoC provides the supplier with how to knowledge instead of awareness knowledge, as it was discussed by Rogers. Overarching complexity is expected to negatively influence diffusion, which results in the third hypothesis:

H3: Complexity is negatively related to the diffusion of SCoCs.
The goal of this research paper was to highlight the role that the contents of supplier codes of conduct play for prompting their diffusion in supply chains, which has so far been neglected by research. We analyzed content-oriented research on both CoCs and SCoCs and introduced diffusion of innovations theory, as established by Rogers (2010), as the frame for our analysis. We arrive at the conclusion that especially in situations where suppliers are not in direct contact with the company that issued the SCoC, its contents are an important driver for both its adoption and further diffusion and thus play a crucial role. They have to promote the notion of relative advantage, compatibility and low complexity among those suppliers.

The presented paper adds to the knowledge regarding the establishment of sustainability in supply chains in three ways. First and most importantly, it guides scholarly attention towards the relevance of the contents of supplier codes of conduct, which has been pointed out as a shortcoming of past research approaches. Second, it provides the possibility for their inclusion as constructs in future research. Third, it can be applied to create a deeper understanding for the general drivers that affect the diffusion of SCoCs from the supplier point of view. It contributes to what Zorzini et al. (2015) call “theory suggesting and explanation”. It enables theory-driven and deductive, rather than a-theoretical and

exploratory empirical research.

Possibilities for future research are manifold. We encourage researchers to empirically validate the framework in different geographical or industrial settings and thus create an understanding of the perception of suppliers and how SCoCs can reach higher rates of adoption. An interesting approach could be to distribute two different supplier codes of conduct, one that adheres to the proposed design principles and one that does not, to two subsets of suppliers of a company and evaluate whether or not the SCoC content actually does play a crucial role in influencing suppliers’ perception.

The conceptualization of Rogers rate of adoption has not been discussed in detail. The rate of adoption is traditionally measured as the number of subjects that adopt an innovation relative to the total number of subjects of a social system. One interesting avenue would be, to assess whether or not SCoCs, which adhere to the proposed quality criteria, show higher rates of adoption among second and even lower tier suppliers. Based on the highlighted hypothesis, we expect that the contents of a SCoC play a crucial role in their diffusion from first to lower tier suppliers, as it is often demanded by focal companies. One large shortcoming can be identified with this approach. A broad consensus amongst scholars exist, that the adoption of a CoC is only a first step in establishing an ethics program, which promotes organizational change (Kaptein, 2011). If not followed by the implementation of supporting management systems, this adoption remains of symbolic nature. Arguable, this is the case for SCoCs as well. We thus propose for future research to assess first how suppliers implement the requirements from SCoCs, which has so far been treated as a black box (Andersen and Skjoett-Larsen, 2009), and second, whether or not their perception of the SCoC content has an influence on those efforts.

Aside from assessing the drivers of diffusion, DOIT can also assist in compiling diffusion programs. In this sense, as we highlighted before, the constructs represent guidelines for the design of SCoCs by companies. For example, in order to increase relative advantage, SCoCs should include statements regarding possible sanctions that suppliers might face for violations.

**Abstract**

Otherwise legal supply chains are sometimes exploited by criminals for their illegal purposes. This research offers a conceptualization of such supply chain infiltration (SCI) as a general problem in contemporary supply chains. The study explores a specific form of SCI, namely illegal wildlife trafficking (WLT) in maritime supply chains. By drawing on criminology theories and empirical evidence from approximately 20 crucial stakeholders, the study develops a framework on how WLT emerges in maritime supply chains and how it can be mitigated. WLT is an important, albeit previously neglected, driver to biodiversity loss.

**Keywords:** Sustainable supply chain management; supply chain infiltration; wildlife trafficking
**Introduction**

Despite decades of practical and scholarly efforts to create more responsible and sustainable supply chains (Gold and Schleper, 2017), supply chains are sometimes used not only for illegitimate, but even for illegal purposes. Research in the supply chain management field has addressed these cases under the umbrella of sustainability, business ethics and corporate social responsibility. Topics such as modern slavery (Gold et al., 2015), conflict minerals (Hofmann et al., 2018), corruption (Arnold et al., 2012) or child labor (Lund-Thomsen and Nadvi, 2010) have been widely discussed in the literature.

However, contexts of supply chain infiltration (SCI), defined as *a situation in which an unauthorized actor succeeds in inserting illegal products into a legitimate supply chain* (cf. D’Amato and Papadimitriou, 2013), have received only scarce scholarly attention so far. Noteworthy exceptions appear in the counterfeiting literature as well as in the literature on cyber security and digital supply chains (Green and Smith, 2002; Corera, 2018). Examples of these SCIs oftentimes refer to either human trafficking or the smuggling of drugs, cigarettes, alcohol or weapons.

Consequently, this study aims to tackle a rather neglected issue in the operations and supply chain management field, namely wildlife trafficking (WLT), often also referred to as illegal wildlife trade. Although WLT has never been officially defined in treaties, the common understanding of this concept involves “the poaching, capture, collection or processing of animals and plants taken in contravention of national laws, and any subsequent trade in such animals and plants, including their derivatives or products” (McLellan et al., 2014, p. 2). Despite extensive efforts by international regulations, laws and initiatives aiming at preventing WLT, recent media reports still list examples of failure, including the auctioning off of hippo teeth in Tanzania (Bale, 2018), tortoise smuggling in Madagascar (Gerety, 2018), or rhino poaching in South Africa (Carnie, 2018). The magnitude of WLT is illustrated by a drastic increase of detected rhino poaching cases from 13 to 1004 between 2007 and 2013 (WWF, 2018). Overall, Interpol (2018) estimates that up to 20 billion USD are annually illegally generated by dealing either with dead or living animals, plant species, insects and orchids, making it a lucrative business for organized crime and casting serious doubt on the effectiveness of existent measures and instruments for preventing wildlife poaching and trafficking (UN DESA, 2018). Together, these illegal activities severely thwart the international community’s conservation efforts and pose a serious risk to the above-mentioned species.

With a few exceptions (e.g., broader risk management and due diligence approaches), supply chain management is hardly concerned with the specific issue of WLT and the more general problem of SCI. In absence of suitable theoretical frameworks, the design of SCI countermeasures in corporate and regulatory practice remains a matter of chance. A key problem in mitigating SCI is to tackle illegal activities without disrupting the legal supply chain or, metaphorically speaking, to remove the parasite without damaging the host. Accordingly, our research-guiding questions are 1) *how does organized crime infiltrate legal supply chains and* 2) *how can SCI be mitigated?*

As WLT can take place through many different supply chains and transportation modes, this study’s scope is narrowed down to so-called “WLT hotspots” in maritime supply chains. WLT hotspots are locations in which a relatively large portion of illicit WLT occurs, allowing for crime problems to be dealt with in a more efficient way (Braga et al., 2014). Furthermore, besides air transportation modes, WLT is mainly present in maritime supply chains. Due to the standardization of transportation...
equipment through containerization and the resulting extreme cost reductions, container ships have become dominant in maritime goods transportation (Kaukiainen, 2009). Consequently, criminal activities, such as smuggling and illegal trade, have taken advantage of the efficiency and limited visibility of this international transport mode (Martin, 2015). For this reason, particular emphasis is given to this specific transportation mode in the remainder of this study. Figure 1 depicts a typical legal containerized transportation process, using an idealized activity sequence including an optional stopover at a transshipment hub and derives an overview of links between supply chain infiltration and most risky situations.

*** Please insert Figure 1 here ***

From a theoretical perspective, this study eclectically incorporated perspectives from criminology, i.e. rational choice theory (RC) (Cornish and Clarke, 2014; Hayward, 2007; Pratt, 2008) and situational crime prevention theory (SCP) (Clarke, 2009; Cornish and Clarke, 2003; Gilling, 2005; Newman and Clarke, 2016). Following RC, criminal behavior is seen as the outcome of various choices (Cornish and Clarke, 1987). Thereby, SCP posits that situational conditions are fundamental in preventing crime (Clarke, 1997). Considering the infiltration of legal supply chains not from a specific issue, but rather as a general phenomenon, criminals as well as the circumstances of a supply chain seem constant. In this manner, SCP and RC seem to be a promising theoretical lens to begin the study of preventing WLT.

Due to the exploratory nature of this study and in order to obtain relevant information on the sensitive topic of WLT, a qualitative data collection approach based on semi-structured interviews with approximately 20 crucial stakeholders along maritime supply chains has been chosen.

The main findings of this study contribute to the literature on supply chain management in the context of WLT and SCI in the following way: 1) This research is one of the first to offer a conceptualization of supply chain infiltration as a general phenomenon that stretches beyond specific issues such as counterfeiting and cyber-attacks. 2) It is among the first papers which tackles the problem of WLT in a (sustainable) supply chain context, with a focus on maritime supply chains. WLT is an important, albeit neglected, driver to biodiversity loss and it has rarely been considered in previous sustainable supply chain management studies. 3) This study furthermore transfers informative criminology theories to the field of (sustainable) supply chain management research and 4) provides methodological novelty insofar as it engages in empirically augmented theorizing.

The next section reviews theoretical foundations related to SCP and its application to SSCM. Thereafter, the case study method is introduced, along with a brief description of data collection and coding techniques. Subsequently, the findings are delineated, which are eventually expected to culminate in a research framework and testable propositions.* The paper concludes with a discussion on the theoretical and practical implications as well as limitations and opportunities for further research.

**Concepsial background**

Supply chain infiltration in the context of WLT

In general, wildlife transportation within maritime supply chains can take several different forms, contingent on the legality of the transported good (i.e., legal vs. illegal)

* Please note that this paper illustrates work in progress. The authors are still working on the backend of the paper, particularly the propositions and the overall framework, which will be developed and presented at the time of the conference.
and the legality of the transportation channel as such (i.e., legal vs. illegal). A transported good is regarded as illegal whenever its transportation – specifically, its import and/or export – is legally prohibited. In the same vein, vessels that are used for the sole purpose of criminal activities are classified as illegal channels, independently of whether they are owned or hired by criminal groups. For a start, wildlife may occasionally move through maritime supply chains for perfectly legitimate reasons, such as repopulation and conservation efforts. In light of the base motivation of this study to explore situations in which an unauthorized actor succeeds in inserting illegal products into a legitimate supply chain, this situation will not be analyzed further.

From other smuggling contexts such as human trafficking or trafficking of drugs and cigarettes, it is known that illegal products often move through illegal channels. Thus, illegal channels are also viable means for engaging in WLT. However, findings from the data and prior literature on WLT and trafficking in general suggest that the maritime transportation of illegal goods through purely illegal channels does not occur very often. It appears that smugglers possess their own sense of economic rationality which leads them to consider expected monetary rewards, associated monetary costs, and detection risks in their transportation planning. As wildlife products, especially animal parts and artefacts, can easily be hidden within maritime containers smugglers can physically be detached from these. Thus, there may simply not be a major need for using illegal maritime channels for WLT purposes.

Applying the aforementioned economic rationality argument reversely, co-relying on legal channels is often much more efficient for smugglers, thereby rendering this situation much more relevant with regards to mitigating WLT and prohibiting SCI. Maritime WLT occurs presumably first and foremost via legal channels. Consequently, a key problem in mitigating SCI is to tackle illegal activities without disrupting the legal supply chain or (i.e. removing the parasite without damaging the host). The remainder of this study therefore focuses on this situation.

Conceptional lens
Assuming that SCI is a criminal activity, this study bases on criminology theories (i.e. RCT and SCP) as a theoretical angle for its analysis. RCT and its cognate field of study, SCP, have a major influence on contemporary crime reduction practice, with many supporters claiming that such strategies represent the most efficient and cost-effective approach to current crime problems (Hayward, 2007).

The RCT approach to crime assumes that crime can be understood from a cost-benefit analysis of the (potential) perpetrator’s situation (Becker 1968; Ehrlich 1974; Eide 1994; Schmidt and Witte 1984). Just like any other individual, perpetrators are self-interested goal maximizer, seeking to maximize their personal benefits (Gul, 2009). Thus, the decision to offend is influenced by people’s preferences, their attitudes toward risk and time discounting, and their estimates of an illegal opportunity’s availability, costs, and benefits versus a legitimate opportunity’s availability, costs, and potential for realizing the same or comparable returns.

In response to this RCT approach explaining crime, SCP comprises opportunity-reducing measures that “(1) are directed at highly specific forms of crime, (2) involve the management, design or manipulation of the immediate environment in as systematic and permanent way as possible, (3) make crime more difficult and risky, or less rewarding and excusable as judged by a wide range of offenders” (Clarke, 1997, p. 4). The need to adapt specific measures to individual offenses implies that the commission of specific kinds of crime depends crucially on a constellation of particular environmental opportunities and that these opportunities may need to be blocked in
highly specific ways (Clarke, 1997). Changing the environment is designed to affect assessments made by potential offenders about the costs and benefits associated with committing particular crimes (Clarke, 1997). This implies some rationality and a considerable degree of adaptability on the part of offenders. All offenders, however emotionally aroused or determined, take some account of the risks and difficulties of particular situations (Clarke, 1997). However, the SCP has failed to pay sufficient attention to the array of criticisms of RCT that have emerged from disciplines such as behavioural psychology, political science and sociology that centre around the simple alternative hypothesis that ‘not all actors are economically self-interested’ (Hayward, 2007).

Given that both RC and SCP have found broad empirical support (Freilich and Newman, 2017; Kliemt, 2018), it will be assumed that these theories are also accurate representations of the behavior of SCI criminals, specifically in the context of maritime WLT (Busse et. al, 2017). This implies that inference from the economic attractiveness of WLT opportunities to the expected behavior of the criminals is possible and that, even more importantly, rendering smuggling opportunities economically unattractive facilitates mitigating WLT. This seems to be particularly true if the mitigation strategies target WLT hotspots where they are supposed to enfold their highest efficiency.

Methodology
Research design
SCI can happen in relation to all kinds of crimes (e.g., smuggling of drugs, human trafficking or WLT) and in connection with various modes of transportation (e.g., air-bound, sea-bound or ground transportation). In view of the fact that single case studies facilitate a particularly deep understanding of the subject matter, this study focuses on a single case, namely WLT in maritime supply chains. As it is virtually impossible to investigate organized crime empirically by means of interviewing the criminals, this study strives to collect empirical evidence from 20+ crucial stakeholders along maritime supply chains to generate potential starting points to effectively combat WLT and SCI.

Due to the exploratory nature of this study, the analysis followed an iterative interview method. Semi-structured interviews allow researchers to adapt the data collection process according to their needs whenever new insights or relevant topics emerge, by continuously moving back and forth between the data and emerging findings (Dubois and Gadde, 2002; Eisenhardt and Graebner, 2007). This technique facilitated identifying key respondents’ insights and opinions and applying these interim findings in subsequent interviews.

Data collection
As WLT is almost never clearly allocated to in specific corporate functions and in order to gain specialist knowledge about detailed processes within maritime supply chains, targeted respondents were preferably experts who have a special or even better exclusive position in the social context of decision-making processes that are impacted by or could potentially impact WLT (Meuser & Nagel, 2009). Overall, the data comprises mainly informants from the purchasing/supply chain, legal and CSR/sustainability department.

Whenever possible, interviews were jointly conducted by two researchers, based on a semi-structured guideline. To this aim, a comprehensive list of 90 relevant parties in the maritime supply chain was created as a first step, including NGOs, public authorities, logistics companies, port authorities, cargo interests, terminal operators, cruise ship operators, and further relevant actors. Out of the 90 contacted SCUs, 16 participated so
far, resulting in 18 interviews yet†. All interviewees agreed to participate under conditions of confidentiality and anonymity. Another 24 SCUs declined explicitly, whereas 50 SCUs did not respond to any interview request at all or changed their mind at a later point. Whenever the respondents consented, the interviews were recorded and subsequently transcribed. In all other cases, extensive notes were taken by the interviewers.

**Coding**
In order to evaluate the statements in the interviews, qualitative research frequently uses categories and types as well as interpretations in order to grasp meaning in addition to content (Titscher et al., 2000; Bryman, 2004; Mayring 2000; Kohlbacher, 2006). To this aim, a qualitative content analysis (Mayring 2000) was employed. Content analysis developed in the 1920s in the United States initially focused on the systematic analysis of large quantities of textual data from the mass media (Mayring, 2004; Titscher et al., 2000). The qualitative content analysis is a systematic procedure that serves to capture text meanings. Within the data analysis process of this study, critical themes emerged which were grouped under more abstract higher-level codes and then linked to existent concepts from the literature.

**Preliminary findings**

*Emergence of the problem*
Although this paper presents an early stage of the analysis and therefore work in progress, the following findings are anticipated:

When considering the plurality of legal channels, a distinction can be made among luxury crafts and yachts, cruise ships (incl. ferries and other passenger ships), bulk carriers and container ships as the most important categories. The former three transportation modes are supposed to be particularly suitable for transporting live animals, whereas containers are not. On the contrary, containers present a preferred and convenient transportation solution for inanimate wildlife products. Seizures of any scale occur regularly as the sheer quantity of containers globally used offers vast opportunities to smuggling.

Illegal products may also be included in shipments that have an import or export certificate and which thus appear to be legal. Another important distinction between the legal channels refers to their relative share in maritime WLT. Due to the standardization of transportation equipment through containerization and the resulting extreme cost reductions, container ships are so dominant in maritime goods transportation nowadays that criminal activities, such as smuggling and illegal trade, have taken advantage of the efficiency of this international transport mode (Martin, 2015).

**SCI mitigation in the case of WLT**
To ensure the protection of the goods and proprietary information (privacy) of the shipper, the container remains sealed and inaccessible throughout nearly the entire voyage. The ensured secrecy of the container content entails important implications for the search of potential entry points for mitigating WLT. However, this lack of visibility is often an integral and intentional part of the transport itself. Sealed containers allow a comprehensive protection of shipped products and prevent external interference. This is particularly important when companies ship confidential goods.

Referring to the idealized chain of operational activities in Figure 1 above, a

† Please note that the data collection, coding and overall data analysis is still ongoing.
substantial probability of interference with containers exists during (1) the filling of containers, (4, 10) any inspections, and (14) the process of container stripping. In the context of WLT, it seems to be most likely that smugglers interfere at the container stuffing and stripping steps as these are the most accessible activities for hiding and removing wildlife products in and from containers. Interference during inspections also seems possible, but it would require bribery and corruption of authorities. Every inspection has disruptive effects on the flow of goods. Against the background of the vast number of containers transiting through ports each month—with a range of between hundreds of thousands and even millions for the largest hubs—these external disruptions have an immense impact on supply chains.

Based on the preliminary and ongoing data analysis, propositions are anticipated which 1) relate to the likelihood of WLT incidents in maritime supply chains as a specific example of SCI (e.g. different structural antecedents (sustainable supply chain risks, monitoring costs, transportation mode, supply chain position, etc.) that make WLT/SCI more/less likely to occur) and 2) link mitigation strategies and practices to these scenarios.

Concluding discussion
Assuming further analysis will proceed as expected, four significant and unique contributions are anticipated. First, to the best of our knowledge, this is one of the first papers to offer a conceptualization of SCI as a general phenomenon that stretches beyond specific issues such as counterfeiting and cyber-attacks. In doing so, SCP represents the most comprehensive approach, as a successfully infiltration presumes feasible situations. In particular, as this study focuses on WLT hotspots. Thereby, firms, governments and NGOs are able to deduce more effective measures and instruments for preventing wildlife poaching and trafficking, as these are novel issues for practice and research. Second, this paper is among the first to tackle the problem of WLT in a (sustainable) supply chain context, with a focus on maritime supply chains. WLT is an important, albeit neglected, driver to biodiversity loss and it has received scarce attention in previous research on sustainable supply chain management. Thereby, this paper provides first empirical insights and a thorough snapshot of corporate practices, key enablers, and barriers regarding WLT among the maritime transport and logistic industry. Third, the finalized study will facilitate the transfer of informative criminology theories to the field of (sustainable) supply chain management research. Previous research in supply chain management has not only shown impacts of supply chain disruptions but also the linking of these to sustainable related risks within supply chains. However, these disruptions haven’t been considered as an infiltration that is occurred because of situational related facts. The afore mentioned first empirical insights can therefore be seen as starting points of a first direction for future theory testing research in the context of SCI as a situational issue. Lastly, the final version of this study will provide methodological novelty insofar as it will engages in empirically augmented theorizing.

Abstract

The recurrence of safety violation indicates that firm’s operational improvements via corrective actions based on violation experiences may be limited. We argue that an adaptive corrective response to the violations might in turn hinder a system-wide improvement. Thus, the improvement from correcting one type of violation may not be effective in reducing other types of violations. We conducted panel data analyses on 2,965 listed firms with 4,474 violation records in the U.S. Our results indicate that past violation experiences are negatively associated with subsequent repeat violations (of the same clause), but positively associated with non-repeat violations (of a different clause).

Keywords: Occupational Health and Safety, Safety Violations, Policy and Operations

Introduction

Governments, media, and consumers nowadays are increasingly concerned about sustainable operations of firms. One of the important dimensions of sustainable operations relates to Occupational Health and Safety (OHS) (Kleindorfer et al., 2005). OHS problems can incur substantial social costs. In the United States (U.S.), on average, there are more than 12 workers losing their lives on their job everyday (BLS Census of Fatal Occupational Injuries, 2016). In addition, firm’s reputation, image, cash flow and productivity would be undermined (Fan et al., 2014; Lo et al., 2014). An improved OHS
performance can reduce operational risks (Wolf, 2001), improved product quality (Das et al., 2008) and increased revenue and profitability (Lo et al., 2014). Previous literature substantially explores factors for OHS performance improvement, including manager’s attitudes (Pagell and Gobeli, 2009; de Koster et al., 2011), OHS management systems (Lo et al., 2014), linearized and decoupled operations (Wolf, 2001; Wiengarten et al., 2017).

In spite of the above empirical evidence for improved firm performance resulting from OHS system implementation, whether violating firms will limit their future transgressions on safety violations, which is the core objective of OHS, has remained uncertain. Ironically, past research documented a low management commitment level of OHS in the industries (Pagell and Gobeli, 2009). In particular, when the operations managers are under productivity pressures, the safety practices may be compromised to meet urgent production goals (Brown et al., 2000; Wiengarten et al., 2017). Drifting away from safe practices often occurs in the firm because of poorly committed managers. This could cause damage, injury and fatality. Since the internal volition is often absent, government enforcement is expected to be the gatekeeper of safe operations. However, the effectiveness of government enforcement in improving safety performance of firms has not been widely examined. Our study aims to fill this gap.

In the U.S., mandatory correction actions are required for safety violation. Corrective actions are monitored by the Occupational Safety and Health Administration (OSHA) as an important element of experimental learning and safety improvement process (Hofmann and Stetzer, 1998; Christian et al., 2009; Catino and Patriotta, 2013). The purpose of levying such government enforcement includes retribution, deterrence, rehabilitation, restoration and incapacitation (Meyer and Grant, 2003). Also, the enforcements are expected to be followed at an organization-wide level, such that not only the violating department but also the other members in the organization will learn from the punitive sanctions (Braithwaite and Petitti, 1992).

Although the mandated corrective action seems to be an effective means to prevent firms from making the same mistake, the scope of improvement might be just at the level of a specific issue and not directed towards making organization-wide improvement, beyond the immediate point of correction. It has been observed that firms violate a variety of safety regulations on a continual basis. For example, Manke Lumber was fined US$ 87 thousand in 2015 for eleven violations, which had caused its workers’ severe injuries and fatalities (OH&S, 2015). Similar cases of violations occurred even in some highly reputable firms, such as Disney and Home Depot, resulting in US$ 21,000 and US$ 150,000 fines respectively (ISHN, 2013). It is therefore unclear whether the lessons learned from the past violation experiences do extend to a more comprehensive improvement, or such regulatory violations are inherent in the systems. Are the improvement practices just Quick Fixes—taken only to respond to the immediate correction action, impeding wider improvements in all kinds of safety compliances?

If the problem of safety violations, like other chronic management issues, is inherent within organizational systems and cultures, it is unlikely that firms would be able to improve extensively, or simply take corrective actions dictated by the government authority (Haunschild and Rhee, 2004). Even if follow-up actions are required after a safety violation, organizations might only resort to an adaptive response to mechanically comply with rules (Fiol and Lyles, 1985; Perrow, 1984). That is, organizations could only fix the specific failure without fundamentally transforming the current organizational systems and cultures underlying the failure. In fact, real organization-wide improvements in OHS require changing current organizational routines, systems and cultures, which are
unlikely to be accomplished by simply taking the required corrective actions. Firms need to proactively identify potentially critical incidents and develop an “early warning system” (Cope, 2005). Such a wider level of improvement, in turn, may require stronger enforcement forces and the interactions of other institutional pressures as an agency for change (Haunschild and Rhee, 2004). External institutional pressures drive organizations to deviate resolutely from their current organizational routines and take actions addressing the root cause(s) of any violations.

In this study, we explore the effectiveness of government enforcement in operational improvement of firms. Specifically, we investigate if safety violation experiences can deter subsequent violating behaviors of the same and different clauses. In addition, we explore the moderating roles of institutional pressures on a firm’s operational improvement, subsequent to OHS violations. Adopting DiMaggio and Powell’s (1983) categorization of institutional pillars, we examine the strength of enforcement as a coercive institutional pressure that is approximated by the amount of penalty, and normative and mimetic pressures approximated by voluntary OHS certification and relative industrial performance.

Drawing on neo-institutionalism (DiMaggio & Powell, 1883), we conceptualize a safety violation order issued by the government as a mandate for safety improvement. We first postulate that a firm’s past violation experience is negatively related to subsequent repeat safety violations (to the same clauses), which indicates the improvement on a specific clause where the hazards were exposed. In addition, drawing on the notions of safety culture and organizational myopia (Staw et al., 1981; Levinthal and March, 1993), we postulate that a firm’s past violation experience is positively related to subsequent non-repeat safety violations (with respect to different clauses), indicating the absence of systematic and wider organizational improvement. We offer evidence to show that the inefficiency of government enforcement reduces subsequent violating behaviors of firms.

Theoretical background and hypothesis development

Coercive pressure of OSHA enforcement

The essential premise of neo-institutionalism is that organizations in an institutional environment are becoming similar or “isomorphic” in nature (DiMaggio and Powell, 1983). Firms become isomorphic because they have to obtain legitimacy for survival (DiMaggio and Powell, 1983; Suchman, 1995). Coercive, normative and mimetic pressures are three primary pressures that make organizations conform to an established institutional environment (i.e., the prevailing organizational structures and practices) (DiMaggio and Powell, 1983; Scott, 2013). In other words, these external institutional forces serve to facilitate the diffusion of operations management practices such as total quality management (Yeung et al., 2006), radio frequency identification (Barratt and Choi, 2007; Whitaker and Mithas, 2007) and shape the standards in an organizational field, including safety requirements in industries (Lo et al., 2014).

Coercive pressure stems from political influence and government mandate (Zukin and DiMaggio, 1990). Organizations are penalized when they do not conform to the coercive pressure (Scott, 2013). The coercive pressures (e.g., government intervention) drive organizations to adopt managerial and technological innovations for environmental and safety enhancements (Gray, 1983). Thus, a firm’s sustainable practices are primarily affected by the role of government-as-coercer (Scholz and Gray, 1997).
From an economic perspective, the market participants often pursue the most economically efficient way to produce goods. Pursuing productivity goal may undermine worker’s safety (known as productivity-safety trade-off) and increase social costs (Lo et al., 2014). The government, as a coerer, aims to correct such market imperfections, which could cause adverse environmental and social outcomes (Scholz and Gray, 1997). Government regulations and enforcements, thus, play an important role in pushing sustainable operations (Tang and Zhou, 2012) by setting minimal environmental and safety requirements that all firms must follow. The fine and penalty of enforcement increase the costs of non-compliance and shape firms’ behaviors (Scholz and Gray, 1997). Therefore, law enforcement imposes a deterrent effect of preventing employers putting worker’s health and safety at risk.

To the violating firms, failure incidents such as safety violation records force to challenge the status quo, initiating necessary changes. A safety violation signals that the safety performance of the firm is in an undesirable state, putting pressure on them to search for new methods, which can improve the current status (Cyert and March, 1963; Madsen and Desai, 2010). The mandated corrective actions following a violation can be viewed as an adaptive approach in response to the OSHA’s enforcement, as the specific actions are laid down according to the hazards exposed in the inspection. These actions provide firms with explicit roadmaps as to what knowledge and alternative methods have to be searched, and allow firms to make the necessary changes and corrections. In addition, improvements are likely to take place because the violating firms are targeted for scrutiny by the authority and other stakeholders (e.g., the public). Firms that fail to respond and commit repeat violations will be penalized more seriously in the future (Desai, 2011; Zavyalova et al., 2012). Therefore, even though the violating firms may not be fully committed to comply with the safety regulations, they are mandated, or coerced, to correct any specific violation or neglect identified during inspection. We thus postulate:

**Hypothesis 1a:** The higher the number of past safety violations recorded, the lower is the number of subsequent repeat violation (to the same clauses) incidents.

Despite the fact that law enforcement may improve firms’ operational systems, Haunschild and Rhee (2004) find that the firms’ lessons learnt from previous mandated product recall experiences can be shallow and symbolic, leading to no fundamental improvement on the firm’s product safety routine and practices. Therefore, it is possible that the mandated improvements set by the government authority can be simply adaptive and reactive in nature, within a limited scope (Scholz and Gray, 1997). It is unlikely that these will lead to a system-wide improvement. If a firm aims to achieve a more fundamental improvement after the corrective action to the specific hazard exposed by the OSHA, the firm needs to proactively seek a deeper understanding of causality between behavior and outcome, and challenge the norms and status quo of the organization (Appelbaum and Goransson, 1997; Argyris and Schon, 1997). Although the adaptive corrective actions might bring immediate performance improvement, it could lead to organizational myopia, making firms overlook the big picture and other potential failures (Levinthal and March, 1993). This is especially the case when the improvements to be adapted are mandated by external parties (Haunschild and Rhee, 2004).

In the context of safety violations, the recurrence of safety violation records might indicate that safety problems of the firm are deep-rooted in its organizational systems and
culture, thus hindering proactive organizational learning for improvements. Reason (2017) pointed out that a safety violation record is often the “sharp-end” of a poor safety management culture. If a poor management culture is entrenched in a firm, although they are willing (coerced) to correct any exposed hazards in an inspection, it is difficult for the firms to proactively introduce organization-wide safety improvements. Previous studies have suggested that recurring safety violations are rooted in enduring organizational schema that hinders correct attribution of failure (Hofmann and Stetzer 1998; Reason, 2017).

From an economic perspective, if the expected penalties are smaller than the investment to explore potential hazards, the deterrent effect of violation would be insufficient to motivate a proactive improvement (Greve et al., 2010). In addition, the inhibited improvement efforts can be caused by a simple correction mechanism after a safety violation (Levinthal and March, 1993). The failure experience could narrow the organization’s focus on the domain of the problem. A firm that consistently resorts to adaptive improvement in response to safety violations is unlikely to take further actions to explore other hazards. First, the simplified correction mechanism narrows the firms’ focus on the specific hazard exposed, making them unable to explore other underlying hazards (Levinthal and March, 1993). In addition, for long, the public and scholars have criticized the penalties from OSHA for being too low (U.S. Government Printing Office, 2008; Viscusi, 1979). Firms may rely overly on government inspections to identify the hazards, rather than investing in an early warning system to proactively explore the safety flaws in the operations system.

Further, a safety violation is an adversity that can damage the firm’s reputation (Lo et al., 2014). In responding to such a threat, the firm’s information processing will be restricted thus increasing its reliance on organizational schema (Ocasio, 1993). The firm may simply refer to the previous method used to cope with the violation. Thus, the cumulative use of adaptive mindset for safety violation increases the firm’s rigidity to undertake comprehensive corrective actions. The lesson learned from the past violation is unlikely to be extended to various other units in the firm, thus inhibiting the spillover effects of corrective behaviors in the entire organizations. Therefore, we postulate that the past safety violations should positively associate with the subsequent non-repeat violations, which leads to an increased number of overall violations.

Hypothesis 1b: The higher the number of past safety violation records, the greater is the number of subsequent non-repeat violation (to the different clauses) incidents.

Hypothesis 1c: The higher the number of past safety violations records, the greater is the number of subsequent violation incidents.

Method

Samples

We sampled a large number of U.S. listed manufacturing firms and developed a firm-year panel data set to examine our hypotheses. The use of panel data has advantages in mitigating endogeneity concerns (Ketokivi and McIntosh, 2017) (see detailed discussion in the robustness check section). Panel data analysis was also used in the previous study whose dependent variable is corporate malfeasances (e.g., Mishina et al., 2010;
Haunschild and Rhee, 2004). Safety violation data were collected from OSHA’s violation database (OSHA, 2017) while other financial data were collected from COMPUSTAT database. The data collection process started with obtaining the name list of 8,953 manufacturing firms (SIC 20 - 39) from COMPUSTAT database. Next we searched for these firm names in OSHA’s violation database for their violation records. From each violation record we were able to obtain the violating firm’s name and address, the violation date, type and other related information. We summed up all the violations of a firm in one year to create the variable of annual number of safety violations as the dependent variable. If a firm was not engaged in any violation in that year, then the observation was coded as “0”. As our analysis involved the comparison with the industry peers, we excluded an industry (at 4-digit SIC) that did not have any violation history within our research window.

We collected the OHSAS 18001 certification data from each firm’s official website, annual report and media report. At the time of data collection, the window of violation database was from 1988 to 2014 at the time of data collection while the OHSAS 18001 was developed in 1999. Thus, we used the violation data between 2000 and 2014 as our dependent variables. We used the one-year lag between dependent variables for independent variables, so our independent list covered the period 1999 to 2013. In the event, we generated a panel data set consisting of 25,273 observations drawn from 2,965 firms. In the data set, 694 firms had at least one violation. In total, 4,474 violations were reported. The remaining firms with no violation record are used as control firms. Adding these control firms may bring a large amount of “0” in our dependent variable. However, Cramer et al. (1999) report that the parameter estimations are robust in samples involving large percentages of “0” observations. In addition, Bayus (2013) argues that it is more difficult to find statistical support with a large number of “0” observations. This suggests that adding firms without violations made the hypotheses testing more conservative.

**Variables**

We use subsequent safety violations rate as a proxy for firms’ safety performance as our dependent variable (Pagell and Gobeli, 2009; Lo et al., 2014; Wiengarten et al., 2017). This was measured by the firm’s annual number of violations to OSHA’s regulations scaled by the number of employees (‘0000) at year t. The violation database categorized the violations under serious, repeat, willful and other violations. We focused on the number of repeat violations (repeat violation rate) for hypothesis 1a to capture a specific safety improvement related to the past violations. Repeat violation is issued when the firm had been cited for the same safety regulation clauses in the past. For example, Metalico Rochester Inc. was cited in 2011 with violations for failing to develop proper safety procedures, which leads to the death of an employee. These are classified as repeat violations by OSHA because Metalico Rochester Inc. was cited for the same violation in 2010. For hypothesis 1b, we excluded repeat violations from our measurement of dependent variable, as our objective here is to test if past violation experiences are related to a higher number of subsequent non-repeat violation (to the different clauses) incidents. For H1c, we considered both repeat and non-repeat violations to examine the impact on overall violation number. We treated all other types as equal while calculating the number of violations, as the classification was not mutually exclusive (i.e., a violation can belong to many types at the same time). For example, a violation can be serious and willful at the same time. This treatment is consistent with previous studies (e.g., Pagell and Gobeli, 2009; Lo et al., 2014; Wiengarten et al., 2017). In our sample, nearly 99% of OSHA visits
were without advance notice, so the firms could not have indulged in last-minute cover-ups before the visits. Accordingly, spot-check inspections should more accurately reflect the safety performances of firms.

With H1a, H1b and H1c, we hypothesized the relationship between past safety violation experiences and subsequent safety violation incidents. The variable, Violation Experiences, was measured by the total number of violations a firm committed in all the years before a certain year (year \( t \)). This measurement was consistent with the studies of organizational learning from failure (e.g., Haunschild and Rhee, 2004; Yiu et al., 2014). This measurement captures the total past experiences in all years before the safety violation incident in year \( t \). In our sensitivity analysis, we replaced this variable by the number of safety violations committed by a firm in one year (instead of all years) before year \( t \) (i.e., at year \( t-1 \); see robustness checks section).

We included a number of control variables in the models to ensure their robustness. We first included the natural logarithm for transformed number of employees to control for firm size, the return-on-assets (ROA) and operating income per employee ratio (Productivity) to control for firm performance because a larger and profitable firm is likely to have abundant resources to invest on safety practices. We included firm age because older firms may cumulate more violation experiences. We also included the financial slacks of the firm because resource abundant firms have higher capability to invest in safety precautions. Financial slacks are multi-dimensional and include unabsorbed slack measured by quick ratio\(^1\), absorbed slack measured by selling, administration and general expenses scaled by sales and unborrowed slack measured by financial leverage (debt/equity) (Wiengarten et al., 2017). Firms may face higher safety risks when their operations are complex. We included labour intensity (total assets per employee) to control for process complexity in the operations (Lo et al., 2014). We included research and development (R&D) intensity (R&D expenses per employee) to control for the absorptive capacity because learning is more effective in highly absorptive capacity firms (Tsai, 2001). We also included annual number of inspections of the firm to control for some firms being targeted by authorities. The size of violation penalty relates to the violation types: willful and repeated violations are penalized more vigorously by the OSHA. Thus, we included the percentage of past willful and repeat violations to the total violations to control for the types of violation experiences. We also controlled for the average penalty the firm received in the past, whether the firms were OHSAS 18001 certified and the number of violations of the industry (four-digit SIC).

Finally, we included the dummy variables of year, industry and state of the firm’s headquarters to control for fixed effects. Except otherwise stated, the independent variables have at least one-year lag, \( t-1 \), to the dependent variable, \( t \), to exclude the alternative explanation of reversed causality.

**Results**

Table 1 presents the results from the OLS analysis with robust standard errors. The maximum variance inflation factor (VIF) of the independent variables is 2.437, indicating that multicollinearity is not a serious concern.

Model 1 examines H1a with the dependent variable as repeat violation rate. We excluded the control firms with no violation records throughout the whole research

\(^1\) Quick ratio was calculated by current assets minus inventory then scaled by current liabilities.
window, because these firms do not possibly have repeat violations. We also conducted a separate analysis by including all sample and control firms, the results are largely similar to our main analysis. In Model 1 of Table 1, the coefficient for past violation experiences is significantly negative (-0.0024, p < 0.05), which supports H1a. With one more past violation experience, the firm’s subsequent repeat violation would reduce by 0.0024 per ten thousand employees, given that the average repeat violation rate is 0.034 and the decrease is 7%.

Model 2 examines H1b with the dependent variable as non-repeat violation rate. The coefficient for past violation experiences is significantly positive (0.0293, p < 0.01), which supports H1b. With one more past violation experience, the firm’s subsequent non-repeat violation would increase to 0.0293 per ten thousand employees. Given that the average non-repeat violation rate to be 1.0992, the increase is 3%.

Model 3 includes both repeat and non-repeat violations in the dependent variable in order to examine H1c. The coefficient for past violation experiences is significantly positive (0.0265, p < 0.01). Given that the average total violation rate is 1.1332, with one more past violation experience, it increases the total violation rate by 2%. This result supports H1c, which suggests that the present violation experience associates with a higher overall violation rate in the future.

Conclusion

This study has explored the relations between the past safety violation experiences and subsequent repeat, non-repeat and overall safety violations. It has presented an analysis of a sample set of 2,965 U.S. listed firms with 4,474 violations issued by Occupational Safety and Health Administration from 2000 to 2014. We find that past violation experience associates negatively with the subsequent repeat violation incidents, which show a certain level of improvement after a firm was cited and the corrective action was conducted. However, the past violation experience associates positively with the subsequent non-repeat violation and overall violation incidents.
The results have shown that firms do not necessarily reduce their safety violations as they accumulate more safety violation experiences. The literature has already captured superior improvement effects from the additional experiences of errors (e.g. Edmondson, 1996; Catino and Patriotta, 2013) and accidents (e.g. Hofmann and Stetzer, 1998; Haunschild and Sullivan, 2002). However, consistent with the notion related to organizational myopia (Levinthal and March, 1993) and the shallow learning effect in mandated product recall (Haunschild and Rhee, 2004), our results show that the adaptive corrective actions to past violations hinders proactive exploration of other hidden hazards in the system. Table 1 shows that adding one violation per (‘0000) employees to the mean of violation experiences (from 3.2898 to 4.2898), the mean violation rate per year is seen to increase by 2.6501. These result findings call for future research to investigate how to motivate firm to better utilize the violation experience and conduct more proactive learning process, which to improve the OHS performance in the industries.

Asper School of Business - University of Manitoba

Abstract
This paper aims to extend the current theory and enhances the practice of supply chain sustainability in emerging economies, where contextual elements are extremely relevant, especially in supply chains predominantly operated by micro and small enterprises (MSEs). A qualitative research approach was employed using team interviews with different members of stakeholder groups of the cashew supply chain in Ceará, Northern Brazil. The findings indicate that supply chain members have different comprehension about the practice of sustainability. In turn, third party actors (e.g. Sebrae, Embrapa) are recognised as central players to spread the practice of sustainability through the cashew supply chain. This paper contributes in advancing the supply chain sustainability literature and show empirical evidences that already well established frameworks developed in the North may not be as relevant to all contexts.

Keywords: Supply chain sustainability, Micro and small enterprises (MSEs), Emerging economy.

Introduction
The literature on supply chain sustainability are increasing in the last years and has been considered a fruitful research field (Ansari and Kant, 2017). Currently, it is urgent the need for empirical research that demonstrate the characteristics of sustainability approaches through supply chains. According to Pagell and Wu (2009, p. 38), "when we discuss sustainable supply chain management we are referring to managerial decisions and/or behaviors", which demonstrate that it is necessary to understand how direct supply chain relationships introduce sustainability advancing the current knowledge based more on the focal company point of view.

By challenging the comprehension of the concept of supply chain sustainability, we believe that there are contextual elements from emerging economies that might affect
most supply chains, but the European and North American perspectives have not covered (Gold and Schleper, 2017). Fritz and Silva (2018) and Jia et al. (2018) corroborate with this idea by arguing that the literature does not adequately deal with the specific issues of SCS in emerging economies. There is a pressing need to stimulate companies to have increased supply chain collaboration in different contexts and that the supply chain complexity should be taken into account. The supply chain sustainability only is possible if a learning process happens and the sector context is effectively observed (Silvestre, 2015).

Thus, according to Cagliano et al. (2016) to have truly food supply chain sustainability (FSCS) it is necessary to align strategies and practices, which is related to innovation. In the current debate, FSCS emerge from practices performed among companies in a multitier level. The levels should encompass all actors involved in the process toward sustainability at the strategic, structural and process levels of the supply chain (Beske and Seuring, 2014). By assuming these comprehension and need for changes in how to apply sustainability in supply chains worldwide, this paper aims to extend the current theory and enhances the practice of supply chain sustainability in emerging economies.

Therefore, this research aims to apply Beske and Seuring’s (2014) framework to explore sustainability issues within the cashew supply chain in Northern Brazil. This research adopts a learning perspective to supply chain sustainability in an emerging economy and aims to understand how applicable this framework would be to different supply chains, especially the ones with predominantly micro and small enterprises (MSEs) within developing settings. There are several gaps that need to be covered by studying contexts such as Latin America (Fritz and Silva, 2018). Aiming to contribute with theory and practice this paper is structured in different sections that challenge the current understanding and meaning on the research topic.

### Supply Chain Sustainability

Discussions about sustainability and SCM have been increasing in the past years precisely because the study of these topics is both timely and significant (Golicic & Smith, 2013). As presented by Ashby et al. (2012), the initial discussions under this perspective point out to the year 2003, but only in 2008 a wider range of articles was being published about the topic. According to Ahi and Searcy (2013), there is at least twelve “definitions” on the perspective published along this decade, however not a theoretical evolution about Sustainable Supply Chain Management, which is the more widespread expression on the topic. From this discussion, it is clear that more than creating new concepts and/or definitions; it is necessary to evolve the field through a new approach that carries both theoretical and methodological consistence.

Focusing on SCS, the organisations "need to satisfy various contradicting objectives such as profit maximization while reducing environmental impacts and maximizing social responsibility" to reach sustainability practices (Ansari and Kant, 2017, p. 874). Therefore, to challenge the current literature is an important step to advance in the comprehension on how to practice sustainability in emerging economies. Within this
debate it is important to highlight the need for more clear comprehension about what is sustainability. According to Fritz and Silva (2018), the Triple Bottom Line (TBL) is not enough to understand sustainability, which could be clearly observed by discussing the sustainable development goals (SDGs). Since other elements are involved with what companies do what they do, it is relevant to demonstrate their comprehension and interactions created to better performance its practices.

In addition to this point of view, it is necessary to understand what is currently presented in the literature. According to Ansari and Kant (2017), there are several framework that represent the topic, some of them following a narrow perspective. This occur aside other reasons, because sustainability has been used in a instrumental and normative perspective (Gold and Schleper, 2017). Although this point of view, other elements (including SDGs) should be used to better capture the complexity of applying sustainability in supply chains. In order to advance in the comprehension of new conceptualization of SCS, Figure 1 illustrate how is possible to observe differences.

![Figure 1: Origami framework for sustainability in supply chains. Source: Fritz and Silva (2018)](image)

The figure show a set of folder considering elements around sustainability and it allows scholars to recognise that sustainability is more complex than observed following the triple bottom line perspective. Fritz and Silva (2018) state that the origami metaphor consider the need of change in the design, because it is not a star, but it can assume different formats. In the SCS literature, there are calls for new ways to analyse true sustainability, which can be delivered by creating another logic of analysis (Montabon et al., 2016). According to Touboullic and Walker (2015, p.21), “future research efforts could seek to develop our understanding of the implementation process of SSCM by framing it as transformation/change in organisational practice”. For this paper we debate about other elements that are around the SCS practice.

According to Beske and Seuring (2014), to understand supply chain sustainability it is necessary to consider a broader discussion using some categories and practices that...
can facilitate the analysis of SSCM. According to these authors, this is possible in three hierarchical levels: Strategic values, Structure, and Process (Figure 2). Each of these levels guide how supply chain may introduce sustainability as well as how it is possible to design a sequence of practices contributing in that way.

![Figure 2: Sustainable supply chain categories and practices](Source: Beske and Seuring (2014))

As presented in the Figure, there is a unique way to introduce elements toward SCS, which not consider other elements such as contingency factors. Tachizawa and Wong (2014) demonstrate that in a multitier supply chain there are several influences beyond what is directly consider in the literature. However, as presented by Mena et al. (2013) and other authors in SSCM, when considering the sustainability in supply chains the economic dimension of sustainability have a little relevance when social and environmental dimension are more difficult to be observed. This paper aims to observe Beske and Seuring’s (2014) framework and its relation with the emerging economies contexts and perspectives.

**Research Method**

A qualitative research was developed using interviews with different members of the cashew supply chain in Ceará, Northern Brazil. The research focus is on cashew production, considering its economic relevance as well as that it is the most exported product in Ceará state, which is the first position in Brazil regarding export cashew nut. To enable a rich and multi-faceted view of the local business practices, ten interviews were conducted with representatives of different stakeholder groups: four farmers, four processing firms (e.g. cashew nut, Cajuina), and two third party members (i.e. Embrapa and Sebrae).

Since our focus is on MSEs, direct supply relations has been identified to ensure evidence of practices that are accessible to these firms. Data gathering was developed
between June and August of 2018. The interviews were conducted in Portuguese, recorded, transcribed and translated to English by both authors to ensure the reliability of the study. The analysis was conducted based on five main categories of Beske and Seuring (2014), namely (1) Orientation; (2) Continuity; (3) Collaboration; (4) Risk Management, and (5) Pro-activity management. Additionally, contingency factors were analysed to better support the argumentation and findings. For that, a content analysis was used in order to understand better the meanings and understandings.

Findings

The cashew supply chain in Ceará is exported-oriented mainly operated by four medium companies. Small and micro operations have been emerging locally in the last decades as an alternative for enhancing community engagement and maintaining the cashew production, an economic activity that has long history and is a regional heritage, i.e., it is part of the local culture and background. The findings indicate that supply chain members have different comprehension about the practice of sustainability (Table 1). For example, farmers believe that their production are sustainable in nature (simply because it’s an agricultural product, with no consideration to pesticide/herbicide usage, water consumption, land management or working conditions) while the processing firms do not recognise themselves as the ones responsible for the implementation of sustainability practices since they have small business.

In turn, third party actors (e.g. Sebrae, Embrapa) are recognised as central players to spread the practice of sustainability through the cashew supply chain. Though the findings was clear that to introduce sustainability, mostly considering the MSEs characteristics, it is necessary to have someone not economically included in the supply chain to have clear practices. Additionally, it was not found elements that demonstrate a clear relation with collaboration, which is a key aspect for Cagliao et al. (2016). There are also a lack of elements that demonstrate pro-activity as an operational level for SCS. It was found that this elements could be better related to orientation, which change the structure of levels presented by Beske and Seuring (2014).

As presented in the table, by applying the Beske and Seuring’s (2014) framework, it was possible to identify some alignments, but more importantly some key inconsistencies that require a broader perspective that would include the specific contextual elements from MSE dominant supply chains in emerging economies to fill the existing gap in the mainstream publications. For example, the category orientation is stressed as totally aligned and necessary when it comes to supply chain sustainability in such a context. The empirical study shows that supply chain members do not feel themselves as part of a supply chain as a system, neither the processing firms have this feeling of being part of a broader system.

This result ratifies the need for awareness and dedication to the TBL principles, which create an opportunity to talk about other dimensions as presented by Fritz and Silva (2018). The continuity category is mostly absent locally due to the fact that relationships are very volatile and no long-standing relationships were identify. Collaboration is based on personal connections and trust in that specific person, as opposed to trust more embedded in the supply chain relationships, which makes it more difficult to involve a broader set of actors and enhance collaboration outcomes. The risk management category is clear for farmers and is influenced by contingency factors.

In a complementary way, contingency factors were identified as relevant by interviewees to understand the local context such as: low productivity (Bloom et al. 2010), business informality (Silvestre, 2015), lack of government incentives and support (Azzi da Silva and da Rocha, 2001) and the extremely dry period facing the region in the last years (Silva et al. 2018). Although these challenging factors were identified, it was found that currently the role of third party is deemed as essential to develop supply chain activities, especially the integration of sustainability business practices to MSEs. The findings also demonstrate that the Beske and Seuring’s (2014) framework requires adaptations since the influence of contingency factors impact directly in how firms manage and practice supply chain sustainability.
Conclusions

From the empirical results, it is clear that the framework does not fit directly with the emerging context of Brazil. The findings demonstrate that contingency factors and third party practices are necessary to reach supply chain sustainability. These elements demonstrate that to discuss about hierarchical levels it is necessary to understand before what is around the relationship analysed as well as how the supply chain members perceive themselves in the process. Research on SCS needs to assume a more behavioural viewpoint instead of assuming everything as static and without influence from the context where the relationship are.

By analysing the cashew supply chain in Ceará, there are two main contributions: (1) theoretically, by providing a critical stance to the mainstream supply chain sustainability literature. It also proposes a framework that extends theory and enhances the practice of supply chain sustainability in emerging economies, where contextual elements are extremely relevant, especially in supply chains predominantly operated by MSEs, and (2) for practitioners there is the indication to understand better what they are doing and making to have sustainability as a truly practices and logic regarding their strategies and operations in the market.

Abstract

Due to growing pressures on global resources such as water, interest in supply chain water use has grown considerably. Water resource accounting is an established method for measuring supply chain water use, but what drives organisations to engage in these accounting activities is unknown. Similarly, what hinders engagement with accounting activities is not known. The research aims are twofold, firstly we review supply chain management and water resource accounting. Secondly, we develop a framework of drivers and barriers to supply chain engagement with water resource accounting. Following this we highlight key future research opportunities.

Keywords: water resource, supply chain management, conceptual framework
Introduction
As populations increase and the world is faced with issues such as climate change, and increased resource pressure, businesses' and their supply chains face an important challenge in ensuring the sustainability of our world. Water is one resource that has received growing attention over the last half decade, reports of droughts and increased water needs for communities across the globe have become increasingly more frequent (Masante et al., 2018). The World Economic Forum’s Global Risk Report (GRR) has listed water crises among the top-five risks in terms of impact for eight consecutive years. Therefore, the practise of quantifying water use is an increasingly popular topic within academia. The idea of quantifying water use has also made its way into mainstream media with online calculators enabling consumers to calculate a water footprint of their diet, of their daily routine in the home and other situations (EasyCalculation, n.d.; GRACE Communications Foundation, 2017).

A water footprint uses the idea established concept of virtual trade water and has been described as a quantitative indicator of the water used to create a product or conduct a process (Allan, 1992; Hoekstra et al, 2011). Whilst individual water footprints are of importance it is argued that the global water footprint of a supply chain is more important due to the increase in magnitude of the water footprint (Christ & Burritt, 2017). Additionally, water related risks can be present at any one stage of a supply chain. Therefore, efforts must be taken by businesses to evaluate, monitor and manage their water use across not only their own activities but also those of the supply chain. Corporate water accounting exists as a methodology to assist in the evaluation of business water use making use of tools such as the water footprint.

Whilst initiatives such as CDP Water (Carbon Disclosure Project, 2017) and the CEO water mandate (United Nations Global Compact, 2011) exist to encourage organisations in the disclosure of their organisational water related risks, it is not widely understood to what extent companies engage or do not engage with water accounting of one form or another. Also it is not clear that what are the barriers that companies face wishing to engage or begin engaging with water accounting activities. This research aims to provide a framework to understand this gap through review of the relevant literature.

Research methodology
The purpose of this research is to explore a new research area and to conceptualise a framework for the understanding of the research area. The literature review process has been described as the process of collecting and analysis research in order to produce new ideas (Seuring & Müller, 2008). Depending on the purpose of the literature review, the research process of collecting and analysing research can follow a structured approach or an unstructured approach (Arksey & O’Malley, 2005). The purpose of this research involves collection and evaluation of relevant material and therefore follows a structured approach.

In order to collect relevant material for this research the first part to material collection involves a scoping study to outline the key concepts behind this research. Following the scoping study several observations can be made. In order to ensure the research is relevant to the water resource accounting within the supply chain context, the term “supply chain” should be included in any search terms. Evident from the scoping study, it is necessary to include one of either “water resource accounting”, “water footprint” and “water
evaluation”. In terms of identifying whether research pertains to the drivers and barriers of engagement with water resource accounting is somewhat less easy to describe in words and is therefore validated by a group of researchers. The next stage in material collection is to implement the search in relevant databases including Google Scholar, Scopus and Web of Science. There also exists a large amount of public research in this area and to capture this, Google was also used. The findings of the literature search are presented in the following section.

**Literature review**

Water resource accounting is an overarching term that refers to practices that enable organisations to quantify and account for their water use, focusing on the collection of relevant data the aim of water resource accounting is to assist decision makers in improving aspects such as water efficiency, total water use, and waste water (Christ & Burritt, 2017). One tool that exists and has been widely applied in many cases of water accounting is a Water footprint. There are differing methodologies for the quantification of a water footprint and this is currently beyond the scope of this research. In this case we simply refer to the volumetric footprint that is an indicator of the water required to produce a product or conduct a process (Hoekstra, 2010).

Both public and academic research have investigated the drivers, barriers and benefits of water resource accounting. In academia, Antonelli & Ruini (2015) focus on understanding the benefits realised by a single company through their engagement in water resource accounting. They show that by using the water footprint as a measure of water use the company is able to improve water use efficiency across a portfolio of products, they also show how this enabled the company to identify opportunities to expand into new product markets. Public research carried out in line with The CEO Water Mandate (Morrison & Schulte, 2010) evaluates the different methodologies available to companies when undertaking water accounting activities. They also outline several drivers for doing so, they outline hotspot analysis as a key driving force as well as potential for operational efficiency improvements and increased communication with stakeholders as well as supply chain partners.

Many barriers have also been identified with regards to water resource accounting, and a large proportion of these challenges focus on methodological challenges. Berger & Finkbeiner (2010) discuss the growing number of approaches available for use in water footprint methods, and how this potentially causes confusion for the decision maker. In further research Berger & Finkbeiner (2013) evaluate the different approaches based on the different nature of data collection and the data requirements. Furthermore, Chenoweth et al (2014) provide a review of all standalone water use indicators and the methodological challenges presented by each indicator. They discuss the inconsistency in terminology between methodologies and raise the issue of correctly identifying water components for analysis.

**Beginnings of a conceptual framework**

This work is the first step towards theory building and conceptualisation of the research field. Therefore, this work will be iterative and the authors predict the framework will
undergo many iterative changes before completion. The framework, as seen in Figure one, will be presented in three parts which are:

- Drivers of engagement with water resource accounting
- Barriers of engagement with water resource accounting
- Benefits of corporate water resource accounting

**Drivers of engagement with water resource accounting**

The first element of the research framework focuses on the factors that drive companies to engage with water resource accounting. Through careful review of the literature several different themes emerged, these themes are then explained in the following subsections.

**Economic self interest**

In the cases when water consumption and withdrawal are two factors directly related to operational costs organisations will hold a clear desire to reduce their water consumption, and withdrawal, to ultimately lower the costs of operations.

**Continual operations**

Where the organisations activities are subject to water risk an element of water risk assessment is necessary to ensure risks are adequately assessed and mitigation or contingency plans are appropriately developed and implemented. Water resource accounting exists as a measure to assist in the identification of supply chain water related risks.

![Conceptual framework](image-url)
**Hotspot analysis**

Water resource accounting can provide specific hotspot analysis which can be beneficial in several ways; where the identified “hotspot” indicates to the organisation that water use in a particular activity is somewhat large in comparison to the water use of the whole supply chain this analysis can prompt organisations to evaluate the water use at the identified activity level. This evaluation could prompt several actions whether they be supplier evaluation or technological evaluation.

**Tools to identify opportunities for innovation and change**

Either as a result of hotspot analysis or independently, water resource accounting can act as a tool to identify opportunities for innovation and change within the supply chain. That is to say that through engagement with corporate water resource accounting organisations may review specific activities or processes within the supply chain with respect to water use and identify opportunities to redesign a process or product resulting in improved water use.

**Stakeholder engagement**

When discussing stakeholder engagement, stakeholder is an encompassing description for the groups with interest in an organisations engagement with corporate water resources. Firstly, shareholders will have their own beliefs and drivers for interest in this topic, these individual drivers are not the focus of this work. However, their collective belief that organisations should engage with corporate water resource accounting is itself a driver to organisational engagement with corporate water resource accounting. Customers form the second body of stakeholders, with their purchasing behaviours they are able to demonstrate their power in encouraging organisational strategy. With the increase in conscious consumers acting in the best interest of planetary resources the change in buying pattern ultimately impacts organisational consideration for water resources.

**Barriers**

The framework also aims to explore and identify the barriers that organisations and their supply chains may face when they are attempting to engage in water resource accounting activities. Again, through evaluation of the literature several themes of barriers are identified and explained in the following subsections.

**Reluctance to self-expose**

In some cases, the exercise of fully disclosing supply chain water evaluation may expose risks within the supply chain. Furthermore, when the organisation does not have the capability to manage the risk this can have detrimental effects on the performance of the organisation and the supply chain.

**Lack of perceived benefit**

Dependent on several ideas including the organisations position within the supply chain, the organisational internal knowledge and the inter supply chain relationships there can be limited perceived benefit for engaging in supply chain water use evaluation. In the instance where the organisation plays a role with limited expose to water use there is no obvious reason as to why the organisation would engage with water accounting and no perceived benefit of doing so. Secondly, if the internal knowledge surrounding the
importance of supply chain water use is lacking limited understanding of the benefits of water accounting will also hinder the organisational engagement.

**Difficulty in obtaining data**

In many cases the resources required to collect and analyse the water use of an organisation and the entire supply exceeds the available resources. When the data is not already held by the organisation and the extra resources required to collect the data can be perceived as too difficult or not worth the extra cost so data is not collected.

**Lack of required technical knowledge**

In comparison to the case where the data is perceived too difficult to collect, another barrier may be the technical knowledge and skills of the organisation. In instances where the data is held by the organisation but the knowledge required to make sense of the data is not present it can be the unfortunate result that no analysis of the data is carried out.

**Lack of consistent terminology**

This barrier focuses more on the shortcomings of the existing methodologies and tools in place rather than the shortcomings of the organisation or supply chain. Several tools exist to measure water use, and different methodologies employ different terminology which can cause confusion to users and hinder the understanding of the methodology itself and therefore limit the application of the methodology.

**Benefits of engaging with water resource accounting**

The third segment of the framework focuses on the benefits of water resource accounting. Identification of the potential benefits to engaging is important in establishing the business case for do so, in cases where benefits are well understood and clearly communicated organisations have succeeded in bring water resource accounting to the attention of the organisation and supply chain. On the other hand, when benefits are unclear and unexplored it can be difficult to make the case for engagement in such activities. By outlining key benefits, organisations who have experienced difficulty in making the business case for water resource accounting are provided with key points that may help develop the case further.

**Increased efficiency**

As a result of analysing water use throughout organisational processes organisations may identify opportunities to redesign or reengineer processes such that the efficiency of the process is increased. This can of course lead to overall operational efficiency improvements both to the focal organisation and to the wider supply chain which potentially lead to greater production capacity, reduced lead times and reduced material requirements.

**Reduced costs**

In many cases the objective of reducing supply chain costs is present, water resource accounting can assist in the realisation of this objective by identifying processes that are unnecessarily costly due to their inefficiencies. Given that inefficiencies are addressed the supply chain can experience cost reductions.

**Competitive advantage**
Aware consumers are increasingly turning their attention to supply chains to understand the water used in producing products and services. So much so that when an organisation can clearly communicate their water intensive activities and the strategies in place to reduce this intensity the organisation holds competitive advantage over the competitors that cannot do so.

**Supply chain awareness**
The nature of water resource accounting requires in depth evaluation of organisational activities and supply chain activities. In doing so, supply chain weaknesses are identified prompting action resulting in a strengthened supply chain. Additionally, complete supply chain evaluation requires communication throughout different entities in the supply chain, where positive relationships already exists these can be strengthened and provide further communication between supply chain entities. On the other hand, where negative relationships exist this opens up opportunities for change in exchanges between entities.

**New opportunities**
Through the process of reviewing supply chain water use, organisations may identify hidden opportunities for product development or redevelopment. With the desire to reduce water use organisations may look to the inclusion of new technologies that can assist in redefining current products or to develop novel products.

**Conclusion**
In this research, we have presented the first thoughts of a framework for supply chain engagement with water resource accounting. This research has practical implications for both practitioners and academics, for those within industry we have highlighted some of the potential benefits of engaging with water resource accounting that may serve as a starting point for internal communications around this issue. For academics, we have developed a starting point for understanding the business environment of engagement with water resource accounting. This provides a solid starting point to further refine and develop this framework. Furthermore, in this first exploratory study of the role of water resource accounting we have explored the drivers and barriers companies face when engaging with corporate water resource activities. We have shown those companies who do engage do so for several reasons, whether it is as a result of indirect or direct pressure from stakeholders or from internal desires to analyse and improve organisational water use.

This study possesses several methodological shortcomings, in order to collect the data, the review process has been conducted by a small team of researchers and in order to increase the validity of the research further researchers should be involved to determine the search terms. Similarly, further input from alternative researchers when determining the corresponding categories for drivers and barriers identified from the literature would only refine the research.

One of the next steps in this research is to involve industry leaders who have shown themselves to be proactive in engagement with water resource accounting to firstly verify the framework developed in this research and secondly, to build a richer picture of the business benefits to water resource accounting.

Abstract

This paper focuses specifically on water resource challenges and examines, via corporate social responsibility disclosures, the emerging resource development and management strategies undertaken by FTSE 100 companies oriented towards their suppliers with regards to water within their supply chains. Findings from 50 multi-national companies listed on the FTSE 100 reveals that it is the consumer facing industries have taken the biggest steps towards demonstrating their development of resources to address sustainability challenges and engaged closer with their supply chain when addressing water challenges in order to generate wider shared benefits across multiple organizations and community regions.

Keywords: Supply chain management, water sustainability, sustainability reporting

Introduction

At an organizational level supply chain manager are placed in a key role in ensuring continued access to critical resources whilst orienting business and suppliers towards building up levels of social, environmental and economic capital. This is a critical strategy as companies are now expected to compete on a sustainable supply chain vs sustainable supply chain basis (Sarkis et al., 2011). Effective governance of sustainability within corporate supply chains requires understanding the roles of different stakeholders (Akhavan and Beckmann, 2017) and how effective organizational collaboration can be utilized to provide the support functions to create shared value from engaging in pro-sustainability operations (Porter and Kramer, 2011). In this context, supply chain managers in large companies find themselves in a position of a unique vantage point and are involved in every aspect of operational activities from logistics through to strategic planning, finance, marketing, and communication which can create positive or negative effects for the company and its stakeholders and simply imposing rules and regulations from above may not generate the required sustainability management practices at the supply chain (Schnittfeld and Busch, 2016), and would still require effective measurement and monitoring processes. Previous research in the field
has attempted to integrate concepts concerned with measuring and monitoring sustainable practices and performances within the supply chain, including the integration of social, environmental, technological, political and economic performance issues (Schaltegger and Burritt, 2014), the efficient use of resources (Koh et al., 2016), or environmental hot spots emerging from certain processes (Acquaye et al., 2017).

The focus on supply chain management is a crucial one as companies are increasingly being held to account for the actions of their suppliers (Hassini et al., 2012). Ensuring sustainability practices in the supply chain is crucial given the popular view of contemporary organizational trends sees the shifting of production networks towards regions where labour costs and environmental standards may be lower, or where legislation is less strictly enforced and therefore seen as a ‘race to the bottom’ (Guenther et al., 2012). The challenge of examining sustainable development across corporate supply chains is vast and this paper therefore narrows the focus to water resources. This is justified on the basis that water pulls together traditional environmental-centric views of sustainability regarding pollution and resource exhaustion. The use of water as a “case” resource fits with a number of the United Nations Sustainable Development Goals such as Goal 6: Clean Water and Sanitation concerning water availability as well as Goal 12: Responsible Consumption and Production which considers indirect focus on the sustainable use of water sources. These goals set out targets by 2030 for: improving water quality by reducing pollution, eliminating dumping and minimizing release of hazardous chemicals and materials; halving the proportion of untreated wastewater and substantially increasing recycling and safe reuse globally the expansion of international cooperation and capacity-building support to developing countries in water- and sanitation-related activities and programs; sustainable management and efficient use of natural resources; and for companies, “especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle” (UN, 2019). At a policy level there is increased pressure on companies to engage in sustainability practices and demonstrate successes. For example the Commission of the European Union references the integration of water resource consumption to consider the ‘efficient’ use of abstracted water as part of its ‘A Resource Efficient Europe’ agenda (Commission of the European Union, 2011, 2012). While this is a start, a draw-back of this approach is that it focuses only on blue water (water that has been sourced from surface or groundwater) and does not consider the green and grey water which can play a prominent role in water resource consumption in many industries and opens up the debate on water sustainability away from a water efficiency perspective, but to also include measures of quantity, quality and re-use (through direct re-use and treated waste water). Here there exists the opportunity to integrate product water footprint, and the virtual water (the water embedded into global trade flows) into corporate management and reporting (Antonelli and Sartori, 2015; Hoekstra, 2017)

This research explores the challenges facing supply chain managers with regards to measuring and monitoring their water consumption. In order to gain an overview on the water challenges presented, this paper takes the case study of 50 large corporates listed on the FTSE100 and examine the reported water challenges from supply chain managers against traditional purchasing and supply chain management criteria. The focus on water is justified in the current research environment, where the role of water in an environmental management strategy is relatively under-developed in comparison to
other sustainability challenges such as carbon emissions and pollution prevention. Focus on large corporations is a suitable starting point as their size and position within global value chains gives them the ability to enforce standards in water consumption and waste water processes in order to create a larger market of potential suppliers and distributors, who in turn are forced to attach greater priority towards environmental performance (Fiorino and Bhan, 2016). The following sections of this paper set out the concepts of sustainable supply chain management with a resource dependency focus. The paper then continues to outline the methodological process of content analysis of corporate water sustainability disclosures. The final sections present the results and discuss the institutional and governance implications for water sustainability management within the supply chain.

**Supply Chain Management and Resource Dependency**

In focusing on water as a natural resource, this paper considers how water can become both a serious constraint for business operations, as well as a resource which can be exploited for sustainable competitive advantage. Water in this sense can be framed as a resource dependency issue, where under resource dependence theory - RDT (Pfeffer and Salanick, 1978) it is theorized that as a company becomes more dependent on a greater number of organizations in its supply chain, it can become more exposed to negative and unintended consequences (Ellram et al., 2013). Under this theoretical perspective, companies will attempt to utilize their power within the supply chain to manage and align their stakeholder interests to meet their own interests, and satisfy the interests of local community groups. These dependence relations on resources such as water give greater strength to the need to engage, manage and collaborate with their suppliers in order to maintain access to physical resources as well as knowledge capabilities, societal connections, and raw materials (Wieland, 2014). Asymmetries in information, knowledge and resource access can magnify power imbalances between the firm and stakeholders, as well as the extent which bounded-rational managers fail to consider stakeholders’ interests to the firm. More powerful organizations are able to exploit their power to suppress their partner organizations, but this also offers the opportunity for a well-made contract structure to negate organizational weakness. RDT has implications regarding the optimal configuration and divisional structure of organizations and their stakeholders in supply chains with the basic arguments of resource dependence theory based along ideas that organizations depend on resource, resources originate form an organizational operational environment, resources required by one organization are often controlled or owned by other organizations, resources are the basis of power and this power and resource dependence are directly linked, and legally independent organizations can therefore depend on each other, such as during the structuring of supply chain relations. The resource dependence concept can be understood through the evaluation of buyer-supplier relationships and these can be uncovered through reviewing Corporate Social Responsibility (CSR) strategies and communications specific to a firm’s water consumption and management.

Effective sustainability supply chain management is closely linked with the leadership activities of firms managing suppliers and weighing up the managerial practices which have a direct link between sustainability and supply chain management outcomes (Beske et al., 2014). Examining CSR reports enables an overview of the firm-stakeholder-
supplier relations, where firm operations, through their supply chain interact with local communities, becoming dependent on local infrastructure, tax and political arrangements and access to water resources. This can be a visible symbol of the relationship between firm and natural resources. These substantive measures can be contrasted with legitimacy-based pro-environmental behavior disclosures, which can be driven by environmental leadership (Bansal and Roth, 2000) and legislative requirements (Hamann et al., 2017). If there is a lack of governmental legislation and governance action taken in addressing water stresses and as result it is left to private companies to develop mechanisms to deal with corporate supply chain water stresses (Hoekstra, 2017). Formal Government backing and indicators are required as CSR disclosures alone lacks the substantive credibility. For example, there is a need for businesses to take a lead role in managing the global water stresses worldwide by considering how concepts such as virtual water is embedded within their supply chain.

**Materials and Methods**

Examining corporate company disclosures as a mechanism to study their water resource dependence can be a useful technique to evaluate what challenges and relations are presented as important enough to be declared in corporate CSR strategies and communications. Relationships existent between resource management can be identified through communication releases from the company. These types of disclosures reflect the governance processes of the firm (i.e. the leadership and monitoring of resource management), as well as reflecting traditional supply chain management strategies such as supplier screening (i.e. monitoring strategies for environmental performance); supplier development (i.e. collaboration with suppliers to generate mutual benefits between the central firm and its suppliers) and external influences from agencies (Akhavan and Beckmann, 2017). Where this research differs from traditional supply chain management is the specific focus on water resources and the attempts to reconcile traditional supply chain management perspectives with methods and techniques such as virtual water and water foot printing.

**Data Sources**

The data sources used in this research are focused on the corporate reporting of 50 companies that were continuously listed on the FTSE 100 stock-exchange between 2007 and 2014 inclusive, giving a continuous sample of companies to investigate over an 8-year period. The FTSE 100 was chosen due to the relatively strong pro-environmental culture of the companies listed, the diversity of sectors represented and the global reach of the companies registered on the exchange (Okereke, 2007; Helfaya and Moussa, 2017). Industrial sectors and companies represented are shown in Table 1. The justification of using formal reports is the acceptance of documents as part of CSR strategies and use by wider stakeholders. This offers advantages over databases such as Asset4 and CDP which are less accessible and often require a financial contribution for access. Annual reports were downloaded from company websites and reports containing information relating to sustainability performance (termed ‘CSR report’, ‘sustainability report’, ‘environmental report’, and other such variations) were obtained, referred to as ‘CSR report’ in this paper.

These texts were analyzed and disclosures relating to water in the supply chain were extracted and classified according to the concept of Sustainable sourcing and supply chain management (SustSSM) framework (Akhavan and Beckmann, 2017). This framework served as an initial starting point to identify the potential resource dependencies under the following categories:

- **Internal integration and governance** – the commitment of senior management within companies towards sustainability activities. This can be through use of internal codes of conduct, guidelines and policies relating to operations and supply chains and can include goal setting, action plans, management systems and provisions of incentives and rewards for company members.

- **Supplier screening with focus on water issues** – the demands placed on supply chain partners, ranging from explicit definition of minimum requirements and standards to become approved suppliers through to formal assessments and strategies as well as enforcing consequences for non-compliance.

- **Supplier development with focus on water issues** – moving beyond supplier screening toward situations where the firm takes an active role in collaborating with supply chain partners and develop joint programs for sustainability. These types of activities include training, education and supplier incentives. Other actions include sharing knowledge resources and capabilities to build resources and assets and be mutually beneficial for both buyer and supplier.

- **External governance, inter-organizational collaboration and collective initiatives** involves macro-level management of sustainability issues such as collaboration with NGOs and collective industry initiatives to develop and enhance knowledge, financial, and capability resources to address water sustainability issues.

Descriptive statistics were developed to identify the dominant classifications of disclosures of supply chain water management. Chi Square analysis was run to assess the variations in these disclosures across different industrial sectors which may hint at sectoral institutional variations in the nature of supply chain water management and inform the development of future typologies of water sustainability supply chain management strategies.
Results
From 800 reports surveyed only 283 references to water sustainability in the supply chain were made and these were concentrated to 59 annual reports and 224 CSR reports across just 20 companies. Comparing across the industrial sectors, consumer staples make up the bulk of the companies disclosing against this criterion with only reports from companies in the Consumer Discretionary and Technology sectors recording multiple supply chain water sustainability disclosures for any one year. The results of the Chi-Square analysis (see Table 2) gives a Pearson Chi-Square statistic of $\chi^2(283) = 54.77$, $p<0.001$, and therefore there is a statistically significant association between industrial sector and purchasing and supply chain management strategy. It is also shown that Consumer Staples accounts for over 50% of the total supply chain disclosures, and accounts for higher than expected disclosures in Internal Integration and Governance; Supplier Development; and External Governance categories. Sectors with higher than expected disclosures relating to supplier screening comprise of the Health Care, Consumer Discretionary and Technology Sectors, accounting for 51.3% of the typology disclosures, whilst supplier development is largely dominated by the Consumer Staples sector, accounting for 66.7% of the disclosures.

Reporting solely on the numbers of CSR disclosures against particular purchasing and supply chain management practices does not reveal the quality and focus of the
dependencies and asymmetries which persist in driving supply chain management practices. As Table 2 indicates, the most common disclosure relating to supply chain water sustainability management is covered by the category of internal integration and governance (accounting for 40% of all disclosures). These disclosures are generally split between how to design and implement water efficiency strategies (and subsequently measure and monitor their effectiveness) and an internal justification for why such strategies are taken. Given that the effects of water impacts are more likely to be felt locally, as opposed to the carbon agenda where impacts are not necessarily felt at the point of operational output, different strategies to deal with these processes and engagement with suppliers are required.

**External Certification and Signaling**
External certification and signaling strategies are associated with external governance, inter-organizational collaboration and collective initiatives in supply chain management, pursued by companies often to gain a degree of legitimacy through involvement in NGOs and international collaborations. These types of disclosure are often symbolic in nature and the substantive element of addressing sustainability challenges are less important than the ability to disclose membership of groups or sustainability awards. The engineering firm BAE systems (Annual Report 2010, p52) discuss the awarding of a certifying seal awarded to companies that ‘demonstrate a continuous commitment to sustainability’ with the rationale that this ‘helps the public to identify businesses that promote sustainability…evaluated against criteria relating to the economy, society and environment’. Whilst these types of activities may appear to be purely symbolic in nature, membership of multi-company initiatives and external prizes can help focus corporate activity and re-organize the power relations between companies and suppliers. Externally accredited stakeholder and supplier forums are highlighted as important activities for bringing sustainability challenges beyond focus on internal operations. The importance of water in these types of forums is highlighted by SAB Miller (Sustainability Report 2009, p15) who state: ‘Water is one of our top three global sustainable development priorities. As a founding signatory of the United Nations CEO Water Mandate, we recognize our duty to promote responsible water use throughout our operations and to encourage our suppliers to do the same’. This type of action can help diffuse pro-sustainable water practices through corporate operations and into wider supply chain management strategies.

**Resource Efficiency in the Supply Chain**
Internal operations management can guide the supplier screening and development practices which firms engage with their suppliers, either directly or indirectly. In this sense, managing water challenges can be achieved through embedding standards, expectations and skills on water efficiency across the full supply chain. From a resource dependence perspective there is evidence of the development of institutional frameworks to begin to converge and align the interests of stakeholders with those of the focal firm via monitoring and measuring systems. An example of this can be found in the brewing sector. Diageo (Sustainability & Responsibility Report 2013) highlight the importance of a collaborative approach to develop supply-chain wide resource efficiency, stating: “we are increasingly looking at impacts from our supply chain. For example, we are
assessing the way our ingredients are grown in terms of the implications for water use” (p31). Supplier screening is also utilized in retail, for example Tesco (Corporate Responsibility Review Report 2012) comment that “Although water used in our supply chain far outweighs that in our direct operations, we believe it’s important to manage our resources carefully and this year we carried out surveys of water use across the Group’ (p19) whilst British American Tobacco take this further, stating in their 2010 Sustainability Summary report (p15): ‘As a business with an agricultural supply chain, we depend heavily on natural resources and ecosystems. We therefore recognize the need for a clear, strategic approach to managing our environmental footprint. It not only makes good economic and environmental sense for us to use raw materials, energy and water efficiency, it is our responsibility’. These are good aspirational settings but require greater collaboration with suppliers to gain full acceptance and implementation.

Managing Power Relations
Sustainable supply chain management strategies ultimately are concerned with managing power relations between actors within the supply chain and here, through the lens of water resources exist evidence of how companies attempt to minimize information asymmetries and misaligned principal-agent challenges. This can be through developing strict codes of conduct and practice, for example by the British Retailer Marks and Spencer (2010), who provide guidance to agricultural suppliers in their ‘How We Do Business Report’, emphasizing the need to perform these supplier assessment strategies. Despite these guidelines and frameworks, there exists little evidence of how these are applied to supplier development strategies. Diageo’s collaborative approach introduced in the previous sector centers around company-centric commitments to reduce water wasted in water stressed areas (Sustainability & Responsibility Report 2013), seemingly as an attempt to manage power relations by enforcing standards onto suppliers with little consideration of formal dialogue or collaboration which might facilitate a two-way discussion between supplier and purchaser. Anglo American (Sustainability Report, 2010, p65) provide an example of weaker symbolic disclosures, stating “we believe that engaging key suppliers on opportunities such as water, energy, carbon, occupation health and safety will lead to new strategic initiatives being implemented in partnership with them”. GSK (Corporate Responsibility Report 2010, p170) discuss formalizing and quantifying supply chain water management, referring to ‘virtual water’ which “represents a major part of our water footprint” and the steps to engage “with suppliers to assess their awareness of, exposure to and plans for mitigating water risks” with plans to use this information to grade suppliers and drive improvement. This is a crucial step to deliver benefits to wider society both environmentally and socially, and highlights the importance of firms acting in a co-operating and interdependent manner to tackle these crucial resource issues (Schnittfeld and Busch, 2016). These types of disclosures and activities are typical of those firms involved in agricultural produce, tobacco manufacture and alcohol production. By integrating supply chain environmental and social sustainability impacts into the formal reporting mechanisms of the firm, and holding the firm account through assessing the extent to which the focal firm collaborates with its supply chain partners to build up product stewardship and sustainable development resources. This type of collaboration also reveals the extent to which the focal firm is vulnerable to supply chain
disruptions concerning the availability of water resources.

**Discussions and Conclusions**
This paper presents an analysis of the water sustainability disclosures from a supply chain management perspective of 50 FTSE 100 firms. From this analysis we suggest that although there is a recognition of the importance for water management in the supply chain for large corporations, this appears to be limited to companies operating in the consumer staples industry. This is likely as a result of the close interaction between the consumer and firm which adds additional consumer legitimacy pressures when arranging supply chains and developing purchasing and sourcing strategies. Additionally, there is also a need to consider the visible supply chains which extend into agricultural communities. Both aspects can have implications for the sustainable strategic competitive advantages. We see that there is currently little evidence of standardization on reporting on water issues specifically in the supply chain and from a resource dependency perspective this leads to persistent information asymmetry problems, where firms become dependent on their suppliers for information regarding the availability and access to water resources. However, the embeddedness of water sustainability disclosures within the supply chain of FTSE 100 firms remains limited and outside of the Consumer Staples sector there is little evidence to suggest that this topic is emerging as a widespread reporting priority in CSR reporting. For consumer staples, producers these companies often exhibit more visible supply chains and are more susceptible to direct consumer pressures, additionally associated with negative health and wider social impacts (in the examples of alcohol and tobacco consumption) which may account for the pressures which result in the push towards greater scrutiny of their suppliers and internal operations, as well as the need to engage with external institutions. Despite the academic literature moving towards conceptualizing competition along a supply chain v supply chain basis, the reflections of water resources remain limited to internal company operations and there is subsequently little written in CSR and Annual Reports of FTSE 100 companies about the water resources within the supply chain.

Future work should address wider reporting on water sustainability, drawing on widely available databases of corporate disclosures and work towards developing tools that can aid in company decision-making. A virtual water management framework could be developed for companies to formally integrate into their supplier screening and development strategies and help alleviate the pressures on water resources and provide the tools for supply chain managers to implement. Our findings have direct implications for governmental policy and business strategy. Governments have the ability to influence and improve the reporting environment. National Governments, Supra-National Organizations and NGOs can work together to influence and improve the reporting environment, set regulations and foster the harmonization of expected standards. This working would aid the development of water supply chain management in SMEs which lack the resources of the larger corporations to implement and shape water resources management within their supply chains.

Measuring the environmental sustainability performance of global supply chains: A multi-

Towards sustainable and resilient production systems: a resource orchestration perspective

Seyoum Eshetu Birkie (seyoume@kth.se)
Department of Sustainable Production Development
KTH Royal Institute of Technology, Sweden

Abstract

Research orchestration (RO) perspective argues that resource orchestration actions are needed to develop unique set of capabilities to effectively implement strategies at different hierarchies. This study sets out to provide a resource orchestration perspective to provide capabilities-based explanation as to why firms having “similar” resources could differ in obtaining competitive performance based on existing empirical studies. The initial part of the study with review of literature indicates that: (i) RO provides a relevant view to explain relationship of resilience and sustainability in manufacturing, and (ii) creating fit rather than linear benefit, should be the aim of resource investments.

Keywords: sustainability, dynamic capabilities, competitive advantage

Introduction

Fulfilling customer expectations amid uncertain global business context with minimum environmental impact is high in the research and managerial agenda today. Having relevant assets and development of suitable capabilities are needed for generating competitive advantages. Such capabilities are required to sustain operations performance upon disruption (Dabhilkar et al., 2016) and may also help to improve sustainability of manufacturing facilities (e.g. Wong et al., 2018). On the other hand, a more stringent action than ever before is needed to address the burden put on the planet and society due to manufacturing activities; therefore, manufacturers have to devise strategies to make their production sustainable and resilient. There are some studies on the issue of resilience and sustainability in production systems. However, it seems that such discussions are often done without a clear perspective on coordination and alignment of assets and capabilities.

Research orchestration (RO) is a perspective that argues that resource orchestration actions are needed to develop unique set of capabilities to effectively implement strategies at different hierarchies (Sirmon et al., 2011). The emphasis of RO is on actions that effectively structure, bundle and leverage firm resources (e.g. skills and knowledge, routines/practices, finance, information and technologies). The resources could be owned by the firm, suppliers, customers or other partners - and accessible by the firm (Raddats et al., 2017).

The purpose of this paper is to discuss how RO could help explain the aspirations of building resilient and sustainable production systems that are able to render greater value to stakeholders and the society in general. It also intends to perform systematic analysis.
of empirical studies to understand why manufacturers with access to a great deal of resources differ in their sustainable performance and resilience against disruptions.

**Approach**
This paper builds on systematic review of extant literature within the supply chain and operations management (SC&OM) domain. Recent guidelines for systematic review (e.g. Seuring and Gold, 2012) and example papers following such methodology (e.g. Golicic and Smith, 2013) have been used in the process.

In the first stage of the study, papers published in years 2011-2018 in SC&OM bearing ROP as theoretical lens have been reviewed. Sirmon et al., (2011) is considered a starting point as it is (one of) the early works and top cited papers describing the theory. The review in this stage dealt with identification of: (i) empirical evidence to validate or extend the theory (e.g. Carnes et al., 2017), and (ii) implications for practical operationalisation of the theory in the domain of interest. The focus of the second stage (ongoing) has been to perform synthesis from empirical studies addressing resilience and sustainability in manufacturing firms.

As a result of the literature search query with “resource orchestration” in topic of papers in ISI Web of Knowledge® database. A total of 145 records were obtained (as of 10 April 2019). Out of these, 85 were journal articles, which were the focus of the review in this paper. The top five journal bearing the most articles were: Strategic Entrepreneurship Journal (5), Journal of Supply Chain Management (4), Journal of Business Research (3), Journal of Operations Management (3) and R&D Management (3). The publication year distribution of the identified papers is shown in Figure 1. The number of publications discussing RO has been increasing over the years since 2012.

![Figure 1. Identified literature by publication year](image)

**Findings**
Preliminary findings suggest that RO has been quickly picked up well by researchers to discuss different operations management related phenomena involving utilisation of capabilities suited for prevailing circumstances. Some relevant ways of developing and renewing capabilities have been noted from reviewed papers such as (i) interactively developing such capabilities with partner firms (Raddats et al., 2017), and (ii) leveraging of resources embedded somewhere in the supply chain or owned by other actors. The orchestration role played by top management as well as the engagement by other management hierarchies appears to be very important according to the reviewed studies;
they are vital to drive competitive advantages from such resources accessible to a firm.

A sample of the reviewed literature is given in Table 1. From these sample studies, some interesting implications are obtained that could be extended in discussing the relationship between resilience and sustainability. For example, it is implied in the reviewed research that RO could lead to better utilisation of resources (Wong et al., 2018). And these resources do not have to be owned by the focal firm to be utilised with orchestration actions; they can be embedded somewhere in the network of actors that the focal firm has access and some form of control over (Raddats et al., 2017). Similar arguments can be found for resilience as a set of dynamic capabilities (e.g. Birkie et al., 2017).

Extension of this would direct to the argument that firms could alter partnership arrangements in their supply chains (Gong et al., 2018) to create better alignment for development of evolving capabilities (Fainshmidt et al., 2017), possibly using interactive means (Raddats et al., 2017).

While the second stage of the study is still ongoing, the observations from stage one of the systematic review suggest that: (i) RO provides a relevant view to explain relationship of resilience and sustainability in manufacturing, and (ii) creating fit rather than linear benefit, should be the aim of resource investments (e.g. Liu et al., 2016). Another preliminary observation is that RO implies views traversing organisational boundaries could enhance synergistic potential of diverse resources (Wong et al., 2018).

Table 2 provides some arguments about the possible relationships of resilience and sustainability within supply chain and operations management context. It also relates this relationship with different tenets of RO. Some of the arguments are taken directly from the respective papers while others are inferred from a combination of studies. The idea behind this table is to provide an initial ground of how these arguments could be addressed using RO perspective.

<tr>
<td>• Opportunities for shared value creation should be identified in sustainable value chain development (Fearne et al., 2012); cooperative and communicative relations (among supply chain actors) has positive effect on resilience, which in turn can increase customer value (Wieland and Wallenburg, 2013)</td>
<td>• Strategic investment in human capital as key elements in production (industrial) systems shall be part of contest-focused effective RO actions</td>
</tr>
<tr>
<td></td>
<td>• Performance and competitive advantage could be different at different levels and hierarchies. Looking at beyond just one level (or company) is necessary; the business context could change continuously</td>
</tr>
</tbody>
</table>
Discussion

Many papers discussing resilience capabilities and managing unanticipated disruptions do not seem to have considered the potential implication of firm life cycle stage on the accumulation of capabilities. One may argue that companies considered in many of such (especially large scale) studies are well established and often publicly traded. This may exclude startup stage of company life cycle stage. However, it does not enable us to understand if differences of disruption mitigation capabilities existed between firms at mature and declining stages.

Epstein and Roy (2001) imply that companies could consciously develop RO actions to improve economic and social performance at different levels. This implication can be taken to address multiple dimensions of sustainability. The question still remains as to how this can be practically achieved. This one of the areas suggested for future research (Hughes et al., 2018). The relevance of human capital in mobilising resources (Miao et al., 2017), and alignment of supply chain integration needs with competencies in areas like IT (Liu et al., 2016) are regarded as important in RO.

An aspect of even higher important but missing from resilience and sustainability literature (with operations and supply chain management lens) is the role of managers in different hierarchy levels in enhancing RO actions (Chadwick et al., 2015). Clearly top management commitment is key for resilience capability development (e.g. Dabhilkar et al., 2016). The same is true in fostering sustainability initiatives (e.g. Giunipero et al., 2012). However, barely any paper has so far discussed how strategic directions about resilience capabilities or sustainability policies are reflected and operationalised by middle and font line managers. Many such papers in fact do not differentiate between capabilities that may reside within the role of the top management, or those traversing multiple hierarchies in the organisation. This could be a point of extension that could help elaborate on how seemingly similar set of capabilities could result in different level of achievement in post-disruption performance or sustainability objective achievement; the managerial actions (at different hierarchies) in orchestrating resources for better effectiveness.

Considering supply chain network level, we have noted that similar resilience capabilities located upstream the chain are generally more effective in disruption mitigation than when located downstream (e.g. Trucco et al., 2018). The effectiveness of resilience capabilities also depends on static supply chain complexity factors (Birkie et al., 2017). However, in those and other similar studies, it is not discussed how effectiveness of capabilities may vary as the composition of the capability set changes, or as the business context (e.g. disruption) drifts, or if the capabilities were dominantly enacted by middle or top management hierarchies. A similar pattern of investigation could be done with sustainability as well.

While the scale of change is different, both management of unanticipated disruptions with resilience capabilities as well as reducing environmental and social impact for better sustainability require adjusting to changing conditions. RO based in prevailing changes in the business environment is suggested to result in new capabilities suited for the context (Cui and Pan, 2015; Fainshmidt et al., 2017). This argument implies that future research in the domain of interest (resilience-sustainability) could investigate if and how this can be explained.

The discussion of making production systems sustainable and resilient is getting a lot of attention recently. However, the practical achievement and what it means in reality is much more sophisticated than the concept appears. Using RO perspective gives an opportunity to discuss what this could mean when taken to ground. For example, if we
are discussing about development of new production systems with sustainability as a core, then the starting point is that the system to be developed (of the company as a whole if it is to be developed for a new one) can be considered to be at startup phase of the firm lifecycle stage. The underlying mechanisms of orchestration for a firm at this stage could be different from the ones used by a mature firm therefore managers would emphasis on different forms of capabilities suited for the stage their firm is at (Carnes et al., 2017). This has different important and interconnected implications with regard to, for example, which actors they chose to jointly invest for capabilities development, which forms of IT and other collaborative platforms they need to decide on and so on. Those decisions surely will have an impact how the business model is formulated for a future production system.

As we have many old production system that will probably continue to operate for some years while advanced and dominantly autonomous production systems start to fully operate, the strategies to be followed in operating those old systems in a new manufacturing business setting will most likely require a different set of capabilities and RO actions that many researchers and managers currently may think of. And the extent of interactive capabilities developed spanning multiple business and economic system boundaries could be the requirement. The overall proposition of this paper, once again is that as researchers, we could use RO to create a way of understanding more details about creating and running more sustainable and resilient production systems.

**Conclusion**

Several empirical studies on resilience, sustainability in operations management concepts do not address issues of resource orchestration with respect to scope, maturity stage, and hierarchy level of firms. This study sets out to provide a resource orchestration perspective to provide capabilities-based explanation as to why firms having “similar” resources could differ in obtaining competitive performance based on existing empirical studies. The findings of the study could inform operationalisation of strategies and empirical research with RO as overarching lens. It is to be noted however that this study is ongoing and the findings stated herein are only preliminary. For this reason, findings in relation to operationalisation of the different RO dimensions to explain the phenomenon of resilience capabilities and sustainability actions has not been discussed in detail.

Abstract
The objective of this research was to identify factors not covered in the Logistics Performance Index (LPI), and their impact on the logistic performance of the countries. For this, a correlation analysis was performed on the LPI dimensions and related variables in the literature, involving social aspects, national infrastructure, and institutional policies seeking to identify these characteristics and their impact in the measurement of logistic efficiency. Results indicate that technological readiness, government effectiveness, and economic freedom have a high correlation with the logistic performance of the countries. The main contributions relate to widen logistic efficiency knowledge and guide policymakers actions.

Keywords: logistic performance; institutional environment; LPI.

Introduction
Studies and research have shown that the quality of the logistics system, both at the level of organizations and global supply chains, is related to interest rates, taxation and costs (Farahani et al., 2009), with the reduction of barriers and commercial intensity (Hoekman & Nicita, 2008); with the level of export (Dennis & Shepherd, 2011) and with economic growth and development (Limao & Venables, 2001, Portugal-Perez & Wilson 2010, Arvis et al., 2012; Bakar et al., 2014). Cross-border trade and economic competitiveness act as an engine in the search for efficiency and logistics efficiency, making monitoring and measurement fundamental.

Despite the importance of measuring countries’ logistic performance, until the early 2000s, there was no general pattern for measuring it. Given the need for a logistic performance measurement model, the World Bank has constructed an index, the LPI - Logistic Performance Index, which allows for global comparison of countries. This indicator is considered an international benchmarking tool, which focuses specifically on measuring the ease and friendliness of trade and transportation in the countries, allowing them to identify the challenges and logistical opportunities encountered (Arvis et al., 2007).

Although it is considered a comprehensive measure to evaluate logistic performance, the LPI presents limitations and has fostered several studies (Guner & Coskun, 2012; Markovits-Somogyi & Bokor, 2014; Andrejić & Kilibarda, 2016; Yu and Hsiao, 2016; to 2017, Rezaei et al., 2018, Wang & Tang, 2018), or to an economic bloc or limited number of countries (Guner & Coskun, 2012). It should also note that the strategic choices of global supply chains in terms of structure, resources and capabilities are affected and dependent on regulations, culture, and values associated with the institutional structures of different
countries (Makino et al., 2004; Richey et al., 2005; Scott, 2008; Miemczyk, 2008). Thus, it is assumed that differences in countries' logistic performance are also explained by political and institutional factors that characterize them (Hausman et al., 2005).

In order to understand the factors that determine the countries' logistical efficiency, how they interrelate and how they affect such efficiency, the following question was posed: "What are the socioeconomic, environmental, and political factors that influence logistics performance and which the impact of the insertion of these factors in the measurement of the logistics efficiency of the countries?"

This article is part of a more extensive survey that seeks to answer the survey question raised. Based on the assumption that socioeconomic, political and environmental factors considered in the measurement of logistics performance, the main objective of this article is to identify those factors that influence the logistics efficiency of the countries. For this, we performed a correlation analysis. We justified this research by the need to expand the frontier of knowledge about the logistics efficiency of the countries, pointing out essential aspects that affect this efficiency. Besides, the practical contribution is to provide policymakers with a guide on how much each of the inputs or outputs needs to be worked on for efficiency.

Theoretical Background

Fugate et al. (2010), define the logistic performance as the degree of efficiency, effectiveness, and differentiation associated with the accomplishment of activities. For Chow et al. (1994), logistic performance is a derivative of organizational performance and may be related to "hard" or objective measures, such as net profit, transport cost, labor cost, number of shipments, order cycle time, and "soft" measures based on qualitative data such as expert ratings and customer satisfaction.

Efficacy is related to production, without considering the resources consumed in the process. That is, it refers to the output of a desired effect or result, in how the outputs combine the desired results (Goldman & Sparks, 1996). Langley and Holcomb (1992) extended the definition of logistics effectiveness, relating it to the capacity to create value for the customer through the exclusivity and differentiation of services.

Efficiency, in turn, refers to the ability to reach a target with minimal effort or wastage (Goldman & Sparks, 1996). According to Andrejić and Kilibarda (2016, p.773) "Efficiency is a significant indicator of operations analysis and is one of the most commonly used basic performances. Measuring, monitoring and improving efficiency are the key tasks for companies in the 21st century." Min and Joo (2006) also recognized the importance of measuring logistics efficiency.

Given the importance of measuring countries' logistical performance, the World Bank has built an index, the LPI - Logistic Performance Index, which allows a global comparison of countries. Since the first publication of the index, inserted in the "Connecting to Compete" report in 2007, new versions published in 2010, 2012, 2014, 2016 and more recently in 2018. The first report included 150 countries, the 2010 reports and 2012 ranked 155 countries, and the two most recent versions cover around 160 countries. Each release contains a ranking with all countries participating in the survey.

The indicator comes from information collected in a questionnaire made to logistics professionals of the leading companies responsible for the movement of goods around the world. The first part of the questionnaire provides information on international logistic performance, where respondents express their opinion on the eight major markets with which they most trade (Arvis et al., 2016). The second part of the questionnaire refers to internal logistic performance and is called the domestic portion of the index.

The LPI survey, therefore, offers two different perspectives on logistic performance. Qualitative assessments in relation to countries, so that they can compare to their competitors
and analyze the costs of poor logistic performance, and a domestic analysis, which provides assessments both as well as qualitative and quantitative data from the countries, which provides details on the environment and logistics processes, institutions, and time and cost performance data (Arvis, et al., 2010).

The LPI has been a benchmark for ranking countries based on the performance of their logistics costs (Mustra, 2011). However, measuring the logistics efficiency of a country requires greater attention because the supply chains are complex, their performance depends mostly on the characteristics of the country, especially the infrastructure and institutions that logistics needs to function well, such as imports, regulations, procedures, and behaviors (Arvis et al., 2018).

Hausman et al. (2005) already pointed out that differences in countries' logistic performance were the result of their different political and institutional structures linked to enforcement or regulation. Lee and Wyk (2015) have found that institutional constructs related to political risk, financial risk, economic freedom, political freedom, and competitiveness directly or indirectly influence logistic performance. Similar results also found Dani, Santos, and Hein (2017), when they studied the correlation between logistic performance and the economic freedom index. More recently, Wong and Tang (2018) sought to identify and understand the main determinants of logistic performance and found among them the level of corruption, as well as better technology, labor, and education infrastructure. Since the first edition of Connecting to Compete in 2007, other methods have been used to measure the logistics efficiency of the countries. However, these researches have been restricted to LPI components (Yu and Hsiao, 2016, Marti et al. 2017), or an economic bloc or the limited number of countries (Guner & Coskun, 2012; Markovits-Somogyi & Bokor, 2014, Andrejić & Kilibarda, 2016).

Therefore, the need to analyze the logistical efficiency of the countries by a more robust methodology and that includes aspects disregarded in previous research. The methodological construction used in the complete research to measure logistics efficiency will be the Data Envelopment Analysis - DEA. Although initially designed to measure a company's performance in a production economy context, the DEA has widely applied in the study of real policy scenarios in different fields such as education, health, transportation, agriculture, energy, among others.

Methods

The present research has a quantitative approach and uses statistical tools for the treatment and analysis of the data. The research method is bibliographical and documentary, with secondary data, collected from the databases: Logistic Performance Index, Global Governance Indicators, Global Competitiveness Index, World Economic Forum, and other bases such as International Transparency, Fraser Institute, and Heritage Foundation. The sample includes the countries classified in the LPI and the sampling period goes from 2010 to 2018, with biannual data. Therefore, there are 155 countries in the years 2010 and 2012, 160 countries in 2014 and 2016 and 167 countries in 2018.

The variables selected for the measurement of the logistic efficiency, next step of the research, will be those that present a correlation, greater or equal to 60%, with the LPI index and its components. We can test some variables in aggregate forms, such as the index of international trade freedom, or its components, alternatively, in the search for the best arrangement of these variables.

The LPI components and the indicator itself will use as inputs and outputs in the structures proposed by the model. Besides the six variables that make up the LPI, variables
that represent socioeconomic, political and environmental aspects of the countries will test.

Table 1 presents a summary of the variables used.

</table>

Once the variables were defined, the Kolmogorov-Smirnov and Shapiro-Wilk tests were applied to verify if the data presented normal distribution. Then, the correlation analysis of the variables was performed, according to Guner and Coskun (2012), to establish the relationship of such variables with the logistic performance of the countries. We chose the Spearman correlation because the data were not standard by the Kolmogorov-Smirnov test (Stevenson, 1981). We used the SPSS software for these analyses.

Kozak et al. (2012) states that correlation is a method used to measure the association or consistency between two variables, pointing out the direction and intensity of the linear relationship between them, without involving a cause and effect relationship. The correlation coefficient \( r \) varies between -1 and 1 and the signal indicates the direction (positive / negative) of the relationship between the variables, whereas the value indicates the strength of the same relation. Regarding the intensity of the correlations, the variables have a strong (direct) positive linear correlation when \( r \) is close to 1, and a strong negative (inverse) linear
correlation when it is close to -1, even if there is no linear correlation or a weak linear correlation, \( r \) is close to zero (Figueiredo Filho & Silva Junior, 2009).

**Preliminary Results and Analysis**

As already mentioned, the primary intention of the research is to obtain an index that represents the "logistical efficiency" construct of the countries, through the DEA technique. One of the requirements of the DEA model is that inputs and outputs are positively correlated (Chen & Chen, 2009). Thus, we expected a high correlation between input and output variables.

Before performing the analysis of the correlation between the variables, tests applied indicates the form of distribution of the data. Table 2 shows the Kolmogorov-Smirnov and Shapiro-Wilk normality test results for LPI components.

Source: Research data.

As can be seen from both the Shapiro-Wilk test and the Kolmogorov-Smirnov test, the LPI variables show a non-normal distribution. Therefore, the appropriate correlation analysis, in this case, is obtained by the Spearman Correlation test (Stevenson, 1981). Table 3 shows the correlations between the input and output variables, used in the different structures to be tested later, in the DEA technique.

3855
The results of Table 3 indicate that there is a high correlation between the LPI and its components (above 0.80). This result indicates the assertiveness of the world bank in choosing these variables to compose the LPI. When analyzing the relation of the LPI and its components to the size of the market, it is observed that the relationship is more expressive...
with respect to the size of the foreign market (0.74), which makes sense, since the LPI is measured based on perceptions of large freight forwarders over other countries with whom they transact.

Regarding social aspects, the highest correlation occurred with the EDUC variable (0.77), indicating that the quality and quantity of higher education and quality training can play an important role in logistics performance. In turn, supply labor did not present a sufficient correlation to insert in the logistic efficiency measurement model. The result for technological readiness (0.81) is consistent with the empirical literature, which shows that technology has increased supply chain efficiency and logistic performance (Will and Blecker 2012, Wong, Soh and Goh 2015, Wong & Tang 2018), placing it at the same level as the LPI components.

For the economic aspects, the results here differ from those of Guner and Coskun (2012), when they analyzed the member countries of the OECD. Guner and Coskun (2012) found a low correlation (0.407) between GDP and LPI. Our results indicate a much higher correlation (0.73 and 0.74) for GDP_PPP and GDP_PCP, respectively, at a significance level of 1%. This difference, however, can be caused by the sample analyzed or even by the variable used. The fact that variables related to GDP show a high correlation with the LPI components may indicate the need for this variable to appear in the efficiency measurement model, although in the form of a control variable. The GDP is also an indicator of the size of the economy, which we can use as a parameter for clustering the sample, which should occur when analyzing the efficiency by the DEA.

Regarding institutional aspects, we can see that the LPI has a significant correlation with both the economic freedom index (0.70) and the political risk index (0.76). We highlight the importance of considering the institutional aspects in the measurement of the logistic efficiency of the countries, corroborating the understanding of Hausman et al. (2005). Separately from the political risk index, government effectiveness also showed a high correlation with LPI (0.80). Although they showed less correlation with the LPI and its components, the variables LEG_SYS and NON_TARIFF (0.67 and 0.67, respectively) will be included and tested in the search for the best DEA arrangement.

Contrary to expectations, tariff barriers, freedom of foreign trade and political stability showed a lower correlation with the LPI (0.30, 0.59 and 0.52, respectively). We noted that these variables are composite indicators and that their components can individually correlate with LPI.

Conclusion

This article is part of more comprehensive research where it is sought to identify and understand the factors that influence the measurement of the logistics efficiency of the countries and the impacts of these factors in the classification of efficient countries, based on an expanded analysis of the LPI using the DEA technique. Thus, this part of the research focused on the analysis of the correlation between the LPI (and its indicators) and some variables, indicated in the literature as determinants of logistic performance, seeking to identify those that will later compose the logistic efficiency analysis of the countries. The results indicate that, given the high correlation with the LPI, considering those with a coefficient of more than 60%, should be included the indicator of logistic efficiency of the countries. Variables related to higher education and training and the level of technological domain (social aspects) variables that characterize the institutional environment of countries such as the index of economic freedom and the political risk index, legal system and non-tariff barriers.

In this aspect this research has proved to be relevant, since it expands the knowledge frontier on the logistic efficiency of the countries, pointing out the essential elements that
affect this efficiency. Also, the final result of the comprehensive research can make a practical contribution by offering policymakers a guide on how much work each input or output needs to do to achieve the countries’ logistical efficiency.

Although this research represents a breakthrough in proposing a global logistic efficiency index from the LPI, we found some limitations. The first of these is the lack of available data from other variables to improve the model, such as the level of CO2 emission, available only up to the year 2014. The second limitation is that the countries analyzed were chosen based on the available data, which may have influenced some of the analyzes.

Finally, correlation tests are essential exploratory techniques for the investigation of the association among the behavior of the variables groups. The simple identification of a significant correlation between two or more variables should interpret with caution. Since such analysis does not provide evidence of the direct dependence or the causality among the variables, but they also tend to vary jointly. What brings security to this research is the fact that the analysis of the correlation favors the elaboration of hypothetical models, which should confirm after, through other tests performed after the development of the research.

When do 3PLs initiate low carbon supply chain integration?

Abstract

As a response to global climate change, decarbonizing supply chains has gained increasing attention from academia and industry. Motivated by the evolving role of third-party logistics providers (3PLs) from a service provider to a resource integrator in supply chains, this paper investigates when 3PLs initiate supply chain integration in order to decarbonize their supply chains. Drawing upon three theoretical lenses, i.e. social network theory, institutional theory and resource-based view of the firm (RBV), this paper develops a theoretical framework and tests it using survey data from 348 Chinese 3PLs. The findings have implications for both researchers and managers.

Keywords: 3PLs, Supply chain integration, Low carbon supply chain

Introduction

With growing pressure on reducing carbon emissions from supply chain management (SCM), decarbonizing supply chains has gained increasing attention from academia and industry. Given the critical role of third-party logistics providers (3PLs) in supply chains, previous research has examined the operational importance of 3PLs in decarbonizing supply chains (Das, 2018). However, the strategic role of 3PLs in decarbonizing supply chains has not received enough attention, although many researchers show that 3PLs have now taken on a more proactive manner for customers by organizing networks, sharing information, managing assets, and reducing inventory (Zacharia et al., 2011).

Further, despite the substantial amount of research on supply chain integration (Flynn et al., 2010; Huo et al., 2017), the majority of these research focuses on manufacturer-initiated SCI, and there is a dearth of research on the antecedents and effectiveness of SCI from the perspective of 3PLs, let alone in LCSC research. To fill the gap of low carbon supply chain integration (LCSCI) from the perspective of 3PLs, this paper focuses on 3PL-initiated LCSCI, namely a customer integration initiated by 3PLs to achieve LCSCs, and investigates the drivers and outcomes of 3PL-initiated LCSCI.

Based on the social network theory (Choi and Kim, 2008), institutional theory
(DiMaggio and Powell, 1983), and the resource-based view of the firm (Barney, 1991), we propose a theoretical framework of the antecedents and consequences of 3PL-initiated LCSCI, including customers’ outsourcing scope, government (environmental) regulation, 3PLs’ decarbonisation capabilities and 3PLs’ financial performance.

The remainder of this article is structured as follows. The subsequent two sections review the literature and develop research propositions. This is followed by a description of research method, in which the sampling method and measures are illustrated. Next, analysis and results are presented and discussed. The conclusion is then put forward.

**Literature review**

*Low carbon supply chain management (LCSCM)*

Low-carbon supply chain management (LCSCM) is considered as the combination of low-carbon operations management and supply chain management in response to climate change, focusing on activities that reduce carbon footprint in supply chains (Damert *et al.*, 2018). Although some researchers argue that the drivers, barriers and performance outcomes of LCSCM should be similar to those of green supply chain management (GSCM), the empirical findings on the determinants and effectiveness of LCSCM have been inconclusive (Rivera, 2004; Zhang and Wang, 2014).

*Low carbon supply chain integration*

Supply chain integration (SCI) refers to “the degree to which a manufacturer strategically collaborates with its supply chain partners and collaboratively manages intra- and inter-organization processes” (Flynn *et al.*, 2010, p. 59), where the inter-organization (or external) SCI includes collaboration that takes place between a focal firm and its suppliers and customers. With the evolving importance of LSPs in supply chains, there is a rapidly growing research on the effectiveness of SCI between a focal firm and its LSPs on firm performance (Huo *et al.*, 2017). The common feature of these research is that they all take the perspective of the focal manufacturing firm; the amount of research on SCI from the perspective of LSPs is limited.

Vachon and Klassen (2006) are among the first who link supply chain integration and the green supply chain practices. Mao *et al.* (2017) show that manufacturing firms’ low-carbon supply chain integration (LCSCI) have positive effects on their environmental and financial performances. Nevertheless, there has been no research on LCSCI from the perspective of 3PLs, and it remains unclear about the drivers and outcomes of 3PL-initiated LCSCI. To fill the research gap, this research takes the perspective of 3PLs and focuses on their LCSCI. In particular, we define 3PL-initiated LCSCI as a customer integration initiated by the 3PLs to achieve LCSCIs.

**Theoretical foundations and hypothesis development**

*Relationship between outsourcing scope and 3PL-initiated LCSCI*

The social network theory (SNT) has conceptualized the supply chain as a functional social network between companies consisting of nodes and links (Carter *et al.*, 2015). Embeddedness is one of the core ideas at the heart of organizational social network theory and is defined as “the extent to which a firm relies on a supply network and perceives the influence of the network” in the context of SCM (Kim, 2014, p.220). Usually, the structural and relational embeddedness are adopted to measure the social capital within supply networks (Choi and Kim, 2008).

The impact of outsourcing scope on the supply network as well as 3PL-initiated
LCSCI can be understood from the perspectives of the relational embeddedness, which refers to the quality or the strength of a relationship (Moran, 2005). Since a wide outsourcing scope is usually associated with increased mutual dependence, commitment and interactions, it gives rise to the strong tie. As the relationship between firms becomes stronger, environmental collaboration in supply chains is more likely to occur (Tate et al., 2013).

Therefore, an increase in the outsourcing scope can lead to an increased level of relational embeddedness of 3PLs, which is positively associated with 3PL-initiated supply chain integration and environmental collaboration. Hence, we propose that the outsourcing scope of 3PL services may have a positive relationship with 3PL-initiated LCSCI.

**H1:** Outsourcing scope has a positive relationship with 3PL-initiated LCSCI.

**Relationship between environmental regulations and LCSCI**

Institutional theory identifies three dimensions of isomorphic drivers as institutional pressures that influence firms to adopt organizational competitive environmental alignment, namely coercive, normative, and mimetic drivers (DiMaggio and Powell, 1983), where coercive pressure refers to pressure exerted by those in power, such as the government environmental regulations (Sarkis et al., 2011). To conform to the environmental regulations by the government, 3PLs are motivated to form environmental collaborations in the supply chain (Vachon and Klassen, 2006), and build the strategic supply chain relationship and dependence with their customers (Huo et al., 2017), and thereby leading to 3PL-initiated LCSCI. Thus, we propose the following hypothesis:

**H2:** Government regulation has a positive relationship with 3PL-initiated LCSCI.

**The role of 3PLs ‘decarbonisation capabilities’**

Decarbonisation capabilities refers to firm-specific capabilities to decarbonize the supply chain. Previous research has indicated that the lack of firm-specific capabilities is one of the most common obstacles to GSCM practices (Wu et al., 2012). According to the resource-based view (RBV), firm-specific decarbonisation capabilities are rare, valuable, non-substitutable, and difficult-to-imitate resources in LCSCM.

We argue that these organization-specific capabilities and resources contribute to the collaborative relationship between the 3PLs and their customers, since the decarbonisation capabilities enable 3PLs to circulate their professional knowledge and resources efficiently to their customers, which is helpful for building strong ties with dependency and trust, thereby increasing the 3PLs’ relational embeddedness (Choi and Kim, 2008). Therefore, we propose that the effect of outsourcing scope on 3PL-initiated LCSCI can be stronger if the 3PLs have higher decarbonisation capabilities.

**H3:** Decarbonisation capabilities play a positive moderating role in the relationship between outsourcing scope and 3PL-initiated LCSCI.

Although 3PLs with higher decarbonisation capabilities can be more able and willing to initiate LCSCI proactively rather than responsively, they may become more self-motivated and less motivated by coercive pressures, such that the effectiveness of government environmental regulations on motivating 3PL-initiated LCSCI could be stronger for the 3PLs with lower decarbonisation capabilities than on their higher capabilities counterparts. Therefore, we propose that 3PLs’ decarbonisation capabilities may weaken the effect of government environmental regulation on 3PL-initiated LCSCI.

**H4:** Decarbonisation capabilities play a negative moderating role in the relationship
between government environmental regulation and 3PL-initiated LCSCI.

Relationship between 3PL-initiated LCSCI and 3PL’s financial performance
3PL-initiated LCSCI is related to interaction and collaboration in the social networks. As 3PLs build tense and strong ties in their networks through frequent interaction and intense collaboration with their customers, operational efficiency and economic performance will follow, as long as they are not embedded too much (Uzzi, 1997). Also, the relational capabilities gained from increased level of embeddedness will ultimately enable them to combine cross-organizational complementary resources in unique ways and realize sustainable advantage over their competitors (Paulay, 2011). Therefore, we propose a positive relationship between 3PL-initiated LCSCI and 3PL’s financial performance.

H5: 3PL-initiated LCSCI has a positive relationship with 3PLs’ financial performance

The theoretical framework in this study as well as the proposed hypotheses are shown in Figure 1.

![Figure 1 - Theoretical framework](image)

**Research method**

*Data collection and sample profile*

The sample was derived from 3PLs located in Guangdong province, China. As one of the earliest regions to open up in China, Guangdong province enjoys advanced economic development; its logistics industry grows rapidly. To collect the data, we collaborated with logistics and SCM organizations in Guangdong province, inviting them to participate in an online questionnaire survey. A total of 1300 3PLs took part in the survey, which was distributed in two rounds. After screening out invalid responses such as blank and incomplete questionnaires, we identified 191 and 157 valid responses for the first and second rounds, respectively, resulting in 348 in total. Thus, the response rate was 26.7%. Table 1 outlines the profile of the sample in line with four characteristics: business origin, ownership, the number of employees, and firm size.

*Construct measurement*

The constructs measured in this study were derived from the existing literature. Since the empirical investigation was carried out in China, we employed back-translation in order to ensure conceptual equivalence (Cai et al., 2010). The measurement scales were first translated into Chinese and further amended by two research assistants. The initial questionnaire was developed and then examined by using a random selection of 60 samples to conduct validity analysis, exploratory factor analysis (EFA), and correlation analysis using SPSS software. After this, three SCM professors were invited to verify the questionnaire, and the final version of the survey used for delivery was confirmed.
The items in the questionnaire were measured using a five-point Likert scale, with a score of 1 indicating ‘strongly disagree’, 2 indicating ‘disagree’, 3 indicating ‘uncertain’, 4 indicating ‘agree’, and 5 indicating ‘strongly agree’.

**Non-response bias and common method bias**

We used the method recommended by Armstrong and Overton (1977) to compare the two samples. As shown in Table 1, a Chi-Square test for the firm characteristics variables indicated that there was no statistical difference between the two rounds, thus confirming that both rounds of samples were unbiased.

Since the data investigated was derived from a single source, common method bias was likely (Podsakoff *et al*., 2003). Therefore, we implemented Harman’s single factor test, whereby we conducted an unrotated principal component analysis, yielding 5 eigenvalues greater than 1 after extraction. The first factor explained 38.203% (lower than 40%). In addition, we conducted a confirmatory factor analysis (CFA) for Harman’s single factor model (Sanchez and Brock, 1996). Compared to the measured model, the indicators of the tested model were poor ($\chi^2$/df=3.297, GFI=0.635, AGFI=0.539, IFI=0.595, TLI=0.551, RMR=0.077, and RMSEA=0.081. This showed that overall, common method bias was not a problem in the data.

**Reliability and validity analysis**

The results of the reliability and validity tests are shown in Table 2. Internal consistency was measured using Cronbach’s coefficient. The Cronbach coefficients of all the constructs ranged from 0.808 to 0.898 (above 0.7). This confirmed that the constructs had psychometric properties. An examination of the CFA of all the constructs showed that all the indicators of the measurement model, such as $\chi^2$/df, GFI, AGFI, IFI, TLI,
RMR, RMSEA, were ideal, and therefore that the constructs were unidimensional (Bentler and Bonett, 1980). In addition, as suggested by Fornell and Larcker (1981), we measured convergent validity. The results showed that all the standard factor loadings were above 0.7, and the t-values were above 10 for all but two items (0.67 and 0.692). Thus, convergent validity was confirmed. Composite reliability and AVE can be used to measure the reliability of constructs (Hair et al., 2006). When CR and AVE are above 0.7 and 0.5 respectively, it indicates a high degree of internal consistency, and that the consistency between the constructs/traits is higher than that of the errors (Hair et al., 2006). As shown in Table 2, the composite validity values of the constructs ranged from 0.807 to 0.873 (above the threshold value of 0.7), and the AVE values ranged from 0.527 to 0.635 (above the threshold value of 0.5). Table 3 presents the arithmetic square roots and correlation coefficients of the constructs. The results showed that the arithmetic square roots were larger than the correlation coefficients of the construct and the correlated construct, thus confirming that the measurement scale of the constructs had sufficient discriminant construct validity, as suggested by Fornell and Larcker (1981).

Results

Using SPSS 20.0 software, we set two explanatory variables (‘government regulation’ and ‘outsourcing scope’) and moderating variables, and multiplied them to obtain interaction items. Next, we set ‘3PL-initiated LCSCI’ and ‘economic performance’ as dependent variables and used stepwise regression to perform a hypothesis test. As shown in Table 4, Models 1-3 set ‘3PL-initiated LCSCI’ as the dependent variable, and Models 4-5 set ‘economic performance’ as the dependent variable. The tolerance of all the models was above 0.15, indicating that multicollinearity was not a problem. In Model 2, the regression coefficients of ‘outsourcing range’ and ‘government regulation’ were 0.579 (t=13.503, p<0.001) and 0.233 (t=5.550, p<0.001). This result indicated that these two factors had a positive impact on ‘3PL-initiated LCSCI’, and therefore H1 and H2 were verified. In Model 5, the regression coefficient of ‘3PL-initiated LCSCI’ was 0.323 (t=0.323, p<0.001), indicating that ‘3PL-initiated LCSCI’ had a positive impact; hence, H5 was verified. Model 3 tested the moderating role of ‘decarbonization capabilities’. With this model, the regression coefficient of ‘outsourcing scope’ was 0.236 (t=3.778, p<0.001), indicating that ‘decarbonization capabilities’ positively moderated the relationship between ‘outsourcing scope’ and ‘3PL-initiated LCSCI’, and therefore that H3 was confirmed. The regression coefficient of ‘government regulation’ and ‘decarbonization capabilities’ was 0.362, indicating that ‘decarbonization capabilities’ negatively impacted the relationship between ‘government regulation’ and ‘3PL-initiated LCSCI’; hence, H4 was verified.

In order to reveal the moderating role of the variables, we set the average of ‘decarbonization capabilities’ as standard, dividing the sample into two groups: high level of decarbonization capabilities (high level) and low level of decarbonization capabilities (low level) in order to conduct a regression analysis of ‘3PL-initiated LCSCI’. Figure 2 shows that in the low-level group, the regression coefficients of ‘outsourcing scope’ and ‘government regulation’ were 0.409 (t=6.619, p<0.001) and 0.378 (t=5.7890, p<0.001), revealing a significant positive impact on ‘3PL-initiated LCSCI’. In the high-level group, the regression coefficient of ‘outsourcing scope’ was 0.526 (t=7.946, p<0.001), indicating that this variable also had a significant positive impact on ‘3PL-initiated LCSCI’, but the degree of impact was larger than in the low-level group. In addition, the regression coefficient of ‘government regulation’ was 0.058 (t=0.89, p>10%), showing that the impact of this variable on ‘3PL-initiated LCSCI’ was smaller than in the low-level group, and was not statistically significant. This analysis further verified H3 and H4.

**Figure 2- The moderating role of decarbonisation capabilities**

**Conclusion and future research**

Drawing upon three theoretical lenses - social network theory, institutional theory and RBV - this study develops a research framework for 3PL-initiated LCSCI, the constructs of which were verified by the empirical investigation conducted in China. The research results highlights the positive impact of 3PL-initiated LCSCI on corporate performance. It appears that, with the advent of decarbonized economies and societies, logistics service provision has been given greater environmental focus, distinct from traditional logistics functions. The emergence of 3PL-initiated LCSCI, to a large extent,
echoes Bowersox’s (1998) prediction that “the logistical mission of yesterday is being replaced by a broader concept driven by social responsibility” (p.2). This study shows that, as a strategic action, 3PL-initiated LCSCI is developed in response to a low-carbon economy. The findings of the current study provided evidence of 3PLs as supply chain orchestrators in decarbonized economies and their strategic benefits. Differing from many previous studies that focused on green SCI and 3PLs, this study provides a new perspective on 3PL-initiated LCSCI in consideration of the role of 3PLs as low-carbon supply chain orchestrators. Thus, the research results can contribute to knowledge development not only for SCI but also 3PLs. The present study also identified practical benefits for 3PLs in becoming supply chain orchestrators in a decarbonized economy and society. It suggests that, although the increasing pressure to outsource low-carbon services from both customers and government regulation, 3PLs be aware of their ability to initiate LCSCI, particularly their decarbonization capabilities. In order to gain the most from this initiative, 3PLs should optimize all their related processes, such as developing low-carbon logistics service design, techniques, and coordination capacity.

The empirical investigation can also provide scope for further exploration. Firstly, in relation to the factors that influence 3PLs to initiate LCSCI. This study assumed the degree of 3PL development to be at the same level. Given the negative role of decarbonization capabilities identified regarding the impact of government regulation on 3PL-initiated LCSCI, future research could examine the impact of these two factors on 3PL-initiated LCSCI in 3PLs at different stages. For example, when 3PL possess mature decarbonizing offerings, what is the impact of government regulation? Secondly, the empirical study was conducted in China; therefore, future research could investigate the differences between LCSCI initiated by 3PLs in cross-culture settings. Finally, the sample used in this study was relatively narrow, as data was only collected from one region. Future studies could expand the geographic coverage of the data.

Abstract

Buying organizations are increasingly exposed to supplier sustainability risk that arises from negative sustainability-related conditions or potential events in their supply base that might provoke harmful stakeholder reactions. Drawing on the behavioral theory of the firm, we develop a conceptual model to explain how three key contextual factors (buyer's slack resources, buyer's perceived sustainability risk, and supplier's dependence on the buyer) may influence the buyer's choice among four risk management strategies: do nothing, monitoring, collaboration, and phase-out. A vignette-based experiment with supply managers is conducted to test the model and its associated hypotheses.

Keywords: Supplier Sustainability Risk; Behavioral Theory of the Firm, Vignette-Based Experiment

Introduction

A growing number of buying organizations (termed “buyers”) are experiencing greater exposure to different types of risk within their global supply chains, and these risks need to be proactively managed to protect them against financial loss and reputational damage. A particularly important topic is supplier sustainability risk (SSR), which originates from the use of poor environmental or social practices by a supplier, or the reasonable likelihood of a negative sustainability-related event within the buyer’s supply base – either of which might provoke negative stakeholder reactions.

Anecdotal evidence suggests that buyers manage SSR in different ways and multiple supplier sustainability risk management strategies (termed “SSR strategies”) have been conceptualized (Hajmohammad and Vachon 2016). Beyond identifying potential SSR strategies, further theorizing based on a synthesis of the supply chain risk management and sustainable supply chain management literatures points to multiple distinguishing factors that tend to favor one strategy over another: degree of proactivity, temporal framing (pace and temporal focus), and onus of action. Moreover, the behavioral theory of the firm (BTF) links these strategies to explain three major underlying factors that shape the buyers’ diverse responses: degree to which the buyer has slack resources,
Managing Supplier Sustainability Risk (SSR)

In this study, we focus on an emerging type of supply chain risk, namely, supplier sustainability risk, which is broadly defined as “[a sustainability-related] condition or a potentially occurring event”, located within a focal firm’s supply base, that “may provoke harmful stakeholder reactions” (Hofmann et al. 2014).

Factors influencing risk management

Risk management strategies that focus on activities in the supply chain before an event has occurred, i.e., pre-event strategies, have been classified into three primary categories: risk acceptance, avoidance, and mitigation (Ritchie and Brindley 2007). We synthesized three important underlying conceptual dimensions from the literature to parsimoniously characterize SSR strategies:

Proactivity: The degree of proactivity of SSR strategies varies along a passive–pre-emptive continuum based on the degree to which the strategy attempts to anticipate, rather than react to, the materialization of risk. In short, pre-emptive strategies focus on prevention rather than correction of supplier misconducts, mishaps, or mistakes.

Temporal framing: Temporality is multi-faceted, and the focus here is to emphasize two dimensions that characterize strategic actions: pace and temporal focus (Kunisch et al. 2017). Pace refers to how fast a strategy can be initiated and implemented (Lee et al. 2014). At the risk of oversimplifying, temporal focus denotes the extent to which a strategy’s focus is on short- or long-term goals and outcomes. Consequently, the temporal framing of the SSR strategies may range along slow – fast and short-term – long-term continuums.

Onus of action: SSR is an inter-organizational phenomenon between a buyer and a specific supplier in its supply chain. Therefore, managing the risk may involve either or both parties (Hallikas and Lintukangas 2016). By definition, the strategy’s onus of action refers to the degree to which both parties initiate actions, bear the burden for resources, and take responsibility for pushing implementation forward.

Toward a typology of SSR strategies

Four general SSR strategies highlight key theoretical differences yet remain parsimonious: do nothing, supplier monitoring, supplier collaboration, and supplier phase-out (Hajmohammad and Vachon 2016). The ‘do nothing’ strategy is primarily passive and fast-paced in nature with a focus on short-term demonstrable outcomes, such as limited commitment of financial resources. Moreover, by definition, neither the buyer nor supplier must shoulder the onus of action, limiting (at least in the short term) the potential for conflicts prompted by the efforts to improve. Management of SSR using supplier monitoring is less passive than the ‘do nothing’ strategy and, depending on the standard employed, also relatively fast paced. The focus clearly is on short-term outcomes that demonstrate passable performance, which potentially might prompt unethical behavior by either the supplier or the auditor. Of particular note, the onus of action is shared to some degree, although often predominantly placed on the supplier. Specifically, while the buyer might initiate a monitoring strategy, either the buyer or supplier might be required to commit resources to monitor achievement of the required sustainability behaviors or performance. Moreover, the supplier might be required to take corrective actions and make significant investments to improve its operating
processes and products to mitigate SSR, further shifting the burden to the supplier. Supplier collaboration strategy is more pre-emptive and aims at mitigating SSR by improving the suppliers’ environmental and social performance through jointly-developed solutions. The temporal focus is a combination of short-term compliance and long-term improvement. Rather than forcing the supplier to improve, the buyer might look for a better supplier and then terminate the existing supplier relationship (Hajmohammad and Vachon 2016). While this fourth strategy represents a modestly proactive means to mitigate risk, the onus of action now falls entirely on the buyer to bear switching costs. Pacing is also likely to be moderately fast, and the relatively short-term temporal focus is simple: dramatically reduce risk, but with financial costs and disruption of integrating a new supplier into an established supply chain.

Predictors of SSR Strategy
The behavioral theory of the firm (Cyert and March 1963) views firms as coalitions of internal and external actors and suggests that boundedly-rational and satisficing managers take strategic decisions primarily based on two different measures: performance level they aspire to (aspirations) and the present conditions (internal and external) of their organization. Organizational aspirations are the desired performance levels in specific organizational outcomes. The BTF suggests that failure in meeting an aspiration level prompts problemistic search (or search for solutions) that results in organizational change. In other words, if the performance is higher than the aspiration level, decision makers will make no changes and continue the status quo as they consider that the firm is performing well, whereas if the performance falls below the aspiration level, the gap creates a sense of crisis and calls for a change, i.e., new strategies, techniques, or procedures to improve the situation (Bromiley 1991; Audia and Greve 2006). Thus, supplier sustainability risk within a buyer’s supply chain threatens to deliver performance below a reasonable aspiration level (i.e., a failure), and needs to be addressed. The BTF’s key concepts of problemistic search and coalitional structure of the firm (Gavetti et al. 2012) suggest at least three notable factors that might account for different firm responses to the SSR: degree to which the buyer has slack resources, buyer’s perception of risk attributable to a supplier, and supplier’s dependence on the buyer. These influential factors and their theoretical foundations are discussed in detail in this section.

Slack resources: Unabsorbed slack
Organizational slack is defined as the cushion of actual or potential resources that are not consumed by the necessity of the firm’s continued daily operations. These slack resources allow the firm to successfully adapt to the internal or external pressures and to initiate changes in strategy with respect to the external business setting (Bourgeois 1981). Slack resources can take two forms: absorbed slack and unabsorbed slack. As a starting point, we focus on unabsorbed financial slack resources that are available to buyers to direct toward SSR strategies and adjustments that flow from these strategies and identified risks. In BTF’s problemistic search model, slack acts as a buffer to absorb business shocks, to facilitate experimentation that generates new ideas and strategies, and to increase managerial discretion to refine established norms, relationships, and processes (Bradley et al. 2011). More importantly, slack significantly influences managerial risk-taking behavior (March and Shapira 1992): when slack resources available to managers decline, they become more passive and open to accepting the risk (Wiseman and Bromiley 1996). Conversely, high levels of slack lower managerial acceptance of the risk: managers will be inclined to increase the scope of their
information acquisition about the supply market and to explore new ways to mitigate or avoid the risk they perceive (Sidhu et al. 2004). As such, slack resources are essential for proactive management of the risk. Greater unabsorbed financial slack resources also tend to insulate a firm from pressure to solely focus on short-term performance and reduce its vulnerability to failure by providing a liquidity buffer in the event of loss (Bromiley 1991). With such a buffer in place, management can extend the time horizons of the firm’s investments and can invest in initiatives with positive performance implications that do not have an immediate pay-off (Martin et al. 2016). Hence,

**H1a:** If a buyer has a low degree of slack resources, the management of SSR favors less proactive and shorter-term oriented strategies (i.e., do nothing or supplier monitoring).

**H1b:** Conversely, if a buyer has a high degree of slack resources, the management of SSR favors more proactive and longer-term oriented strategies (i.e., supplier collaboration or supplier phase-out).

Buyer’s perception of risk

The shifting-focus model by March & Shapira (1992)—an extension of the problemistic search model—suggests that decision makers evaluate performance not only relative to an aspiration level (i.e., an acceptable or desired level of performance) but also relative to a survival point (i.e., performance is so low that the firm might fail). This relative evaluation influences the decision maker’s inclination to be risk-averse or risk-tolerant in their decisions. Focusing on a survival point might induce decision makers to be more risk averse because they interpret low performance as a step toward failure. In contrast, their risk aversion might decrease if decision makers assess the firm’s low performance relative to an aspiration level and interpret any gaps as repairable. Yet, even the reference point might change as decision makers potentially shift attention between the two (i.e., survival vs. aspiration) depending on which is perceived to be closer to actual performance (Audia and Greve 2006). By extension, when buyers perceive a high level of risk, for example, a serious threat to their firm’s reputation and image that might greatly hurt the firm’s survivability, the tendency is to become both more proactive and risk averse. Options include phasing out the problematic supplier or initiating collaborative actions to improve supplier performance, respectively. Collaboration also potentially reduces the information asymmetry and helps the buyer to more accurately assess supplier-related risks; however, when the buyer perceives a low level of risk, firm survival is less of a concern. As a result, the firm can afford to be more passive and willing to accept the risk by doing nothing or monitoring the supplier.

**H2a:** If the buyer’s perception of a supplier’s risk is low, the management of SSR favors less proactive strategies (i.e., do nothing and supplier monitoring).

**H2b:** If the buyer’s perception of a supplier’s risk is high, the management of SSR favors more proactive strategies (i.e., supplier phase-out and supplier collaboration).

When faced with problems, however, the viable solutions available to managers are limited in firms with low degree of slack resources (Yasai-Ardekani 1989). Without slack resources, carrying out the strategies that require a high onus for buyer action would be very challenging, if not impossible (e.g., when buyer needs to make sizeable investments to have a collaborative relationship with their suppliers or switch from one supplier to another) since these strategies require changes to the scope and/or volume of their supplier management processes and activities. In other words, the strategic actions taken by managers are well limited by the degree of resources at their disposal. Hence,

**H2c:** The hypothesized relationships between perception of risk and choice of SSR
strategy are moderated by the degree of slack resources. More specifically, with lower degree of slack resources, the management of SSR favors strategies with lower onus for buyer action. Thus, do nothing is favored for lower levels of the buyer’s perception of supplier risk, and supplier phase-out is favored for higher levels.

Supplier dependence
Organizations are not self-sufficient and their survival would ultimately depend on their ability to properly manage their external and internal coalitions (Pfeffer and Salancik 2003). When the performance falls short of the aspiration level, the problemistic search might lead to changes in structure, procedures, or routines of an external coalition rather than an internal one. For these changes to be implemented, organizations must negotiate and use their bargaining power to make proper adjustments. The organizations’ ability to implement such changes depends on the level and nature of the dependence they develop and the relative power of all players (Pulles et al. 2014). By extension, the level of supplier dependence on the buyer influences which firm is more likely to bear the costs of either controlling or improving environmental and social performance. In practical terms, the onus of action is likely to fall to the firm with higher dependency, i.e., less power, in this buyer-supplier relationship. As supplier dependence increases, the buyer’s relative power increases in the buyer-supplier relationship, enabling the buyer to more strongly influence the actions and behaviors of the supplier (Bastl et al. 2013). Particularly, supplier dependence enhances the buyers’ ability to effectively monitor the supplier or push the supplier toward a more collaborative relationship whereby new practices are introduced at the supplier’s facilities beyond the buyer’s direct control (Hoejmose et al. 2013). In contrast, when the supplier has low dependence on the buyer, the buyer has limited influence and is in a poor bargaining position, thereby limiting the buyer’s ability to either impose monitoring or encourage collaboration (Parmigiani et al. 2011). Therefore,

H3a: If a supplier has a high degree of dependency on the buyer, the management of SSR favors strategies with a higher onus for supplier action (i.e., supplier monitoring or supplier collaboration).
H3b: If a supplier has a low degree of dependency on the buyer, the management of SSR favors strategies with a lower onus for supplier action (i.e., do nothing or supplier phase-out).
H3c: The hypothesized relationships between supplier’s dependency and favored SSR strategy are moderated by the degree of slack resources. More specifically, with lower degree of slack resources, the management of SSR favors the lowest cost approach. Thus, supplier monitoring is favored if a supplier has a high degree of dependency on the buyer, and do nothing is favored if a supplier has a low degree of dependency.

Methodology
We used a vignette-based experiment to examine the factors affecting the buyer’s choice of SSR strategy (Rungtusanatham et al. 2011). Drawing from supplier sustainability risk events reported in the media, we developed two scenarios about fictitious mid-sized multinational companies. In each scenario, participants were asked to adopt the role of Procurement and Supply Management Director, review the profile of one supplier, and then indicate what actions, if any, they would take regarding the safety or environmental issues at that supplier’s facilities. Eight vignettes for each scenario were carefully designed to allow the manipulation of all three independent variables at two levels: degree to which the buyer has slack resources (high and low,
i.e., S+ and S-), the buyer’s perception of risk attributable to a supplier (high and low, i.e., R+ and R-), and a supplier’s dependence on the buyer (high and low, i.e., D+ and D-). This resulted in a 2x2x2 full-factorial design, with other descriptive elements of the scenarios unchanged. Full-time supply managers currently working for medium or large companies (i.e., more than 100 employees) in the U.S. were targeted, and our sample was drawn from an internet panel recruited by Qualtrics. Data collection was open for two weeks, after which our targeted sample size of 200 complete responses was achieved. Two responses were discarded because of their poor response patterns (straight-lining), yielding 198 completed responses (396 vignettes).

Data Analysis and Results
Moderated multinomial logistic regression model (Jaccard 2001) allowed us to assess the effect of slack resources, perceived risk, and supplier dependence on supply managers’ specific choice of SSR strategy. With multinomial logistic regression, the log-odds of the outcome categories are modeled as a linear combination of the predictor variables. The two levels of each three predictor variable were modeled as a dichotomous variable, with the reference group being a buyer with a high degree of slack resources (S+), a buyer with a low perception of risk attributable to the supplier (R-), and a supplier with a low degree of dependence on the buyer (D-). The logistic regression model describing the relationship between logit(\( y_{ki} \)) (the log-odds that the strategy \( k \) is selected compared to the reference strategy \( l \)) and our set of predictors is:

\[
\text{logit}(y_{ki}) = B_0 + B_{1kl}S + B_{2kl}R + B_{3kl}D + B_{4kl}RD + B_{5kl}RS + B_{6kl}DS + B_{7kl}RDS \quad \text{(Eq. 1)}
\]

We ran three multinomial logistic regressions using ‘do nothing’, supplier monitoring, and supplier collaboration as the reference group to complete the comparison. Table 1 summarizes the regression analysis results, including the models’ goodness of fit information, regression coefficients, relative odds ratios, and their significance level. As indicated in the table, the fit statistic (-2 Log Likelihood (-2LL)) improved significantly when the main effects and full factorial interaction effects were added to the intercept-only models (significant chi-square tests at p<0.001), confirming that the complete interaction models most accurately predict manager’s choice of SSR strategy. In addition, the Pseudo Nagelkerke R2 (48.3) for the complete interaction models indicates that the predictors and their interactions account for almost 50% of the variance in the respondent’s choice among the four strategies.

In the main effect models (Table 1, Panels A-I~VI), the exponent of the logistic coefficient (i.e., Exp(Bi)) for each predictor variable is equal to the odds of the specific strategy being selected compared to the reference strategy within group 1 of the predictor variable divided by the same in its reference group, holding constant all other predictor variables in the equation. The significant main effect of slack resources in Panels A-II and A-III that compared to collaboration and phase-out strategies, the ‘do nothing’ strategy was significantly more likely to be selected in case of low slack resources (\( B=-2.018; B=-1.484, p<0.001 \), respectively). Similarly, monitoring strategy was significantly more likely to be selected compared to collaboration and phase-out strategies in a low slack situation (Panels A-IV and A-V; \( B=-1.275, p<0.001; B=-0.741, p<0.05 \), respectively). Together, these results provide support for H1a and H1b, suggesting that pre-emptive and long-term oriented strategies are preferred in high slack situations, whereas passive and short-term oriented strategies are favored when slack resources are low. In addition, perceived risk negatively influenced the likelihood of the ‘do nothing’ and supplier monitoring strategies being selected compared to
collaboration and phase-out strategies. Particularly, collaboration and phase-out strategies were 18.29 and 10.63 times more likely to be selected in high risk situations compared to the ‘do nothing’ strategy (Panels A-II and A-III), and 5.1 and 2.96 times more likely compared to monitoring strategy (Panels A-IV and A-V). Together, these results provide strong support for H2a and H2b, suggesting that managers prefer preemptive strategies to passive ones when they deal with high supplier sustainability risk. Lastly, the results supported H3a and H3b, demonstrating that the monitoring and collaboration strategies were significantly more likely to be selected compared to ‘do nothing’ (Panels A-I and A-II; B=2.101, p<0.001; B=1.908, p<0.001) and phase-out (Panels A-V and A-VI; B=2.11, p<0.001; B=1.918, p<0.001) strategies when the supplier was highly dependent on the buyer. However, supplier dependence did not have a significant effect on the preference between phase-out and ‘do nothing’ strategies (Panel A-III; B=-0.009, p>0.1) and between collaboration and monitoring strategies (Panel A-IV; B=0.193, p>0.1).

The complete interactive logistic models (Table 1, Panels B-I–VI) include the product terms in addition to the main effects. In these models, the main effect coefficients for each factor are conditioned to the reference groups of two other factors. In addition, the exponent of the logistic coefficients for the product terms will be “the ratio of predicted odds ratios” (Jaccard 2001). To better appreciate the results of the interactive logistic models, we used Equation 1 and the coefficients reported in Panel B to calculate the predicted logit($y_{kl}$) for each cell of the 2x2x2 factorial design. We then converted these log-odds to relative odds of strategies by calculating the exponent of each (Figure 1). As demonstrated in Figure 1, the odds ratio of collaboration strategy compared to the monitoring reduced from 0.38 in S+ R- D+ to 0.16 in the S- R- D+ situation (Cell II vs. Cell II’) and from 5.14 in S+ R+ D+ to 0.27 in the S- R+ D+ situation (Cell IV vs. Cell IV’). In fact, the monitoring strategy was the most favorable to the buyers for highly dependent suppliers in low slack condition. In addition, the insignificant logistic coefficients for slack resources (S) effect in Panel B of Table 1 indicate that in R- D- situations, managers’ preference amongst the four strategies does not change based on degree of slack resources (i.e., S+ vs. S-). Particularly, low degree of slack does not increase the likelihood of the ‘do nothing’ strategy, which has lower onus for buyer action compared to the phase-out strategy when buyers deal with low-risk independent suppliers. However, the ‘do nothing’ strategy remained the most preferred strategy in S- R- D- similar to S+ R- D- cases (Fig. 2, Cell I’ and Cell I). Besides, although the odds ratio of phase-out strategy compared to the ‘do nothing’ strategy decreased significantly from 27.99 in S+ R+ D- to 1.13 in the S- R+ D- situation (Fig. 2; Cell III vs. Cell III’), the ‘do nothing’ and phase-out strategies were almost equally likely to be selected in the S- R+ D- case (Fig. 2; Cell III’). Hence, the results only partially support H3c. Finally, the likelihood of phase-out compared to the collaboration strategy significantly increased from 0.17 in S+ R+ D+ to 0.78 in the S- R+ D+ situation (Fig. 2; Cell IV vs. Cell IV’) and, surprisingly, decreased from 2.33 in S+ R+ D- to 1.54 in the S- R+ D- situation (Fig. 2; Cell III vs. Cell III’). Besides, the monitoring strategy turned out to be the most preferred strategy in S- R+ D+ (Fig. 2; Cell IV’) and the ‘do nothing’ and phase-out strategies were almost equally likely to be selected in the S- R+ D- case (Fig. 2; Cell III’). Therefore, our results provide only partial support for H2c.

Discussion and Conclusion
The theoretical development and empirical results of this paper extend the literature to date in six important ways. First, our findings call for more scholarly attention to the
crucial effect of slack resources on the strategic decisions made by middle managers, in this case, supply managers. In short, the decision outcome of “which risk management strategy to use” varies depending on if a desired strategy is deemed to be affordable. Second, this study extended the behavioral theory of the firm to explain the decision making within inter-organizational buyer-supplier dyads rather than intra-firm contexts. Also, additional empirical support is provided for the problemistic search model and firm’s coalitional structure. Third, our study contributes to the literatures that speak to risk management in supply chains by providing theoretical foundations to differentiate among the four SSR strategies often discussed in the literature. Particularly, a synthesis of theory established that, in addition to their fundamental differences in how they target the risk (avoid, mitigate, or accept), four distinct strategies also differ in their level of proactivity, temporal framing (pace and temporal focus), and onus of action. Fourth, the results of this study provide additional support for the resource dependence theory from a risk management perspective. Fifth, our findings add depth to the literature on sustainable supply chain management by extending a risk-based framework and empirically examining the concept of SSR strategies and specific predictors. Finally, from an empirical standpoint, the vignette-based experiment methodology allowed for more controlled examination of the causal relationships with a sample of practicing supply managers.

Abstract

This paper provides an explorative study on digitalization and sustainability from the angle of industrial firms. The paper presents case studies on application of the Triple Layered Business Model Canvas, which allowed for relevant insight into the field. The findings in this study show that companies do not capture sufficient sustainability data along their supply chain in order to conduct an overall sustainability assessment. The opportunities lies in adaptation of new technologies, which allow collecting data along each phase of life cycle of a product. Four Sustainable Development Goals by United Nations that are aligned to Industry 4.0 are addressed.

Keywords: Sustainability, manufacturing, clusters, digitalization

Introduction

Digitalization and sustainability are two terms that have gained increased attention the recent years since they are representing potential transforming forces of businesses and society. Sustainability has moved from being regulative pressure from the surroundings and a corporate buzzword, to becoming an encompassing concept that businesses has to relate to and implement in their activities. Sustainability is “a radical transformation towards a sustainable society” (Grin et al., 2010, Joyce and Paquin, 2016).

The fourth industrial revolution is envisioned based on innovations in technologies, smart materials and manufacturing operations. The revolution includes initiatives termed Industry 4.0, the Industrial Internet, Factories of The Future, and Cyber Physical Systems. A driving force for this development is the accelerated use of Internet of Things (IoT)-technologies (Porter and Heppelmann, 2015, IEC, 2015). Companies have common needs across sectors for optimizing operations, for managing parts and raw materials, in production, assembly, packing and dispatching. Digitalization can play a vital role in
providing valuable data to help making businesses more efficient and sustainable (EMF, 2016). A relevant perspective of a sustainable development adopting digital technologies should adhere to the 17 Sustainable Development Goals (SDGs) by the United Nations (UN, 2016b, UN, 2016c). How these goals are aligned to Industry 4.0 in practice among industrial actors are still unclear (Bonilla et al., 2018). Bonilla et al. (2018) have identified four of the goals of particular relevance for Industry 4.0: Goal 7 Affordable and clean energy, Goal 9 Industry, innovation and infrastructure, Goal 12 Responsible consumption and production, and Goal 13 Climate actions. Each goal is complemented by a set of sustainability-targets and indicators to measure and drive performance towards meeting the goals (UN, 2016a).

In order to transform companies to become sustainable, a new theoretical basis is needed. Digitalization of global value chains and sustainability are however, representing separate fields of research within operation management. This paper aims at exploring the territory represented by the intersection between digitalization and sustainability, and propose a set of potential research directions.

Sustainability measurement as whole requires comprehensive data and information. However, the evidence of some studies is that part of the firms are at the stage where they are not capturing the entire data and information on their business processes. This paper aims at exploring how industries approach the expectations and needs to become more sustainable, and how digitalization may solve the challenges in this context. The study is based on in-depth studies of two companies in the maritime and marine sector in Norway (Klymenko and Nerger, 2018). In these case studies the Triple Layered Business Model Canvas (TLBCM) (Joyce and Paquin, 2016) is applied to test this tools applicability, as well as mapping the challenges for using such framework in the companies’ development towards sustainability. Based on this, we discuss how digital technologies may solve some of these challenges.

Digitalization and Industry 4.0
The term digitalization has grown fast within operation management in industry as well as in academia in the past decades. Digitalization addresses the transformation of information flows and data through usage of new technologies and tools, that is, reconstruction of business processes towards more efficient. The term “Industrie 4.0” which concern digitalization in the manufacturing industry, was coined at the Hannover Fair in 2011, describing how digital technologies will revolutionize the organization of global value chains (Schwab, 2016). The term originates from a governmental high-tech strategy in Germany, promoting the computerization of manufacturing (Zuehlke, 2010). Industry 4.0 encompasses a broad range of technologies and concepts. In the context of manufacturing, Industry 4.0 focuses on intelligent products and production processes (Brettel et al., 2014). In the envisioned factory of the future, or smart factory, cyber physical systems will enable communication between machines, products and humans, vertically as well as horizontally. The products are intelligent and customized, to accommodate for the increased need for rapid product development, flexible production and increasingly complex environments (Vyatkin et al., 2007). Brettel et al. (2014) point out that the concept of Industry 4.0 is being used in different contexts, but is lacking an explicit definition. Based on a literature review, Hermann, Pentek, and Otto (2015) provide the following definition of Industry 4.0:

*Industry 4.0 is a collective term for technologies and concepts of value chain organization. Within the modular structured Smart Factories of Industrie 4.0, CPS monitor physical processes, create a virtual copy of the physical world and make decentralized decisions. Over the IoT, CPS communicate and cooperate with each*
other and humans in real time. Via the IoS, both internal and cross-organizational services are offered and utilized by participants of the value chain.” (Hermann et al., 2015, p. 242)

This definition itself contains several terms and concepts, as IoT, CPS and IoS. However, the core of this definition is that items, systems and humans communicate with each other over the Internet in real time. This implies that everything is connected. The second main aspect is the development of services based on this connectedness. According to World Economic Forum, the fourth industrial revolution is being driven by extreme automation and extreme connectivity in combination with artificial intelligence (UBS, 2016). The extreme connectivity enables global and instant communication enabling new business models, which is second aspect of the fourth industrial revolution. The development of new business models is also made possible by the advances in data processing capacity enabling the analytics of “Big Data”. Hence, the fourth industrial revolution encompasses a variety of enabling technologies, as CPS, IoT, Big Data, RFID, cloud computing 3D printing and blockchain (Bonilla et al., 2018).

**Digitalization, sustainability and business models (BM) for sustainability**

Digital technologies provide the information needed to create iterative and restorative systems enabling the companies to move towards sustainable operations and products. Coupling IoT-enabled innovation with sustainability principles can help companies identify new business models. Some examples of areas where the ongoing digitalization have been used to move towards more sustainable operations are optimization of capacity utilization, implementation of predictive maintenance, and automation of sales and inventory management. Digitalization is seen to enable sustainable business models in several areas, including (EMF, 2016):

- **Knowledge of the location of assets** (products, production resources, humans). Tracking to determine the location is an enabler of sharing models, and it contributes to bring down the costs of operations. This allows improved resource utilization, rapid redeploying of resources, and keeping assets in service over an extended period of time. Tracking also facilitate auditing and consolidation of records in an efficient manner reducing the costs.

- **Knowledge of the condition of an asset.** Sensor data can monitor environmental conditions to keep track of the performance of an asset and its use patterns providing data for sustainability indicators driving their operations towards their sustainability goals.

- **Knowledge of the availability of an asset.** The availability data supports increased sharing of assets and development of new more sustainable business models. It promotes the shift towards a more service-oriented economy, for example in energy systems, data about usage and demand of energy at a given location and a given point in time enable more efficient usage of the energy.

Digitalization can be identified as one of the enablers of sustainability in terms of improving resource efficiency, manufacturing performance and as an opportunity to establish accessible data system and obtain flexible and smart use of data through application of information technology. Another contribution of digitalization is strengthening firms’ ability to respond on internal and external uncertainties and changes (Gürdür et al., 2019).

There is a growing literature exploring how Industry 4.0 related technologies could contribute to achieving the sustainable goals. According to de Sousa Jabbour et al. (2018), Industry 4.0-associated technologies have the unique potential to unlock environmentally-sustainable manufacturing, however there are few emerging works
providing insights into these two fields. Stock et al. (2018) have recently published a relevant study addressing this issue. Based on a literature review and expert interview, Stock et al. (2018) qualitatively assess “the potential of industrial value creation in Industry 4.0 in terms of it contribution to the shift towards sustainable value creation for sustainable value creation” (p. 255). The point of the departure for this study is the United Nations’ 17 SDGs and the characteristics of Industry 4.0, which in this paper are referred to as Cyber Physical Systems (CPS), Cloud Computing, and Digital Twin & Digital Shadow. The study assesses the macro and micro potential. The macro potential encompasses business models and value creation network and product life cycle. The micro potential covers quantity of materials used, shared of reused, remanufactured and recycled materials total amount of waste, energy consumption, use of renewables, energy efficiency, greenhouse gas emissions, water use emissions of pollutants and noise, working conditions, information and transparency, and utilization of data. For some of these indicators, specific technologies are given, as RFID and 3D-printing. The above study gives some relevant suggestions of how Industry 4.0 related technologies may facilitate sustainability. However, little attention is devoted of what are the main challenges of the industry, and how technology may accommodate these. In order to shed light on this, we need to introduce a tool that companies can use in the process to address sustainability goals, called the Tripe-Layered Business Model Canvas.

The Triple-Layered Business Model Canvas

The literature suggests a vast number of frameworks and methodologies on sustainability. Some scholars propose various business models, for instance business models for sustainability, circular business models (Schaltegger et al., 2012, Bocken et al., 2014, Joyce and Paquin, 2016). The TLBMC, first introduced in 2016, belongs to the field of sustainable business model. A business model (BM) is a conceptual model that integrates coherence of processes and information necessary for value creation of a firm (Teece, 2010), and the TLBMC tool integrates business model innovation with sustainable business model development. The TLBMC integrates sustainability as part of their business models across three layers: economic layer based on the original business model canvas, environmental layer based on a life cycle approach and social layer based on a stakeholder view. It designed to address three dimensions of sustainability based on the original business model Canvas (Osterwalder et al., 2005).

The TLBMC describes how the company generates economic, environmental and social values. The template of the Environmental layer is presented at the Figure 1. According to Joyce and Paquin (2016), there are horizontal and vertical coherences between each layer. In horizontal coherence of TLBMC, each of three layers is being examined separately, while the vertical coherence combines the value creation of the three canvas layers (Lozano, 2008).

The Economic layer is directed to assessment of nine interdependent components, such as customer value proposition, segments, customer relationship, channels, key resources, key activities, partners, cost and revenues.
According to the framework, the Environmental layer is based on a life cycle perspective of environmental impact. The layer assesses environmental benefits and environmental impacts of the company. Moreover, as business model canvas evaluates how revenues outweigh costs, the Environmental layer aims to assess where the company’s highest environmental impacts compared to environmental benefits that can be a potential area for implementation of sustainability-oriented innovations (Joyce and Paquin, 2016). Due to this approach, organizations might search for environmentally oriented solutions, especially when its environmental impacts are large. The TLBMC does not use the entire approach of the LCA. However, it provides a perspective of the LCA while integrating it to the environmental phase of the business model. The Environmental layer consists of nine components, which together give the holistic view on environmental performance of the company.

The Social layer explores the social impact of an organization on its stakeholders. The stakeholders may include employees, shareholders, customers, suppliers, community, government, interest groups, media, etc. The template is based on the original business model canvas with a stakeholder approach.

Similar baseline can be drawn at the perspective of UN SGDs. The seventeen SDGs as well as TLBMC are based on the Triple bottom line concept (Elkington, 1997). These are directed to enhance economic, social and environmental value creation. However, the framework of SDGs is broader in scope and can be relevant for different groups of stakeholders (private households, businesses, cities, industries).

**Design/methodology/Approach**

The issues addressed in this paper are explorative in their nature, and hence call for an open and explorative approach. Initially, we address the evidence for sustainability measurement and the role of digitalization from industrial perspective by presenting the case study of two Norwegian firms. Furthermore, the UN SDGs are presented with relevance to digitalization and Industry 4.0. Finally, the discussion of findings provides the overview of current extent and solutions for data availability and information flow issues along the value chains with respect to sustainability assessment.

**The companies of the case study**

The methodology of the TLBMC was applied on two companies from marine and maritime industries (Klymenko and Nerger, 2018). The companies were selected based on their practices and focus towards sustainability. Company A is a maritime mechanical equipment suppliers and it is one of the leading firms in Western Norway. The company holds control over the whole value chain that involves various activities starting from
design, manufacturing, marketing and after-sales service for maintenance and repair. The production facilities are located in the region. From a sustainability angle, the firm focuses on providing maintenance, upgrade service for the equipment in order to extend the lifetime of equipment. The product range includes environmentally friendly products with lower energy consumption, low noise and vibration.

Company B is a fishing company that provide catching, processing and delivery of fish fillets. It uses a eco-friendly factory trawlers with hybrid propulsion and low NOx emissions. The company focuses on sustainable harvesting techniques that minimizes emissions and utilize 100% of the fish and aims to provide a high degree of transparency as all fish caught are traceable. Both companies are categorized as small and medium-sized companies representing two different and important industries in Norway. Consequently, the selection of companies provides for comparison, and for in-depth insight into different types of companies.

**Findings of the study**

The studies of the two companies show that the economic layer of the original business model canvas were proven sufficient for both cases (Klymenko and Nerger, 2018). Not surprisingly, most information related to economy, consisted of straightforward facts that can quickly be revised by managers. Unlike the economic layer, the data collected for the social and environmental parts did not completely fulfill these two corresponding layers. Some components of the social layer were difficult to define and measure, for instance, social value, scale of outreach and social impacts. The study of Joyce and Paquin (2016) suggests limited and brief description of the elements of the layers. Thus, some additional sources were applied in order to develop the insight of the components and indicators, for instance, Guidelines for social life cycle assessment of products (Life Cycle Initiative at UNEP, United Nations Environment Programme, 2009). Finally, the data and information for the environmental layer provided a generalized understanding of the impact. The study revealed, however, that there is a lack of data on greenhouse gas (GHG) emission for distribution, energy requirements during the operation, etc.

The case of company A emphasize the differences regarding product types, as this have impact on the following manufacturing, energy consumption for product use, and finally the environmental impact. Unlike the study described by Joyce and Paquin (2016) where the TLBMC framework was applied on Nespresso capsules, the products in company A was very complex. The complexity led to challenges in applying the TLMBC framework. Nevertheless, company A produces several kinds of product units and some of them identified as environmentally friendly products, that have lower energy consumption, low noise and vibration. The interviews revealed that company A does not have a single storage of data and information. The data is distributed according to the organizational structure of the firm and separate pieces of data belong to specific department or to responsible of those employees. Consequently, there is a lack of a systematic approach to information storage, where the data can be organized in accessible and structured way. Sustainability from the perspective of the TLBMC, is directed towards detailed review of all business processes, starting from raw materials delivery by suppliers, along the manufacturing, logistics, warehousing, towards customer use, and finally finishes at the end of use stage. The challenge with availability and easy access to data and information made it difficult to map the different elements in the TLBMC, which is a key to complete sustainability evaluation.

The case of Company B differs in terms of shorter value chain, which is integrated in one vessel. According to Ziegler et al. (2016), fuel use is the main driver to greenhouse gasses (GHGs), eutrophication or depletion of abiotic resources. The fishing phase
consumes most fuel and contributes 75% - 79% of GHGs. In this case, fishing is one of the central activities of the company. However, information about fuel consumption and emission NOx were not available at the company. General information about consumption level came from the ship building company in Spain. Hence, the data collection time was significantly longer than initially planned. To apply life cycle approach to the environmental layer, it is imperative to take a broader view on the entire life cycle. For fishing companies, suppliers include firms who provide packaging material, processing factory manufacturers, fuel providers, and vessel maintenance companies among others. In this case, the conduction of a more comprehensive sustainability assessment was limited due to the absence of necessary information about suppliers that are part of the product’s life cycle and hence are contributors to the emission level of the product. Generally, where the company has control over its value chain, it was possible to obtain sufficient data and information to conduct the sustainability assessment, however, when it comes to suppliers and distributors less relevant data was available. As a result, a more thorough sustainability assessment would require more time and information from distributors and suppliers.

To visualize the understanding of data and information availability from the case study across the layers, the summary of information received is presented in Table 1.

</table>

Exploring the interrelations between digitalization and sustainability measurement, the findings reveal on high data requirements especially for the environmental layer of the TLBMC. Based on the case study example, the information collected partly fulfill the requirements for production phase analysis for both companies A and B. For company A
data on energy consumption in production facilities for 2012-2017 was received. The analysis showed a reduction in energy use in the last years. However, the cause for this decrease is not quite clear. According to the findings in company B, the resulting data consisted information on fuel used for catching, processing, freezing on the vessel, and storage/freezing after taken from the vessel per 1 kg of fish. The information for material phase for company B provides particular insight on packaging materials. Although, the first common issue for those companies is absence of the information from the suppliers, for instance, environmental impact from raw materials supply and logistics. Furthermore, customer use and end of life stages are not at the main scope of the businesses. As a result, the responsibility for the product impact often ends when the supplier role finishes. At the same time, the information flow on business activities generally are not completely shared between supplier firms across the value chain.

Hence, based on the data and information collected during the interviews and secondary data assessment, the environmental impacts and benefits are not addressing the entire impacts and benefits of the activities of the companies A and B. Consequently, the result estimated in the study provides limited findings.

The result shows that important data and information are not available or even not accessible for the companies. Firstly, there is a lack of supplier materials information. Both case companies receive general data and information about resources and materials they supply. However, there is no complete information flow from supplier to buyer firm. Bonilla et al. (2018) underlines the principle of Industry 4.0 to promote real-time shared information through supply chain tiers that can help companies to understand patterns of consumption and increase transparency of a product information. Another essential phase for sustainability assessment is use phase and end of life of a product, which also defined as lacking of data. Industry 4.0 fundamental technologies can help in resolving this gap. First is cyber-physical systems (CPS), which establishes connective and communicative solutions that allows sufficient information exchange and control between humans, machines and products (Bonilla et al., 2018). According to Bonilla et al., (2018), the second is Internet of Things (IoT), which is essential for data mining and recording, and directed to information exchange from physical things to Internet. The collection of data and information is carried out through installed sensors, actuators and communication technologies. In fact, digitalization and novel emerging technology solutions are crucial for industrial sustainability, which is directed to redesign for value creation in sustainable production and consumption.

**Digitalization and the SDGs**

Drawing on the study of Bonilla et al. (2018) and the findings from the case study above, we address the collaborative linkage between Industry 4.0 components and SDGs. The SDG 7 Affordable and clean energy is directed to ensuring access to affordable, reliable energy and particularly improvement of industrial energy efficiency (UN, 2016 b). As an illustration, the case studies of companies A and B reveal on importance of assessing energy consumption along the whole life cycle of a product. Technology for monitoring and data collection is crucial for further adjustments in energy efficiency of a product. In the same way, the SDG 9, which aims to enhance innovation and sustainable industrialization, can be flourished by digitalization in order to define weak and potential stages for sustainability improvements. The case study underlines the lack of tools for systematic data and information collection at the stage of supply materials, production and material phases, thus, it lead to the lack of complete sustainability assessment. Finally, the SDG 12 Responsible consumption and production, which requires data and information from use phase of a product as well as manufacturing phase in order to make
further improvements. The actions towards contribution to SDG 13 Climate actions, aims to assess COx, NOx emissions, hazardous waste and other chemicals that have negative impact on environment and climate change overall. Thus, the initial stage towards sustainable development is in reliable technologies for critical assessment of today’s impact, followed by further sustainability-oriented decisions.

Discussion
The concept of sustainability is a transdisciplinary field by nature. Whether it is sustainability evaluation through variety of tools such as sustainable business models, or whether it is assessment through indicators of SDGs, one and the other requires accurate and detailed data and information. According to the study findings, the example of case study of the TLBMC application underlines that sustainability is a data- and information-demanding area. The study indicates that examined companies are at the stage where they are not capturing entire data and information along the supply chain. Consequently, it is more difficult to conduct overall sustainability assessment.

However, gathering data is not enough for holistic pictures of sustainability measurement. It follows that the data should be processed and transformed into information and knowledge categories. When evaluating some of the SDGs indicators, the process relies on available data, preferably in time-series, accessible and timely updated (Bastianoni et al., 2019). Schaffartzik et al. (2015) propose that the data and information in form of macro- and micro-economic aggregates are historically easier to report and it is more sufficient than the information and data reported in physics-based units, as most of the environmental dimension data is.

High data requirements for sustainability measurement underlines how important the focus on digitalization of the businesses is. Digitalization from the perspective of business model for sustainability can be defined as a procedure to create a common system for storage of data and information, its processing and structuring, and approach to the effective interpretation of data crucial for business model redesign and sustainability assessment. An important contribution of the study is that it through these case studies show the importance of data availability is for both sustainability measurement in general and for application of the TLBMC in particular.

Conclusion
The paper presented an explorative study on digitalization and sustainability from the angle of industrial firms, and a case study on application of the TLBMC for two companies. The results show that the companies do not capture enough sustainability data along their supply chain in order to conduct an overall sustainability assessment. Thus, this also indicates that the companies do not have enough information on their operations to manage their processes in a way that enable them to move towards their sustainability goals. The opportunities lies in adaptation of new technologies, which allow collecting data along each phase of life cycle of a product. Industry 4.0 has brought beneficial changes towards digitalized infrastructure and essential for sustainability assessment.

Abstract

Our paper highlights the various consequences of implementing information technology in sustainable supply and value chains of industries. With a particular focus on studying the digital transformation of the European Components and Systems (ECS) industry, our research examines the progress made by industry practitioners in implementing new, digital technologies and the impact achieved. We conducted an exploratory multiple-case study that included a qualitative content analysis of four selected industrial cases from a major European innovation project. The results contribute to the theory of how value chain process improvement can be assessed after innovative technical adaptations have been made in factories.
Keywords: Digital Transformation, Case Study Research, Impact Assessment

Introduction
The trend towards an increasingly digitalized manufacturing environment is an emerging topic for researchers and practitioners of different fields (Hannola et al. 2018, Richter et al. 2018). Various European manufacturing industries have invested into a rising number of activities to develop and explore the potential of digital technologies to remain competitive within an era of a digitally transformed world. The integration of intelligent and smart systems, digital technology adoptions and new management approaches in the context of Industry 4.0 becomes increasingly important due to improved value chain management. Other new technologies may include innovative applications such as real time monitoring, controlling systems or advanced process digitalisation (e.g. visualization methods along the horizontal and vertical supply chain). The implementation of digital technologies may affect different issues of core business processes such as production processes, product development, organizational structures and supply chain management (Sjödin et al. 2018). To ensure the improvement of such processes, it is of high interest to measure the impact of digitalisation activities. Therefore, a company must identify the relevant performance indicators while implementing new technologies or sustainable programs and compare the results to the desired performance change.

Hence, one objective of our research is to present novel holistic insights of conducted digitalization efforts within a large-scale European innovation project in the European Electronic Components and Systems (ECS) domain. The focus is put on impact assessment of developed and (partially) implemented digital technologies. We intend to measure the dynamic interaction among the various dimensions i.e. the effect of digital transformation projects on production workers, organizations, fabs, internal supply chains, and the society (Felsberger and Reiner, 2018). Another objective of our paper is to make the organizational, economic and social impacts of digital advances within the ECS industry more visible and thus better explainable to decision makers, using the Triple Bottom Line (TBL) approach (Elkington, 1998). Impact evaluation is amongst others crucial to justify future investments into Industry 4.0 under consideration of management implications as well as research and development activities. Our research contributes to improving performance evaluation of smart factory technologies and theory development. Furthermore, it closes the gap in the scientific literature concerning the properness and comprehensiveness in evaluating the impact of digital technologies. Our objectives lead to the following research question: What are the main impacts and benefits of digitalized operations with respect to sustainable value creation in selected areas of the European ECS industry?

This paper is structured as follows: First, we review the existing literature that relates to the core of our paper. We then focus on introducing into our methodology, case study research, including case descriptions and research structure. Finally, we present the comprehensive results of our multiple-case study on the achieved impacts of conducted digitalization projects, give a conclusion and an outlook.

Related work
Manufacturing performance is a much-discussed topic in operations management research for which there is no uniform definition, model or measurement system. Past research has for example focused on manufacturing metrics based on quality and output
(Leachman et al., 2005), the overall equipment effectiveness (OEE) measure (Jonsson, 1999, Schwab et al. 2017), or mapped the area of operational decisions during a growth period to the three performance dimensions of the Triple Bottom Line (TBL), economic, social, and environmental. However, an explicit focus on assessing the impact of digitalisation projects on manufacturing performance has not received sufficient attention. Hence, approaches must be identified to make the impact of digitalisation initiatives – i.e. the impact of current ICT phenomena – visible and measurable. However, digitalisation is changing the landscape in manufacturing as enterprises begin to use internet of things to connect manufacturing assets, big data analytics to monitor plants, and artificial intelligence to support decision making processes. Therefore, manufacturing operations has become smarter by slowly adopting ICT approaches and technologies (Kusiak, 2017) and merging them with production and process technologies on the threshold of a fourth industrial revolution affecting different industries. Electronics components and systems (ECS) are widely understood as enablers for multi-layered innovation in various industries, from automotive to healthcare. According to the European Industrial Strategic Roadmap, the European Components and Systems (ECS) industry employs about 250.000 people, while more than 800.000 people work on the integration of components to systems and further 2,500,000 are employed in the components value chain. Therefore, research into how the ECS industry itself will benefit from digitalisation is of great importance.

Methodology
Instrument development and case selection
To answer the underlying research question of our paper, we apply a multiple-case study approach, including four different industrial cases of digitalization in the production environments of European ECS companies. All four cases outline different digital solution approaches – related to topics including cyber-security for legacy systems, agile manufacturing maintenance, or machine learning for improved decision-making. From a methodological point of view, case study research is an appropriate technique for describing a phenomenon within its real-life context – here the digitalization of manufacturing environments (Yin, 2003, Voss et al., 2002, McCutcheon and Meredith, 1993). Our study uses primary data from expert interviews and assessments with people in charge of digitalization projects in the case companies. We assess the current situations and challenges leading to digital transformation projects, the implementation of digital technologies to solve these challenges, and the achieved impacts. A qualitative content analysis is applied to gain valuable information and investigate the impacts of digitalization efforts in the ECS domain referring to our four individual cases. The approach enables us to retain the holistic and meaningful characteristics of real-life events such as individual life cycles, small group behavior, organizational and managerial processes, international relations, and the maturation of industries (Yin, 2009). To structure our multiple-case study research, we followed the concept by Stuart et al. (2002). Therefore, we used their five-stage approach. The first stage of this research model handles the development of the research questions, followed by the second stage “instrument development” which deals with the selection of representative cases including their description and the development of the research instrument, that serves as a written guide to conduct further investigation. The third stage is concerned with the collection of required data by means of open, unstructured, semi-structured and structured expert interviews, focus-group discussions, analysis of documents and questionnaires.
The data collected is examined in the next step by using qualitative content analysis for extracting relevant information (e.g. deducing categories). Finally, our investigation is concluded with the documentation and dissemination of the results and the subsequent testing of internal, external validity, and reliability (Stuart et al., 2002).

**Introducing the cases**

In this subsection, we outline the characteristics and background information of the case study sample (Table 1). The presented case description is based on the original documentation of four selected cases. The industrial partners of the European project SemI40 (semiconductor manufacturer, (Case A) component supplier of ECS industry (Case B), PCB assembler (Case C) and semiconductor manufacturer (Case D)) are responsible for the case description. Here, we introduce each case by describing the industrial challenge and the envisaged solution. Afterwards, we set the focus on the case analyses to explore the expected impact behind the single cases.

<tr>
<th>Case</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Secure production networks are a central prerequisite for implementing Industry 4.0 applications in real production environments. In today's production plants, many different machines communicate intensively over the network. Compared to an office IT network, the communication behavior of nodes in a Machine-to-Machine (M2M) communication network is generally relatively stable. A human intervention (from outside) in this communication violates this stability. The use of Intrusion Detection Systems (IDS) is a way to detect such deviations from normal behavior in the production network. However, classical IDSs require the definition of rules for the execution of applications on a host machine or the communication behavior in the network. These rules are manually defined by experts based on their understanding about the known signatures of the running applications on a host or the traffic exchanged over the network. If one of these rules is violated, an alarm is triggered, and analysis can be started to identify the possible causes. For large systems such as production networks, however, such rule-based IDSs are very complex to configure and maintain, requiring extensive domain knowledge to map the entire production network and its acceptable behavior and to keep these rules or signatures updated.</td>
</tr>
<tr>
<td>B</td>
<td>The production of sputtering targets is a powder metallurgical process that involves many critical production steps and tight requirements. The sputtering targets are treated in production lots of up to 10 pieces. No or only a few process parameters are recorded along the supply chain, but the combination of this data with the production lots was either impossible or only possible by hand. The main production step - hot deformation - was planned by hand and the heating times are determined on the basis assumptions. The challenge is to integrate single piece traceability into the entire production chain and to optimize and more accurately design the main production process step. Single piece tracking is achieved by a unified unit number, which will be implemented in the ERP/MES and on each single material ingot. With new tailored process models and advanced model-based control tools, the production step deformation will be controlled more efficiently and accurately. In the final production steps, single piece production is installed together with almost paperless production.</td>
</tr>
<tr>
<td>C</td>
<td>Embedded components directly in the printed circuit board (PCB) increase the complexity of PCB production, especially the process steps copper plating and photo (etching) process. The general trend in the electronics industry is towards smaller, more compact and more powerful devices. To meet the new requirements, the case company developed and patented its technology several years ago. The aim was to integrate the active and passive components attached to the outside of printed circuit boards inside the boards in order to reduce the overall size and protect the components. The current quality control of the copper plate thickness is performed after each individual copper process. The complete production process for a lot size of 30 working panels can be traced on the collected data based on manual operator input into Excel documents. These Excel documents are not standardized for all users and process steps and are stored on local storage devices.</td>
</tr>
<tr>
<td>D</td>
<td>In addition to cost and time, effective quality assurance is one of the most relevant parameters for efficient manufacturing in the semiconductor industry. Up to now, the detection and classification of quality issues has mostly been carried out by skilled employees. Over the last years, the increasing level of fab automation requires enhanced and fully automated quality controlling methods with extensive measuring instruments and tools. The implementation of automatic control serves to overcome the limits of the human operator's performance to detect defects. A central IT platform must capture and process quality data from a highly automated semiconductor manufacturing process in real time. Based on this data, especially trained employees will only have to inspect wafers that are marked as defective.</td>
</tr>
</tbody>
</table>

**Data gathering**

In total 22 different digitalisation projects were carried out under the umbrella of this large-scale project and have been fully documented. They describe different digital solution approaches related to the topics cyber-security for legacy systems, agile manufacturing maintenance, machine learning for improved decision-making and fab digitalization and virtualization. In our study, we selected four of these 22 specific cases that represent all four areas and have achieved and documented the most meaningful
results. At the suggestion of case study researchers such as Senger and Österle (2002), who have requirements from business engineering for a generic case structure, we have developed a template to achieve a structured description of the digitalisation cases in a first step. This template was completed by all industrial case owners supported by us to ensure a high-quality case documentation. As a result, all 22 case studies were documented in a unified structure: describing current situation and challenge to be solved, digital solution approach to be implemented, the target situation to be achieved, and the expected impact to be generated in a first step within the first 18 months of the project. In the last six months of the three-year innovation project, an impact assessment was carried out by the case owners using a template developed by us, which was also the basis for the analysis in this paper. This impact assessment template consisted of two separate sections: In the first section, all case owners had to update the status of their cases with respect to the degree of implementation, while in the second section, case owners had to answer specific questions about the concrete impacts of the implemented digital solution. However, the core of the impact assessment form consists of a broad listing of KPIs that help case owners evaluate the technical impact in the three dimensions of the TBL-model. The KPIs they had to consider included, IT/information security in manufacturing environment, production flexibility, transparency, traceability, availability, reliability, dependability, data and information quality, process quality, product quality, expandability, OEE, material resource efficiency, workforce satisfaction, satisfaction of the internal customer, satisfaction of the external customer, innovation and problem-solving skills, knowledge development and gain, operating costs, process lead time, productivity, and energy consumption. The effect of the digitalisation project on each impact aspect had to be quantified by the case owner on a 5-point scale. In addition, the case owner had to describe in the prose how an impact was achieved and what the strengths and weaknesses as well and what the threats and weaknesses of this impact were. All completed impact assessment forms were reviewed by us to high quality documentation, followed by one requested for content elaboration by case owners.

Data analysis
This section gives an overview on how our results have been gained. We apply the method of qualitative content analysis for extracting relevant information e.g. impact on defined performance measures, from the impact self-assessments and documented case descriptions. Data was analyzed in the text coding program NVIVO 12, and we conducted a cross-case analysis (Seawright and Gerring, 2008). Finally, our investigation is concluded with the documentation and dissemination of the results and the subsequent testing of internal validity, external validity and reliability (Stuart et al., 2002). To increase the rigor of the content analysis process, we asked the case owners to check the results of the filtered descriptions for incorrect formulations and wrong interpretation of their formulations. We developed a case analysis table in which the four cases are coded and filtered. The results were divided into three categories: The first category describes the economic impact of the process, method, application or tool. The second category deals with the social dimension and its impact on workforce satisfaction and/or problem-solving skills. The third category illustrates the impact of the individual cases on environmental performance indicators such as energy efficiency and material efficiency (Felsberger and Reiner, 2018). The last step of the analysis comprises the documentation of the achieved impact. We adhered to the TBL evaluation framework and evaluated the individual cases according to their impact on the most relevant KPIs mentioned by the case owners.
Findings
Already an informal analysis of the cases before the content analysis has shown the disruptive impact of digitalization on manufacturing environments in the ECS industry. In addition, an overview of different impacts is developed from the results of the individual impact assessments. Selected findings show that digitalization efforts in manufacturing environments positively affect the performance of production processes, sustainable value chain management and overall supply chain productivity. In this regard, digitalized operations offer the potentials to decrease defects, reduce costs and increase the overall company’s sustainability. Our results are partially congruent with the findings of Ron (1998), as flexibility, material handling and life cycle performance are important aspects for assessing a company’s sustainability performance. We make the current challenges of the European ECS industry more visible, discuss the consequent digitalization projects addressing these challenges, and discuss the achieved impacts.

Assessed case-specific impacts and benefits of digitalized operations
Case A – Semiconductor manufacturer
The benefits of exploiting an anomaly detection system in an Industry 4.0 production network is threefold: First, it helps to detect any suspicious network traffic that can be caused either by a legitimate user (due to misuse) or by a malicious attacker (e.g., due to attempted sabotage, intellectual property theft, or product quality degradation). Unlike commercial solutions, which rely on a priori known signatures of known threats, network anomaly detection systems rely on machine learning or statistical algorithms to learn regular communication patterns exchanged between different equipment and machines. Any significant deviation from regular patterns (normal behaviour) is flagged as an anomaly. An interesting property of these systems is that they are able to detect any new attack even if their signatures do not exist in the database (i.e., detecting zero-day attacks). Second, detecting abnormal behaviour at an early stage can allow the security department to take proper countermeasures to neutralise potential attacks or minimise their risk, which can have a positive impact on systems availability, reliability and dependability. Third, detecting and preventing any malicious network activity can ensure that the production processes cannot be touched by an attacker or a competitor to compromise the product quality. It is also worth mentioning that the collected data for this case from a real production network and the designed algorithms for anomaly detection can be exploited as a baseline for any project related to cybersecurity in Industry 4.0 CPPSs.

Case B – Supplier of the ECS industry
First, there has been an increase in quality improvement: focusing on a zero-defect strategy requires the operator’s cooperation and a corresponding focus on quality. For this purpose, the optimization algorithm should give the operator recommendations as to (1) how, (2) when and (3) where products are to be manufactured. There was also a significant increase of energy efficiency: Since the heating of the ovens is the main energy factor, the optimal use of heated ovens and the potential decommissioning of unused ovens contribute greatly to energy efficiency. The optimization of oven usage has been added as a goal in the optimization algorithm in order to avoid the heating of material without subsequent rolling. Furthermore, the throughput was increased by 3-5%. Besides, the implemented traceability of single pieces along the whole internal supply chain
increased data quality, speed of complaint handling and product and process development. The implementation of MES solution in the first production step of powder pressing and sintering further improved the interface between supply chain and shop floor and thus the speed of order handling. Finally, paperless production in the final production step, the mechanical processing of sputtering targets, reduced costs of operating supplies (paper and palettes) and reduced the likelihood of confusion in order handling.

*Case C – PCB assembler*

The successful completion of the digital traceability project will allow the case company to fully trace produced cards and embedded components. This will improve product quality, customer satisfaction and employee satisfaction, by reducing the time spent on analysis and searching for errors. In short, the traceability project is running at the case company as planned, with a larger scope and a longer schedule than expected in the beginning. The experience gained so far greatly supports the future implementation of machine learning for traceability and quality improvement as a following project. The target is to have full unit traceability, which is also a customer requirement. The exact technical solution cannot be described due to confidentiality reasons, but it will allow the case company to ensure knowledge about which PCB was produced when, on which machine, by whom and with what components from which supplier and lot.

*Case D – Semiconductor manufacturer*

Due to the camera system implemented, no human intervention is required anymore to fully track all data and monitor production processes. Better and more reliable KPIs now enable more effective decisions, gaining more control of the production processes, increasing flexibility, reducing costs and increasing quality. It is also possible to optimize maintenance scheduling by detecting machine weaknesses at an early stage. The process is continuously monitored while the system is in operation. The process quality is more stable by increased reliability regarding standardized errors. The new process provides the permanent quality of process controlling and product quality control. The scrap rate is drastically reduced. The camera system provides 100% quality control through algorithms. Therefore, quality inspection is no longer subject to the errors made by human operators, and a consistent quality level is ensured.

*Cross-case analysis: Aggregating case-specific impacts on performance dimensions*

The qualitative analysis of the collected case data led to the identification of different impacts and improvements identified by the case partners during the impact self-assessment. Based on the impact rating (scale from no impact “1” to very high impact “5”) of the case owners, we identified four main KPI categories with the highest ranking at a rate of 4-5 on the scale (very high impact). These KPIs are listed in the table below: the impacts and increases in the level of automation, the impact on process quality such as quality assurance processes that lead to higher productivity and reduction of operating costs, the improvement of traceability and, finally, most cases ensure an increased transparency within the system or fab.

*Table 2. Overview about the impact on performance dimensions*
<table>
<thead>
<tr>
<th>Level of Automation</th>
<th>Case A</th>
<th>Case B</th>
<th>Case C</th>
<th>Case D</th>
</tr>
</thead>
</table>
|                     | Proposed detection system does not require any manual update of attack signatures. | Case increase traceability along the supply chain and set up systems/models help the operator with decision making. | Interconnection of two separate process steps on a data exchange level provides the enabling baseline for further automation of processes. | Solution will increase the automation for the manual control from 0 to 100 %.
|                     | It learns the normal traffic behavior by observing the benign traffic crossing the network. | Give optimized recommendations and model-based process times. |                                                    |                                                    |
| Process quality     | • Adopting an IDS can help detect any attack to manipulate the production processes. | • Temperature and format based inline releasing time calculations will improve the quality of the spattering targets. | • Process quality is improved by the possibility to fully trace back all steps, recipes and settings. | • Process is continuously monitored as long as the system is up and running. |
|                     | • By analyzing the network traffic commanding physical processes rather than relying only on checking the HMI system. | • Especially the microstructure which plays a crucial role for material performance at the customer. | • Knowledge was generated through testing within the project. | • Process quality is more stable due to an increase of reliability related to standardized errors. |
| Traceability        | • Early detection of an anomalous network traffic can support to trace any changes in processes or harm induced by cyberattacks. | • Each product can be traced through single piece tracking along the production chain, ERP and on the shop floor by implementing marking via engraving machines. | • Enable full unit traceability this will in turn enable further opportunities to enhance processes and quicker pinpoint and tackle problems. | • Camera system provides 100% quality control through algorithms. |
| Transparency        | • Implementing an IDS can help improve the transparency of industrial communication systems by timely detecting any irregularity that may happen due to cyberattacks or misuses. | • Every employee has access to the relevant context he/she needs for the work through installing SDI terminals, part of the MES, directly on the shop floor. | • Full unit traceability will allow perfect accountability for all parts and increase transparency of all production processes internally as well as externally. | • Stable quality level is ensured |
|                     | • Detailed planning boards are available on every workplace via the SDI terminals. | • Detailed planning boards are available on every workplace via the SDI terminals. | • Constant monitoring of the processes by collecting data in a timely manner and higher sample sizes. | • Several sub use cases were implemented. |
|                     | • Each production group has a screen where workers can see actual planning status and availability of the equipment. | • Each production group has a screen where workers can see actual planning status and availability of the equipment. | • Its correlation to product quality data will logically lead to more stable processes and higher product yields. |                                                    |

**Cross-case analysis: Impact on TBL dimensions**

**Economic dimension**

Most of the cases deal with production process improvements. As a result, we have identified some overlaps in the economic impact when comparing cases. When assessing the operational level of a case organization, several impacts of individual process improvements are evident. Not only internal but also external improvements can occur. For example, the IDS of Case A will detect any suspicious activity within the information network supporting the production environment, caused either by an insider (misuse) or by an outsider (attacker). This will help make Industry 4.0’s production environments more resilient to potential cybersecurity attacks. Employing a network anomaly detection system can prevent any cyberattack to compromise production quality. Furthermore, increasing traceability along the supply chain and establishing systems/models that help the operator in decision making by providing optimized recommendations and model-based process times are fundamental impacts of the proposed solutions. Automated early and precise detection of faulty items lead to a more reliable inspection rate and thus to a reduction in variability within control processes. This allows operating departments to increase throughput. This also has an impact on costs. A company can reduce operating and production costs by improving overall product and process quality (Felsberger and Reiner, 2018).
Social dimension
Digitalisation is leading to an increase in know-how and skills. The implementation of further visualization tools and the increase of transparency and traceability of products and production systems leads to improved usability and acceptance among the employees. An increase in knowledge of individuals leads to a higher qualification and a better understanding, thus raising employee satisfaction and the general knowledge level in the departments. The better qualified the employees are, the better a product can be delivered on time. The digitalization efforts lead to higher process knowledge of employees. A fundamental insight is also the fear of losing one’s job – a general fear of "Industry 4.0" and related topics is noticeable in the workforce. The case companies expect significant knowledge development and gain, especially for specific process experts. The developed digital solutions are very innovative, using different hardware and software components. Therefore, employees develop improved problem-solving and innovation skills. Companies benefit from these developments. In a highly automated fab, no human resources are available for non-value adding jobs e.g. manual quality inspection. Quality inspection is a very monotonous and exhausting task, which is rationalized in the future factory. The operator can therefore be used for performing much more important tasks, which also increases workforce satisfaction (Felsberger and Reiner 2018).

Environmental dimension
The optimization of production processes makes it possible to shut down machines based on the capacity requirement forecast and thus save energy costs. For example, case B deals with the reduction of heating times, based on online temperature measurements, leading to a reduced energy consumption reflected in less electric energy and pure hydrogen. Furthermore, high potentials can be identified to reduce electrical power. Production costs can be reduced by using more energy-efficient manufacturing systems. This leads to price advantages over competitors and strengthens the competitiveness of European ECS companies. Modern production equipment and optimally operated machines will emit fewer pollutants and use limited resources more sparingly in order to protect the environment. The very high impact of energy and resource savings could be demonstrated by an excellent energy data management concept. The improved data quality and the link between the different process steps will lead to fewer sample parts being produced, which slightly reduces the usage of material leading into an increase in resource and material efficiency. With improved process stability, product quality will also improve, further resulting in a reduced scrap rate. Europe’s resource dependency on other countries is a problem regarding the competitive advantage for the future development (Marre et al., 2015; Felsberger and Reiner 2018).

Conclusion and outlook
The results of our multiple-case study contribute to the evaluation of process improvement through the implementation of digital technologies. Our investigation underlines the concrete benefits of digitalization efforts in the European ECS industry. The impact assessment aims to rigorously analyze the added value gained through the implemented technologies in the case companies. In order to analyze the impact of technology adoption on various levels in a company, the TBL-model is used, which differentiates between the social, economic and environmental dimensions. The results of our study support industrial decision makers in assessing the relevance to invest into digitalization. Consequently, this may lead to a further increase in operational efficiency.
performance and competitiveness of manufacturing companies in Europe. In particular, we wanted to show the influence of digitalisation efforts and new technological solutions (algorithms/sensors) in the production sector (cases A-D). Furthermore, our insights regarding the effect of learning from data over time offer decisive potentials and opportunities for future developments related to Industry 4.0 projects. In a follow-up paper, we will also include impact assessment data from the remaining cases.

Acknowledgement
This work has been carried out within the scope of the project Power Semiconductor and Electronics Manufacturing 4.0 - (Semi40), under grant agreement No 962466. The project is cofunded by grants from Austria, Germany, Italy, France, Portugal and - Electronic Component Systems for European Leadership Joint Undertaking (ECSEL JU). Is 3D printing a myth and hype to achieve sustainability?  
An evidence from Chinese Manufacturing firms

Abstract

3D Printing (3DP) is a new technology with the ability to provide companies or industries with an additional competitive edge. We aim to explore how 3DP complement conventional manufacturing process by improve sustainability in Chinese manufacturing firms under the lens of actor network theory. Through ten semi structured interviews with different manufacturing enterprises from different industry who has adopted 3DP, we discovered that 3DP is undeniably perceived as a tool to facilitate design to prototyping in manufacturing process, however, the sustainability performance of this adopting 3DP is limited by the technology own’s bottleneck.

Keywords: 3DP, sustainability, Chinese manufacturing firms

Introduction

3D Printing (hereinafter 3DP), also known as additive manufacturing or rapid prototyping with first appearance in the 1980s, is a disruptive and innovative technology with the ability to provide companies or industries with an additional edge in the current era (Phaal et al., 2011; Chan et al., 2018). The 3DP industry is expected to rise to $13 billion by 2019 and $49 billion by 2025 globally (Wohler Report, 2018). Currently, 60% of this skyrocketing growth of 3DP applications has penetrated the United States’ manufacturing processes (Faludi, 2015). It is a revolutionary technology in which an abstract digital computer-aided design (CAD) design file can be transformed into physical object as long as it is paired with a 3D printer. This trend of 3DP will reconfigure enterprise’ existing supply chain, because it breaks existing performance trade-offs in two fundamental ways. First, 3DP reduces the capital required to achieve economies of scale. It has lowered entry barrier to manufacturing. Second, it increases flexibility and reduces the capital required to achieve scope. Economies of scope decide what and how a product can be manufacture. Flexibility of 3DP is able to offer enterprises with more customized product with lower unit cost than conventional manufacturing technology. The leverage between capital and scale has the potential to impact how supply chain is reconfigured; while the leverage between capital and scope has impact on how a product is design or manufacture. And both reconfigurations will influence an enterprise on the decision of which level of deployment of 3DP in their business model.
This simplification of the supply chain process benefits the quantification of material flow throughout the supply chain. Under this observable phenomenon, we applied the lens of Actor Network Theory (Latour, 1996) to explain the study. The core concept of ANT presenting an idea of how human (actors) and non-human elements (actants) are linked, interact and associated with different elements to generate a socially constructed phenomenon. Actor is nothing more than whatever it modifies, transform or creates (Latour, 1999). Base on this concept, we explore the operation of 3DP involves a series of interactions between human and technology. In order to stay focus in the study, we narrowed our lens to study how does 3DP improve manufacturing process and achieve sustainability in Chinese manufacturing firms.

The rest of the paper is organised as follows. Section 2 reviews related studies. Section 3 presents the research method employed in this study, including the data collection and analysis procedures. Section 4 summarises and discusses the results from the interviews and Section 5 concludes this paper.

**Literature Review**

*The complement of 3DP in current traditional supply chain*

Supply chain, with term’s first use in 1982, indicate its meaning of a linear process. The development of linear manufacturing method under the boost of globalized supply chain, third world country’s labor inputs, advance manufacturing technologies has grown the global GDP for 20 times in last decade. However, the characteristic of linear manufacturing method which is one-way track that is without planning in “after-sale” phase such as reuse, recycle (Ashby et al., 2012) has led to enormous wastage that harm the economic, societal and environment. In this “take-make-dispose” traditional manufacturing method, approximately 80% of the materials resources are ended up in landfill, wastage, incinerator, when the economic value is not being fully exploit. For instance, the input of powder-like materials that pass through the printer’s extruder is equal to the final product, while pre-stock materials meet almost exactly the company’s customer demand. In other words, the quantification of materials is accurately reflecting in the beginning of production stage base on the design of the product. Hence, the 3D printable design file at the forefront of 3DP ecosystem is critical, in the sense that it possess direct causal effect to the supply chain performance.

On the other hand, the advocate of Industrial 4.0 in Germany, and Made in China 2015 has indicated the rise of governmental level to emphasize in adoption and implementation of advance manufacturing technologies such as 3D Printing in manufacturing industry to improve the linkage of value stakeholder through supply chain with the objective to achieve sustainability.

*From Design to Manufacturing in ANT Lens*

The core concept of ANT theory is translations which is the processes that generates consequential effects, i.e. formation of actor network, such as devices, agents, institutions organisation (Law and Hassard 1992). Translation of actors and actants always follow by transformation that making two elements equivalents. For example, design stage is the forefront of the product manufacturing cycle, based on ANT, besides produce an object with particular function, design could include specific meaning and social implication through this objects and technology.

The interaction of 3DP in the ecosystem is seen as a patterned network consisting of heterogeneous materials with multiple actor and actants. The process of penetration through availability of 3D printable design file are formation of human agency (designer) to non-human objects (3DP technology). Base on ANT, beyond creating objects with particular function,
design adds specific meaning and social implication to objects (Harman, 2015). In the process of constructing non-human actors (3DP ecosystem), designers hold an ethical responsibility for the impacts of their work, as the design work will interact with other elements and evolve to new network. In particular, it is argued that 3DP ecosystem in China can be understood as an outcome of negotiations among diverse actors when each attempt to extend the network.

3DP and Sustainability

Extant literature on how 3DP technology leads to sustainability remains at the conceptual stage from a management perspective. 3DP, a data-driven technology, possesses fast visualisation that enables the realisation of complex freeform products (Gebler et al. 2014) and contributes to the transition of current economic structure to a knowledge-based economy, which has been described by Anderson (2013) as a ‘new industrial revolution’. However, it is not a type of technology that is applicable to all industries; hence, the adoption of 3DP in different industries will lead to various types of business models. A few researchers have studied the application of 3DP in achieving a circular economy (Despeisse et al. 2017) and closed-loop supply chain and identified that 3DP is promising for sustainability and circular economy. Orientation towards sustainability and 3DP operating skills limit firms’ realisation of the ability of new technology to achieve the merit of sustainability.

3DP with the fancy characteristic of fast visualisation and customisation, customer dominance at product development stage, decentralised supply chain that promise for a more agile (Mohr and Khan, 2015), lean(Ghobadian et.al, 2018), responsiveness(Laolume et.al, 2016), cost effectiveness (Choonara et.al, 2016) that indicate the sustainability performance. The upmost characteristic we discussed in the study is the offering of 3D printable design that work as foremost of 3DP value chain, is an important penetration actor that promise for innovation activities in the manufacturing process, as it holds an ethical responsibility for the impacts of work because it will continue evolve with other new heterogeneous network and get new identity subscribe to it. This is the research gaps we identified after a thorough literature review in 3DP application and sustainability context. 3DP technology made local enterprises easier access to achieve product and process innovation with sustainability implication, but the low entry barrier of technology can also be seen as a two edge sword, it can be considered as a friendly technology to facilitate knowledge creation or a loss intellectual property monitoring system where right of creator are bypass and being used abusively.

Research Design and Method

Based on the findings of the literature review, one research question is formulated: How does 3DP in manufacturing process improve sustainability in Chinese manufacturing firms. Because these questions are open-ended in nature and no prior studies have proposed a research model or theory to address them, it is necessary to explore the responses to these questions. In order to fully capture insights in addressing the above research question in an explanatory manner, an empirical qualitative approach is adopted. We conducted 10 semi-structured interviews with companies from different industries that have already established 3DP technology in their business model.

The overall interview process and interview data analysis are described as below. First of all, we identified and contacted local 3DP enterprises and asked the counterpart to assign representatives whom are familiar with the operation of business. The interviewees of this study are either founder, CEO or engineers. All interviews were conducted in Mandarin, and the recorded interviews were transcribed. The transcripts were then translated, and the authors cross checked the interview data to make sure original meaning of the English translations are accordance with Mandarin interviews. The interview data are extracted following the standard content analysis procedures based on seven themes, which are 3DP application process,
economic, society, environment, sustainability to reflect the research question. The question includes of the origin of the design files, how does 3DP complement current business model, the perception of how 3DP improve firm’s environment, economic and societal performance and so on. The findings are summarised in Findings and Discussion.

Findings and Discussions
According to Williams and Kent (1993), the authors perceived that technology is “a design for instrumental action that reduces the uncertainty in the cause-effect relationships involved in achieving a desired outcome”. The outcome of interviews reveals that 3DP is an important driver to innovation that facilitate process efficiency throughout the supply chain to achieve sustainability. However, we argued that the application of 3DP itself does not constitute to improvement in sustainability. As suggested by actor network theory, where actor (3D printable design file) is nothing more than whatever it modifies, transforms or creates, the source of 3D printable design file which are origin from open source from the internet is difficulty to guarantee the genuine of the heterogeneity network. As open source allows anyone to modify, to remove an actor from a network as they wish, by constant injecting or creates multiple untraceable actor to the network, it is not a new network that each contributor should carry the responsibility on the work. Hence, the responsibility that hold to the masterpiece itself become vague.

In the analysis of 3DP impacts in economic dimension, some interviewees suggest that the fast visualization that 3DP offers shorten the lead time of product design and prototyping process. For instance, a spare part company manager expressed that spare part that required huge dedication as the structure of the spare part is very complex. By implementing 3DP in their production, it helps the firms to save human resources costs that initially assigned to designer, as the computer-aid-design tools will improve the task deliverable time and hereby shorten the overall work time allocate to the design. On the other hand, our findings demonstrate that 3DP is a novel technology to the healthcare industry, where 3D-printed prostheses are customisable which allow users, especially children, with fragile bone structure to easily upgrade or replace the prosthetics according to age and bone development. With the combination from 3D scanner, the 3D-printed prosthetic permits the patients to obtain 3D-printed prosthetic devices with higher precision and greater comfort.

Lastly, it is remaining controversial if 3DP is an environment friendly tool or even harmful to the environment (Hsiao, 2013). Although a few interviewees support that the concept of 3DP which transform materials-powder to a final product which lead to shorter journey of logistics that eventually benefits the environment with lower carbon footprint. However, the bottleneck where in current stage, 3D printers accepts solely certain type of materials. Hence, if a production of a product required formation of different type of materials, it does not have significant difference compare with conventional manufacturing process, besides the fancy of one-off printing 3DP could offer. Meanwhile, we should not underestimate the impact of emission of artificial powder materials to the environment.

Conclusion
Indeed, the development of 3DP, in which all items’ input and output waste are calculated through back-flow product-processing decision support, is critical for the manufacturing sector because the post-sale stage is not visible, and the waste impact is currently unquantifiable at current stage. But, regardless the hype of how 3DP could recast the current supply chain and achieve sustainability, what remain priority is manufacturers should still hold a conservative attitude on fully replace of technologies on traditional manufacturing process, especially at high production volumes (Petrick et.al, 2013). 3DP is undeniably perceived as a tool to facilitate design to prototyping process, the firms which is failed to reap the benefit at this stage
finds it is difficult to realise economic benefit of 3DP; Vice versa, our investigation show that firms will continue to achieve environmental and societal sustainability after they reap economic benefit at design to prototyping stage.

Grocery retail and food security in urban neighbourhoods: a case study of South Africa

Virva Tuomala (virva.tuomala@hanken.fi)
Hanken School of Economics

David B. Grant
Hanken School of Economics

Abstract

Food security is a complex issue, encompassing both societal and household level factors, but has not been deeply researched in the context of urban areas. This study explores grocery shopping dynamics of poor urban residents and the effect of those dynamics on food security. This study was conducted as a single case study comprising of 49 semi-structured interviews with residents of a South African township. The findings highlight the importance of micro retailers and issues with food quality. This study presents opportunities for further interdisciplinary work to investigate purchasing and consumption behaviour towards certain staple foods that make up a majority of current diets.

Keywords: Urban neighbourhoods, food security, grocery retail

Introduction

This paper represents the first in a series of empirical investigations into urban poor neighbourhood grocery retail dynamics and how it impacts food security in those areas. It builds on a literature review (Tuomala, 2019), which highlights the interdisciplinary nature of urban food security research and brings forward avenues for empirical research. This paper explores the specific dynamics of poor urban dwellers’ grocery shopping habits as well as the importance of micro retailers in urban communities.

The data was gathered in a small urban neighbourhood, referred to as a township, in the Western Cape, South Africa. Semi-structured interviews were conducted with 49 people living in the township, 25 of whom were beneficiaries of an NGO that assists the families of malnourished children with different livelihood programmes and food parcels. All the beneficiaries were unemployed women. The remaining 24 were ordinary residents of the township. The assistance of the NGO was invaluable due to security concerns and their knowledge of the township and its residents.

This paper first presents a short literature review on urban food security and sustainable supply chain management (SSCM), followed by the research design. The findings from the empirical data are presented in the subsequent section, and further divided into subsections on urban food retail, hampers and specials and quantity versus
quality. The conclusions sum up the paper and present the main takeaways and future research avenues.

This paper contributes to a research gap in urban food security and empirical research from a supply chain management and food retail perspective. As urban dwellers are mostly net food buyers, this point of view brings an important angle into the whole food security discourse.

**Literature**

The FAO (2009) has defined food security to include all people having ‘physical, social and economic access to sufficient, safe and nutritious food to maintain a healthy and active life’. As over half the global population resides in cities, the urban population should be prominently featured in food security discourse. However, in an overview of both international and specifically African food security agendas, Crush and Frayne (2011) found little reference to the urban context. While the FAO definition specifically mentions access to food in its definition, food security agendas mostly focus on ensuring fundamental availability through increased agricultural production rather than e.g. strengthening distribution networks (Battersby and Crush, 2014). South Africa for example produces enough food to feed all its citizens but has high levels of household food insecurity (Mushunje et al., 2015).

Household food insecurity often stems from financial or spatial constraints (Battersby and Crush, 2014). Financial constraints refer to inadequate entitlements, as brought forward by Sen (1981). According to his essay *Poverty and Famines*, a majority of malnourishment is not caused by insufficient availability but rather a lack of the means to acquire food. Spatial constraints are linked to financial prowess as limited entitlements can force people to live in marginalised neighbourhoods, characterized by e.g. precarious housing structures, inadequate access to basic services and overcrowding (Fox, 2014). As the global urban population continues to grow, so do the poor and informal neighbourhoods in cities. South Africa is already 66% percent urbanised and the global urban population is estimated to reach a similar figure by 2030 (United Nations, 2018).

Marginalised neighbourhoods and urban food insecurity are a result of urban inequality and poverty. A useful theoretical framework for examining these phenomena is urban political ecology (UPE). UPE considers the city to be made up of socio-economic processes, which mediate natural resources and their distribution (Swyngedouw and Heynen, 2003). UPE lends itself well as a lens to specifically examine urban food security for several reasons (Agyeman and McEntee, 2014). The main benefit is that it can analyse the hybrid relationships between physical, social and economic factors that result in the production of the urban environment. Food requires such tools, as it intertwines the physical and the social. Power relations are an example of such factors, as neoliberal market forces ensure food security is not an issue for everyone in a given city. Placing these processes into a physical location functions well in urban food security research, as spatialization is one of the material conditions and affects the relationships that determine who is food insecure and why (Agyeman and McEntee, 2014; Swyngedouw and Heynen, 2003).

Urban inhabitants regardless of social status are net food buyers. Market dependency results in financial capacity limiting choices in terms of where and what to purchase. Supermarkets are often located in wealthier areas, where business is expected to be profitable. In an analysis of supermarkets in Cape Town, Battersby & Peyton (2014) found that there are eight times as many supermarkets in richer areas of town as in the poorer areas, where population density was much higher. The few stores that were easily accessible to poorer consumers, such as those near transport hubs, did not stock a lot of
fresh produce, thereby limiting nutritious options. Consumption of fresh and nutritious food is driven by both supply and demand, but as posited by Weatherspoon et al. (2015), the causality is not always apparent, as can be observed from ‘food deserts’. A food desert in an area where fresh and healthy food is unavailable for purchase for residents, due to either spatial or financial restrictions (Myers and Sbicca, 2015). The difficult question is whether these areas form because residents do not demand fresh food or because they would not buy if it were available (Weatherspoon et al., 2015). Underlying these questions are classist and racist connotations as well as power relations relating to decisions on what who eats. The food desert concept is useful here, as it spatializes food insecurity. However, it does not always grasp the complexity of the underlying factors regarding supply and demand (Battersby and Crush, 2014; Weatherspoon et al., 2015).

The complexity of the global food system further exacerbates the notions of power in urban food retail (Tuomala, 2019). Supply chains are becoming increasingly centralised due to global large retailers (GLR) dominating the market (Maertens, Minten, and Swinnen, 2012). GLRs are generally managed in a Western country and therefore the subtleties of different contexts may be bypassed. SSCM literature is widening its focus to better include external stakeholder pressure, diverse contexts and social issues in addition to economic and environmental sustainability (Touboul and Walker, 2015). Nonetheless, social issues still remain under researched in SSCM as identified by Yawar & Seuring (2017). They specify several social issues that have appeared in SSCM literature, for example, excluding marginalised populations from supply chains. Marginalisation derives from many factors, but in the case of South Africa, poverty and race dominate. Employing a predominately Western and MNC perspective on sustainability ignores the different nuances of e.g. supply chain dynamics in marginalised neighbourhoods in emerging countries (Pagell and Shevchenko, 2009; Touboul and Ejodame, 2016).

GLRs have been able to penetrate the emerging markets largely due to foreign direct investment (FDI) and liberalization of trade in these countries (Nguyen, Wood, and Wrigley, 2013). However, failing to adapt to local grocery shopping habits and dynamics can lead to business failure, and has done for many chains (e.g. Amine and Tanfous, 2012). The informal sector and micro retailers are a relevant part of grocery shopping in emerging countries and poor urban neighbourhoods (Nandonde and Kuada, 2016). Micro retailers are located within easy reach, provide a social backdrop for purchasing with e.g. credit systems and enable people to purchase food in smaller quantities than formal supermarkets might (Minten, Reardon, and Sutradhar, 2010; Nandonde and Kuada, 2016). Empirical research into the shopping habits of urban poor and informal neighbourhoods is needed to further explore the specific dynamics, and this paper contributes to this research gap.

**Research design**

The data for this paper was collected in a township located in the Western Cape in South Africa, about an hour outside of Cape Town. The township is small, especially compared to others in the same area, such as Khayelitsha or Mitchell’s Plain. This single case study (Ellram, 1996) is the first in a series of research endeavours around this subject. Urban food security is context specific and suffers from a lack of interdisciplinary data (Nguyen et al., 2013). Single case studies are useful, as they provide a starting point for future comparative studies.

The interviewees are divided into two distinct groups: beneficiaries of the NGO and township residents with monthly income. The data was collected in cooperation with an NGO working in the area. The beneficiaries of the NGO are unemployed women, whose
children have been deemed malnourished in an annual check-up the NGO conducts at schools in the township. The remaining 24 residents were people living in the township who have some form of income, through either a salary or entrepreneurial activities. Their ages ranged from 18 to 60+ and out of the 49 total residents interviewed, only three were male. Table 1 summarises the interviewees and the acronyms used in the findings section of the paper.

Most of the beneficiaries were originally from the Eastern Cape (EC) or Zimbabwe. The residents were all South African nationals. Especially for the beneficiaries, being an immigrant poses some additional challenges as they are not eligible for government grants and finding employment can be difficult without the proper documentation, such as refugee status. Many of the Zimbabwean beneficiaries were especially dependant on the NGO and their monthly food parcel for this reason.

The interviews were conducted either at the NGO offices or around the community. Working with the NGO was highly valuable, as moving around the neighbourhood would have been impossible without local knowledge and guidance. Security issues had to be considered carefully, as townships often have high crime rates and it would have been dangerous for an outside researcher to walk unaccompanied around the neighbourhood. Language was another issue. Many of the interviewees spoke Xhosa and very limited English. There was always a translator present if English was a challenge. The interviews were always recorded and transcribed in their entirety and any Xhosa segments were translated later. It would have been difficult for the researcher to approach the residents, asking for interviews regardless of whether or not they spoke English, so this was always done by the NGO staff. A lot of the residents interviewed were chance encounters on the streets, which adds diversity to the interviews. The township was a challenging backdrop for an outside researcher to gather data in, not just because of language issues but also due to cultural differences and the racial tensions in South Africa. While interviews are one of the most common ways to gather qualitative data, it is important to reflect upon the interview as a complex social encounter with biases and preconceptions on both sides (Alvesson, 2003).

The interviews were conducted over a period of two months. Questions were arranged in a semi-structured manner, with basic information about interviewees asked first, followed by more specific questions about groceries. Basic information included the name and occupation of the interviewee, whether their household depended on the grants or if there was a salary involved, and how much of whatever income they had was spent on food. The more specific questions about grocery shopping habits asked whether a majority of the household shopping was done in supermarkets or small tuck shops in the community, locally referred to as spaza shops, how often and what kind of things were bought. Meat and vegetables were asked about specifically, as fresh food or lack thereof is a good indicator of food security (Weatherspoon et al., 2015). The transcripts of the interviews were coded in Nvivo, using codes such as ‘supermarket’, ‘meat’, ‘hamper’ and ‘transport’. 
Findings

Food retail outlets

The grocery market in South Africa is strongly divided among the LSMs (Living Standards Measurement), which is a unique market research tool in the country. Residents of townships are largely found in the lower LSMs (1-4 out of 10). However, in terms of how much of their income is spent on food, there are apparent differences even between the two different groups of township dwellers. This can be observed from Figure 1.

Figure 1 Portion of income spent on food among beneficiaries and township residents

Out of the NGO beneficiaries, i.e. unemployed women who receive government grants or help from family members, all spent at least half of their monthly income on food, with the majority claiming that most of their money goes towards groceries. The residents, who have some form of salary, are more likely to spend less than half of their income on groceries. This difference is not apparent in what people buy and when. Monthly groceries were bought with similar patterns across both groups. Both spaza shops and supermarkets are utilized by most respondents, with only a few exceptions who exclusively use one or the other. A common monthly grocery shopping pattern is buying a ‘hamper’ or a ‘combo’ of staple products in the spaza shop and topping it up with vegetables, meat and canned goods from the supermarket or a specialty shop, such as a butcher. “What we do from the spaza shops there’s this hamper that has 10kg [packages] of groceries so we only buy that hamper and then the other small necessities we buy from the supermarket” (BEN8). The hampers will be discussed in more detail in the next subsection.

Supermarkets are used by a majority of respondents and relied upon for consistency of quality and product availability. “I prefer shopping in town because they are never short of anything like in spaza shops where you would try buying something and find that they do not have it” (BEN16). The township itself has a small shopping centre along the main road close to the train station. Many respondents use the small supermarket there as one of the main sources of groceries, but also the larger supermarkets in the nearby town centre were used. A few respondents also said they prefer to use a certain supermarket chain in town because they collect loyalty points and are able to get discounts. For some people, especially those living in the further edge of the township the distance to the local supermarket was an issue. “The thing is I love to buy and support the spazas around us but the thing is the food that they were selling is not good for us. So I would like to take
the shops that we are using [like the local supermarket] to be closer to us because they are selling fresh food” (RES7). Others were concerned about product availability claiming that some of the brands or products they like to use were unavailable at the local supermarket, and therefore prefer to shop in the bigger stores in town.

Spaza shops were unanimously deemed convenient because of their location in the neighbourhood, within walking distance in even the furthest edges of the township. All respondents were nonetheless also of one mind about the shortcomings of the spaza shops, mainly regarding their product quality and hygiene. Spaza shops are generally informal and unregulated, private businesses run mostly by immigrants from e.g. Somalia. In fact, respondents would often refer to buying from a spaza shop as “buying from the Somalians” or “from the foreign shops”. Spaza owning Somalians are mostly refugees, but they are both generally (Battersby, Marshak, and Mngqibisa, 2016) and among the respondents viewed as stealing livelihoods from domestic entrepreneurs. This xenophobic atmosphere was likely the reason why no foreign spaza owner was willing to participate in this study. Despite the negative connotations around the foreign shops, people were willing to use them because of their cheap prices.

Keeping the prices down does however affect product quality in the spaza shops. Most respondents had experienced purchasing expired or faulty goods but did say that it is usually not a problem to return and exchange them. Respondents said they are very diligent about checking expiry dates and how the product is looking before making the purchasing decision. What makes this slightly challenging is that customers do not choose their own products at spaza shops, as they are operated through a window that the customer stands outside of requests the products from the sellers. However, it was said that spaza owners do take advantage of e.g. children by short changing them or selling them faulty products on purpose.

Respondents used several different types of outlets to buy meat. The monthly shopping patterns for meat also varied more than the other types of products. In purchasing meat is where the income differences became the most apparent, both in how often it was bought and where. A common pattern among the residents was to buy a 5-10kg bag of chicken and keep it in the fridge to be eaten throughout the month. Many of the beneficiaries of the NGO were unable to do this, as they did not have electricity at their dwelling, so were unable to store perishable food such as meat. If this was the case, they would buy meat in smaller portions at the spaza or butcher shop on the day it was to be eaten and cook it immediately.

Questions of meat quality were discussed during the interviews as well. Many residents were able to make the choice of not buying meat at the spaza shops because of the bad quality and hygiene. “One time I buy a chicken, the one in plastic bags... the chicken was bad smelling with a lot of flies around the pot and I just took it off... I don’t buy chicken here anymore” (RES14). If the beneficiaries wanted to buy meat, many of them felt they had no alternative except to buy at the spazas because of price and occasionally distance to the other outlets. The butcher shop was located near the local supermarket, so spatially there was no difference between the supermarket and butcher. The selection was deemed better at the butcher’s and it was possible to also buy smaller portions, compared to the supermarket. Meat and other protein sources, such as baked beans, are also bought in cans. Canned fish and corned beef were mentioned by several interviewees and were also included in the food parcel given to the beneficiaries by the NGO. Protein sources are scarce in the staple diet of township dwellers, especially those of lower income who cannot afford it. As RES1 put it, “we use lots of starch in Africa”.
Hampers and specials
The prevalence of starch in the staple diet is very apparent in the contents of the ‘hamper’. A ‘hamper’ or ‘combo’ is bought once a month at a fixed price either on payday or the day government grants arrive, depending on the interviewee.

People generally bought two different types of combos, one containing dry goods and cooking oil and one of vegetables. The contents of the dry goods hamper varied slightly between respondents, though not in the amount of starch. A common combination was 10kg or 5kg packages of flour, mealie (corn) meal, sugar and two litres of oil. Some of them had rice as well and occasionally also beans and samp, a coarser version of the mealie meal. They were generally purchased at the spaza shops in the community, where people had the chance to price compare between the sellers. When buying packages as large as 10kg, location of the outlet is an important factor, but price is still the deciding one. “Because the spaza shops have hampers [they are cheaper]. The prices are not the same but when you buy in town you find that they also have hampers, but you also have to consider the transport costs” (BEN6). If there are several shops within a convenient distance, respondents chose the cheapest hamper. They might also buy the hamper in a different shop from month to month, depending on special offers or other price fluctuations. Hampers were usually purchased by households with four or more people. If for example the children from a household were staying with family elsewhere, there was no need for a hamper during that time.

The vegetable hampers included long shelf life vegetables such as 7 kg of potatoes, 3 kg each of onions, carrots and pumpkin. This hamper had to be purchased in a specific supermarket in the nearby town centre, but the transport cost was worth it as the hamper is priced so well. It is only sold for a short period each month, around payday and when the government grants arrive. “If you go let’s say on the 25th, there are people getting paid on the 25th, on the 15th on the 31st. If you go let’s say 1 o’clock in the middle of the day, you can’t get it because it’s finished” (RES10).

Grocery shopping among the respondents was extremely systematic and diligent. The dates of the grants and payday are important not only among the township residents but also among the retailers, as the vegetable hamper demonstrates. Respondents follow advertisements for specials through pamphlets, window ads and online. A lot of time and effort is put into price comparison, as even a R10 (0,60€) saving is valuable. “What I normally do, I make sure I have a lot of time when I am doing shopping because I collect all the pamphlets so if I see maybe one of the supermarkets I can save R10 on rice, I go for it.” (RES18).

Quantity versus quality
In terms of food security, for most interviewees it is not so much the quantity or availability of food that is an issue but access to higher quality food. From the interviews, it is evident that spatial and financial constraints brought forward by Battersby & Crush (2014) are indeed legitimate concerns for the township inhabitants.

Healthy protein sources and sufficient fresh vegetables are beyond the reach of most respondents, and sugar consumption is extremely high. For example, monthly hampers bought at informal traders contain no protein, and usually a large bag of sugar. When asked what the interviewees would like to eat if they could eat anything they wanted, the most common answer was fresh vegetables and meat. For many of the respondents, especially the beneficiaries, the only food source is the hamper and the food parcel received at the NGO. Compared to the hamper, the food parcel is slightly healthier. In addition to similar items such as rice and mealie meal, the food parcel also has oats, beans, canned fish, peanut butter and a soup mix which all contain protein. The parcel has been put together by a dietician, however with respect to donor wishes and product availability.
Many interviewees admitted to health issues such as high blood pressure and weight problems, which are linked to diet. Measuring food security in urban areas is increasingly leaning towards malnourishment and dietary diversity, rather than merely the more traditional undernourishment (Carletto, Zezza, and Banerjee, 2013; McCordic and Frayne, 2018). It is not uncommon to refer to the ‘triple burden of malnutrition’, which encompasses undernourishment, micronutrient deficiencies and obesity (Gómez et al., 2013). Due to the high starch, low protein diet of most interviewees, the latter two are more relevant in their case. As demonstrated by their wish to eat more vegetables and meat, there is some awareness about the lack of dietary diversity but little opportunity for action.

Battersby and Crush (2014) suggest that the food desert concept be moulded to fit the modern African city perspective. As opposed to the more Western perspective of a food desert where complete lack of outlets is assumed for the definition to be met, in an African context the concept needs to be a lot more fluid. The data collected here supports this notion. There are plenty of outlets, but the entitlements of the inhabitants are lacking as well as the quality of products available. Due to its size and proximity to the nearby town, this township also has good connections to major supermarkets in wealthy areas. Financially many of the respondents were however unable to shop in those outlets, because even the R10 (0,60€) bus fare was a factor in their monthly spending.

The spaza shops therefore play a significant role in the urban food security discourse. For the lowest income demographic, their low prices ensure that they are at least able to get something to eat and they purchase perishable items in small quantities, so they do not require storage. The proximity to where people actually live was a pertinent factor for the residents with incomes as well. Spaza shops were used at an almost daily basis for small top ups of both groceries such as salt, milk and stock cubes as well as for other necessary items e.g. mobile phone data, paraffin and cigarettes. Because the spaza shops are unregulated and informal, there is no official accountability for the quality of the food. It was possible to exchange expired or otherwise faulty goods, but this was done on a case-by-case basis: there is no official stance and spaza shop owners can refuse to do so. As Nandonde and Kuada (2016) posit, and is evident from this research, micro retailers are the key to retail in Africa. This has opportunities for both large grocery (and other) chains, as well as private entrepreneurs. Price remains a deciding factor, but quality is also important.

The hampers could potentially provide an avenue to improve the quality of the food people eat. The contents of the hamper, i.e. the starchy staples of the South African diet are very ingrained in the societal psyche of the people that live in townships. There are deep historical roots as to why this is the case; the legacy of apartheid is particularly evident in township issues. Urban planning and the spatial inequalities that derive from it in terms of e.g. supermarket location are still heavily influenced by the segregation enforced by apartheid politics (Haysom, 2015). The food eaten in townships is also a vestige of what life was like for Africans during that time. Starchy staples were all that was available and culturally it remains the standard a quarter of a century later. To elicit change into this mind set would require a cultural overhaul and thus would also require extensive empirical research on hampers and the staples of the South African diet.

Conclusions
Underlying factors to food security in townships are varied and complex. While food is readily available, access to it requires a financial stability not many residents in townships have. The government grant system assists those with the least means, such as single unemployed parents, but the grants are meagre and many, such as immigrants, do not
Further, issues stemming from larger societal structures, such as the legacy of apartheid, have significant effect on the food security of people living in townships. Access to more nutritious food is a serious issue in a township setting. Staple foods that make up the majority of a common township dweller’s diet are predominately carbohydrates and very little protein or fresh vegetables. Many of the respondents recognize the deficiencies in their diet, but also the restrictions they have on doing something about it. Improving retail in and around townships is an important step in increasing food and nutrition security in these areas. The *spaza* shops and other micro retailers have an important role to play, as their business models fit into the dynamics of townships better than large supermarkets. The hampers of staples that people buy regularly are also an interesting potential avenue for improving nutritional value in diets. In this paper the focus was on township dwellers and their particular grocery dynamics, but empirical data from the retailer side would provide a more holistic picture of the current situation. Unfortunately, data from the spaza shops is unavailable, as the shopkeepers are very hesitant to talk to outsiders about their businesses, likely due to the apprehensive and xenophobic treatment they have received in South Africa.

The main contributions and suggestions for expanding this research are the following:

1. The shopping habits of the township dwellers are systematic and diligent. People spend a lot of time planning and comparing prices through specials and hampers. Making nutritious options more available and visible could improve food and nutritional security.
2. Lack of outlets is not an issue in the township as much as the quality of the produce available and the lack of storage opportunities in people’s homes. Vegetables and protein sources are difficult to come by in the township and for some people the larger supermarkets are too far to frequent regularly. Regulation of the *spaza* shops, e.g. requiring them to have proper storage for fresh produce and banning them from selling expired goods is a potential course of action.
3. More interdisciplinary empirical research in contexts such as townships is needed. SCM, development studies and urban geography are examples of disciplines where urban food security research should be prominent, as well as fields such as public health and nutritional studies.

**Acknowledgements**

The authors would like to thank and acknowledge the Hanken Foundation for funding the research trip to South Africa, as well as Professor Jan Havenga for hosting the researcher. A special thanks goes to the wonderful NGO who despite being busy with their own work provided a welcoming and extremely helpful atmosphere to conduct this research.

Stakeholder management in sustainable supply chains: The case of Chile

Abstract

The purpose of this paper is to analyze how stakeholder can contribute to create more sustainable biomass-to-energy supply chains (SC) in emerging countries by conducting a case study in Chile. The data sample consists of a total of 39 semi-structured interviews with internal and external stakeholders of biomass-to-energy-SCs. The results indicate that stakeholder can pressure a focal firm to adopt sustainable practices to mitigate further reputational losses. Moreover, stakeholder can facilitate the awareness for sustainability frauds in SCs by addressing possible concerns before they start to pressure SC members. Furthermore, collaborations with non-traditional SC stakeholders can help to solve sustainability issue.

Keywords: Supply Chain Management, Stakeholder Management, Sustainability

Purpose

Biomass has significant potential to overcome the shortcomings of fossil fuels and works as a substitute to heat, power as well as chemical production (Peters et al., 2015; Dale et al., 2018). Besides alternative energy sources like nuclear (4.9%), hydro (2.5%) or other renewables, solar PV, wind, solar thermal or geothermal, (2%) (International Energy Agency, 2018), biomass provides with 10% a remarkable contribution to the global energy production. Because of declining stocks of fossil fuels, the worldwide energy production will be shifting more towards renewable energy. Hence, it is to be expected that bioenergy, as a renewable energy, will still play a significant role for the future energy mix (Dale et al., 2018; La Fuente et al., 2017).

While well designed bioenergy systems promise several benefits and solutions (Hong et al., 2016; Dale et al., 2018), different social, environmental and economic issues communicated by stakeholders along the supply chain (SC) can be identified (Gold and Seuring, 2011; Dale et al., 2018). Despite the competing land use between biomass production for food, material and energy, multiple studies point out a crucial role to the (sufficient) supply of biomass (e.g. Lautala et al., 2015; Hong et al., 2016). Moreover, air emissions or noise pollution because of the transportation are problems to be considered.
(Sharma et al., 2013). Since those issues affect stakeholders, they put pressure on the companies. For example, the society has forced energy companies to a nuclear phase-out in Germany (Rehner and McCauley, 2016). Another example is that communities and NGOs have protested together against hydropower projects in South America which has led to a redesign of the future energy mix (by the government) (Siegel, 2016). To address these challenges, using a sustainable supply chain management (SSCM) perspective might be fruitful because it takes into account stakeholder sustainability concerns. Therefore, stakeholder theory as well as SSCM are taken as the theoretical starting points for the research, where a particular contribution has been made by the framework put forward by Gold (2011) for biomass-to-energy SCs.

Taking this as a theoretical starting point, the following research questions can be derived:

- Which stakeholder groups and sustainability issues are evident?
- How can stakeholder management contribute to realize a more sustainable biomass-to-energy supply chain?

Analysing biomass for bioenergy SC in Chile is relevant for two main reasons. First, Chile provides an interesting and diverse setting to analyse stakeholder management in bioenergy SC because of existing challenges (e.g. negative perception of or long transportation distances for biomass) and opportunities (e.g. unused local biomass or job creation). Second, sustainable SC issues are normally discussed against a Western perspective and empirical data, also from South America, is still scarce in the current discourse (Jia et al., 2018).

**Literature review**

*Stakeholder issues in biomass-to-energy SCs*

From a risk-based perspective (Gold and Schleper, 2017), external pressures can lead to e.g. reputation losses and sanctions by the government (Seuring and Müller, 2008; Meixell and Luoma, 2015). For avoiding these risks, stakeholder management is of strategic relevance in sustainability management (Hörisch et al., 2014). This also holds for the successful implementation of SSCM for biomass-to-energy (e.g. Hörisch et al., 2014; Dale et al., 2018) which is also concerned with economic, environmental and social issues in order to “[…] meet stakeholder requirements and improve the profitability, competitiveness, and resilience of the organization” (Ahi and Searcy, 2013, p.339). While there has been a growing interest in SSCM in the last years (Beske and Seuring, 2014), the literature on stakeholder and SSCM for biomass-to-energy is still scarce. The most comprehensive framework has been proposed by Gold (2011). This framework is selected and modified to narrow the current study because this conceptual framework covers most frequently described stakeholders as well as challenges and benefits of biomass-to-energy-SCs.

Freeman (2010) defines a stakeholder as “any group or individual who can affect or is affected by the achievement of the organization’s objectives” (2010, p.25). Therefore, governmental bodies, NGOs, associations, residents, consumers or citizens are possible stakeholders for biomass-to-energy SCs (Gold, 2011). To supply the power plant with sufficient biomass, for instance, causes increasing truck traffic, emissions and dust which impact the residents near the streets (Dale et al., 2018). Additionally, biomass power plants can produce odor by chemical reaction and emissions due to combusting biomass. Despite the challenges, biomass-to-energy SC operations produce also local jobs, they invest in the infrastructure or provide an extra income by using / adding a value to unused resources (Dale et al., 2018; Peters et al., 2015)
In contrast to the challenges or benefits, governmental bodies influence directly biomass-for-energy SCs by determining the legal framework. They can impose new regulations, tax the CO2 emissions, offer subsidies for attracting new biomass-projects or provide standards and certification for the bioenergy systems to reduce social or environmental impacts (Gold, 2011; Beske and Seuring, 2014). Moreover, NGOs can launch campaigns against biomass producers when being aware of negative sustainability issues such as erosion or loss of biodiversity due to monoculture.

While most studies cluster stakeholders against generic classes such as NGOs, citizens or employees (Dale et al., 2018; Freeman, 2010), other researchers criticize this because a generic classification results in fuzzy and unclear groups (e.g. Perrault, 2017). For instance, one individual might be part of different classes at the same time by being employed as well as a customer. Furthermore, one issue can be addressed by different stakeholder groups and stakeholder groups can have different concerns regarding a SC. This interconnection of a broad set of stakeholders and issues leads to a complex nexus of stakeholders. To overcome this issue, Mitchell et al. (1997) present one of the most used decision models to focus on the most important stakeholders and their claims by structuring them against the attributes power, legitimacy and urgency. However, Busse et al. (2017) pointed out that even a stakeholder group with initially one attribute (e.g. legitimacy of the issue) can get the support by another stakeholder with enough power to pressure the firm.

**Stakeholder management in SSCM**

Because the framework of Gold focuses more on the management of internal and external relationships rather than how to make a biomass-for-energy SC more sustainable, we extend its framework with SSCM practices from Beske and Seuring (2014). The set of possible practices are helpful to deal with sustainability issues of stakeholders. However, stakeholders can occupy different roles to contribute to a more sustainable SC. They can (1) put pressure on a focal firm to adopt sustainable practices (e.g. Meixell and Luoma, 2015; Maas et al., 2018), (2) they can facilitate the awareness of a fraud (e.g. Busse et al., 2017) and (3) they can help to solve the risk (e.g. Beske and Seuring, 2014).

(1) Stakeholders might directly pressure a firm to adopt certain sustainable practices. For instance, when residents or citizens are impacted by emissions from a bioenergy power plant (La Fuente et al., 2017), they might communicate their concerns via letters or mails. However, when there is no willingness to pay attention to the issues, they also start to protest against the business activities – even with violent demonstrations. For fulfilling the claim, possible practices are technology integration or SC partner development for improving the production process of the SC (Beske and Seuring, 2014), e.g. by implementing a new filter system into the power plant.

However, (2) stakeholders are also helpful, e.g. in the case of low SC visibility, to facilitate the awareness of risks or frauds in the upstream or downstream part of the SC. Since SCs become more complex and intercontinental, focal firms are more often confronted by low supply chain visibility. Busse et al. (2017) pointed out, that most focal firms are just aware of the first or maybe second tier of their SC. However, if the focal company has no chance to make spontaneous audits or to visit their supplier, it’s likely that it is unaware of risks such as inadequate protection equipment for the working staff of the biomass supplier. Cooperation with third parties (e.g. NGOs) can be a way to control the working conditions and address potential risks. This would also enhance the transparency of the SC activities which would ultimately lead to risk reduction and more legitimacy by stakeholders.
Furthermore, (3) different stakeholders can support the focal firm to mitigate or solve a risk when the issue is known but there is a lack of knowledge how to deal with it. Regarding Dale et al. (2018), forest areas might face an increased erosion of the ground or less nutrition in the soil. The cooperation with third parties such as research institutes or universities with a broad knowledge about different topics are a common way to solve a complex issue.

The different roles of stakeholders and their specific issues regarding biomass-for-energy SCs by Gold (2011) frame the further research process. The findings are then used to derive recommendations how stakeholder management can contribute to a more sustainable SC.

Methodology
This research project was embedded in a multi case study with the aim of theory elaboration (Ketokivi and Choi, 2014). Compared to large-sample theory testing methods, case studies have the advantage of getting close to a theoretical item and to enlighten underlying causal relationships (Siggelkow, 2007). Furthermore, the evidence of the case study value regarding the analysis of bioenergy-SCs can be clearly seen in other research projects such as Ahl et al. (2018) or Dale et al. (2018) where the authors interviewed stakeholders and experts. Furthermore, our comparative analyses between the empirical results and the theory allow us to provide theoretical propositions. According to Eisenhardt and Graebner (2007), a case study needs a clear research process. We followed the suggestion by Stuart et al. (2002) to define the research question, determine the research instruments and field, gather and analyze the data and finally disseminate the entire process.

Description case study / case selection
The research is based on extensive field work in Chile from November 2016 to July 2017. The unit of analysis were supply chains of the Chilean pulp and paper industry which produce energy as by-product. The industry considered as apt because of two reasons: first, using second generation biomass embraces the advantage of avoiding the trade-off of the land use for the food or biomass production and the use of the biomass for wood products or combustion (Awudu and Zhang, 2012). Second, the use of production residues generates further income by adding a value to the unused biomass (Cambero and Sowlati, 2014).

While Chile has arguably only two big companies in the pulp and paper sector (when comparing turnover and owned forest area in ha), we focused the data generation mainly on their SCs and the surrounding stakeholder environment. For having a further possibility to contrast the findings, we included one smaller company and their suppliers. To get a deeper understanding of the (implemented) SSCM approach, we collected data from more than one firm in each SC, as suggested by Pagell and Wu (2009). While the main data source were semi-structured interviews, we used site visits, workshops and secondary information of the companies to triangulate the information from the interviews. The basic structure of the interview guideline was the modified framework of Gold (2011). In order to ensure that the questionnaire provided the expected richness of information, multiple drafting stages had been held before the questionnaire was rolled out in Chile and slight modifications were made, based on the first experiences. The main objective was to interview representatives holding management positions and other powerful decision-makers in the bioenergy field. As proposed by Wolf (2011), newspapers and business magazines were used to identify possible interview partners in the context of bioenergy SCs. Additionally, institutions such as the German Chamber of
Commerce Abroad (Deutsche Außenhandelskammer) in Santiago de Chile, universities or local researcher were helpful to acquire information and contacts.

Every interview was carried out face-to-face by one researcher and subsequently audiotaped. A total of 39 interviews were conducted with all actors of the biomass SCs as well as related stakeholders (see Table 1).

To gain / ensure a better understanding of the business operations and processes, side and field visits took place as well as secondary data from each interviewed company was obtained. Moreover, we organized three stakeholder workshops to discuss the abstracted findings with the involved actors.

Reliability and validity

Further internal validity is ensured by returning summaries of the interviews to the interviewees. The qualitative content analysis is used to evaluate the conducted interview material. Kassarjian (1977) stated that a content analysis should follow a clear and expedient operational structure. Therefore, a six-step content analysis based on the suggestions by Mayring (2015) is applied. Due to abductive reasoning (Locke et al., 2008), the main frame of the coding system is derived from existing theoretical frameworks, which contributes to external validity, and secondly further (sub-) categories and/or items are later added. This yields a certain transparency for third parties and allows them to verify and replicate the analysis.

Findings

Based on the first research question, the results of the case study can be divided into the three dimensions of sustainability: (1) economical, (2) ecological and (3) social.

At the economic dimension, the two most present challenges are the cost of biomass and transportation – both challenge the success of bioenergy business operations as well as are interdependent and influenced by the petroleum price. While mainly the supplier of the biomass is facing these challenges, the focal firm starts to cooperate with a non-traditional SC-member – the main competitor. By exchanging the rights to harvest forest areas which are located closer to the plants of the other one (e.g. P8A or P8B), the cooperation has cut down transportation distance and therefore reduced emissions and improved the competitiveness.

Regarding the ecological dimension, the two main challenges are emissions and a decrease of biodiversity. In relation to the latter, the case study shows that several stakeholders have the concern that the current forest management causes a loss of biodiversity. As one stakeholder said: "a monoculture of pine, of eucalyptus, is a symbol
for a loss of biodiversity (U6C: par.: 69). While multiple stakeholders are aware of this issue, no focal firm is dealing with the topic.

The results indicate that the issue of emissions can be divided into emissions stemming from (1) the burning of forest or production residues, (2) the power plants and (3) transportation.

(1) By burning biomass such as forest or production residues, GHG emissions are produced. “There is still a lot of biomass, […] which they burn in the field […] and therefore produces a huge contamination and the energy is lost, it kills the bacterial flora of the soil, as well.” (U6A: par. 21). Due to top-management and employee engagement, the win-win cooperation between a focal firm and sawmill have been established. The saw dust provides a sufficient feedstock supply for the focal firm. Therefore, they could reduce emissions as well as the energy costs and generate an extra income (for the sawmill).

(2) Further emissions are emitted by the power plant itself. As one interviewee pointed out, their energy facility emitted emissions and a bad odor which affected the near community – which consists to 25% of the own employees. For answering the pressure due do demonstraions and strikes, the company installed a high class filtration system (well above the minimum requirements). As a result, the emissions and the odor are minimized.

(3) The transportation of the biomass from the forest to the power plant leads to further emissions, “[…] because all the trucks are running with diesel” (P1B). As the company is aware of the issue and willing to find a solution, they cooperate with third parties (e.g. consulting companies or universities) to improve the current technology and to identify new operations models or strategies which could cut down the emissions and costs.

At the social dimension, missing knowledge or education about the technology behind bioenergy, a common view amongst interviewees, leads to misinterpretations and, therefore, rejection of bioenergy projects by citizens. “But the society does not have an idea about this technology and how they would benefit. (U6A: par. 59). For instance, the steam coming out of the energy plant was put on a level with emissions such as smoke. Consequently, two-way communication and knowledge transfer are in use to invite communities to an open house day to demonstrate the process of generating bioenergy and to create a discourse on new bioenergy plants.

The case study reveals also that citizens or indigenous have a negative perception of forest industry because they see no direct / personal (economic) benefit. This causes demonstrations and rejection of bioenergy projects. To overcome the issues, linkage developments are in place to get more legitimacy for the business operations. For instance, one company uses their waste heat of their production process to feed the local heat grit and to offer affordable energy to the citizens.

Furthermore, the trucks loaded with biomass damage the local infrastructure and produce dust which impacts the human aspiration system. As an answer, one focal company demanded that their supplier adds an irrigation system and phone number to each truck. Additionally, they invested in the infrastructure after each harvesting season. Therefore, the residents are less impacted by dust, have a repaired infrastructure and an option for direct denunciation of future issues.
Discussion and Conclusion
The case study shows that stakeholders in their possible role as a pressure group as a facilitator or a solver can contribute to a more sustainable SC and their issues need to be managed right.

In line with Seuring and Müller (2008) or La Fuente et al. (2017), stakeholders, for instance when citizens are affected by emissions from a bioenergy power plant, are willing to pressure a focal firm to adopt SSCM practices. In both cases, the origin of the issue was localized in the SC and modernization could directly abolish the issues and avoided a further reputation loss.

Hence a focal firm can also lose reputation by a general negative perception, for instance, no visible economic benefit or a feeling of unfair treatment by the forest industry, the development of common wealth projects can stop a further loss of legitimacy. Sauer and Seuring (2017) have revealed similar practices and labeled them as linkage development.

Therefore, we propose that:

**Proposition 1a:** Because of sustainability issues, stakeholders are willing to pressure a focal firm to implement sustainability practices (such as modernization).

**Proposition 1b:** When a focal firm is already facing pressure, the company can just be reactive and seek to stop the reputation loss – like acting as a firefighter.

However, sometimes missing knowledge or misinterpretation can also lead to reputation loss. In line with literature (e.g. Beske and Seuring, 2014; Gold, 2011), the case study shows that active two-way communication or knowledge transfer are possible ways to deal with the issue and yields the opportunity to change a pressure group to a future facilitator. By exchanging possible concerns with stakeholders, their issues can be recognized even before they start to pressure a SC.

As outlined by Busse et al. (2017), stakeholders are aware of issues, for instance, the loss of biodiversity, and could act as a facilitator for the focal firm. An ongoing discourse with stakeholders about possible issues as well as benefits such as job creation or decreasing of erosion might be a way to overcome a reputation loss (e.g. Gold, 2011). As a result, we propose:

**Proposition 2:** Using a stakeholder as facilitator leads to the awareness of sustainability issues and enables the possibility to avoid possible pressure groups (and the loss of reputation).

In two cases, issues are known, for instance, the problem of transportation, and are solved by cooperation with non-traditional SC-members such as competitors (Beske and Seuring, 2014). As a result, the transport emissions and costs are decreased as well as the competitiveness is increased.

In the best case, stakeholders reveal an issue and support the focal firm to solve the challenge. Stakeholders are aware of issues, for instance, production residues can be a valuable resource, and they are an instrument to solve it, for example, by launching a cooperation. Therefore, the emissions and energy costs are decreased and an extra income is created (Dale et al., 2018) – an improvement of the environmental and economic performance. Therefore, we suggest that:

**Proposition 3:** Stakeholders are a helpful “instrument” to identify and solve sustainability issues in a proactive way.

Limitations and research quality
The contribution of this paper is an extended explorative analysis in the setting of an emerging country. First, this research comes up with a refinement of previous theoretical
ideas to the still under-researched intersection between stakeholder management and SSCM.

Second, to the best of our knowledge, this is the first empirical validation of the theoretical constructs of the framework by Gold as well as our investigation has provided evidence on stakeholder issues and how they might be solved in the context of biomass SC, as demanded by Mafakheri and Nasiri (2014).

Third, while the current SSCM discourse is clearly dominated by a western perspective (Jia et al., 2018; Gold, 2011), this piece of research work is one further step to fill the gap by being based on an emerging country setting. However, this refinement of the framework extends the understanding how stakeholders might contribute to a more sustainable SC, for instance, by acting as a pressure group, a facilitator or a solver.

Nevertheless, the empirical qualitative study has its limitations both on the theoretical as well as on the empirical side (Eisenhardt and Graebner, 2007). Therefore, three mayor limitations can be identified. (1) While we grounded our research on the conceptual framework of Gold, a more reflective approach on stakeholder management as well as SSCM might yield additional insights. (2) even though we based our research on a framework and the data analyzing process followed strict rules (e.g. Mayring, 2015), the subjectivity of the researcher in the analyzing process could not be avoided. Because the more the researcher had to interpret the data, the more the results and the propositions were influenced by his subjective opinion. (3) The data, restricted to one industry in one country, might cause a limited generalizability of these results.

However, the limitations of our study causes future research opportunities. The empirical propositions of our study should be anchored in a more comprehensive way in the existing body of literature. Here, a literature review applied in the field of SSCM and stakeholder management might validate or reject our propositions. While the generalizability is currently restricted, further empirical studies in a diverse setting, for instance, another industry in an industrialized country can extend it (Eisenhardt and Graebner, 2007). This would also provide further empirical evidence as requested by Meixell and Luoma (2015).

Abstract

Ecological concerns such as global warming have become crucial for global business. Accordingly, green supply chain management has received tremendous attention; but we are still witnessing a series of firm’s green-related scandals caused by suppliers. In this study, we argue that this chronic problem might be due to the limited diffusion of process and product green innovation across the complex supply network. Building on a complex adaptive system perspective, this study conducts an empirical study on why and how the diffusion of green innovation is limited, and on how possible it is to amplify the limited diffusion within the network.

Keywords: green innovation, multiple supply networks, complex adaptive systems

Introduction

Over the decades, ecological concerns such as global warming, climate change, and air/water pollution have become critical for global business. Many executives now aware that the challenge of ‘green’ will largely affect the way they do business, and even determines their survival in the market (Lubin and Esty, 2010). The rising interests greening an entire supply chain have reshaped existing practices in supply chain management. Accordingly, green supply chain management (GSCM) has received tremendous attention (e.g., Zhu and Sarkis, 2004; Srivastava, 2007; Lee et al., 2014; Dai et al., 2015) with regard to “the integration of green concerns along the supply chain embedded in inter- and intra-organizational practices” (Schmidt et al., 2017, p. 4). This study regards GSCM as a form of green innovation within the supply chain.

Despite the recognized importance of GSCM, and the resulting efforts being made by many stakeholder groups including academics and practitioners, we are still witnessing a series of corporate green-related scandals caused by suppliers. One of the infamous cases would be Sony. In 2001, 1.3 million game consoles were blocked by Dutch officials due to high amounts of cadmium detected in the console’s cables, manufactured by one of...
Sony’s suppliers. Recently, toxic food scandals grew in China, where the quality of the product materials supplied to major brands such as McDonald’s was called into question (VOA News, 2014). We observed that supplier-induced scandals are not just confined to green products; more oftentimes, they are also associated with green processes such as pouring toxic metals into rivers around the factory (for Nike, Adidas, Puma, H&M, and Apple cases, see Foster, 2011; Mozur, 2013).

In this study, we argue that such a chronic problem might be due to the limited diffusion of process and product green innovation across the complex supply network. We are not alone in this opinion; extant studies argue that in many cases, GSCM innovation works up to the tier-one level, and thus lower-tier (i.e., tier-two and -three) suppliers remain the weak link for environmental sustainability (Mena et al., 2013; Tachizawa and Wong, 2014; Wilhelm et al., 2016a; 2016b). In general, lower-tier suppliers are small in size, and thus less (or no) visible to the public in the country of buyers. They are also mostly located in third world countries where green regulations are very loose. Consequently, they tend to take a passive (wait-and-see) approach, i.e., not managing green issues properly until their customers get punished by stakeholders (Villena and Gioia, 2018).

Recently, very few studies have demonstrated how risky these supplier-driven issues are, and how much damaging this is to dominant buying firms. For instance, Kim et al. (2019) found that buying firms that are caught in such scandals face an abnormal reduction in shareholder value of 1.00%. Focusing on green issues, Lo et al. (2018) also revealed that environmental incidents caused by Chinese suppliers are associated with a decrease in shareholder value of 1.13%. Given that such “supplier sustainability risks” (Foerstl et al., 2010) are caused by not only tier-one, but more often lower-tier suppliers (Plambeck, 2012; Tachizawa and Wong, 2014; Grimm et al., 2016; Wilhelm et al., 2016b), buying firms should extend their attention to inter-organizational green practices, particularly to ones with lower-tier partners in the complex supply network.

Meanwhile, supply chain scholars have argued that supply networks should be understood as a complex adaptive system (CAS) that emerges, rather than under the control of focal buying firms (Choi et al., 2001; Surana et al., 2005; Pathak et al., 2007; Nair et al., 2009; Carter et al., 2015). This profit-focused view is now applied to another pillar of sustainability: green. For example, Nair et al. (2016) were first to bring the CAS perspective to GSCM, suggesting that “[green] innovations that originate in the dominant buying firm continue to develop beyond that firm’s boundaries” (p. 67). Similarly, Touboulic et al. (2018) argued that the pressure imposed by the central controller on green initiatives could not be successful without understanding its emergent nature in the supply network. Indeed, green innovation emerges in supply networks, rather than being controlled by focal buying firms; but more evidence is needed (for conflicting results, see Villena and Gioia, 2018).

In this study, we extend the existing studies by conducting an empirical investigation on the following research questions (RQs): (1) why and how the diffusion of green innovation is limited across a complex supply network? (2) how is possible to amplify the limited diffusion of green innovation within the network? To this end, we focus on the role of customer pressure and supplier capabilities, and the balance of them. Specifically, we use the CAS perspective as our theoretical lens, which is useful for this study given that green ideas are not only simply forced by a focal controller (i.e., customer pressure), but also emerge (i.e., supplier capabilities) in a complex supply network. On top of that, following prior studies (e.g., Gilley et al., 2000), we examine green innovation across the supply network based on the process versus product distinction. This approach would allow the authors to arrive at deeper insights into the literature.
**Literature review**

Innovation is a means to generate and sustain competitive advantage and ultimately leads to firm performance (Ahuja and Katila, 2001; Jansen et al., 2006; Laursen and Salter, 2006). In a sustainability context, green innovation is understood as the application of various resources in novel ways using unique capabilities to a product or process with intent to reduce environmental impact (Srivastava, 2007; Vachon and Klassen, 2006). Research indicates green practices to generally foster both firm sustainability and financial performance (Ates et al., 2012; Ketchen and Hult, 2007; Zhu and Sarkis, 2004).

As many practical and academic examples show (see Choi & Lin, 2009; Hora et al., 2011), firms are increasingly held accountable for environmental misconduct in lower tiers of their supply chain, termed supply chain liability, which can generate various negative consequences (Hartmann and Moeller, 2014; Schmidt et al., 2017). Consequently, firms are starting to take responsibility for their supply chain and actively propagate green innovation to suppliers and customers (Hajmohammad and Vachon, 2016). Research has identified several drivers of the adoption and propagation of green practices along different tiers in the supply chain (Lo, 2013; Mitra and Datta, 2014; Paulraj et al., 2015), most prominently stakeholder pressure and firm green capabilities. While diffusion of green innovation to low-tier supply chain partners is increasingly gaining attention, as earlier discussed, the most severe environmental breaches still happen in the upstream supply chain, beyond the first-tier level (Foerstl et al., 2015; Wilhelm et al., 2016). Thus, research must identify the contingencies affecting the diffusion of green innovation across complex and globally distributed multi-tier supply chains.

Green innovation can take various forms, mainly product innovation and processes innovation (Azadegan and Dooley, 2010; Swink, 2006). Scannell et al. (2000) define product innovation as “the ability to develop new products and/or technologies in anticipation of, or in response to, customer requirements” (p. 32). Green product innovation relates to new product development aiming to reduce energy consumption, pollution and waste by the means of product design and material use (Nidumolu et al., 2009; Parmigiani et al., 2011). Subsequently, Scannell et al. (2000) define process innovation as “the ability to develop new processes using the latest technologies in anticipation of, or in response to, customer requirements” (p. 32). Green process innovation is concerned with all firm operational processes, including manufacturing, logistics, and lifecycle management, in order to reduce impact on the environment (Srivastava, 2007).

Several studies explore the differences and complementarities between product and process innovation in a sustainability context. In a buyer-supplier setting, for example, Wagner and Bode (2014) were among the first to explicitly distinguish between both types of innovation when the success of exploring push and pull innovation strategies. Focusing on purchasing sustainability, Foerstl et al. (2015) show that both process-related and product-related factors drive high-tier supplier green innovation implementation. While there are some notable exceptions, many previous studies have taken on an integrated view of product and process innovation. However, we argue that a more nuanced perspective is needed to derive new insights into green innovation diffusion and contingent factors.

**Theory and hypotheses**

*Supply network as CASs*

A supply network can be defined as “a network of firms that exist upstream to any one firm in the whole value system” (Choi et al., 2001, p. 352). In general, the network is nonlinear and complex. It is also difficult to predict, manage and control. Thus, the focal buying firm’s visibility toward upstream suppliers is inevitably limited. This nature of
complexity makes it difficult for the buying firm to fully control their supply networks. In this sense, the supply network should not be treated as a system that results from purposeful design. Rather, it should be more recognized as a CAS that “emerges over time into a coherent form, and adapts and organizes itself without any singular entity deliberately managing or controlling it” (Choi et al., 2001, p. 352).

Since the seminal work by Choi et al. (2001), there have been many studies that examine the CAS view within the supply chain domain. Among them, Surana et al. (2005) and Pathak et al. (2007) provide a concise overview of supply network as a CAS, saying that a CAS (1) consists of agents (e.g., suppliers or OEMs) that possess schema (i.e., norms, beliefs, etc.), (2) is self-organizing with respect to behavior of the individual agents, (3) exhibits nonlinear dynamism that affects the system, (4) exists in a state of quasi-equilibrium (stability versus change), and (5) evolves over long length and timescales. All these properties are summarized into the Choi et al.’s (2001) three foci: internal mechanisms (agents, self-organization & emergence, connectivity, and dimensionality), environment (dynamism, and rugged landscape), and co-evolution (quasi-equilibrium & state change, nonlinear changes, and non-random future) (for a review, see Nair and Reed-Tsochas, 2019).

Given the above-mentioned properties of CAS, it is important for buying firms to find out a balance of control versus emergence (Pathak et al., 2007; Nair et al., 2009; Carter et al., 2015). Here, controls such as rules and policies may act as a form of reducing degrees of autonomy. Thus, exerting too much control might detract from innovation generated by suppliers within the network. In contrast, emergence can be understood as self-organization that allows that the appearance of supply network beyond the scope of control. Thus, like controls, too much emergence can be problematic as it might lead buying firms to lose the leadership (Choi and Linton, 2011). Indeed, “when managing supply networks, managers must appropriately balance how much to control and how much to let emerge” (Choi et al., 2001, p. 351).

![Conceptual framework](image)

**Figure 1 – Conceptual framework**

**Hypothesis development**

In this section, we first discuss why and how the diffusion of green innovation is limited in a complex supply network. We then describe how possible it is to amplify the limited diffusion of green innovation in the supply network. For our purpose, we introduce
customer (green) pressure and supplier (green) capabilities as proxies for the control and emergence of green innovation. Our premise is that buying firms may try to control suppliers through, e.g., contractual terms (i.e., control); however, these suppliers are also able to make their own decisions when it comes to developing green capabilities (i.e., emergence). Figure 1 depicts our conceptual framework.

Limited diffusion of green innovation. In complex supply networks, green innovations are usually initiated by focal buying firms. These large, oftentimes brand-owning firms are so visible that they draw greater attention from the general public, and thus are easily coming under increased legal exposure and stakeholder scrutiny. Indeed, based on a longitudinal case study, Nair et al. (2016) found that green innovations emerge from a focal buying firm sensing the environmental stimuli, which then spread in the entire supply network. But, once in the supply network, diffusion of green innovation was found to be no longer under the control of the buying firm; rather it is an emergent phenomenon. This finding is further supported by a recent carbon reduction study in a food supply network (Touboulic et al., 2018).

However, as earlier noted, the current consensus is that the diffusion of process and product green innovation is limited mostly to tier-one suppliers, and thus lower-tier (i.e., tier-two and tier-three) suppliers remain the riskier members of the network (Tachizawa and Wong, 2014; Villena and Gioia, 2018). This might be simply because of high costs of development, and/or a lack of financial resources. That is, in general, focal buying firms have only limited information about distant suppliers (Choi and Hong, 2002), and subsequently, it is costly and time consuming to exert direct control over the entire supply network (Ciliberti et al., 2008; Grim et al., 2014; Foerstl et al., 2015; Wilhelm et al., 2016b). This often leads the buying firm to manage their supplier sustainability indirectly (Meinlschmidt et al., 2018; Villena, 2018); e.g., setting requirements for direct (i.e., tier-one) suppliers, so that they propagate the buyer’s green innovation vision in their own supply network.

The problem of this so-called “mandated fashion” (Brockhaus et al., 2013) is that there would be always a lack of consistency across the supply network. That is, the level of requirements set by focal buying firms does not necessarily spread to the entire supply network at the same level. Some evidence supports this statement. For example, using a sample of 172 Chinese suppliers, Christmann and Taylor (2006) found that the level of compliance differs depending on the level of customer involvement. Moreover, based on data from multiple sources, Villena and Gioia (2018) revealed that buying firms monitor their direct suppliers’ green compliance; but oftentimes, these suppliers do not demand the same level of compliance from their own (lower tier) suppliers.

There are arguably two reasons for this limited diffusion of green innovation in a complex supply network. First, compared to higher-tier firms (tier-one and OEM), lower-tier suppliers typically have more limited resources and consequently, lack of expertise in managing the green requirements (Lee and Klassen, 2008; Ayuso et al., 2013; Grimm et al., 2014; Lee et al., 2014). Therefore, suppliers with limited resources may likely face greater difficulty in allocating their efforts to the green initiatives originally initiated by the focal buying firms. Second, as earlier discussed, lower-tier suppliers are less visible to the general public, and thus perceive a lower risk of being penalized by the market for not addressing green issues (Tachizawa and Wong, 2014; Villena and Gioia, 2018). In this regard, there is no reason for them not to take a passive approach, which may cause the limited diffusion of green innovation. Given the discussion, we posit the following hypothesis:
**Hypothesis 1 (a-b).** *In multi-tier supply networks, lower-tier firms are less likely to adopt (a) process and (b) product green innovation, compared to higher-tier firms.*

*The role of customer pressure.* Customer has been perceived as an important group of stakeholders for GSCM (Kim and Lee, 2012). Accordingly, a myriad of studies show how pressure from customers affects suppliers’ environmental strategy. Jira and Toffel (2013) found that suppliers who face the pressure from their buyers are more likely to engage in climate change mitigation actions. Gualandris and Kalchschmidt (2014) also revealed that customer pressure has a positive impact on suppliers’ sustainable (process) initiatives. Chavez et al. (2016) verified the causal relationship between customer pressure and suppliers’ GSCM practices. These studies all highlight the importance of customer pressure for initiating suppliers’ green practices. However, their scopes are limited largely to top-tier (i.e., tier-one) suppliers, which may be not enough to cover the green issues driven by lower-tier suppliers.

Extending the literature on the role of customer pressure in GSCM, we argue in this study that such buyer’s attention to environmental-related issues is a catalyst even for the adoption of green innovation by lower-tier suppliers. Unlike dominant buying firms, lower-tier suppliers are less visible to stakeholders outside the supply network (e.g., NGOs), and thus may take a passive approach for green initiatives. However, looking inside the network, even such passive suppliers are by nature sensitive to customer demands. Their decision making might thus be influenced inevitably by requests from customers, especially from their direct customers.

Recently, Villena and Gioia (2018) find that lower-tier suppliers do not likely prioritize green initiatives unless they are pressured by customers to do so. That is, when the level of customer pressure is high, such suppliers may likely become more proactive, increasing their level of commitment toward the required green innovation (also cf. Christmann and Taylor, 2006). In a similar vein, when faced with high customer pressure, even resource-poor suppliers may likely dedicate part of their resources to comply with customer’s green requirements. Indeed, not to mention higher-tier firms, customer pressure changes the behavior of the passive suppliers. Given the abovementioned discussion, we posit the following hypothesis:

**Hypothesis 2 (a-b).** *The higher the level of green pressure a firm experiences from customers, the larger the adoption of (a) process and (b) product green innovation by the firm.*

*The role of supplier capabilities.* Likewise, supplier capabilities have been discussed as an important source of buyers’ GSCM. As observed by many studies, suppliers can choose to develop GSCM practices, independent of buyer influence (Lee and Klassen, 2008; Tate et al., 2011; Huq et al., 2016; Nair et al., 2016; Touboulic et al., 2018). In fact, such “environmental championing” (Lee and Klassen, 2008), or “supplier innovation capabilities” (Huq et al., 2016) are likely to be motivated by the opportunity, they identify or anticipate, to leverage green initiatives in their process and product innovation (Wagner and Bode, 2014; Foerstl et al., 2015). These capabilities then facilitate cooperation and partnership relationships with buying firms, thereby enhancing the network’s ability to better manage environmental issues.

It is intuitive that such capabilities would be less likely among lower-tier suppliers. As earlier discussed, lower-tier suppliers are rather passive, acting only in response to customers’ green demands. Indeed, in their qualitative sample, Villena and Gioia (2018) found almost no lower-tier suppliers that are willing to develop their own GSCM
initiatives. Consequently, the adoption of green innovation is more likely among suppliers that are larger, and that have more slack resources, or specialized assets (Delmas and Montier, 2009; Jira and Toffel, 2013). That is, the development of own green capabilities might tend to decrease as they go further up in the supply network.

However, it is not quite like that. Consider the lower-tier suppliers observed in Huq et al.’s (2016) study. These suppliers are located in Bangladesh, a country far from the Western markets. They may be visible to the local public but not likely to those in the county of buying firms. Nevertheless, they choose to go beyond the passive approach, developing own social capabilities. Even smaller suppliers (19–239 employees) take this path; Lee and Klassen (2008) found that few of the lower-tier suppliers appear to improve GSCM practices even though they perceive little or no pressure from customers. In this study, we argue that such supplier capabilities generate “spillover benefits” (Busse, 2016) that enhance the buying firms’ green ability. This means that when the level of supplier capabilities is high, buying firms may be able to deal with environmental issues more effectively. Hence, we posit the following hypothesis:

**Hypothesis 3 (a-b).** The higher the level of green capabilities a firm benefits from its suppliers, the larger the adoption of (a) process and (b) product green innovation by the firm.

**Research methodology**

**Sample**

A total of 693 randomly selected companies from German-speaking Europe (Germany, Austria and Switzerland) were contacted via e-mail and invited to participate in an online survey. Overall 284 usable responses were obtained, resulting in an effective response rate of 40.98%. Non-response bias was assessed by comparing the answers of early (n =168) and late respondents (n =116) for one item randomly selected from our green innovation constructs (Armstrong and Overton, 1977). Responses of these two samples did not significantly differ at the 5% significance level.

The sampling population included executives, directors, supervisors, and managers as firm informants on business unit level across different industries. We selected the German-speaking because the German business environment has been exposed to green management practices and green supply chain management some time further ruling out the impact of recency effects on our results (Ehrgott et al., 2011). Moreover, German consumers and businesses are recognized for their green awareness and demand for corporate citizenship (Brown and Dacin, 1997; Maignan and Ferrell, 2003), thus promising theoretically interesting and practically insightful findings.

**Measures**

The variable assessing green process and product innovation was measured based on a nine-item scale adopted from Sarkis et al. (2010). Each scale captures the extent to which the participants’ employing company invests in each environmental improvements initiative on a five-point Likert-type scale (1 = not at all to 5 = a very great extent). For a more detailed analysis the nine items were split into green product and green process innovation practices. Customer pressure and supplier capabilities were estimated using the scale of prior studies (e.g., Vachon and Klassen, 2006; Ateş et al., 2012). In addition informants were asked to choose their firm’s position within the supply chain on a four option ordinal scale of end customer proximity/distance: the differentiation into (1) raw material supplier, (2) component supplier, (3) system supplier, and (4) manufacturer was adopted from Wynstra et al. (2010). By using these categories, we account for the cross-
industry nature of our study and different supply chain complexities. Our non-tabulated test results support their reliability and validity.

Due to the significance of the supply chain position item, our subjects’ supply chain position assessment was cross-validated based on secondary data. Two authors independently categorized each company to one supply chain position based on the 3-digit SIC code in combination with the descriptions of their core business activity provided in the Hoppenstedt firm database. Moreover, information obtainable on the company website was used for further triangulation. Further, firms were seen on a business unit level. This enabled us to have multiple recipients from different business units within one big company. Therefore, supply chain position can be assessed more precisely avoiding the problem of big multinational companies operating at various stages of the supply chain at least to a certain extend. Table 1 presents descriptive statistics and correlation results of the measures used in this study.

Results and discussion

To test our first hypothesis (limited diffusion of green innovation), we conduct an analysis of variance (ANOVA) and the Scheffe method. As shown in Table 2, we found that tier-one suppliers have the highest level of green innovation for both process and product categories. Going by mean values, OEM seems to adopt green innovation more than tier-two suppliers. However, as the Scheffe test shows, there is no significant difference in the adoption of green innovation between the groups. For the product category, the level of adoption by tier-two suppliers is similar to that of tier-one suppliers. But, unlike tier-two ones, we found that the level of green innovation adopted by tier-three suppliers is significantly lower than that of all customers (for both process/product). These findings support H1a, but partially support H1b.

Our findings suggest that tier-one suppliers seem to lead both process and product green innovation in its supply network. This is followed by OEMs, albeit not statistically significant between the groups. Indeed, tier-one suppliers to OEMs are responsible for ensuring green sustainability throughout the network (Brockhaus et al., 2013; Grimm et al., 2014; Foerstl et al., 2015). Contrary to expectations, yet, tier-two was found to adopt the level of green innovation similar to those of tier-one and OEMs. This is an interesting result given that
most of the prior GSCM studies argue that green-related scandals are generated by lower-tier suppliers (e.g., Tachizawa and Wong, 2014; Wilhelm et al., 2016a; 2016b; Villena and Gioia, 2018). But, it should be noted that this is only for the product category, not for the process one. Finally, as expected, we found that tier-three suppliers are weak links for network sustainability.

To test our hypotheses 2-3 (the roles of control and emergence), we conduct a 4 (tier-three, tier-two, tier-one, and OEM) × 2 (high versus low customer pressure, by mean split) × 2 (high versus low supplier capabilities, by mean split) factorial ANOVA. This analysis has been widely used for comparison, not only in supply chain research (e.g., Frohlich and Westbrook, 2002; Shin and Benton, 2004; Koh and Saad, 2006; White et al., 2011), but also in other fields such as marketing (e.g., Gong et al., 2013), information systems (e.g., Sengupta et al., 2018), organizational behavior (e.g., Hepburn and Barling, 2001), etc. Following prior studies (e.g., Shin and Benton, 2004), for succinctness, we omit the higher-order interactions of the variables.

Note: Higher interactions are omitted for succinctness; \(^a\)multi-tier supply networks; \(^b\)customer pressure; \(^c\)supplier capabilities \(^p < 0.10;   \)**\(^p < 0.01;   \)**\(^p < 0.001.\)

As Table 3 demonstrates, for using process green innovation as dependent variable, we found a marginally significant interaction between multi-tier supply networks (MtSN) and supplier capabilities (SuCa). Looking at the individual effects, we found a statistically significant difference in the adoption of process green innovation between each network member, and also between high and low supplier capabilities. On the other hand, for using product green innovation as dependent variable, a marginally significant interaction was also revealed, but this time between multi-tier supply networks (MtSN) and customer pressure (CuPr). Likewise, as the individual effects, we found a statistically significant difference in the adoption of product green innovation between each network member, but not between high and low customer pressure.

To provide additional evidence for our hypotheses 2-3, we conduct regression analysis for each group. As shown in Table 4, control (customer pressure) has a positive impact on the adoption of process green innovation by tier-two, and of product green innovation by tier-two and tier-one. For the others in the network, contrary to our expectations, the control approach was found to be ineffective. In contrast, we found a relatively extensive impact of emergence (supplier capabilities) for each tier’s green adoption. The results shown in Table 4 reveal the significant positive impact of supplier capabilities on the adoption of green innovation by all tier members (tier-three to OEM), for both process and product categories. This means that supplier capabilities indeed increase the adoption of green innovation by buying firms.

</tr>
</tbody>
</table>

Note: The highest VIF for all the variables in each model is 3.27, with almost all scores falling between 1 and 2; \textsuperscript{a}customer pressure; \textsuperscript{b}supplier capabilities; standard errors are shown in parentheses; *p < 0.10; **p < 0.05; ***p < 0.001.

Finally, based on the results, we discuss the issue of control versus emergence for the diffusion of green innovation across complex supply networks. As summarized in Table 5, our findings suggest that control is not a panacea for network’s green innovation. More importantly, this study suggests that for each network member, different approaches need to be considered, a point that has been largely ignored. Therefore, the results of this study provide new insights (e.g., fine granularity) into the CAS/GSCM literature, where the empirical evidence remains conflicting (see Nair et al., 2016; Touboulic et al., 2018; Villen and Gioia, 2018).

Conclusion

The results of this study make several contributions. First, we uncover who is the riskiest of the risky in the supply network. Despite scholarly efforts, it is still unclear exactly which member of the supply network is leading green innovation, and which member is a ‘troublemaker.’ Second, we shed light on the issue of control versus emergence for the diffusion of green innovation. This issue has been recognized as an important agenda when managing a multiple, complex supply network (Choi et al., 2001; Pathak et al., 2007; Carter et al., 2015), so it does for the diffusion of green innovation within the network (Nair et al., 2016). Third, we respond to the call for research on sustainability in multi-tier supply chains (Wilhelm et al., 2016a; 2016b; Villena and Gioia, 2018). Results from this study provide additional insights into the theory of GSCM, where most of the studies are limited in scope to buying firms or tier-one suppliers.

Abstract
Sustainability is becoming a key aspect to compete in nowadays fashion market since customers, NGOs and governments are pressuring companies to become more sustainable. Having full knowledge of all actors and activities carried out along the supply chain is therefore becoming an essential factor for the fashion industry to ensure adequate levels of sustainability. In this context this study aims at investigating the issue of supply chain traceability. Secondary sources were analyzed to deepen the adoption of traceability, in particular by analysis the blockchain technologies, along fashion supply chain in order to support sustainability purposes.

Keywords: Sustainability, Traceability, Blockchain, Fashion

Introduction
Sustainability has become more and more a fundamental driver to the competitive success of fashion firms. In recent times, due to environmental and social scandals, as mistreating of animals, application of unequal working and payment conditions to employees, and the creation of eco-unfriendly collections based on polluting industry, we have witnessed the creation of a profound furrow in customers minds, dividing clearly companies which behave in a sustainable way and which are worth to be taken into account, form those which do not.

Literature maintains Supply Chains (SC) in Fashion Industry are tightly chained with the question of contributing to business sustainability (Caniato et al., 2012, Li et al., 2014). Many activities related to the production of fashion products are affected by critical environmental and social issues indeed, as the use of chemical reagents to obtain precise aesthetic features (e.g. tanning activities, Masilamani et al., 2017), or the lack of regulations for employees. Consequently, achieving a high degree of sustainability performances in SC has become strategically crucial for competing in the fashion markets.

A review on the issue has showed how scholars evaluate diverse viewpoints on how to pinpoint the right SC strategy to reinforce the responsibility of company towards the environment and society. One of them is enhancing the visibility level along SC by mean...
of a traceability system (Macchion et al. 2018; Moretto et al. 2018), to identify the sources of contamination, or defects or critical nodes, or to assure trust among the peers of the SC network (Marucheck et al., 2011), and to make decisions in a consistent manner with the own values.

In this perspective, the digital era has been providing companies with many opportunities offered by technology advancements to be exploited in operations. One example is blockchain technology (Casey & Wong, 2017; Tapscott & Tapscott, 2017), but how it can be practically useful for trace objects and elements along the fashion SCs is still missing in literature.

Based on these gaps, this paper aims at investigating the adoption of traceability practices along fashion supply chain in order to support sustainability objectives. In particular the blockchain will be investigated based on cases of application of this technology within the fashion supply chains.

This goal is tackled through the analysis of secondary sources, specialized in the fashion context, which describe examples of companies that have adopted, or are adopting, blockchain technologies to track their internal processes and supply chain for sustainability objectives.

**Literature review**

*Sustainability in the fashion industry*

The recent environmental and social scandals emerged across the world and the growing pressures by non-governmental organizations (NGOs) have brought under the public spotlight the topic of sustainability as an urgent issue to be addressed (Ageron et al., 2012).

Companies in several industrial contexts, therefore, have become always more sensitive to such challenge and started working on the internal processes and on the products/services they deliver. However, this is not enough, as the public community realized that managing environmental and social issues is not only confined to the boundaries of focal companies, but must be extended to the supply network (Krause et al, 2009) and through the distribution channels as well (Zhu et al., 2005). It follows that companies have now moved to address the emerging issue related to the challenge of sustainable supply chain management, which is defined as “the management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account which are derived from customer and stakeholder requirements” (Seuring and Müller, 2008).

The extension of these virtuous behaviours from focal companies through their supply networks might not be easy to accomplish and could rely on different strategies. For instance, some players, in several industrial contexts, have decided to abolish those current suppliers that are not proactive on sustainability, in favor of new ones more sustainable; in some other cases, the focal companies themselves developed sustainable capabilities to be forcefully extended to suppliers. In some other situations, the focal companies developed green and social capabilities, but in partnership with current suppliers; finally, there are also cases in which companies cooperate with competitors in order to develop sustainable standards and grow sufficient levers to exert such behavior to suppliers (Zhu et al., 2010). Notwithstanding such strategies, the extension of sustainability practices to an entire supply chain represents one of the most complex business challenges of the moment, as the globalization has brought to a fragmented scenario, in which suppliers are dislocated in different parts of the world, below different environmental and social regulations (Sarkis, 2012).

These issues are more than relevant for the fashion industry (de Brito et al., 2008), whose entire business model has been mainly built on the use of fragmented suppliers - often located in low-labour cost countries and where environmental and social regulations are not strict - and on
production processes highly polluting and consuming (Lo et al., 2013). The fashion industry, in fact, is now acknowledged as a business in which there is a high level of pressure on costs and prices, leading several fashion producers, in order to meet such requirements, to offset their workers’ rights and environmental emissions. This has attracted the attention of several NGOs, which have considerably raised their attention to such industrial context, starting numerous initiatives (such as the known Detox Campaign by Greenpeace) which aim is to inform the public opinion about the unpleasant aspects behind this industry.

**Traceability and blockchain in the fashion industry**

Notwithstanding the recent interest by academics on the issue of sustainability in the fashion industry, tracing all the actors in the supply chain still remains a discussion point. In the fashion market, in which the identification of suppliers collaborating in the production is becoming a weapon of success, giving evidence (and therefore tracing) of the origin of supply chains is assuming a key role. However, the development of traceability for the network remains an open challenge due to the difficulty of structuring traceability practices across national boundaries to identify suppliers located internationally (Macchion et al., 2017). In structuring traceability systems, companies must define tools and mechanisms to transmit information, by focusing not only in their internal processes but on the development of a complete inter-organizational traceability that could align different actors of the supply chains and ensure the data exchange in a standardized way. The development of traceability practices should be supported by proper tags, labels, barcodes, microchips or RFID, applied directly to each product or batch, but nowadays new tracking technologies are developing in the market thanks to the growing possibilities offered by new digital technologies: the blockchain.

The early blockchain concept was proposed by a developer hiding behind the pseudonym Satoshi Nakamoto, which has been fully validated through the bitcoin system implementations since 2009. Even if the blockchain was born for bitcoin contexts, paradoxically, it could also save the fate of fashion market, that increasingly requires the most complete traceability of garments and production, to guarantee both social and green supply chain sustainability. The blockchain, in fact, allows to check the history of the product along the supply chain, as well as the prevention, or at least the reduction, of the phenomenon of counterfeits, by leaving the final consumer the possibility to verify this information. As stated by Fu et al. (2018) “The blockchain entries could represent transactions, contracts, assets, identities, or practically anything else that can be digitally expressed using smart devices. New versions of blockchain technology implementation offer support for the implementation of smart contracts encoded in ledger’s blocks, which implements different business rules that need to be verified and agreed upon by all peer nodes from the network. When a transaction arrives, each node updates its state based on the results obtained after running the smart contract. Such replication process offers a great potential for control decentralization”. Based on this structure composed of nodes, it represents a weapon to protect the consumer on one side, and the brand itself on the other side, considering the possibility that some stocks end up in the so-called Gray market (i.e. the parallel sales market outside official circuits of the brand). Moreover, its development could be supported by greater consumer demand for tracked products. According to a recent Pwc report, customers would be willing to pay 5 to 10% more than the list price to buy traced products.

**Research aim and research methodology**

This paper revolves around the role of technology advancements to achieve higher level of sustainability within supply chains, by understanding to which extent they could be catalysts of a progress in the sustainability performance of SCs. In light of this consideration, the following research question is formulated:
RQ: How advanced Digital Technologies, such as Blockchain, might improve SC sustainability?

In pursuance of our aim, for the exploratory nature of the topic under investigation this paper is based on a secondary data qualitative analysis methodology on five different companies. This methodology provides the opportunity to understand complex phenomena in their whole facets by examining companies’ documents and code of conducts, newspaper reports and sustainability and CSR reports available on the company’s website and represents an important source for empirical studies (Harris, 2001). In fact, in order to plan how to select and invest on technologies to address the sustainability journey at a SC level, a profound understanding of all the practices undertaken in the field is needed. Thus, to explore our research question we embraced a supply chain perspective, and we selected five important firms consistent with the following eligibility criteria:

1. The selected company is the focal firm of each SC and is large size brand owner. Hence, it has sufficient levers to structure and influence its entire supply chain;
2. The selected company delivers products at the international level; therefore, the whole supply chain has to be compliant with different national and international sustainability regulations.
3. The selected company must have begun the path of digitalization and sustainability to study sustainability implications due to technological changes over the years.
4. The selected company must publish available information related to their commitment to sustainability and digitalization also in their online site as evidence of their sustainable path.

In order to collect data, we focused on gathering two diverse type of information consistently to the researched field. First, the different digitalization practices and projects to assess and measure the digital maturity of companies, and in particular of their SCs (Plomp, 2010; Schumacher, et al., 2016; Bienhaus and Haddud, 2018). Second, the environmental and social strategies and practices adopted by the companies during the considered years. All the collected practices of digital transformation and sustainability have been catalogued in a spreadsheet and they have been analyzed. The whole analysis has been conducted during the years 2018 and 2019 and information were collected starting from the first implementation of digital transformation and sustainability principles and practices within the supply chains. As specified, the research was conducted on a group of 5 international companies belonging to different SC networks and market segments. The selected firms all belong to the fashion industry; they are positioned in different market segments; they are homogeneous in terms of size (i.e. more than 1bn revenue), brand longstanding existence (i.e. 150 to 50 years); they show a high level of world-class operational and organizational practices; they state to pay attention to sustainability (i.e., mentioned as a competitive priority); and they are at diverse stage in the approach to digital transformation, showing to have conducted explorations on the chance offered by technology to digitalize their SCs.

Moreover, the selected companies are heterogeneous per type of products (i.e., clothes, accessories and jewelry) to cover the variety of products of the fashion industry and per country of origin of the headquarter, to understand the impact of country of origin in the approach to digitalization and sustainability.

Table X summarizes the profiles of the chosen companies.

The selected companies

- LVMH is a French luxury company founded in 1987 as result of the merger between Louis Vuitton and Moët Hennessy. Over the years, it has progressed by acquisition, adding to its portfolio more than 60 brands such as Bulgari, Céline, Christian Dior, Givenchy, Loro Piana or Sephora. LVMH group has produced 46.8 bn € revenue in 2018 (+10% on 2017) and it counts 150.000 employees. Besides the fashion industry which amount to 40% of the revenues, its business comprises also selective retailing, wine, cosmetics, and jewelry. (LVMH, 2019).

  LVMH in 2017 has created a blockchain-dedicated team to develop MVP of a blockchain-based traceability system. The platform AURA leverages on Quorum by JP Morgan, an industrial adapted version of Ethereum. Within the network of companies, Louis Vuitton and Parfums Christian Dior have been elected to test the MVP with the purpose to scale-up the solution to the entire company. The strategical idea at the bottom is to co-opt inside this network not just the entire SCs but also the competitors as well. However, the project is still in its infancy and it has not been officially confirmed by LVMH. (Coindesk, 2019)

- De Beers and Alrosa are two leaders of the diamonds industry. Their business owns the entire Supply chain: form the exploration in search mineral deposits, to the mining process, and to the production and B2C selling of jewelry. Since its foundation in 1888, De Beers has been based in South Africa. Its business spreads toward 35 different countries with a revenue of 6.1bn € in 2016 and more than 20.000 employees. (De Beers, 2019). The Russian Alrosa, founded in 1954, follows De Beers as the second largest player of the sector, with revenues audited around 4,09 bn € in 2018 (300bn Rub) (Alrosa, 2019). De Beer and Alorsa have joined their forces on the development of a traceability system to combat the illegal diamond trafficking and forgery. From their union rose Tracr, a blockchain system with the purpose of tracking the gems status form the mining process to the customer ownership. Ensuring the quality and the history of a diamond is important also to safeguard the overall value of the market. Indeed, incumbent as De Beer or Alorsa are continuously threatened by innovation in chemistry like the synthetic diamonds, or changes in customers priorities. (Trackr, 2019)

- With 5,5 bn€ revenue divided between more than 110 countries, Levis Strauss is a US global general-purpose clothing producer and seller. Its brand is worldwild recognized mainly for its historical leadership in jeanswear. The origins of the company date back in the 1853’s California, and to date the company comprises more than 15.000 employees. Recently, the firm has signed a partnership with
Harvard University to investigate how blockchain may be used to reinforce the workforce welfare. The project pilot has gained the sponsorship of the U.S. Department of State, and it aims at monitoring the workers’ condition within the entire Supply Chain (Coindesk, 2019).

- Hugo Boss Group is one of the world market leaders in the premium segment of the apparel market that accounts almost 14000 employees and in the fiscal year 2018 it achieved net sales of 2.7 billion euro. The actions of the company are guided by the vision of being the most desirable fashion and lifestyle brand in the premium segment, and by the believes that the desirability of its brands will be the most important factor in the group’s long-term success. Hugo Boss’s management has claimed in diverse occasion to foresee Blockchain as a disruptive technology, which potential need to be explored. In particular, it is currently studying how to leverage on a blockchain-based system to track products along their Supply Chian (SCF Briefing, 2019).

Results and discussion
Thanks to the analysis of secondary data from companies listed above, the potential contribution of visibility and traceability through blockchain for sustainability was hinted.

The term Digital Supply Chain (DSC) refers to the data exchanges between actors involved within a supply chain. As stated by Büyükozkan and Göçer (2018), DSC is about “how supply chain processes are managed with a wide variety of innovative technologies”, as IoT, Big Data Analytics, cloud computing and blockchain itself.

This great volume data shared between actors in a supply chain is increasingly growing and offers a wide range of opportunities for enhancing the chain efficiency and effectiveness, yet creating complexities, uncleranness and issues in data management. Moreover, many supply chains still suffer from lack of integration between parties, many documents are still paper-based, and a lack of visibility on processes is still evident. Businesses are therefore trying to focus on integrating processes and transactions, which generates a huge challenge. According to Santos and Eisenhardt (2005), supply chain integration constitutes a key driver for minimization of network’s governance costs, in particular the costs associated to information exchanges with other actors in the ecosystem. Scholars agrees in recognising that integration between participants in a supply chain builds supply chain efficiency.

The key area in which supply chain digitalization can provide benefits is integration between actors, in complex supply chains.

Blockchain technology can create a support towards supply chain integration. According to Korpela, et al. (2017), blockchain can address DSC limitations thanks to the following features:

- A distributed ledger of transactions replicated to every node of the blockchain network. As already discussed, the distributed ledger is open to all nodes (which may have restrictions depending on the permission level). Transactions create new blocks that are chained to the previous, and everyone who has read permissions can verify the validity of transactions (for instance, the seller can notify the buyer about a transaction, and verify the existence directly from the ledger).

- The possibility to develop smart contracts, for automating business transactions and document exchanges between parties within the supply chain. Smart contracts are
developed on blockchains and can be used to “automate DSC transactions at a very detailed level” (Korpela, et al., 2017). As an instance, smart contracts could enable automated transactions in dependence of pre-determined agreements between parties.

- The use of public key cryptography (PKC), to encrypt and decrypt a transaction. This feature ensures a high security level, as well as sustaining the whole architecture.

As a result, blockchain could enable a quick, reliable and efficient execution of transactions and document exchanges, in a secure way and at low cost (Korpela, et al., 2017).

According to evidences provided by secondary case studies, blockchain adoption in business transactions is not supposed to replace enterprise systems, but to be integrated with them in order to receive and store data in ERP’s relational databases, while leveraging distributed ledgers properties to provide trust and accountability to business processes.

An insight on some benefits that can be achieved by integrating enterprise applications with blockchain is provided by Banerjee (2017).

- ERP store information about purchase, storage, production or shipment of a product. Integrating with blockchain can provide a copy of this information into the network, which is indelible, immutable and trackable at any time.
- ERP generate financial transactions. Integrating with blockchain can make transaction transparent and reliable.
- ERP holds procurement information, like purchase order and purchase agreements. These can be registered in digital formats in a blockchain and made available only to the intended parties through their private key. This would harshly reduce the need for emails or other means of communication.
- Integrating ERP with blockchain can reduce disputes over invoices. From the results of an IBM survey (Guarini, 2016), over 100 million of dollars of invoices worldwide are subject of disputes. According to IBM estimations, blockchain could avoid this kind of disputes in 90-95% of cases.
- Integrating ERP with blockchain can replace Electronic Data Interchange protocols (EDI). Messages can be transferred across members via blockchain nodes, with confidential data stored and accessible with a private key.

Pandey (2019) proposes a framework for implementing blockchain in company’s ERP databases, with the purpose of solving the issue of inconsistencies in data flows. The solution is proposed in the case of two actors (a buyer and a seller), within a generic interaction based on contract, order, payment and delivery. If records are correctly uploaded on a blockchain platform, this becomes a single source of truth, and both actors can access to relevant information in real time. This approach can be followed also at a full supply chain perspective, with more actors involved. In the same way, blockchain provides a ledger where to keep record of all transaction and information exchanges.

Cases have also allowed to identify where blockchain could play a stronger role to increase transparency within companies’ processes and along the supply chain. The main potential benefits are the following:

- **Transparency and auditability**: The distributed ledger is replicated to every active node, capable of communicating with ERPs. The ledger is immutable, and each
member of a transaction channel can have access, read or write according to their permissions. Moreover, auditability is made easy thanks to data integrity: for instance, financial audits are immediate and certain.

- **Transaction processes**: The most important information transactions occurring between actors are automated thanks to smart contracts, making the process smoother, more efficient and less subject to errors.

- **Visibility**: Data about the status of purchase orders are constantly updated, and information is available almost in real time.

- **Trust**: The adoption of smart contracts and of a shared ledger provides the highest possible level of trust between parties. Data are shared and immutable, and each involved party has access to the same version of truth. For this reason, it is expected to reduce disputes on orders or invoices.

- **Multi-party collaboration**: Actors can easily exchange digital information and access to shared data uploaded on blockchain.

- **Document exchange**: Paper flows are replaced with digital data exchanges, which can easily synchronize data that were previously spread across systems. Moreover, documents can be digitally stored in dedicated databases and are fully auditable.

- **Failures identification**: Thanks to the increase in visibility on flows, and the reduction of information asymmetry, detection of issues is easier and faster.

- **Lead time**: Increase in visibility and data sharing efficiency could reduce downtimes due to slow exchanges of information. However, no evidences that time savings are expected to be significant, if compared to the overall process lead time, can be obtained.

- **Cost**: Increase in process efficiency is expected to reduce time required by operators in repetitive tasks, which can be dedicated to more value-adding activities. However, due to the high costs implied by the blockchain service provision, these cost savings are not relevant.

Thanks to the preliminary analysis of secondary case studies, we were also able to link benefits of blockchain listed above with sustainability practices, to understand for which practices blockchain could also become an enabler of sustainability practices.

### Conclusions and future developments
This paper investigates the topic of traceability for supply chain sustainability, with a main focus on the contribution that blockchain technology could play to foster these benefits. Whether the relevance of sustainability for the fashion industry is well recognized by both practitioners and scholars, companies are still struggling in identifying methods to enable and foster sustainability at the supply chain level. Literature presents visibility and transparency as key drivers to push sustainability, and blockchain technology appears as one of the most promising tools to enhance transparency. Through the analysis of secondary data from leading fashion companies, this paper identifies the main potential benefits of blockchain technology and makes a possible link between these benefits and the main supply chain sustainability practices.

This paper is just a preliminary step of a broader research project, oriented to investigate how blockchain technology could enable the achievement of sustainability in the supply chain. Further steps have the purpose to make direct interviews with selected companies, to triangulate data collected through secondary resources. Moreover, future research aims at assessing the potential contribution of blockchain, selecting cases that already implemented the technology to compare the ex ante and the ex post performance in terms of sustainability and the consequent level of implementation of practices.

The Impact of Organizational Health Management on Organizational Performance
A Meta-Analysis and Meta-Regression

Maurer, Timo (tmaurer@ipri-institute.com)
Master of Science

Abstract

Demographic change is a challenge for organizations. One consequence is the change in organizational age structures. Organizations need to motivate their employees for longer durations of work. One possibility to meet these challenges is to promote their employees' health through Organizational Health Management (OHM). Despite possible positive effects, OHM has been extensively implemented in a few organizations. This is due to the unknown effect of an OHM. By using meta-analyses and metaregressions, this paper answers the question of the link between OHM and organizational performance and moderating influences. Recommendations for organizations as well as implications for further research are given.

Keywords: Organizational Health Management, Organizational Performance, Meta-Analysis

Introduction

Demographic change is a challenge for organizations. One consequence of this is the change in organizational age structures. As a result, organizations need to motivate their employees for longer durations of work and maintain their capacity to maintain competitiveness despite aging workforces (Lück et al., 2008). One way for organizations to meet these challenges is to promote their employees' long-term health and work capacity through Organizational Health Management (OHM). Numerous studies have shown that, despite possible positive effects (e.g. such as reduced absenteeism), OHM has so far only been extensively implemented in a few organizations. This is due to a lack of resources and to the unknown effect of an OHM on organizational performance, which must be shown to organizations. The following research question arises: What influence does the implementation of an Organizational Health Management (OHM) have on the organizational performance? Based on previous empirical studies, it is not possible to derive any unambiguous statements on the effect on organizational performance measures (Bechmann et al., 2011). The claim to research is growing to prove the suspected effects of an OHM on organizational performance. Special attention is given to the term "evidence-based". The goal of the evidence base is to create a basis for decision-making based on a compilation of the currently best available evidence. So far, such compiled information is missing in the form of a meta-analysis, from which even insufficient recommendations for the implementation of an OHM can be derived. Precise research questions arise:
• What effect on organizational performance does the implementation of an OHM have?
• What influence do moderating factors have on the effect of an OHM?
• How generalizable are the results of the effects of an OHM?
• What are the recommended courses of action for organizations, which implications for further research?

Theoretical Background and Hypothesis

Operationalization of Variables
Organizational Health Management (OHM) is a management task of an organization whose primary objective is to maintain and promote employee health at the organizational level. The OHM thus comprises the planning, control, and monitoring of specific measures that serve to prevent occupational accidents and work-related health hazards and therefore relate to risk factors and their avoidance (pathogenetic OHM measures) as well as measures to promote health resources (salutogenic OHM measures). In order to maintain and promote employee health, the OHM is intended to promote the health-specific further development of existing conditions, work processes, structures and systems. An OHM consists of operational policy elements (e.g. policy document), organizational elements (e.g. health committee), the core process (OHM measures) as well as a continuous improvement process (in the sense of a control loop).

There are numerous approaches to how the success (organizational performance) of an organization can be categorized or operationalized. At Nagel (1997), the subdivision is found in social and economic success. Social success refers to changes in material and immaterial working conditions, as well as behavioral changes and relationships between employees. Economic success is understood to mean changed values of monetary quantities (e.g., profit, turnover) and non-monetary quantities (e.g., product quality, market share). In the context of this research project, the focus is on non-monetary economic variables which have a proven relation to the health situation in the organization (e.g., sickness absenteeism, productivity).

Conceptual Framework and Hypothesis
Draw on the resource-based view (Barney, 1991) and health-specific models (e.g. Edington, 1983), a conceptual framework was derived (see figure 1). It explains how an OHM can affect organizational performance. According to the resource-based view, material and immaterial resources must be combined to generate superior resources. The OHM measures can be interpreted as material resources. The employees with their characteristics affected by the OHM measures can be interpreted as immaterial resources. The combination of material and immaterial resources results in superior resources, which have an effect on organizational performance. The superior resources represent a mediator of the relationship of an OHM and the organizational performance. Accordingly, mediators include all effects of an OHM on employees and their social relationships as well as the associated changes in attitudes, behavior or abilities and their effects on health-specific aspects (Edington, 1983) and (Badura et al., 2008). In spite of the impact of OHM on organizational performance via mediators described above, primary studies will be considered that report relevant statistic on the direct link. The conceptual framework of this research project integrates the results of all selected primary studies.
The focus here is on the question of an impact-oriented design from a management perspective, which is discussed on the basis of the moderator analysis. Basically, moderators (see figure 2) are variables that can affect the direction and strength of the relationship between an independent and a dependent variable. The hypotheses H2-5 refer to the moderators.

<table>
<thead>
<tr>
<th>Moderator</th>
<th>Description of Coding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-systematic OHM vs. systematic OHM</td>
<td>The dummy variable is encoded with 1 if it is a systematic OHM, otherwise 0.</td>
</tr>
<tr>
<td>Purely pathogenetic approach of OHM vs. salutogenetic approach of an OHM</td>
<td>The dummy variable is encoded with 1 if it is a salutogenetic approach of an OHM, otherwise 0.</td>

<tr>
<td>Uncertified OHM Vs. certified OHM</td>
<td>The dummy variable is encoded with 1 if it is a certified OHM, otherwise 0.</td>
</tr>
<tr>
<td>Newly implemented OHM vs. existing OHM</td>
<td>The dummy variable is encoded with 1 if the effect of an existing OHM is measured, otherwise 0.</td>
</tr>
</tbody>
</table>

Figure 2: Coding scheme

An OHM has the primary objective to promote employee health. The OHM measures can be interpreted as material resources (e.g. imparting knowledge to managers for health-oriented leadership). The employees with their characteristics affected by the OHM measures can be interpreted as immaterial resources (e.g. coping strategies of the employees). The combination of them results in superior resources (e.g. reduced sensitivity to stress, psychological and physical well-being), which have an effect on the organizational performance (e.g. less absenteeism). H1.1: OHM improves health-specific organizational performance. H1.2: OHM improves economic organizational performance.

An OHM can be very different and differs in the amount and intensity of implemented OHM elements. Various descriptions can be found in the literature (e.g. maturity levels (Zwetsloot, 2000)). An OHM with all kinds of elements rather represents a complete management process. This gives the OHM its systematic character. An underlying complete management process ensures continuous improvement. H2.1: A systematic OHM has a stronger effect on health-specific organizational performance than non-systematic OHM. H2.2: A systematic OHM has a stronger impact on economic organizational performance than a non-systematic OHM.

In the purely pathogenetic OHM approach (only with pathogenetic OHM measures), the focus is on the identification of existing diseases and risks as well as prevention in the sense of avoiding such procedural and physical risks. In the salutogenetic OHM approach (pathogenetic and salutogenetic OHM measures), the focus is also on strengthening health resources. Since the salutogenetic OHM approach represents a supplementation of the
pathogenetic, a stronger effect is to be expected from the former. H3.1: A purely pathogenetic OHM approach has a weaker effect on health-specific organizational performance than a salutogenetic OHM approach. H3.2: A purely pathogenetic OHM approach has a weaker effect on economic organizational performance than a salutogenetic OHM approach.

Health and safety certifications (e.g., OHSAS 18001 or DIN SPEC 91020) are based on management systems of other domains (e.g., quality) and therefore provide a systematic implementation. By contrast, non-certified OHMs cannot be systematically available, so that a stronger effect of the certified OHM can generally be assumed. H4.1: A certified OHM has a stronger effect on health-specific organizational performance than a non-certified OHM. H4.2: A certified OHM has a stronger effect on economic organizational performance than a non-certified OHM.

For existing OHMs, there is the opportunity to profit more from the process of continuous improvement. Through learning effects and experiences, both the OHM itself and the employees’ behaviors become better, so there are stronger effects on organizational performance than with newly implemented OHM. H5.1: A newly implemented OHM has a weaker effect on health-specific organizational performance than an existing OHM. H5.2: A newly implemented OHM has a weaker effect on economic organizational performance than an existing OHM.

Methods

Search Strategy
There are two basic approaches to literature research: systematic and cumulative research (Reed and Baxter, 2009). In systematic literature research, databases are systematically searched using search terms. Within the cumulative literature search approach, the bibliographies of the recorded primary studies are searched for further relevant ones.

Within the systematic approach quite general terms of the research field were used, which are assumed to be found in titles, abstracts or keywords (search terms: health management OR safety management OR health and safety management OR health programs OR safety programs OR health practices OR safety practices). As a result, fewer studies are overlooked compared to more specific expressions. However, the number of studies to be manually reviewed increases.

Various electronic databases were used to identify relevant studies: Academic Source Premier, Business Source Premier, EconBiz, JSTOR and Springer: Business and Economics, Science Direct were used. To identify unpublished dissertations, Dissertation Abstracts on-line is consulted. In addition to the named databases, Google Scholar was also used to identify scientific documents in the form of doc, docx, and pdf. documents that have not yet been published.

In the cumulative search, the bibliographies of all relevant primary studies were searched. In addition, by using the Social Sciences sub-database of the Web of Science (Social Science Citation Index (SSCI)) articles were researched, which refer to the examined article.

Selection Criteria
Primary studies that are selected must examine the relationship between an OHM and one or more organizational performance measures. In this context, indicators or key figures of economic success are selected that are directly related to the health situation of an organization and that influence financial measures. Thus, primary studies with absenteeism and accident/injury rates are considered as organizational performance
measures. These are grouped together into a health-specific performance. In addition, productivity is considered separately as a purely economic organizational performance measure. This had to be a productivity indicator that relates to enterprise-level productivity.

The primary studies must ultimately be quantitative studies that report relevant statistic for the direct link between OHM and organizational performance. Studies are considered which were published in 1975 or later. The limitation of the period to be considered was made since the mid-1970s, the number of companies implementing a health promotion program has increased significantly. In addition, Antonovsky coined the term Salutogenesis in the 1970s. The restriction to English-language studies has been made since scientific papers are mostly written in English and due to the language skills of the author, it cannot be credibly asserted that studies in other languages are verifiable.

Integration of Effect Sizes
The correlation coefficient was used here as a uniform effect size measure, since it can be interpreted as the covariance of two standardized random variables and thus indicates to what extent the independent and the dependent variable covary, according to how strong the relationship between the two variables is. It is scale-invariant and conceptually corresponds to effect size. To integrate the effect sizes, the Hunter and Schmidt (2004) approach was used. Hereby, the non-transformed correlation coefficients are used to integrate the effect sizes and the moderator analysis with the correction of artifacts in the primary studies to obtain as accurate as possible estimates of the population effect.

An alternative approach from Hedges and Olkin (1985) based on a Fisher’s z transformation weights large correlations more strongly than small ones, thereby overestimating the true correlation. Therefore, the more conservative approach of Hunter and Schmidt (2004) was used. Corrective procedures have been used which have become established in social science and for which the necessary information is given in the primary studies: sampling errors and measurement errors of the variables.

The sampling errors are considered here on their weighting. The weighting is done via the inverse of the variance. The measurement errors of the variables were corrected by the reliabilities specified in the primary studies.

For the integration of the effect sizes and the moderator analysis, the random effects model (RE) was chosen. The RE model assumes that, unlike the fixed effects model (FE), there is not only a constant “true effect”, but that this “true population effect” can vary and therefore has a distribution. The reasons for this dispersion are the “within study” variance (see FE model) and the “between study” variance. The main difference between the RE model and the FE model ultimately lies in the consideration of this additional variance component of the “between study” variance. This results in different variances and consequently different weightings in the integration of the effect sizes. Consequently, the values of the integrated effect sizes, the confidence intervals and the derived statements on significance differ (Borenstein et al., 2009).

Metaregression
The RE meta-regression implemented here is used for the hypothesis test. It is based on the assumption that the overall variability of the effects is not fully explained by the moderators considered. Therefore, besides the “within study” variance, the additional component of the “between study” variance has to be integrated into the regression model. Both variance components are also taken into account in the calculation of the weighting factors, as part of the weighted regression. The general model of RE meta-regression (Eisend, 2014) is shown below:
\[ ES_i = \beta_0 + \sum_{k=1}^{l} \beta_i X_i + e_i, \text{ with } e_i = v_i + \zeta_i \]  

(1)

\( \beta_0 \) corresponds to the constant factor, \( \beta_i \) are the regression coefficients preceding the independent moderator variables, and \( e_i \) are the error terms. \( e_i \) is composed of the “within study” variance component \( v_i \) and the “between study” variance component \( \zeta_i \). The dependent variable \( ES_i \) is the effect size, which indicates the strength of the relationship between an OHM and organizational performance. The independent variables \( X_i \) correspond to the moderators. Eight metaregressions are performed in which each moderator variable is merged individually with each organizational performance measure in a regression. The calculated regression coefficients \( \beta_i \) indicate the difference between the average effect sizes for the different forms of moderators. The regression coefficient \( \beta_i \) is tested for significance using a t-test, where the null hypothesis is: \( H0: \beta_i = 0 \). The two-tailed t-test is based on the following test statistic:

\[ t = \frac{\hat{\beta}_i}{\hat{\sigma}_\beta_i} \]  

(2)

\( \hat{\sigma}_\beta_i \) indicates the standard error of the regression coefficient and \( \hat{\beta}_i \) expresses the difference between the effect sizes within the two moderator categories. The choice of the standard error to be estimated is essential as it could result in errors in the calculation of statistical significance. In this work, the revised robust HC3 standard error is used because it provides more reliable results in small samples (N <250) and is robust in terms of heteroscedasticity (Long and Ervin, 2000). The p-value of the t-test provides information about the significance of the difference. Due to the small sample sizes, a bootstrapping is performed to calculate the p-value.

**Results**

The following figure shows the result of the meta-analysis, the calculated integrated effect sizes for the two organization performance measures. In addition to the integrated effect sizes for the health-specific and economical organization performance, the p-values of the z-test and the t-test are shown as well as results of the sensitivity analysis in the form of fail-safe N and a rank correlation test.

*DV: Dependent Variable of Metaregression; HS: Health Specific Performance; E: Economic Performance; K: Number of Effect Sizes of the Primary Studies; \( ES_{\text{integrated}} \): Integrated Effect Sizes; \( P_z \): P-Value of z-Tests; \( P_t \): P-Value of t-Tests; \( P_{rc-test} \): Begg & Mazumdar Rank correlation test; ***/**/*: Significance at 0.01/0.05/0.1-Significance Level, based on P-Value of the t-Tests.

Figure 3: Results of meta-analysis: Integrated effect sizes

The effect size of an OHM for health-specific organizational performance is significant at the 1% level (p = 0.000). This means that the implementation of an OHM has a significant effect on health-specific organizational performance and can lead to a reduction in absenteeism. With regard to the sensitivity analysis, the fail-safe N of 320, as measured by the recommendation of Rosenthal 1979 (5k + 10 <Fail-safe N, i.d.F. 5 * 24 + 10 = 130 <320), is sufficiently large and the rank correlation not significant. Thus,
publication bias can be excluded with high probability. H1.1 can be maintained. The effect size of an OHM for economic organizational performance is significant at the 10% level (p = 0.065). That means the implementation of an OHM has a significant effect on organizational performance and can lead to increased productivity. Here, however, the fail-safe N (= 8) is not sufficiently large. The probability of publication bias is relatively high, even if the rank correlation is not significant. H1.2 can be maintained.

Looking at the results of the metaregressions, it should first be noted that the effect of a systematic OHM on the health-specific organization performance at the 5% level is significantly greater (p = 0.026) than in a non-systematic OHM. Thus, a systematic strategic implementation has a stronger effect on the health-specific performance in terms of a reduction in absenteeism, as the implementation of individual elements. H2.1 can be maintained. The effect of systemic OHM on economic organization performance tends to be stronger (β = 0.0450) than in non-systematic OHM, but the difference is not significant (p = 0.811). The assumption suggests that a systematic OHM also has a stronger effect on economic performance in terms of increasing productivity than the implementation of individual elements. However, it is statistically undetectable in this case. H2.2 must be rejected.

Figure 4: Results of Meta-regressions

In addition, there is no significant difference in the effects on the health-related organizational performance of a purely pathogenetic OHM approach and a salutogenetic OHM approach (p = 0.629). In terms of absenteeism, a purely pathogenetic OHM approach tends to have a stronger effect (not statistically detectable) than a salutogenetic OHM approach (β = 0.0783). H3.1 must be rejected. There is also no significant difference between a purely pathogenetic OHM approach and a salutogenetic OHM approach in terms of effects on economic organizational performance (p = 0.945). In terms of productivity, a salutogenetic OHM approach tends to have a stronger effect (statically not detectable) than a salutogenetic OHM approach (β = 0.0144). H3.2 must be rejected. Also, there is no significant difference in effects on the health-specific organizational performance between a certified OHM and a non-certified OHM (p = 0.891). In terms of absenteeism, a non-certified OHM tends to have a stronger effect (not statistically detectable) than a certified OHM (β = 0.0163). H4.1 must be rejected. The same applies to the economic organizational performance measure, whereby a very low
p-value based on the applied bootstrapping is recorded here (p = 0.391, pt bootstrap = 0.115). Nevertheless, H4.2 must be rejected.

H5.1 and H5.2 must also be rejected because there is no significantly different effect between a newly implemented and existing OHM. In terms of absenteeism, a newly implemented OHM tends to have a stronger effect (not statistically detectable) than an existing OHM (β = 0.0712). In terms of productivity, it is the other way round (β = 0.0318).

Discussion

Recommendations

For organizations, the implementation of an OHM is recommended. Implementation can reduce absenteeism and increases productivity. Here are both direct, as well as permanent effects recognizable. In addition, to improve organizational performance, it is not absolutely necessary to have a certification that often appears to be laborious. The implementation can be started with little use of resources. For organizations, the implementation of a systematic OHM is recommended. In principle, however, the focus should not only be on diseases and risks, but also on strengthening health resources. Often it is useful in organizations to start with the implementation of occupational safety management (or use of an existing one) and to carry out a gradual expansion. This can be, for example, through the extension of occupational health and safety committees by health commissioners and other managers as well as employee representatives or through the introduction of health promotion measures.

Implications for further research

20 of the 28 primary studies are from 2010 or later. Further studies on the investigated relationship are expected in the next few years. Thus, after some time, an update of the present research work would be possible. Here, the meta-analyses and metaregressions could be performed without the primary studies that report only betas from multiple regression analyses. For while carrying out this research, Roth et al. (2018) note in their work that the inclusion of betas from multiple regressions can lead to strong distortions of results. In the context of this work, betas from multiple regressions were included in the meta-analysis (Peterson and Brown, 2005). However, the calculated integrated effect size has been reduced, so that this procedure corresponds to a more conservative variant. Inclusion in the metaregressions changed the results negligible. In addition, an extension of this study could follow, in particular with regard to the performance measure of productivity (8 primary studies) to verify larger sample results. In addition, other dependent variables could be considered. Since the present work only examined the direct relationship between an OHM and the organizational performance, further studies on this topic should also include mediators in their analysis in order to answer not only the question of the benefit, but also more detailed recommendations for the procedure for the implementation in organizations. A meta-analytic structural equation model could offer here. Future research on the relationship between OHM and organizational performance should focus more on salutogenetic OHM approaches and its long-term impact. Most of the identified studies investigated the effect of a purely pathogenetic OHM approach and extended to less than five years. It would be interesting to consider the effect of salutogenetic approaches, which in particular would have to be designed in the long term until additional effects through the strengthening of health resources become visible. Finally, a more in-depth analysis would be interesting to address the reasons for the non-existent differences between a certified and non-certified OHM (e.g. Lack of
Commitment in Certified Organizations vs. High Awareness of Systematic Implementation in Non-Certified Organizations).

Abstract

This study brings the underrepresented perspective of third-party certifiers to the social sustainability literature and explores the ways through which third-party certification can lend legitimacy to organisations. Drawing on Suchman’s (1995) legitimacy theory, we reveal that organisations can purchase pragmatic legitimacy, garner moral legitimacy but cannot arguably achieve cognitive legitimacy through simply adopting standards. For would-be adopters, managers need to consider what types of legitimacy can best be gained from the adoption of a certain social sustainability standard. Certifiers also need to develop a better understanding of how their initiatives promote each type of legitimacy.

Keywords: Social sustainability, Legitimacy, Third-party certifier (TPC)

Introduction

A series of different campaigns by non-governmental organisations (NGOs) has heightened public awareness of the potentially unethical conduct of multinational organisations (Burchell and Cook, 2013). Multinationals often struggle with social sustainability issues regarding, e.g. child labour, health and safety, and human rights (Huq et al., 2014; Yavar and Seuring, 2017). As the risk of public criticism about social sustainability issues has increased, third-party certification of social sustainability standards (e.g. Fairtrade and Rainforest Alliance), have been voluntarily adopted by multinational supply chains (Reinecke et al., 2012). These standards are used by multinational organisations as a means of gaining perceived legitimacy (Brunsson et al., 2012) and/or reducing potential legitimacy threats for stakeholders in the supply chain (Vurro et al., 2009). Legitimacy motives are key drivers for social sustainability initiatives, outstripping in popularity those related to profitability (Branø and Vidaver-Cohen, 2009). It is argued that new actors including NGOs, industry associations and public-private partnerships currently provide the normative framework that corporations use for social sustainability legitimacy (Giovanniucci and Ponte, 2005).

In consequence, firms are progressively implementing social sustainability ‘signals’ in the form of certifications, codes of conduct, sustainability standards and product
guidelines to improve sustainability across their supply chains (Gereffi et al., 2005; Mueller et al., 2009; Wijen, 2014). Given the proliferation of social sustainability initiatives, the legitimacy of the competing assessments is of vital importance to their longevity. Each one, therefore, draws on particular legitimacy grounds as the justification of their approach as the logical – ergo legitimate – choice for firms seeking external validation of their social sustainability credentials.

Signalling theory (Spence, 1973) suggests a relationship between the adoption of social sustainability standards and legitimacy because “without legitimacy would-be adopters are unlikely to follow a standard” (Brunsson et al., 2012, p. 619). This argument assumes that third-party certifiers (TPCs) lend legitimacy to would-be adopters in gaining perceived legitimacy or reducing potential legitimacy threats; an assumption that has yet to be examined. Most studies of legitimacy have sought to understand the motivations and approaches of the adoption (e.g. Bowler et al., 2017) and consumer’s attitudes and perceptions of certified products and retailers (e.g. Anagnostou et al., 2015). However, little is known of the mechanisms for lending legitimacy from the perspective of TPCs. We draw on Suchman’s (1995) three forms of legitimacy – pragmatic, moral and cognitive – to investigate what types of legitimacy are associated with these assessments.

We present an exploratory, multi-case study of 8 global TPCs to explore ways through which third-party certification can lend legitimacy to would-be adopters, asking: How do third-party social sustainability certifiers lend legitimacy to multinationals in the supply chain?

**Literature review**

Suchman (1995, p. 574) defines legitimacy as “a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs and definitions”. As there are competing TPCs, none of which has a status clearly above the others, the legitimacy of each TPC comes into question. Sustainability ‘signalling’ increases the legitimacy of the firm only if the TPC holds sufficient levels of legitimacy. Yet legitimacy is one of the key criticisms against TPC (Mueller et al., 2009). As Ashforth and Gibbs (1990, p. 177) aptly describe legitimacy: “like beauty, it resides in the eye of the beholder” it follows that TPCs must first have legitimacy in order to then lend legitimacy to supply chains. In this section, three forms of legitimacy - pragmatic, moral and cognitive - as presented by Suchman (1995) are thus presented and discussed in relation to social sustainability in supply chains.

Pragmatic legitimacy relates to the self-interested calculations of the audience of the entity seeking legitimacy (Suchman, 1995). Pragmatic legitimacy can take two forms: exchange legitimacy and influence legitimacy (Suchman, 1995). The former relates to support for an entity’s policy based on its expected value to the entity’s constituents (Dowling and Pfeffer, 1975). For example in the wood industry context firms only want certificates that provide some marketplace benefits to them and are reasonably priced, thus highlighting the importance of pragmatic legitimacy to those considering certification (Schepers, 2010). In the case of social sustainability, this translates to firms selecting third-party certification because of its positive impact on business, e.g. through avoidance of consumer boycotts and/or increased sales (Cashore, 2002). Product labelling that incorporates social sustainability credentials can therefore act as a signal or product quality and a source of competitiveness (Hartlieb and Jones, 2009). The latter, influence legitimacy, concerns constituents supporting an entity because it fits with their larger interests rather than any specific beneficial exchanges. Social sustainability certifiers must therefore understand the self-interest of the supply chain actors that they are
attempting to persuade. Actors may raise concerns about the ease, flexibility and speed with which the certification can be conducted, the relevance of the certification, the availability of suppliers with desired commodities on offer, and its overall financial and efficiency benefits (Cashore et al., 2003; Castka and Balzarova, 2008; Glover et al., 2014; Heugens and Lander, 2009; Schepers, 2010). Such overall benefits may focus on, for example, increased supply chain visibility offered by the audited chain, and different assessment options for products with different characteristics (Awaysheh and Klassen, 2010; Barratt and Oke, 2007).

Moral legitimacy, on the other hand, does not relate to transactional benefits but to what is seen as the right thing to do, e.g. in relation to social welfare (Suchman, 1995). It involves moral judgments on an organisation’s output, processes and forms of management (Palazzo and Scherer, 2006). The pragmatic legitimacy of governance schemes does not remove the need for them to also possess moral legitimacy; they need to have sufficient procedures to gain approval (Schepers, 2010). A clear linkage between moral legitimacy and social sustainability signalling is evident; adhering to a TPC because providing a fair wage and living conditions to workers and suppliers is the altruistic, right, and moral expectation from any firm’s actions. Moral legitimacy can be categorised into several alternatives (Suchman, 1995): (1) consequential (based on what the entity accomplishes), (2) procedural (based on what the entity does to achieve the outcomes) and (3) structural (based on how the entity is organised). As for social sustainability, these categories would relate to (1) achieving social justice and balanced global trade, (2) the intensity of monitoring and audit processes, and (3) clear and transparent governance including e.g. the openness of the standard-setting as well as which entities are involved in it (Cashore, 2002; MacDonald, 2007; Prado, 2013; Schepers, 2010).

The third form of legitimacy, cognitive, establishes an entity as legitimate “when there is little question in the minds of actors that it serves as the natural way to effect some kind of collective action” (Hannan and Carroll, 1992, p. 34). An entity or a form of organising is seen as the only comprehensible option that fits with everyone’s view of the world, or it has become a given, taken for granted where alternatives are unthinkable (Robey, 2003; Suchman, 1995). To date, this form of legitimacy is unlikely to reflect social sustainability certification, as it has not reached a level of being seen superior to others in every way.

According to signalling theory (Spence, 1973), would-be adopters are very likely to follow a social sustainability standard to signal their legitimacy (Brunsson et al., 2012). This notion relies on the assumption that TPCs can actually lend the three types of legitimacy to would-be adopters who seek to gain perceived legitimacy or reduce potential legitimacy threats; an assumption that has yet to be examined. In response, we conducted a multi-case study of 8 global TPCs to explore ways through which third-party certification can lend legitimacy to would-be adopters.

**Research Methodology**

Data was collected via semi-structured interviews with representatives from 8 global TPCs by telephone or Skype (due to the global locations of the representatives) and then transcribed for analysis. In addition, internal documents (i.e. policy and strategy documents), and websites of the certifier were used in the analysis. Data were then coded, compared and discussed. We use Suchman’s (1995) three forms of organisational legitimacy (i.e. pragmatic, moral, and cognitive) as a theoretical lens for analysis. Table 1 provides an anonymised overview of the TPCs that took part in the interviews.

Findings
Despite what might have been expected given the topic, examples of moral legitimacy were less prevalent than those related to pragmatic legitimacy. For pragmatic legitimacy interviewees stressed the flexibility of their third-party certifications: “[For auditing] internally our rules say they [supply chain actors] will have an initial, renewal and one per year audit but it is possible one maybe skipped according to our internal risk-based methodology, but this is more of an exception than a rule” (D). “Depending on the nature of the outcome of the risk assessment, it will be different for each member, so we will look at the complexity of the organization, the supply chain and how many products they have, this will determine their risk level - low to high - and their audit frequency” (E). “We take as a starting point the realities and impossibilities of producers within a certain context, that is, for example, one reason why we don’t have time frames for compliance progress... and if there is a non-compliance with an issue that is not part of our central requirements then we allow the members to draw up an improvement plan” (F). The competitive cost of the TPC’s audit programme was an important differentiator for Certifier E: “If you remember we say that if you behave well we will reward members, so having an audit only every 6 years is good as costs are reduced every year compared to other systems” (E). Others focused on the availability and credentials of their auditors: “We have local 120 auditors and we look for local ones [to complete an audit]” (D). “It’s a more focused approach. It takes longer, it takes our assessors longer to do this type of assessment” (G) and “we have more than 50 people in the field supporting producers...who are well connected in the country and with our members” (A). Certifiers D and E were also explicit about the financial benefits of their TPC: “[supply chain actors] have an increase in 10-15% of trade through [social sustainability signal]” (D). “I think most members [of the social sustainability signal] have reported increased sales” (E).

In drawing on moral legitimacy, Certifier A used its advocacy role as a differentiator. “We do more than getting them [supply chain actors] to adopt certification, we do advocacy on trade justice...this is an example of what makes us different. We are actually interested and would actively advocate for issues on social sustainability” (A). Certifier
D focused on collective bargaining being the morally right thing to support. “We believe in the power of many. So if you have a collection of farmers rather than a single one, their bargaining power is much greater and so they are able to get a better deal out of whatever they are trading” (D). A point also echoed by Certifier A when discussing their approach to supporting the sale of goods at a fair price as the correct thing to do because “you are not doing me a favour by buying it” (A). Morality appeared to underpin the ethos of Certifier F. “We don’t stop talking about it [social sustainability] with our members. About how to maintain moral values and respect these and not become cold and sterile in our procedures” (F). Making reporting publicly available was used as a moral legitimacy argument from Certifier G. “The fact that it [social sustainability] is still reported out publicly, I think sets us apart from what I’ve seen from other [social sustainability] organizations as well” (G).

In considering assessment procedures as moral legitimacy arguments, stringency was highlighted by Certifier D. “[For assessment] I know we have a reputation within the trade as being one of the strictest and most rigorous” (D). Developing bespoke assessment procedures was also viewed as important. “We have our own standards and our own compliance criteria that are different from some other (social sustainability assessment) organisations” (E). Certifier B was very clear that standard setting and governance procedures were driven by the producers. Apart from Certifier C, moral legitimacy was used by all TPCs in the study. It seemed to be used to distinguish one TPC from another, with each TPC providing evidence of how their particular approach to social sustainability was based on a moral obligation, stringent assessment procedures and/or transparent governance.

As expected, we did not find evidence of any of the TPCs using arguments based on cognitive legitimacy. There was, however, some discussion about the merging of TPCs “if competition becomes too tough” (A) and the move towards a more uniform or ‘superstandard’. One TPC, in particular, was less in favour of this approach: “For social sustainability to have this uniformisation taking place it does worry me. In the end, there will be an orientation to one type of criteria with different franchises who administer these types of criteria but they will have to be very similar or the same...but in the end, if you look from the poor side of the world and poor producers this becomes a barrier for help and development, the original idea of certification becomes more a filter than a development” (F). This sentiment was not echoed by all. “We should not compete in this field...in the end, the aim is to improve the working conditions. So why not work it together?” (H). These comments could relate in some way to a cognitive legitimacy argument based on social sustainability being the only way to organise supply chains; nevertheless, there was a lack of consensus as to how this can or should be operationalised.

Discussion
In the following, we will provide a discussion of the competing forms of legitimacy as evident among the TPCs.

Third-party certifiers (TPCs) in competition to promote their legitimacy
Recent studies have documented the increase in proliferation of sustainability certifications, particularly within the coffee sector (Ingenbleek and Reinders, 2013; Reinecke et al., 2012). For quality and environmental management systems, there are standards that dominate (Boiral, 2003, 2007). Yet this is not the case for social sustainability where a variety of norms, codes of conduct and initiatives are present (Castka and Balzarova, 2008). It is argued that the proliferation of social sustainability
assessment has led to competition for adoption by multinational organisations in order to reinforce the legitimacy of particular assessment practices (Gereffi et al., 2001). The likelihood of organisational survival increases with legitimacy (Dowling and Pfeffer, 1975), and thus it should be unsurprising that our research identified that these competing TPCs have to defend their own legitimacy, just as the firms that acquire their certification have to. As our interviews demonstrated, the TPCs have some awareness of the potential competition and vocalised potential risk in not being seen as the legitimate alternative. Being very specific about how they articulate their distinctiveness using different forms of legitimacy was a clear illustration of this. Organisations that do not have complete legitimacy as perceived by their constituents must not only exemplify desirable characteristics but also promote them (Ashforth and Gibbs, 1990). As none of the TPCs in our study possesses the cognitive, taken-for-granted legitimacy, they must argue for their own legitimacy to become perceived as the preferred option. The field of social sustainability is demonstrating meta-standardization, where there is agreement about the ‘rules of the game’ at a general level, but differentiation exists as regards its assessment (Reinecke et al., 2012).

The TPCs in our study seem to utilise multiple legitimacy arguments; although most focus on either a more strategic or a more ethical standpoint to set them apart. Specifically, pragmatic legitimacy appears to be an important emergent theme in our study. In the following section, we discuss this finding in more detail.

**Pragmatic legitimacy a key element**

Most institutional scholars focused primarily on conformance discuss adoption to gain acceptance, whereas organizational performance scholars argue that firms will always prefer practices that give financial benefits over social conformity (Heugens and Lander, 2009). Firms can take up sustainability standards for instrumental, relational or moral drivers (Wijen, 2014). Motivations to adopt objects of institutional pressures (such as total quality management, sustainability standards or corporate social responsibility) can stem from endeavors for legitimacy and ethical objectives as well as more calculated economic and strategic objectives or infrastructural convenience (Castka and Balzarova, 2008; Crilly et al., 2012; Ingram and Simons, 1995; Kennedy and Fiss, 2009). Sustainability standards may be a mechanism to differentiate and charge a premium price (Wijen, 2014). As Kennedy and Fiss (2009, p. 911) succinctly state: “wanting to look good does not preclude also wanting to do better”.

Our study indicates that these social sustainability TPCs have recognised the coexistence of economic and legitimacy motivations in their target population, as many appear to focus almost exclusively on the pragmatic legitimacy of their scheme through, e.g. a focus on continuous improvement, flexible audit cycles, branding and marketing to assist in sales and providing traceability of the chain. Our findings are in line with Oliver (1991) and Goodstein (1994) who argue that if institutional pressures clash with organisational goals, or reduce decision-making discretion, resistance is more likely. Thus the social sustainability TPCs appear to be offering firms a path of least resistance by developing processes such that they fit with, and provide benefit to, their existing business practices. Environmental supply chain practices have been able to present tangible operational and financial benefits through, e.g. waste reduction and lowering the costs of inputs (Bansal and Roth, 2000; Roome and Wijen, 2006; Russo and Fouts, 1997). Yet for social sustainability in supply chains, the measurement of financial benefits is both less developed and has fewer demonstrable supporting findings (Pullman et al., 2009; Sancha et al., 2015), prompting the need to emphasise pragmatic legitimacy as identified in our findings.
Standards differentiation is partly driven by “claims to moral authority over the definition of what a sustainability standard should provide” (Reinecke et al., 2012:798). This was evident in our findings as we noticed parallel strands of what is the ‘right thing to do’ depending on the focus of the certification under scrutiny. For example, TPC D was explicit about its reputation for ‘stringent processes’ whilst TPCs A and B, for example, spoke about social sustainability as being the morally correct course of action. It is important to note, however, that these parallel strands may exist within each TPC, and that a focus on one does not preclude the occurrence of the other. For example, a TPC may focus on the moral imperative of social sustainability yet this does not necessarily mean that its standards are weak or its governance lax.

Cognitive legitimacy was not evident from our interviews; which is logical given how we view the issue of social sustainability certification as still only becoming institutionalised. As nongovernmental organisations are increasingly under constant public examination, they could attempt to increase their legitimacy by co-developing sustainability standards (Wijen, 2014). While a couple of the interviewees mentioned that perhaps in the future a ‘superstandard’ or greater collaboration between TPCs could emerge, none of them actively mentioned their collaboration with other social sustainability TPCs during the interviews, nor brought it forward as a key aspect of their operations. This finding is in line with studies on emerging domains, in which mutual interests are recognised by the actors, yet little coordination is observed (Avetisyan and Ferrary, 2013).

Conclusion
The study has attempted to bring the underrepresented perspective of TPCs to the social sustainability literature and explored the ways through which third-party certification can lend legitimacy to organisations. We reveal the mechanisms used to lend legitimacy to supply chains seeking to gain three different types of legitimacy, i.e. pragmatic, moral, and cognitive legitimacy (Suchman, 1995). Results demonstrate that the most common type of legitimacy lent by TPCs is pragmatic legitimacy, i.e. based on self-interest calculations (Suchman, 1995). Certifiers stressed the availability and flexibility of their auditing programmes and highlighted the financial benefits and rewards of their standards. For example, one certifier mentioned that most firms had reported increased sales after the adoption of their social sustainability standard. In terms of moral legitimacy, based on normative approval resting on what is the right thing to do (Suchman, 1995), certifiers put forward different initiatives to promote moral legitimacy, e.g. advocacy on trade justice, collective bargaining, stringent assessment procedures, and public disclosure. Adopting firms can, therefore, garner moral legitimacy by embracing these initiatives. As expected, cognitive legitimacy, based on comprehensibility and taken-for-grantedness (Suchman, 1995), is unlikely to reflect social sustainability standards, as socially sustainable goods have not reached a level of being seen superior to others in every way. In other words, organisations can purchase pragmatic legitimacy, garner moral legitimacy but cannot arguably achieve cognitive legitimacy through simply adopting standards.

For would-be adopters, managers need to consider what types of legitimacy can best be gained from the adoption of a certain social sustainability standard. For example, TPCs are confident of lending pragmatic legitimacy through, e.g. flexible audit cycles, branding and marketing to assist in sales and providing traceability of the chain. Managers also need to be aware that cognitive legitimacy is unlikely to be obtained through the adoption of a standard. For certifiers, work is needed in developing a clearer understanding of how their initiatives promote each type of legitimacy and hence are attractive to supply chains.

Abstract

The purpose of this research is to answer the question what are the social sustainability indicators for the food supply chain, from food manufacturing firm’s perspective in Thailand. There has been an increased interest in sustainability during the past decades, particularly in social sustainability aspect. However, a study of social sustainability indicators is still in its infancy (Popovic et al., 2019). To date, there are still no specific indicators to measure social sustainability, particularly in the food industry. Hence, this research aims to fulfill the literature gaps by exploring the social sustainability indicators in the food supply chain in Thailand.

Keywords: food supply chain, sustainable supply chain, social sustainability

Introduction

The purpose of this research is to answer the question “what are the social sustainability indicators for the food supply chain, from food manufacturing firm perspective in Thailand”. The concept of helping operationalize sustainability is the triple bottom line (TBL), which provides a framework for measuring the performance of the business and success of the organization using three dimensions: economic, social, and environmental (Goel, 2010).
Social sustainability is one of the dimensions in TBL, but this dimension has received less attention in the literature and in practice, compared to the other two dimensions which are economic and environmental sustainability (Mani et al., 2016b; Eizenberg & Jabareen, 2017). The social sustainability refers to how social issues should be managed in a way that increased a corporation’s long-term survival (Carter and Rogers, 2008). Social sustainability in the supply chain can be narrowed down to the product and process measures that determine the safety and welfare of the people in the chain (Mani, Agrawal & Sharma, 2015b), including suppliers, customers, employees and community. Despite the increased interest in social sustainability, a study of social sustainability indicators is still in its infancy (Popovic et al., 2019). Therefore, this research aims to explore social sustainability indicators through 4 cases with leading companies in Thai food industry.

This paper is exploratory research. It begins with the introduction, literature review on social sustainability in supply chain and social sustainability indicators, followed by research methodology to explain how the research was conducted. Based on the literature review, the conceptual framework on social sustainability indicators is developed as a data collection tool. Then, the data from 4 case studies are presented, followed by empirical studies and cross-case analysis which refine and enrich the conceptual from the literature. The paper ends with the conclusion that show the key findings and limitations.

Literature review
This research aims to answer the question “what are the social sustainability indicators for the food supply chain, from food manufacturing firm’s perspective in Thailand”. Hence, this section seeks to explore the existing literature beginning with the concept of Triple Bottom Line (TBL), social sustainability in the supply chain, its key indicators as well as its applications in supply chain context as described below in order to identify the key theoretical gaps as well as to build the conceptual framework from the existing literature.

Triple bottom line
The triple bottom line (TBL) is a sustainability-related construct (Elkington, 1998), provides a framework for measuring the performance of the business and the success of the organization using three dimensions: economic, social, and environmental (Goel, 2010). Elkington (1998) defined three dimensions as the economic dimension refers to company practices that affect to the economic system, the environmental dimension refers to a company practices on preserve the environmental resources for future generations, and the social dimension refers to fair practices and benefit to the labour, human capital, and to the community. TBL is the concept beneficial for a company to operationalize sustainability to achieve the economic, environmental, and social dimensions (Seuring and Muller, 2008). Therefore, firms need to adopt the TBL as a framework for firms’ sustainability practices.

Social sustainability in the supply chain
Social sustainability is one of the dimensions in TBL, but the dimension has been received less attention in the literature and in practice (Mani et al., 2016b; Eizenberg & Jabareen, 2017). Social sustainability is about verifying and managing both positive and negative business impacts by focusing on social interactions, and is also related on how social issues should be managed in a way that increased a company’s long-term survival (Carter and Rogers, 2008). Social sustainability in the supply chain can be narrowed down to the product and process measures that determine the safety and welfare of the people in the chain (Mani, Agrawal & Sharma, 2015b).
To adopt sustainability into a firm, firm need to adopt social sustainability toward all stakeholder in every stage in the supply chain that consist of suppliers, employees, consumers and community (Mani, Agrawal & Sharma, 2015a) to make the social impacts to society. This paper attempt to find how company could adopt sustainability with stakeholders in the supply chain by addressing social issues into their practice.

**Social sustainability indicators**
Sustainability indicators in economic and environmental dimensions have been increasingly addressed in several papers. However, the social dimension indicators receive less attention from both academia and practitioners (Ahi & Searcy, 2015), the increased interest in social sustainability there is still lack of information for the social assessment (Popovic et. al., 2019). In addition, the literature on sustainable development reveals that the social aspect is still in its infancy due to the lack of theoretical and empirical studies (Eizenberg & Jabareen, 2017). The most commonly mentioned of social sustainability indicator is the rather general category “occupational health and safety” (Mani et al., 2016a; Hutchins & Sutherland, 2008) and other social sustainability indicator such as gender equality (Mani et al., 2016b), labour equality (Hutchins & Sutherland, 2008) and income level and distributions (Spangenberg & Bonniot, 1998). United Nations Division for Sustainable development (UNSD) classified sustainable indicators framework in social dimension such as equity, education, health, housing, security and population (UNSD, 2001). Market indices that incorporate use to measure the sustainability, such as the Dow Jones Sustainability Index (DJSI) and FTSE4Good Index, do not fully capture the challenges of measuring sustainability at the level of the supply chain (Ahi and Searcy, 2015).

Therefore, this research on social sustainability indicators will be refined and enriched from 4 companies in the Thai food industry and aims to fulfil the literature gaps by exploring social sustainability indicators.

**The conceptual framework**
Social sustainability indicator in supply chain divided by the stakeholder that consist of suppliers, employees, consumers and community (Mani, Agrawal & Sharma, 2015a). Each supply chain units consist of social sustainability indicators shows in Table 1 that developed from literature.

**Research methodology**
This paper is exploratory research and adopted a qualitative research method to answer the research question “what are the social sustainability indicators for the food supply chain, from food manufacturing firm’s perspective in Thailand”.

To achieve the paper’s purpose, a multiple case study (Yin, 2009) is applied. Semi-structured and in-depth interviews were conducted with 4 companies in the food manufacturing industry. Cases are selected based on 3 criteria; (i) companies within the food manufacturing industry, (ii) leading companies in sustainable performance and (iii) all companies are based in Thailand. Each firm has been socially contributing to society and is regarded as one of the best social practices in Thailand. In addition, each firm is financially sustainable. Food industry was picked in this research as Thailand’s food export value is ranked amongst top five in the world, as a result, the practices in Thai food industry can be one of the world’s leading practices. Table 2 presents the 4 companies’ profile of this research.

The conceptual framework on social sustainability indicators is developed as a data collection tool. Three interviews were conducted face-to-face with the managing director at the company headquarters, another one was conducted over the phone for approximately 60 minutes. Data is collected by using a semi-structured interview in this research and conducted in order to provide the informants a freedom to discuss over the topic. Interviews were conducted by one of the authors while the other two transcribed and observations.

To analyze the collected data, each case was analyzed individually then cross-case analysis was used. Finally, the conceptual framework on social sustainability measurement in the food supply chain is refined.

**Empirical study & case analysis**

*Company #1*

Company #1 is a dairy products manufacturer, transforms raw milk into wholesome dairy product. The company aims to foster organic ecosystems, free from a synthetic chemical.

The first for supplier, the company provides the supplier’s training in manufacturing processes that help to reduce the problem on the lack of suppliers’ know-how on production efficiency, which later can help improving their own productivity. Second, the company lets suppliers set the raw material prices themselves that aims to provide financial sustainability for suppliers. Lastly, the company provide fund for supplier's raw material and micro-lending as an initial investment for suppliers, helps tremendously to initiate the first loop of supplier’s operations and keep them going. For employee, the company provides low interest micro-lending and high interest deposit fund to help decreasing employees’ financial problems, and also pay wages slightly above the national legal minimum wages.

*Company #2*

Company #2 produces cereal-based products. The company provides knowledge for organic farming to farmers to stop pesticide usage, sources supply from them with fair price, then produces all products in-house and distributes to modern trade.

The company designs work process to avoid employees’ heavy lifting. Employees receive individual health insurance and also annual medical examination which exclude
the nation labour law. For financial support, company provide education fund for employees’ education for employee retention and also provides fund for supplier’s raw material and machine which helps tremendously to initiate the first loop of supplier’s operations and keep them going.

**Company #3**
Company #3 produces roasted ground coffee, sources coffee bean and coffee cherry from local villagers in the mountains. The company mainly focuses on suppliers’ well-being economically. Raw material price based on negotiation between all of supplier and the company that is 15-20% higher than market price. In addition, the company provides knowledge to villagers from a local university.

**Company #4**
Company #4 collaborates with senior citizens club to educates retirees for urban organic farming and lets all retirees become urban farmers which generate their own revenue. Then all products deliver to nearby customer, which reduces logistic cost and maintains product freshness.

The company aims to solve the problem of aging society that retirees doing nothing at home, have no income and also seeing consumer’s problem of unaffordable price of organic premium vegetable and how busy of urban life. For community, company generates revenue for retirees and recruits their family member to work with the company.

The case studies enriched and defined the conceptual framework. The cross-case analysis in the Table 3 and Table 4 shows that all of stakeholder consists of each own social sustainability indicators. Practices in all cases almost similar due to a similarity of the main objective that aimed to be a social enterprise.

The new indicators are added for two stakeholders; employees and suppliers. The first two indicators for employees are financial and family aspects. The employees’ financial indicators are low-interest micro-lending and high-interest deposit fund for employees in a company for employee retention. The employees’ family indicators are employees' children education fund and family involvement in company events, which retain employee relationships. The indicator emerged for suppliers is only from the financial aspect. The emerged supplier financial indicator is financial access (micro-lending) for suppliers which aims to help tremendously to initiate the first loop of supplier’s operations and keep them going.

8
Conclusion
According to the case studies, we identified similar and different social sustainability indicators adopted by each company that include an organic dairy product manufacturer, an organic cereal-based products manufacturer, a roasted coffee manufacturer and an urban farming vegetables firm. Results are shown that the majority of social indicators in food manufacturing is related to employment, human development, health and safety, and wages. This is in line with the literature review which states that social sustainability determines the safety and welfare of the people in the chain.

Practices learned in all cases share the similarity of the company’s objective on making social impacts to the society. The new indicators are emerged for two stakeholders; employees and suppliers. The first two social sustainability indicators for employee are financial and family aspects. Social sustainability indicator emerged for supplier is financial accessibility.

This paper fulfils theoretical gaps in social sustainability indicators, particularly in the food industry where social issues are highly emphasized and yet to be explored. The findings from this paper are beneficial for both academia and practitioner who seek to develop social sustainability indicators in supply chain. In addition, this research illustrates social sustainability indicators that each firm practices to all stakeholders in food supply chain, the findings will benefit food manufacturing firms in general, not limited to only in Thailand.

Last but not least, the results are based on the findings from only four case companies in the Thai food industry, more cases from different industries can help generalizing the research findings.

Abstract:
This paper validates the social sustainability performance dimension from the fifth round of the Global Manufacturing Research Group survey. The scale is validated using exploratory factor analysis to ascertain no communality among factors. Common-method bias, discriminant and convergent validity, group measurement invariance for economy type (developing and industrialized) are satisfactorily tested. A structural causal model is offered, inspired by the structural contingency theory of organizations, the resource-based and the natural resource-based view of the firm. Future research aim at falsifying theories on the relationships between the type of economy and social sustainability, mediated by environmental management and moderated by uncertainty.

Keywords: corporate social responsibility, multi-group analysis, measurement invariance

Introduction
Sustainability issues are receiving increasing attention from academics and practitioners alike. Despite a growing number of publications on the subject, most papers have focused on environmental or economic sustainability, with relatively few publications focused on social sustainability and its effect on firm operational and strategic performance. However, sustainability effects on performance are often contradictory and may vary according to sustainability dimensions and context (Magon et al., 2018). Furthermore, sustainability practices effects may also differ for strategic and operational performance. For example, regarding context, Betts et al. (2018) found that the adoption of environmental practices and its effect on sustainability performance differ in advanced and developing economies. Manufacturing plants in developing economies appear to be more prone to engage in environmental management practices neoterically than manufacturers in developed economies. These results corroborate earlier findings from
Zhu et al. (2008) that found that manufacturers from the automotive industry in China were adopting more environmental practices than in the UK. It is also consistent with Schoenherr’s (2012) findings on environmental practices effects on manufacturing operational performance according to the type of economy. Despite these earlier findings, there is no evidence that the same differences remain for other dimensions of the sustainability triple bottom line (Elkington, 1998), such as the economic and social dimensions. Furthermore, there is no evidence the effects of economy type act on both operational (say quality, costs, delivery and flexibility) and strategic performance (e.g., environmental and social sustainability).

This study combines the lenses of the contingency theory (CT) (Donaldson, 2001), the resource-based-view (RBV) of the firm (Barney, 1991), and the natural resource-based view (NRBV) of the firm (Hart, 1995) to shed lights on the sustainability practices – performance relationships. The CT states that contingencies affect organizational structure, the organizational structure affects performance, and the effects vary according to the context in which the organization operates (Lawrence and Lorsch, 1967, Thompson, 1967). In other terms, according to the CT, there is no unique or universal effect of sustainability practices on social sustainability performance. In Betts et al. (2016), internal monitoring, supplier monitoring and environmental management systems were mediators of the effect of the type of economy on sustainability performance, moderated by production capability. This paper posits that environmental uncertainty (EU) moderates the environmental practices-performance relationships. EU is a contextual variable moderating supply chain (SC) integration and operational performance (Wong et al., 2011), firm orientation, situational uncertainty and business/firm performance (Sitkin et al., 1994; Reed et al., 1996), platform strategy effects on product quality, innovation and profitability (Koufteros et al., 2005), among others. Despite its ample use in operation management practices contingency research (Sousa and Voss, 2008), the literature still fails to fully explore the moderating role of EU on the sustainability practices-performance relationships (Magon et al., 2018). The RBV and the NRBV complement the CT perspective. They help in understanding different mediating effects of the valuable, rare, inimitable and non-substitutable (VRIN) resources, such as the internal and external management practices of sustainability. Within the NRBV, resources that are rare and inimitable are deemed most important, such as pollution prevention technologies (Klassen and Whybark, 1999), and environmental management systems (e.g., Christmann, 2000).

In this context, this paper intends to answer the following research questions (RQs):

RQ1 – Do the type of economy (advanced & developing) have an effect on improved social sustainability and operational performance at the plant level?

RQ2 – To what extent do the internal, external and management environmental practices mediate the effect of the type of economy on improved social sustainability and operational performance at the plant level?

RQ3 – Are the direct and the mediated relationship between economy type and performance moderated by environmental uncertainty?

This paper contributes to filling the gap in the literature in important ways. First, it proposes the validation of a social sustainability scale, which will allow further development of causal models of sustainability practice effects on firm strategic and operational performance. Second, it tests a social sustainability scale for multi-group measurement invariance with a large international data set. Third, it offers a structural model and research hypothesis, based on CT and the RBV/NRBV theories, suggesting new research avenues. After this introduction, the next section presents the structural
model and hypothesis. The description of the methodology ensues. Conclusion and future research close the paper.

**Structural model and hypothesis**

This section introduces the key constructs guiding the research, and define the structural model and underlying hypothesis relating sustainability practices to operational and social sustainability performance.

**Internal and external environmental practices**

Sustainable manufacturing practices goes beyond the borders of the focal company in the SC. Internal sustainability management practices include sustainable new product development, procurement, production/manufacturing and remanufacturing. External sustainability includes suppliers and customers in efforts towards green and sustainable SC management (Kleindorfer et al., 2005). Yu et al. (2014) define internal Green SC management as the adoption of sustainability practices within a company, including environmental management systems and certifications (e.g. ISO 14001) and cross-functional cooperation for sustainability. External sustainability practices encompass the inclusion of the focal company’s suppliers and customers in planning and management of sustainability practices. Together, internal and external sustainability management practices should lead to improved operational and sustainability performance.

**The effect of the type of economy on sustainability performance**

Schoenherr (2012) looked into how environmental initiatives such as ISO 14000 certification, pollution prevention, recycling and waste reduction impacted the competitive operational capabilities (quality, costs, delivery and flexibility) of plants in developing, emerging and developed countries. The author concludes that environmental initiatives have been greatly emphasized in emerging economies when compared with industrialized and developing economies. Furthermore, environmental management practices were more prevalent in emerging and developing economies than in the industrialized ones.

A greater effect of environmental management initiatives on operational performance is expected in developing and emerging nations due to the contingent effect of economic development on a plant’s operational performance. Here, the location of the plant is used as a proxy to economic development, consistent with Zhu et al. (2008), Schoenherr (2012), and Betts et al. (2018). Plants in industrialized economies are more likely to have implemented sustainability management practices further than their counterparts in emerging and developing economies. Thus, a higher level of effort in applying sustainability practices would be required in industrialized economies to reach the same effect on operational performance. Therefore, the following hypothesis is put forward:

H1 – Environmental management practices’ (internal monitoring, external monitoring, environmental management systems) effect on manufacturing operational and social sustainability performance will be higher in developing economies than in more advanced economies.

**Mediating role of sustainability management practices**

The RBV posits that VRIN resources will be conducive to superior performance. Hart (1995) considers sustainability practices as being VRIN resources. It is expected, according to theory, that plants engaging in higher levels of VRIN management practices will attain higher levels of performance. Consistent with Betts et al. (2018) this research posits that sustainability management practices of internal monitoring, monitoring
sustainability practices with suppliers and the use of sustainability management systems are the “causal mechanisms” explaining how operational and environmental gains are realized. Thus,

H2 – Higher levels of environmental management practices (internal monitoring, external monitoring, environmental management systems) results in higher levels of operational and social sustainability performance

H2a – Engagement in the practices of internal sustainability management mediates the effect of type of economy on operational and social sustainability performance

H2b - Engagement in the practices of external sustainability management mediates the effect of type of economy on operational and social sustainability performance

H2c - Engagement in the practices of sustainability management systems mediates the effect of type of economy on operational and social sustainability performance

The moderating role of environmental uncertainty
Uncertainty can manifest itself as the impossibility to assign probabilities to future events or by difficulties in accurately predict the outcomes of decisions (Zhao et al., 2018). Furthermore, uncertainty may relate to market forces and to the speed of technological change. In this paper, uncertainty embraces market and technological dimensions. Based on Porter’s market strategic forces, this paper posits that uncertainty emanates from the degree of difficulty in predicting inputs and demand for products, the intensity of new competitors entering the market, the existence of substitute products, the intensity of competition, and the bargaining power of customers and suppliers. In consequence, the paper posits that:

H3 – Market and technological uncertainty moderates the relationship between type of economy and operational and social sustainability performance.

H3a - Market and technological uncertainty moderates the relationship between type of economy and sustainability management practices.

Figure 1 depicts the structural model.

Methods
Data were collected during the fifth round of the Global Manufacturing Research Group (GMRG-V) survey. The unit of analysis was the plant level and in the majority of cases the respondent was the plant manager. Table 1 depicts the sample distribution of countries by economy type.

</tr>
<tr>
<td>4. We actively monitored the long-term health of our employees at our facilities</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>S04 During the past two years, to what extent did you engage in the following activities:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. We provided major suppliers with written occupational health and safety requirements and monitored these</td>
</tr>
<tr>
<td>2. We sent occupational health and safety questionnaires to major suppliers in order to monitor their compliance</td>
</tr>
</tbody>
</table>
3. We monitored major suppliers’ commitment to occupational health and safety improvement goals
4. We conducted audits of the occupational health and safety of major suppliers’ employees

S06 Compared to the leaders in your industry in occupational health and safety management, to what extent does your plant engage in the following activities within your facility?
1. We systematically control the impact of our production process on occupational health and safety
2. We implement a systematic approach to setting occupational health and safety targets
3. We implement a systematic approach to achieving occupational health and safety targets
4. We implement a systematic approach to demonstrating that occupational health and safety targets have been met

S08 During the past two years, please indicate the extent to which your plant has performed from a health and safety perspective.
1. We have reduced the number of occupational-related accidents at our facilities
2. We have reduced the number of occupational-related injuries at our facilities
3. We have reduced occupational-related ill health at our facilities
4. We have reduced the number of occupational-related insurance claims at our facilities

Note: all items are on a seven point Likert scale (1 = “not at all”; 7 = “to a great extent”)
* Item #2 dropped due to high covariance with Item #3

Table 3 depicts the scale items for uncertainty.

Table 3 – Scale items for uncertainty

CG02 Please indicate your level of agreement with these statements on competitive environment:
1. The availability of critical inputs is difficult to predict
2. The competitive intensity in your industry is high
3. There are many substitutes in the market for your products
4. Demand for your products is difficult to predict
5. Suppliers of critical inputs have significant bargaining power
6. Your customers have significant bargaining power
7. Your industry is subject to rapid technological change
8. Your competitors are mainly local
9. Each year many new competitors enter your industry

Note: all items are on a seven point Likert scale (1 = “not at all”; 7 = “to a great extent”)

All descriptive statistics and correlations were performed with SPSS 25 and measurement invariance was tested with Mplus 8.0.

Results

The validation of the scales was conducted with exploratory factor analysis to ensure all factor loadings in one dimension only, with no primary factor loadings, no cross
loadings among factors, and no communalities (Hair et al., 2006). The results from the exploratory factor analysis using maximum likelihood estimation, varimax rotation with Kaizer Normalization are shown in Table 4.

Extraction Method: Maximum Likelihood.
Rotation Method: Varimax with Kaizer Normalization.
a. Rotation converged in 5 iterations.

Convergent and discriminant validity and common-method bias were evaluated (Hair et al., 2006). The social sustainability scale was validated for discriminant validity using the Fornell-Larcker (1981) criterion, as shown in Table 5.

Confirmatory factor analysis (CFA) was used to ascertain multi-group equivalence across advanced and developing economies and test for measurement invariance, consistent with the procedures presented in Byrne (2013). First, the baseline models were shown separately for each group, followed in a hierarchical manner by progressively more restrictive models: fully unconstrained (configural), equal factor loadings, intercepts, variances, means, covariances, and latent correlations. Table 6 depicts the results from the analysis of measurement method invariance.

Nested models were evaluated using the RMSEA Model Test and the Practical Significance Test (ΔCFI>.01)

**Conclusion and future research**

The model had an overall good fit to data. The social sustainability scales were consistent in convergent and discriminant validity, and passed the measurement invariance tests, allowing its use for multi-group analysis.

This is the first validation of the set of social sustainability scales from GMRG-V. The results set the ground for full development and application of structural causal models investigating the determinants, moderators and mediators of social sustainability performance using GMRG-V data.

Future research will be directed towards fully testing the research hypothesis outlined in the structural model of Figure 1. Hierarchical conditional process analysis (Hayes, 2013) will be applied to GMRG-V dataset for theory falsification and hypothesis tests for the moderated mediation model. This research will shed lights on the relationships between economy type and operational (costs, quality, flexibility and delivery), and strategic (social sustainability management) performance. It is equally expected that the mediating role of environmental management practices on the relationships between economy type and operational and social sustainability performance will be further tested,
as well as the moderator role of uncertainty, an under researched area in the contextual analysis of sustainability-performance relationships.

Abstract

Healthcare systems are under huge pressure to improve efficiency and quality due to increasing cost and demand. To address such challenges, there is an increasing awareness on the utilization of lean in healthcare applications, which aims to implement waste-free operational processes. Another potential approach that can be merged with lean is systems approaches, such as System Modelling Techniques (SMTs), to help identify comprehensive list of wastes in a systematic way. To investigate the potential linkage between lean and SMTs, this paper reviews the literature in the field and provides a conceptual framework for potential link between these two complementary approaches.

Keywords: Healthcare systems, Lean, System Modelling Techniques
Introduction
Healthcare organizations are under huge pressure to enhance the efficiency of their organizational operations due to high cost and demand. In line with this, effective utilization of critical resources, such as design of facilities and human resources, is imperative to provide high quality of care (Hicks et al., 2015a). To improve utilization challenges, healthcare organizations have begun to adopt a range of tools and methods that are successfully employed in other industries, such as manufacturing. From these tools and methods, there has been a growing awareness and interest in lean and systems approaches.

There is an increasing recognition in the healthcare industry to apply lean philosophy to improve the competitiveness with efficient processes since the 1990s (Aherne and Whelton, 2010; Graban, 2016; Mazzocato et al., 2010). It has been applied in particular healthcare settings in various countries (Coletta, 2012; Fillingham, 2007), and a range of tangible and intangible benefits, such as reduction on medical errors and better teamwork; respectively, have been shown in the previous studies (Ballé and Régnier, 2007; Fillingham, 2007). Despite all these benefits, still the usability and sustainability of the lean in healthcare context remains unclear, as its applications are limited to specific healthcare processes (Mazzocato et al., 2012, 2010) and lack of validation of the improving ideas with engagement of the healthcare stakeholders (Baril et al., 2016).

Earlier studies showed that stakeholder’s engagement boosts the implementation of the lean applications and sustainability. It may be considered challenging since it requires stakeholders to identify wastes in the work in which they are so invested. Recognizing that a significant number of their daily tasks is wasteful and does not add value can be difficult for them to address. Lean experts noted that by engaging stakeholders, there is a potential that they will better understand how the system works and behaves, understand each other’s roles and appreciate the future change. The continuous willingness to participate in process improvement is a good indication of stakeholder’s acceptance and satisfaction (Sibbald et al., 2009).

In addition to that, a clear process understanding leads to a more effective improvement (Spear and Schmidhofer, 2005). Lean has a large pool contains more than a hundred tools with specific characteristics and focus, such as root cause analysis, Takt time, project charter, spaghetti map, risk analysis, Kaizen, and amongst others. To visually describe and quantify the system, one of the most popular tools is the Value Stream Map (VSM). It is used extensively since most people find it much easier to understand the process if it was presented visually rather than verbally (Jun et al., 2009). It helps plot all value added and non-value added activities required to bring a specific service or product to the customer in the value chain.

The VSM helps managers and stakeholders in understanding the process, recognize the problems and identify the wastes in the system. However, there are some limitations with using VSM since it is originally created to serve lean implementation in manufacturing. The typical VSM may not always represent important support activities in the patient flow that directly affect the patient journey and process performance. In addition to that, the VSM does not present the processing of materials, such as medication, since it mainly focuses on patient flow and related information (Henrique et al., 2015). Looking at the VSM building process, it is not typical to include customer in this stage, although their voice is an important component in the improvement process, especially in healthcare system where patient-provider relation and behaviour may affect the quality of care (Ramaswamy et al., 2017a).
To describe system structure and behaviour, studies proved the effectiveness of using systems approaches, such as System Modelling Techniques (SMTs), in the healthcare industry, they can specify care in a highly visual way and enhance the understanding of caregivers which will help them in waste and risk identification comprehensively (Jun et al., 2009). So far, very limited range of SMTs has been used in healthcare, such as flow chart, sequence diagram, and hierarchical task analysis diagrams. Past research evaluated different SMTs to provide an indication regarding the potential of using them in identifying different hazards and risks affecting patient safety (Simsekler et al., 2018). However, SMTs were not evaluated in terms of their utility and usability in waste identification in the healthcare field, in particular in lean applications to identify wastes. Further, there is no clear evidence on what types of wastes can be identified by using a particular type of SMT.

In order to shed light on this, this paper reviews the application of lean and SMTs in healthcare further, and provides a conceptual framework for potential link between these two complementary approaches.

Review

Lean thinking, definition and principles

Based on the Toyota Production System (TPS), the concept of Lean aims to improve the overall operational performance of a firm by distinguishing value-added steps from non-value-added activities and eliminating all forms of waste (or muda in Japanese) (Sugimori et al., 1977; Womack and Jones, 2005). The fundamental aim of lean thinking is to transform organizational behaviour and culture over time (Smith et al., 2012; Ulhassan et al., 2013).

Lean principles firstly developed in the manufacturing industry, and have been adopted in a range of industries, including service industries and public sector organizations (Radnor and Walley, 2008; Womack and Jones, 2005). Such lean adoptions have also been experienced in the healthcare industry to better utilize the resources and improve the competitiveness with efficient processes since the 1990s (Aherne and Whelton, 2010; Graban, 2016; Houchens and Kim, 2014; Mazzocato et al., 2010).

There are various inherent trade-offs in healthcare. For instance, it can be said that quality of care is equally affected by financial resources and efficiency of resource allocation, such as human resources and space utilization (Leatherman and Sutherland, 2004; Mason et al., 2015). The utilization of human resources is vital to respond to patient demand on time with effective care. Not only human resources but also design of facilities have a huge impact on efficiency and care delivered (Hicks et al., 2015a). For instance, poor utilization of examination & treatment rooms is a huge challenge for healthcare organizations to respond to patients’ needs on time. Therefore, any solution should consider the elimination of waste by efficient distribution of all possible resources. For instance, it may be recommended to have better utilization of rooms and space in hospitals with the provision of no single patient rooms. Though this action could increase the room utilization and decrease the number of staff required, it may also cause privacy issues for some patients and increase the rate of infectious diseases. Therefore, reallocation of the resources should consider trade-offs in a structured manner to have a positive impact on patient experience and quality of care delivered.

To consider such trade-offs, Lean offers systematic approaches to develop safe, efficient and waste-free operational processes, as well as suggesting the removal of duplicate processes and unnecessary procedures (Robinson et al., 2012). For instance, (Grunden and Hagood, 2012) used a set of lean tools, such as value stream mapping, takt
time, Just in Time (JIT) and total quality management (TQM), and showed how they can be systematically utilized in healthcare settings.

The application of lean in healthcare is primarily aimed to address the increasing demands on healthcare services and provide efficiency and better quality of care delivered (Drotz and Poksinska, 2014; Joosten et al., 2009; Souza, 2009). Outcome of the lean use in healthcare showed a range of improvements on time savings, cost savings, capacity enhancements and reduction in medical errors, increase in patient satisfaction and reduction in mortality (Fillingham, 2007; Houchens and Kim, 2014; Mazzocato et al., 2010; Shannon et al., 2006). For instance, the Production Preparation Process (3P), which is part of the lean design process, has been applied in a number of US hospitals, and saved huge costs (Coletta, 2012; Nicholas, 2012; Pelly et al., 2013). Studies in the UK also showed improvement via Lean applications on better teamwork, reduction in length of stay and mortality (Fillingham, 2007). Research in French healthcare settings also showed reduction on medication errors and infection rates with the application of Lean (Ballé and Régnier, 2007).

As one important delivery of lean is to focus on value creation through waste elimination. The following type of wastes are expected to be identified through lean (Daultani et al., 2015; Ōno, 1988).

- **Transportation:** waste generated from the movement of product that are not required to perform the process. For example, sending overstocked inventory back to warehouse.

- **Inventory:** waste in result of components, work in process and finished product not being processed. For example, unused or rarely used equipment.

- **Motion:** waste produced when people or equipment moving more than what is required to perform the process. For example, people moving around searching for tools and material.

- **Waiting:** it’s simply delay, where product stays idle waiting for the next production step. For example, manufacturing process stopped waiting for component delivery.

- **Overproduction:** waste as a result of production ahead of the demand. For example, the production of component before the next station is ready to receive them.

- **Overprocessing:** waste because of doing work that doesn’t add value, usually resulted from poor tool or product design crating activity. For example, interring the same information in more than one place.

- **Defect:** waste of the effort involved in inspecting and fixing defects. For example, manufacturing parts that does not meet requirement.

- **Human potential:** waste due to not engaging employees. For example, employees do not engage and are not provided feedback for improvement.

Despite various wastes that need to be identified, there is no comprehensive study showing the particular role of VSM in waste identification. Further, the general usability, utility and sustainability of lean in general healthcare context remains unclear, as applications are limited to particular healthcare processes within one unit or department (Mazzocato et al., 2012, 2010). Many studies in the literature have a speculative character and not provided empirical evidence (Drotz and Poksinska, 2014; Poksinska, 2010). Previous studies indicated that the nature of lean appears to vary significantly from place to place. Moreover, depending on the scope of the application from a single healthcare setting to whole health system, variation has been experienced in its implementation and
outcomes (Holden et al., 2015; Mazzocato et al., 2010). Only a few implementation
efforts crossed the organizational boundaries (Mazzocato et al., 2010). While most
research so far indicated successful applications of lean interventions, only a few has
shown failed attempts or challenges in its application in healthcare (Mazzocato et al.,
2012). Overall, limited embedment of the organizational culture (Burgess and Radnor,
2013) and little evidence on the full implementation of lean activities in healthcare
applications have been noticed (Robinson et al., 2012).

System Modelling techniques (SMTs)
Enhancement efforts in healthcare generated various quality improvement
methodologies, lean is one of them as explained in the previous sections. Most of the
methods require a thorough understanding of the existing system before attempting to
implement the improvement actions. The power of process mapping in facilitating the
system understanding makes it suitable to serve this requirement (Buckle et al., 2006;
Colligan et al., 2010; Jun et al., 2009).

Varies patient flow modelling techniques are reported in the literature (Colligan
et al., 2010; Deniz and Özçelik, 2018; Henrique et al., 2015; Hicks et al., 2015b; Mazur
and Chen, 2008; Pinto et al., 2013; Ramaswamy et al., 2017b; Robinson et al., 2014).
They proved its effectiveness in better understanding the system’s operations, also it helps
in identifying various problems and improving the performance of the system. Some
methods are limited to be used for a single model and may not be expanded into a bigger
scale. Others are specified for showing the inpatient length of stay and their clinical
patient flows (Bhattacharjee and Ray, 2014). Also, the value stream map that was used
extensively in healthcare has some limitations as mentioned earlier.

Researchers were interested in investigating the effect of using a set of process
modelling methods or diagram in implementing improvements in quality, safety, and risk.
Some investigated the influence of different process mapping on quality improvement.
The authors compared between using two diagram. Results showed that the organization
of information in an external representation affects the stakeholder’s decision making.
The participant’s preference of one diagram over another depended on the context in
which they would be used (Colligan et al., 2010). Others considered wider range of
diagrams to evaluate how healthcare employees perceive the usability and utility of each
diagram (Jun et al., 2010, 2009). In more dedicated studies, the diagrams were evaluated
based on their potential in risk identification (Simsekler et al., 2018), risk identification
framework was developed based on that (Simsekler et al., 2018).

Comprehensive research on the system modelling techniques (SMTs) was carried
out in the development of prospective hazard analysis (PHA) toolkit (Ward et al., 2010).
This study reviewed number of SMTs to find their practical applicability in healthcare
particularly in safety management. The toolkit involved the common SMTs that focus on
the main element of the system; people, information, and process. The relationship
between the elements is categorized into two classes as structural and behavioural
categories. While the structural diagrams present the architecture of the system and define
its boundaries, the behavioural diagrams further expand the system description within the
defined system boundaries, it presents the details of the communication and flow of
people and information within the process. Following is the list of SMTs, where the first
three are categorised as structural diagrams, and the rest are behavioural diagrams (Ward
et al., 2010):
- **Organizational diagram**: describes the hierarchy of people and/or roles within the organization. The departments, teams, and individuals presented as nodes and the relationships as links. It is helps identify the key stakeholders in the system and define the system boundary.

- **Information diagram**: describes a hierarchy of information and/or material used in physical or electronic way. The information or document presented as nodes and the relationships as links. It is useful in understanding the documentation issues, such as the amount of electronic documents used, their link with the physical documents, and the content of each document.

- **Task diagram**: describes a hierarchy of operations (tasks) and plans, the plans present the necessary conditions to undertake these operations. The activities presented as nodes and the relationships as links. The hierarchical nature allows a detailed or brief description of the tasks based on the implementer objective, which makes it appropriate for describing the entire process as well as a specific issue.

- **Flow diagram**: it includes flow diagrams and swim lane diagrams; they describe activity occurrence in sequence or parallel. Activities presented as nodes and the conditions for moving between them as links. The key stakeholders are presented in lanes, and the activities they are responsible for, are located in their lanes. This diagram is useful in creating an understanding of the process.

- **Communication diagram**: describes information and material flows between stakeholders linked by some common process. Information and material flow presented as links and stakeholders as nodes. It is effective in describe the interactions between the stakeholders.

- **System diagram**: describes how data are transformed through activities, where the data are stored, and the sequence of the activities. This diagram is suitable in creating a collective understanding of the overall process. The diagram presents the patient state and the transition condition to transfer patient from one state to another.

**Implementation of SMTs in Lean**

In lean applications and implementation, stakeholders’ involvement and engagement have a vital importance to identify all potential wastes in dynamic and complex healthcare systems. To guide stakeholders and provide a comprehensive picture about all system-wide wastes, system modelling techniques (SMTs) can be used during the kaizen events or any other related lean applications, such as brainstorming sessions, root cause analysis, etc.

After reviewing lean implementation in healthcare and system modelling techniques, it can be said that there is a potential to implement SMTs in lean to identify a comprehensive list of wastes. With the potential integration, waste identification framework, as conceptualized in Figure 1, can be developed to navigate which SMTs can be used in the identification of particular types of wastes.
Not only SMTs but also VSM can also be evaluated to see its potential benefits and limitations in current kaizen applications, and potential contribution of SMTs to help reflect the system behaviour further for identifying system-wide wastes.

Conclusions
In lean applications and implementation, stakeholders’ involvement and engagement have a vital importance to identify all potential wastes in dynamic and complex healthcare systems. To guide stakeholders and provide a comprehensive picture about all system-wide wastes, system modelling techniques (SMTs) can be used in lean approaches, such as kaizen meetings. Future research needs to evaluate different types of SMTs in a real healthcare setting with healthcare stakeholders to see their potential impact on stakeholder involvement and particular type of waste identification.

Quality Management for High-Contact Professional Service Firms: A Multiple-case Evidence from Indian Law firms

Dr. Anupama Prashar (anupama.prashar@mdi.ac.in)

Assistant Professor, Management Development Institute, Gurgaon, India

Prof. Jiju Antony (j.antony@hw.ac.uk)

(Professor of Quality Management, Heriot-Watt University)

Abstract

This paper presents an exploratory study to understand the distinctive quality dimensions of high-contact Professional Service Firms (PSFs). The paper is based on empirical evidences from multiple cases in leading Indian law firms. The paper adopted an exploratory, multiple, embedded and comparative case study design. The empirical evidence from multiple case studies in 10 law firms was used to explore the QM dimensions for PSFs. The results showed that QM in PSFs is a multifaceted and continuous process rather than a straightforward and episodic one. The findings reveal three distinctive dimensions of QM for PSFs.

Keywords: professional service firms; quality management; service quality;

Introduction

Globally, the professional service firms (PSFs) are at an inflection point of growth, facing an ever more demanding clientele and ensuing pressures to cut prices and expand service value. For instance, the waxing client dissatisfaction with legal advisory services (or law firms) is evident from a worldwide stagnant growth in legal service demand (between negative 4% and positive 6%), declined lawyer productivity (from 134 to 122 billable hours) and reduced collection realization rates (from 94.6% to 89.1%) during the past decade (Georgetown Law & Thomson Reuters Legal Executive Institute, 2017). Yet, there is limited Service Operations Management (SOM) research to investigate what PSFs should do, and how they should be managed to achieve superior quality (Jayaram and Xu, 2016; Lewis and Brown, 2012; Goodale et al., 2008, Zhao et al. 2004; Harvey, 1990). The established service quality literature ascribed the inconsistencies in
PSFs’ service outcome to their emblematic operational characteristics viz. knowledge intensiveness, professional autonomy, altruism, self-regulation and customization (Lovelock, 1983; Schmenner, 2004). However, lately, even the most autonomous services of medical practitioners (Sabella et al. 2014), accountants (Jeffords and Thibadoux, 1993) and engineering designers (Boone, & Ganeshan, 2001) have recognized the economic benefits of a systematic implementation of customer-focused quality management (QM) systems and practices (work measurement, coaching, employee training and reward system to name a few) that have paid manufacturing sector off in a big way in the past (Flynn et al., 1994).

Considering the academic research on QM in PSFs, the recent editorial note for the special issue of Journal of Operations Management (JOM) on “Professional Service Operations Management” (Harvey et al. 2016) emphasized the role of client awareness and precision in the recognition of relevant service quality attributes. The authors also highlighted the role of proxy indicators of quality (such as partnership-based organization structure) in the firm’s service quality assessment. Additionally, the need for managing the network or interactive quality during the extended service delivery process typical to PSFs was also highlighted. A large part of service quality research on professional services is into modelling the client’s expectation-perception gap (Parasuraman et al., 1988; Zeithaml, 1988). There has been little focus on how PSFs should be managed to achieve superior quality (Zhao et al. 2004). A process-focused research for exploring such service provider’s activities, procedures and behaviours that drive the client’s expectations and/or perceptions during the extended service delivery process in professional services is scant in the literature (Svensson, 2006). Therefore, this paper presented an exploratory study to understand the distinctive quality dimensions for professional services followed by the development of a conceptual model for QM in PSFs. The study used empirical evidences from multiple case studies in law firms to examine the QM practices in high-contact PSFs. The study was narrowed down to a specific professional service sector (legal advisory services) in line with the past research (Brandon-Jones et al. 2016; Lewis and Brown, 2012), which established that sector-specific insights played a crucial role in deriving competitive advantage in professional services. Given the exploratory nature of the research, the study adopted multiple, embedded (Yin, 2003), and comparative (Dul and Hak, 2008) case research design to achieve the research objectives. This
qualitative research design was suitable to gain a holistic (systematic, encompassing and integrated) view of the context of study.

**Literature Review**

*Distinctive characteristics of PSFs and associated QM challenges*

PSFs are conceptualized as one service category in generic service typologies in the service marketing literature (Silvestro et al., 1992; Schmenner, 2004). For PSFs, these typologies have emphasized some shared operational characteristics such as high level of customer contact and labour intensity (Lewis and Brown, 2012). However, these typologies fell short in recognizing the distinct QM and operational (control) challenges related to programmability of tasks and measurability of outcome faced by various professional service providers (Goodale et al., 2008). Harvey (1990) emphasized that unlike other service firms, the nature of operations management decisions in PSFs are driven by the relative power of the three stakeholders i.e. the professionals, the clients and the top management (firm). In a study based on the evidences from a specific PSF setting (law firms), Lewis and Brown (2012) emphasized that unlike other service categories, in PSFs the professional-client exchange is asymmetrical and required varying degree of customization in process design for different clients; there are less variables involved in the processes, creating an opportunity for commoditization; and the notion of professional identity greatly influences the efficiency of a PSF. Based on an empirical investigation in Management Consulting firms, Brandon-Jones et al. (2016) demonstrated the need for a contingent approach towards management of operational quality in PSFs. The authors showed that both the firm-level (scale of operations, degree of specialization) and individual-level (leverage, partnerships) characteristics impact the planning and control of the professional service quality.

Researchers have extensively discussed the QM challenges in PSFs using theoretical and conceptual research approaches (Fischer et al., 2014; Goodale et al., 2008). Some of these challenges are high process variability (due to high level of customer contact); limited scope for standardization and automation (due to high level of customization and knowledge intensity of the processes); input/output based operational planning and control measures (hours billed instead of process measures); and limited emphasis on the internal quality monitoring (due to strong
influences of explicit code of conduct and implicit norms). Further, defining the direct QM measures for PSFs can be tricky due to disparate quality evaluation criteria adopted by the service provider and receiver (Haywood-Farmer and Nollet, 1994; Lehtinen and Lehtinen, 1991). Therefore, it is important for the professional service providers to understand the direct and indirect QM indicators and manage them effectively to warrant a satisfying client experience.

**Research Methodology**

The purpose of this exploratory study was to develop a conceptual model for QM in high-contact PSFs. Adoption of a qualitative research design was appropriate for the early stages of theory-building to achieve the research objective, considering the limited research done so far on the complex phenomena of QM in PSFs (Miles and Huberman; 1994; Siggelkow, 2007; Eisenhardt, 1989). The paper used multiple, embedded and comparative case-study research design (Yin, 2003; Dul and Hak, 2008; Silverman, 2002).

**Case Selection**
This study was conducted in the Indian legal service sector. The Indian legal advisory service sector is world’s second largest legal market (in terms of number of lawyers with 1.3 million lawyers) and is currently preparing for opening-up to foreign legal professionals (INBA, 2017; Chinna, 2012). For the exploratory study, the Indian legal sector was represented by 10 leading law firms with leverage ratio (i.e number of non-partner lawyers to equity/salaried partners) of 8.5 to 3.3. All the selected firms were general partnership firms known for Corporate & Business Law advisory services (though these firms also offered advisory in mergers & acquisitions, insurance, tax, and capital markets) and were ranked in band 1 & 2 (law firm ranking from 1-6, 1 stands for best; ranking is based technical ability, professional conducted and other quality attributes) by Chambers and Partners (Chambers and Partners, 2017).

Data collection and analysis
The data was collected at multiple points in time in the selected case settings during the fall of 2017. The primary method of data collection was semi-structured or standardized open-ended interviews (Rubin and Rubin, 1995) using an interview protocol as the instrument. For a detailed description of case findings, multi-stage data processing and analysis process, suggested by Miles and Huberman (1994) was adopted.

Findings
The major findings regarding the design of QM activities in the case studies are summarized in Table I and Figure 2.

6
Discussion and Conclusion

Broadly, the empirical findings showed that the unique personnel (lawyer) and organizational characteristics of law firms make QM a multi-dimension and continuous effort rather than a straightforward and episodic process. This observation is in line with (Ritsema et al. 1992) the definition of professional service quality as a process of continuously meeting the specification agreed by the client and the professional, considering the efforts and anticipated outcome, and incorporating all the self-evident needs of both the parties. Additionally, the findings also support the observation by Harte and Dale (2005) that it is difficult to define quality measures and controls in professional services because of their highly intangible, labour intensive and customer-centric nature.

It was substantiated that external image/reputation (corporate quality), internal client interface & support process/procedures (interactive quality) and perceived value for monetary and non-monetary costs (physical quality) broadly cover the complete scope of quality management in PSFs (Lehtinen and Lehtinen, 1991). Further, for managing the corporate quality, the findings illustrated that projection of firm's 'corporate image' should be targeted especially at the client-market served (global and domestic corporate clients...
in these cases) with thorough understanding of the competition. This observation is aligned with the argument by Jääskeläinen and Laihonen (2014) that lack of awareness about the alternative service providers makes the 'image and reputation' crucial in client's selection of professional services. In fact, managing partner in one of the firm with international reputation explicitly endorsed "the need to work on developing a brand identity" to attract corporate clients worldwide. Additionally, a great degree of creativity and diversity was observed in firm's choice of image-building solutions, owing to the regulatory restrictions on legal advertising (in India) (Figure 2). This observation is in line with Nachum's (1999) proposal that creativity and reputation are variables that drive a PSF's competitiveness. The observed solutions for image-building were not only driven by senior management (firm representation in prominent forums by partners) and dedicated internal teams (practice development team working on continuous personnel engagement) but also steered by specialized external professional (external PR arranges and realizes publicity opportunities for the firm). On the content of corporate image building activities, endorsement of firm's legal acumen (trainings/workshops on recent statute, representation in law conferences) emerged as the primary agenda followed by highlighting the social responsibility endeavours (pro-bono work in association with NGOs).

This paper contributes to the SOM theory by focusing on the operational quality aspects in PSFs from service provider’s perspective, which was mainly explored from customer’s perspective, so far. The paper contributes proven QM attributes and dimensions for PSFs to the existing knowledge base on operational control and QM issues unique to professional services (Brandon-Jones et al. 2016; Lewis and Brown, 2012; Holschbach and Hofmann, 2011, Goodale et al. 2008). An indirect control on firm’s image through a constant engagement of professionals (people outside the marketing function) emerged as the primary dimensions of QM in PSFs (Cameran et al. 2008). Further, the findings showed that an effective design of service encounters in PSFs is achieved through instilling tangible and intangible components in the client-interaction (including both front-end and backend aspects) (Ponsignon et al., 2011; Svensson, 2006). Finally, due to the ambiguity in the definition and scope of service outcome in PSFs, managing the perceived value of services vis-a-visa costs (and efforts) is crucial for these firms (Lapierre, 1997).

Abstract

This paper aims to present challenges of quality management in cross-cultural settings and suggest possible handling strategies for quality managers based on a multiple case study. The result suggests that management leadership, employee engagement and empowerment, and continuous improvement are the QM values affected the most by national culture of subsidiaries. However, the degrees of discrepancy depend on the strength of organizational culture. Hence, the suggested handling strategy is to educate employees with standardized QM techniques and tools to establish means and measures for QM values that are promoted via strong organizational culture focusing on quality and customers.

Keywords: cross-cultural management, quality management, multinational company

Introduction

Quality management (QM) has been known as a strategy to establish, improve and sustain quality of products and services (e.g. Flynn et al., 1995; Weckenmann et al., 2015). QM is based on a set of values such as management commitment and leadership, customer focus, employee engagement and empowerment, continuous improvement, process management, and decisions based on facts (Sousa and Voss, 2002). These values are basics for QM practices or techniques that are supported by tools (Dean and Bowen, 1994; Hellsten and Klefsjö, 2000; Kim et al., 2012). Many studies have indicated that the way an organization perceives QM values and uses QM techniques and tools depend markedly on culture (Hellsten and Klefsjö, 2000; Prajogo and Sohal, 2006; Gambi et al., 2015). Therefore, culture influences the perception of QM values and the practice of QM.

As companies nowadays go beyond national borders, their multinational settings are complex with high cultural diversities. Subsidiaries are a part of the company networks having the company’s organizational culture, but they are as well embedded in local contexts shaped by national culture (Drogendijk et al., 2010; Schotter and Beamish, 2011). Since culture affects how people think, feel and act (Hofstede et al., 2010), employees with different national cultural backgrounds tend to have different expectation and understanding toward the same values (Brislin, 1993). As for QM, there is a tendency that employees in subsidiaries might understand the concept of quality, perceive QM values, practice QM techniques and use QM tools differently. This may cause issues of mismatch quality levels – such as higher defect rates, uneven product quality, and unstandardized processes between the subsidiaries creating challenges for quality managers (Vecchi and Brennan, 2009; Barouch and Kleinhans, 2015). According to
Thiagarajan and Zairi (1997), employees in the company must have a shared understanding of QM values leading to common practices to effectively manage quality. Therefore, the purpose of this paper is to explore challenges of QM in cross-cultural settings of multinational companies and to suggest possible strategies for quality managers to handle those challenges.

**Theoretical framework and conceptual model**

*Culture*
Culture is defined as “the collective programming of the mind which distinguishes the member of one group or category of people from another” (Hofstede et al., 2010). It influences individual behavior and the interpretation of other people's behavior (Spencer-Oatey, 2004). Schein (2010) defines three levels of culture: underlying assumptions, espoused values and artifacts. The underlying assumptions are common beliefs and values in a group that are difficult to change. They actually guide behavior and tell the group members how to perceive things. Espoused values can be seen as a result of group learning. It is a shared beliefs and values that have been proved to be accepted by the group members such as strategies, goals, or philosophies. For example, if a manager successfully convinces the group to act according to the strategy, and if it works well in reality so that the group has a shared perception of this succeeded strategy; then this strategy starts transforming into the group’s espoused value. Finally, the artifacts are at the surface level and can be seen, heard and felt. They are, for example, organizational structure, processes, or products of the group.

According to Schein (2010), these three levels of culture are mutually depended. The underlying assumption is the essence of a group’s culture influences espoused values and reflect into the observable artifact on the surface. On the contrary, artifact can gradually affect the espoused values which might finally transformed into the underlying assumption in some cases. However, this transformation is not common and usually takes long time.

*Quality management (QM)*
QM is a management strategy consisting of technical and social aspects (Sousa and Voss, 2002; Vecchi et al., 2011). The technical aspect consists of methods and tools focusing directly on product and process quality such as process management tools, measurement method, and statistical process control (Flynn et al., 1995; Fotopoulos and Psomas, 2009; Vecchi et al., 2011). On the other hand, the social aspect is related to people and organization as a set of values creating environment to support effective use of the technical one (Flynn et al., 1995; Fotopoulos and Psomas, 2009; Vecchi et al., 2011). These social and technical aspects of QM cannot be performed separately, as they are interrelated and mutually support each other (Anwar and Jabnoun, 2006).

However, the general issues of sustainable QM adoption in organizations are those related to the social aspect. Previous studies show that the foundation of common QM practices based on a shared understanding of QM values that are uniformed across culture will facilitate sustainable QM adoption (Vecchi et al., 2011). Therefore, it is important for a company to establish a shared value of QM throughout their multinational settings. Based on literature review, these are the common QM values adopted in this study.

- *Management commitment and leadership* aim at managers to emphasize on quality and quality management, to set up quality strategies and to promote them throughout the whole company (Flynn et al., 1995; Lagrosen, 2002).
Management is expected to provide support and resources for activities such as employee training and continuous improvement (Flynn et al., 1995).

- **Customer focus** implies that organizations always focus and try to fulfill customer needs (Dean and Bowen, 1994; Lagrosen, 2002). Customers can be viewed as two different kinds: external and internal. The external customer usually means the end customer outside the organizational boundary, while the internal customer refers to the next process step down the line of work (Bergman and Klefsjö, 2010).

- **Employee engagement and empowerment** promote the idea of giving quality responsibility to the employees, not just to the quality department (Lagrosen, 2002). Employees can design and make decisions about their own tasks (Dean and Bowen, 1994) and supervisors function more as coaches than controllers (Anderson et al., 1994).

- **Continuous improvement** means everybody improving, everywhere and every day (Imai, 2012). Organization must always strive to improve products, services or processes for better performance (Bessant et al., 1994; Lagrosen, 2002). It needs to be managed strategically as a continuous process with a clear framework and supportive infrastructure such as flatter organizational structure, employee involvement and empowerment, and scientific approach to decision-making (Bessant et al., 1994).

- **Process management** as a value refers to how company organize and develop its structure based on a chain of activities creating values for customers (Lagrosen, 2002; Bergman and Klefsjö, 2010). Improving one process step would impact the other, leading to higher performance of the whole organization (Dean and Bowen, 1994).

- **Decisions based on fact** indicates that decisions should be made based on systematically gathered and analyzed information (Dean and Bowen, 1994). Several QM methods and tools can be used to support the data collection and analysis – e.g. checklist, statistical process control (Bergman and Klefsjö, 2010).

**Quality management from a cross-cultural perspective**

Previous research in cross-cultural QM shows that culture and QM are related. At national level, many studies reveal that QM perception and practices varies across countries which might be implied as a result of national culture differences. For example, Mathews et al. (2001) studied QM practices in UK, Finland, and Portugal, and found some differences that could be related to national culture in the way QM was adopted in each country. Lagrosen (2002) suggests that meaning of quality and problems concerning quality are differences in different country, and they tend to have diverse strategies to overcome the problems. In terms of cultural dimensions, power distance and uncertainty avoidance (Hofstede et al., 2010) are the dimensions that seem to mainly affect national differences of QM (Mathews et al., 2001; Lagrosen, 2002). However, several studies present different QM values that tend to be influenced by national culture. Flynn and Saladin (2006) suggest that leadership, employee engagement and empowerment, process management, decision based on facts are the QM value that have correlations with dimensions of national culture. According to Lagrosen (2003), customer focus, process management and continuous improvement are the most influenced by culture. Moreover, Vecchi and Brennan (2009) suggested that some cultures are more suitable to implement specific quality program. Therefore, company should develop quality strategy that can be
effectively adopted in any local culture and then adapt their quality practices to the local national culture of the subsidiaries.

Conceptual model
The conceptual model of this paper is presented in Figure 1. The underlying assumptions are seen to be influenced by national culture of each subsidiaries. The espoused values related to strategies, goals and philosophies are represented by QM values, while the artifacts at the surface level are linked to QM tools and techniques that can be clearly seen in the company and working processes.

![Conceptual model of the paper based on Schein (2010)](image)

The model suggests that national culture of subsidiaries influences the employees’ perception of quality and understanding of QM values which in turn have an effect on the use of tools and techniques to practice QM. Therefore, there might be discrepancy between subsidiaries of the same multinational company situated in different countries in QM values and practices. Nevertheless, as artifacts can slowly influence espoused values that might finally transform into underlying assumptions (Schein, 2010), there is also a chance that standardized use of QM tools and techniques in multinational settings might induce common understanding of QM values creating a unified quality culture in an organization. This quality culture can act as a strong organizational culture that might overcome the differences stemming from national culture.

Methodology
The paper is based on a multiple case study in a manufacturing sector. The data was collected via semi-structured interviews with quality engineers, managers and directors in seven multinational companies, resulting in total 11 interviews. The interview questions were designed based on various QM values and practices to discuss the interviewee’s experiences of working with quality management in a complex cross-cultural setting of multinational company. Besides, some related documents were studied – e.g. company annual reports, quality strategy documents, meeting presentation.

The collected data were analyzed using qualitative content analysis (Corbin and Strauss, 2014). The first step was to identify differences and similarities of perception of quality and QM values, as well as how employees in different subsidiaries of the same multinational company practice QM, and use various QM methods and tools. Then, the advantages and challenges of cross-cultural QM were determined. Finally, the strategies to handle those challenges were suggested.
**Case company descriptions**
As the cultural influences could come from either national or organizational culture, the case companies were carefully selected to represent multinational companies with manufacturing subsidiaries in different countries. Consequently, in each case company, the organizational culture could be predicted to be a common culture of the global company, while the cultural differences were expected to be stemming from the local national culture of each subsidiary. The case companies vary in terms of products, size and time on the market, as shown in Table 1, representing a diverse group of samples.

**Empirical findings**
Based on the interviews, all companies claim to have strong focus on quality and substantial experiences with quality management. However, they have different levels of international experiences. *Omega* and *Mu* are small companies that do not have long experiences in working globally. They have not yet established close collaboration between subsidiaries and their organizational cultures is rather weak. For example, there is no globally standardized quality strategies in *Omega*. The subsidiaries have been operated quite separately because the management thinks it is easier. On the contrary, in the large companies with long history – company *Alpha*, *Gamma*, and *Phi*, they have more experiences in internationalization and the organizational cultures are much stronger. For example, in *Phi*, they setup global quality strategy every year which is broken down to each business unit and department. As for company *Beta* and *Delta*, they are somewhere in the middle. Although they are younger than both *Omega* and *Mu*, they have more international experiences.

**Perception of quality and QM values**
In *Alpha*, *Gamma*, and *Phi*, the interviewees claim that perception of quality among employees in various subsidiaries are quite the same. Although there are some differences in *Phi*, the interviewees explain that the deviation is very small compared to the local society outside the company. Regarding to *Beta* and *Delta*, they work with quality quite differently in various subsidiaries. For example, quality is self-responsible by the production teams in some subsidiaries of *Delta*, while it is still traditional control with sampling check by quality department in some other. The interviewee thinks this is partly
because of cultural differences that employees do not have the right perception of quality and QM values to take responsible for quality by themselves, so that they still need to do this quality control in those subsidiaries. Moreover, the interviewee from Mu express that employees from some countries have difficulties in understanding the concept of QM.

Regarding management commitment, the studied companies have not experienced differences in this QM value. However, leadership style is influenced by local national culture of the subsidiaries as stated by all the interviewees. In Phi, managers need to locally adapt how they lead people to fit local culture and organizational settings of the subsidiaries such as hierarchical structure. However, the differences in leadership style among subsidiaries can be mitigated by moving around management between the headquarter and the subsidiaries to learn about each other’s local culture and organizational settings, as well as promote and strengthen the common organizational culture. Moreover, the company try to establish the mindset for the leaders to accept the diversity of national culture.

Based on the interview, all companies try to setup strong focus on both internal and external customers. However, there are different levels of customer focus in Mu and Omega. For Mu, the main reason is because they have not yet tried to cooperate between subsidiaries, so the internal customer focus is rather low. In Omega, employees in some cultural backgrounds take product specification for granted. They think it is just slightly outside the specification and will not harm the customers. In other cases, they have not experienced big difference in customer focus as a value between subsidiaries. However, there are differences at practical level in terms of management of customers, such as personal contact in customer service and complaint handling, in Beta. Though employees in both Delta and Phi seem to have different pictures toward external customers, the interviewees state that it depends more on their distance to the customers rather than culture.

In all cases, levels of employee engagement vary among the subsidiaries, but at different degrees. The interviewee from Alpha stated that national culture influenced employee engagement, especially the dimension of power distance. This view is agreed by the interviewees from Beta, Delta and Gamma. They think that employee empowerment significantly affects engagement. In Mu, despite the same level of commitment, there are differences in employee engagement due to different norms, perception of quality and understanding of QM values. At Phi, management needs to understand local culture and hierarchical structure of the local organization in order to create a proper working environment for the employees to enhance their engagement. Therefore, employee engagement and empowerment are closely related to the leadership style of management. The leaders are trained to deal with power distance and hierarchical structure by trying to be open-minded and give positive feedback to quality problems and promote quality in the suitable way. Also, they try to delegate, involve and give responsibilities to the employees in the line organization to empower them and make them feel engaged. An interviewee from Phi accept that this process of empowering and engaging employees is more difficult in some cultures, but Phi tries to overcome these national culture obstacles using strong and unified organizational culture.

Since all the case companies have some experiences in QM, they have established routines to systematically collect information and analyze data. However, there are still differences in decision making process in terms of formality and to which degree the employees should make decisions on their own without escalating the issues to supervisors or managers, as seen in Gamma, Phi and Omega. Consequently, Beta, Delta and Phi provide a lot of training in quality techniques and tools so that the employees have knowledge to deal with quality issues and can make decision by themselves to some
extent. Also, Phi tries to standardize decision making processes and set standards for all the subsidiaries. Yet, there are still some differences in solving small quality problems, while the severe cases are more of the same practice.

Continuous improvement is promoted everywhere in all companies. Nevertheless, there are differences in the practices among subsidiaries, for example, how to share ideas, how the continuous improvement events are organized or how to manage change caused by improvement. Special reward and competition are used in some cases. For example, they set up monthly improvement competition between subsidiaries to urge continuous improvement at Mu. Delta needs to have special rewards to employees in some subsidiaries in order to promote continuous improvement and encourage idea sharing. On the contrary, this special reward has been seen as a counter-productive solution for continuous improvement in Phi and they had stopped doing it quite a long time ago. Instead, they treat continuous improvement as a part of the working task that every employee needs to perform. It is not an extra event, but a part of the working routine. The interviewees from Alpha and Gamma agreed that culture influenced continuous improvement, especially the dimension of power distance, in connection with employee engagement and empowerment.

As for process management, all companies except Mu have strong focus on processes and quality methods, and they promote standardized process maps in all subsidiaries. Yet, there are small differences in how subsidiaries are more process- or result-oriented. Interviewees from Beta, Gamma and Phi similarly agree that some culture tend to focus more on processes while other are more result-oriented. As a result, employees from various cultural background collaborate differently, but it is important on how they try to accept the diversity and understand each other.

Challenges and possibilities of cross-cultural QM
Some challenges have been pointed out by the interviewees. Both interviewees from Beta and Mu express that it is hard to standardize a joint view of quality and to perform up to the same quality level in all subsidiaries. This relies heavily on how the employees perceive the quality concept and QM values, and then how they practice and work using methods and tools to ensure the same quality level. Also, it is challenging to engage and motivate employees with different cultural backgrounds to understand and accept the diversities and see the benefits of working together, as stated by interviewees from Delta and Gamma. Lastly, it is ambitious for Phi to create strong organizational culture and promote it globally especially in this rapid changing world.

Although there are many challenges in cross-cultural QM, some possibilities are mentioned. All interviewees agree that the diverse cultural backgrounds of employees provide different ways of thinking and solving problems. It also gives a lot of inspirations and good discussions in Delta, Gamma and Phi. Moreover, new values and traditions enter the company by themselves through this multinational setting. Even though they might take more effort in training employees in some subsidiaries due to their cultural backgrounds, there are also chances to develop the employees as well as learn from each other.

Analysis and discussion
The findings suggest that leadership, employee engagement and empowerment, and continuous improvement are the QM values that seem to be affected mostly by national culture of subsidiaries. Differences in these three QM values have been experiences in all the case companies, just with various degrees. Moreover, they are the QM values that are directly related to people and closely correlated with each other. Precisely, continuous
improvement substantially relies on employee engagement and empowerment enhanced by management leadership. This result partially supports both Flynn and Saladin (2006) and Lagrosen (2003). Decision based on facts suggested by Flynn and Saladin (2006) to have correlations with national cultural dimensions does not have significant differences in terms of values, but rather in practical level of decision-making process in this study. For customer focus, the difference seems to be stemming from distance to end customers rather than culture which is not in line with Lagrosen (2003).

These discrepancies in perception of quality and QM values are mutually dependent, as QM values are intertwined (Anwar and Jabnoun, 2006). For example, the need for different management styles in various subsidiaries could lead to different level of employee empowerment and engagement. Then, different levels of employee engagement and empowerment affect how the employees solve quality problems, and how they perform improvement work. Consequently, subsidiaries might try to locally cope with the issues resulting in even bigger discrepancy at the artifacts level, such as different hierarchical structures and various rewarding systems to enhance employee engagement in continuous improvement. This sub-optimization might be beneficial in a short run as it leads to the desired results, but it creates wider gaps between the subsidiaries at both values and artifacts levels. Hence, the challenges in cross-cultural QM arise from national cultural differences between subsidiaries affecting the understanding of values and reflected in the tools and techniques as shown in figure 2.

![Figure 2 – Model of challenges in cross-cultural QM and suggested handling strategies](image.png)

Nevertheless, the differences in each QM values vary significantly between the case companies, mostly due to how strong their organizational cultures are. Companies with less experiences in internationalization and weak organizational culture have more differences in perception of quality and understanding of QM values, as well as practices of QM tools and techniques. They also face bigger challenges in establishing a joint view of quality and to ensure the same quality level among subsidiaries. As for the companies with high experiences, they have been focused on training of QM tools and techniques to setup the same understanding of the technical aspects of QM in all subsidiaries. Then, they sustain the standardized use of the QM tools and techniques by unified organizational culture. One strategy is to rotate leaders, mostly at top management level, among the headquarter and subsidiaries to learn and adapt leadership style, as well as promoting the same perception of quality and QM values. Moreover, these rotating managers act as agents transferring QM practices and values, and contribute to the creation of strong quality culture throughout the whole company.
Therefore, the possible strategy for companies to handle cross-cultural challenges in QM is to focus on tools and techniques. This is illustrated with the green arrows in figure 2. Employees in all subsidiaries need to be trained about the standardized QM tools and techniques to establish means and measures for practicing QM values, which also act as a supporting structure for the whole QM system. Regarding QM values, a strong focus on quality and customer can be used as a basis for building strong quality culture throughout the whole company. This strong quality culture as an organizational culture together with the supporting QM tools and techniques is suggested as a strategy to mitigate national cultural influences at subsidiaries.

Conclusion

There are differences in perceptions of quality and QM values between subsidiaries situated in various countries that can be stemming from national cultural differences. These discrepancies lead to different practices of QM techniques and tools that might result in mismatch levels of quality between subsidiaries, creating challenges for quality managers in cross-cultural settings. Based on the result, the most affected QM values are management leadership, employee engagement and empowerment, and continuous improvement. These three QM values are directly related to people and strongly contingent on each other. However, the degree of differences varies from company to company based on the strength of organizational culture focusing on QM. In the companies with strong quality culture, the differences seem to be rather small in perception of QM values and appear mostly at practical level such as how to organize continuous improvement work. On the contrary, companies with weak quality culture face bigger challenges stemming from various perceptions of QM and unstandardized practices of techniques and tools.

Based on Schein (2010), the possible strategy to handle QM challenges in cross-cultural settings is suggested. Multinational company should focus on QM tools and techniques by standardized them throughout the whole company and provide substantial training to the employees in all subsidiaries. This will act as a supporting structure for the QM system, establishing means and measures for QM values. In order to promote strong quality culture, QM values must be made clear to all employees in all levels. Moreover, one strategy to mitigate national cultural gap is to rotate managers between headquarter and subsidiaries acting as agents promoting quality culture in the global organization and transferring common QM practices and values in between subsidiaries.

Revisiting the linkages between safety and quality in manufacturing firms: a thematic literature review and research agenda

Tri M. Tran (tri.tran@aalto.fi)
Department of Information and Service Management
Aalto University School of Business, Espoo 02150, Finland

Abstract
This paper provides a thematic literature review on occupational safety, quality, and the linkages between safety and quality. Quality is a well-developed concept in Operations Management (OM) and there exist numerous quality management programs and frameworks. Occupational safety is an established concept in safety literature, yet there are only a few studies in OM literature on safety. The reason for the oversight of safety in OM literature is speculated to be the absence of linkages between safety and competitive constructs (e.g. quality, productivity). This paper aspires to call attention to and spark interest in safety research in OM literature.

Key words: quality, safety, operations management

Introduction
Employee and employee involvement are widely recognized as a critical factor in quality management and quality improvement, noticeably through the concept of quality circle (see e.g. Reddy & Berger, 1983; Snee, 1986; Takeuchi & Quelch, 1983; Walter, 1983) and Deming’s 14 principles for effectively managing quality in the organization (Deming, 1981, 1982, 2000). Worker involvement in continuous quality improvement activities (e.g. recognize problems on the shop floors as they occur) is a determining factor of well-run quality management programs. However, employees must be motivated to participate in these activities. As safety is a basic need, motivational theories suggest that worker perceptions about workplace safety will play a key role in creating or prohibiting this motivation (see e.g. Argyris, 1957; Kaminski, 2001; Murray, 1938). Nevertheless, with a few noticeable exceptions (e.g. de Vries et al., 2016; de Koster et al., 2011), the role of employee safety in operations management (OM) has been overlooked. Furthermore, Brown’s (1996) proposition to include workplace safety among the competitive priority constructs (i.e. quality, cost, delivery, flexibility) until this day remains largely unanswered.

Consequently, despite tremendous technological advancement and Industry 4.0, the increases in fatal work-related diseases and fatal occupational accidents during the period 1998-2015 are alarming. It is estimated that there are more than 7,500 job-related deaths every day: 1,000 from occupational accidents and 6,500 from work-related diseases (Hämäläinen et al., 2017, p. 11). One of the possible reasons for such inconceivable increases
is the fact that many corporate decision makers still see safety as an annoying cost or an inevitable regulatory threat (see e.g. Brown, 1996; Das et al., 2008). Until corporate decision makers are convinced of the competitive benefits of employee safety, this problem will persist. As a response to such issue, OM literature has theoretically linked employee well-being and operational performance (Brown et al., 2010; Das et al., 2008). Specifically, Das et al. (2008) establish a theory of the linkages between safety and quality. Nonetheless, empirical tests of these linkages are “surprisingly absent” in OM literature (Pagell & Gobeli, 2009, p. 281).

This paper aims to voice support for Brown (1996)’s seminal call for more safety research in Operations Management and aspires to advance her proposition to include occupational safety among competitive priority constructs.

**Literature review**

1. **Human resources in quality management**

Employees and employee involvement have long been among the most critical factors of quality management programs and are featured widely in quality literature. By the end of 1980s, many prominent quality researchers have identified employees as a critical factor of quality management. Saraph et al. (1989) synthesize earlier quality literature and identify employee training, employee relations, and employee participation in quality data collection and reporting as three of the eight critical factor to quality management in both manufacturing and service sectors. Among those numerous quality gurus that emphasize the significance of employees and employee involvement in quality management by the end of 1980s, Kaoru Ishikawa is considered by Saraph et al. (1989) the leader in highlighting employee participation and quality circles. Ishikawa (1976) emphasizes total quality control and stresses the importance of training supervisors and employees to improve quality. Philip Crosby is also best known for his people-oriented issues in quality management (Saraph et al., 1989). Crosby (1979) demonstrates his proponent of the cultural and behavioral aspects of the quality management process, for e.g. employee motivation and rewards. Leonard & Sasser (1982) also endorse open participation by employees in quality improvement and emphasize employee training and development. Adam et al. (1981) adopt an organizational theory perspective toward quality that also includes employee training and employee relations. Reddy & Berger (1983) suggest an independent product assurance group that is staffed by cross-functional employees. The well-known Deming’s 14 principles for effectively managing quality in the organization prescribes the removal of barriers to employee participation and teamwork, the removal of numerical goals and quotas for employees, underlines effective communication between foremen and employees, and endorses companywide training and education in quality (Deming, 1981, 1982, 2000). Since the 1990s, an increasing number of companies have focused on improving business processes through comprehensive adaptation of total quality management (TQM) to the entire organization (Tanninen et al., 2008). More recently, Kaynak (2003) reviews literature on TQM, identifies the relationship between TQM practices, and studies the direct and indirect effects of these practices on different performance levels. Accordingly, employee training, employee relations, and employee involvement in quality management practices are still
featured prominently in more recent quality literature, namely: Flynn et al. (1994), Ahire et al. (1996), Black & Porter (1996), and Malcolm Baldrige Award (Criteria for Performance Excellence, 2002).

2. Occupational safety
Workplace safety as a thematic focus is well-represented in applied psychology, organizational behavior, business ethics, and safety research journals. For e.g., Barling et al. (2002) study how safety-specific transformation leadership predicted occupational injuries. Ansari & Moderress (1997) illustrate best practices in safety at Boeing. Smith (1995) discuss safety management and its empirical effects at a Baldrige award-winning company. Among different aspects of occupational safety, employee perception of occupational safety, more specifically safety climate (from the employee side), and safety-specific transformational leadership (from the manager side) attract attention from safety scholars.

2.1. Employee perception of safety
Employee safety perception is a well-established concept and one of the main components of occupational safety literature. Three key dimensions of employee safety perception in safety literature are: (i) employee perceptions of supervisor safety practices, (ii) employee perceptions of managerial attention to safety, and (iii) employee perceptions of formal safety procedures and information dissemination (Hofmann & Stetzer, 1998; Zohar, 2000; Katz-Navon et al., 2005; Das et al., 2008).

Safety climate denotes employee perceptions of the organization’s policies, procedure and practices concerning occupational safety (Barling et al., 2002). According to Griffin & Neal (2000) and Neal & Griffin (2002), perception of safety climate predicts safety knowledge and motivation. Moreover, Hofmann & Stetzer (1996) also find that perception of safety climate predicts safety behavior. Cree & Kelloway (1997) find that employee perceptions of managers’ and supervisors’ commitment to safety are strongly related to perceived risk and willingness to participate in safety programs. The direct impacts of employee perceptions of safety on actual safety performance are also demonstrated in a growing body of literature (e.g. Wallace et al., 2006; Zacharatos et al., 2005; Hyekye, 2005; Cooper & Phillips, 2004; Zohar 2002; Oliver et al., 2002; Barling et al., 2002; Brown et al., 2000; Hofmann & Stetzer 1998; Zohar, 1980).

Evans et al. (2005), in a study of wood manufacturers, find an indirect relationship between quality perceptions and safety performance through productivity perception. Accordingly, employee quality perceptions are negatively related to their productivity perceptions, which in turn negatively correlated with safety performance. Aside from this notable exception, there has not been much research on how safety climate affects competitive factors (Das et al., 2008).

2.2. Safety-Specific Transformational Leadership (SSTL)
SSTL is a form of transformational leadership focusing on achieving safety outcomes (Barling et al., 2002). Similar to generic transformational leadership (Avolio et al., 1991), SSTL comprises of four factors: (i) idealized influence: acting as a role model with regards to safety, (ii) inspirational motivation: communicating a vision in which safety plays an essential role, (iii) intellectual simulation: encouraging employees to think about how they can work more safely, and (iv) individualized consideration: being actively involved with the
Barling et al. (2002) and Kelloway et al. (2006) find that SSTL is indirectly associated with occupational safety and that SSTL predicts occupational injuries through the effects of perceived safety climate. De Koster et al. (2011) note that SSTL affects safety performance directly. De Vries et al. (2016) report a negative relationship between SSTL and occupational accidents. De Vries et al. (2016) also examine the relationship between SSTL and quality/productivity; nevertheless, they do not identify any statistically significant relationship.

It is also worth noting that despite its popularity in safety and applied psychology literature, with a few exceptions, e.g. de Koster et al. (2011), de Vries et al. (2016), occupational safety has not been featured widely in OM literature. Das et al. (2008) and Pagell & Gobeli (2009) speculate that a possible reason for such scarcity is the lack of theory and evidence linking safety to the competitive factors (e.g. quality, productivity, delivery, etc.). Pfeffer & Velga (1999) claim that practitioners often struggle with the connection between employee well-being and operational performance. Not only do practitioners struggle with such connection, but also do academicians. It is challenging to reach a definitive conclusion about the relationship between any aspects of employee well-being, specifically employee safety, and operational performance from any stream of literature. A notable exception is the meta-analysis by Orlitzky et al. (2003) that establishes a positive relation between corporate social performance and economic performance. Das et al. (2008) also establish the theoretical linkages between safety and quality; however, they also lack empirical evidence due to the limited sample size.

2.3. Safety disconnect
There is a fundamental unidimensionality of the way safety literature approaches safety perception. The concept of safety perception in safety literature is primarily from the employee side. Safety perceptions of individual employees are the only reflector of the informal safety climate in an organization (Das et al., 2008). Concentrating merely on employee perceptions ignores the role that managers’ perceptions and actions has in safety climate (DeJoy, 1994; Flin et al., 2000; Neal & Griffin, 2002). Coyle et al. (1995) acknowledge that a gap between managerial and employee perceptions of safety is a signal of a dysfunctional safety climate. Conversely, the absence of such gap is a crucial enabler of a safety climate (Clarke, 1999). Prussia et al. (2003) note that as the gap between managerial and employee perceptions of safety grows, the likelihood of the two parties disagreeing about the causes of unsafe behavior also grows, affecting negatively the development of safety programs. To overcome this unidimensionality and to gain a more comprehensive understanding of safety perception, Das et al. (2008) propose to incorporate manager safety perceptions and coin the term safety disconnect to describe the discrepancy between employee perceptions of safety and organizational (managerial) perceptions of safety. As the notion of disconnect is based on perceptions, it is conceptualized at the individual level.

The concept of disconnect is not new in management literature. Generally, disconnects represent inconsistency, cacophony, discrepancy, or incompatibility in the perceptions about a specific aspect of workplace conditions and policies. Disconnects can exist at various levels in an organization, e.g. individual and organizational-level perception (Hofmann & Stetzer, 1998). Disconnects can be about different organizational aspects, e.g. disconnects on competitive priorities and practices (Swamidas, 1986; Kathuria et al., 1999) or disconnects on manufacturing investments and executions (Boyer & McDermott, 1999). Disconnects can
develop between different groups of people in an organization, e.g. managers and operators (Boyer & McDermott, 1999), blue-collar and white collar employees (Moris et al., 1999), or factory workers and miners (Gyekye, 2006). The concept of disconnect has been linked with competitive outcomes. Dess (1987) reports a negative correlation between the disconnect in business priorities and financial performances. St. John (1991) finds that the perceptual disconnects between marketing and manufacturing affect negatively market performances. Similarly, Pagell & Krause (2002) find that the absence of disconnects between manufacturing and purchasing improves manufacturing performances. Based on such rich body of literature on disconnect, one can expect that safety disconnect would impact adversely safety performance (Das et al., 2008). Nevertheless, before Das et al. (2008), there had been no researches studying the impacts of safety disconnect between managers and employees on competitive constructs, specifically quality outcomes.

Using motivational theory and cognitive dissonance theory as the premise, Das et al. (2008) theorize the linkages between safety disconnect and quality outcomes and find a negative relation between safety disconnect and quality outcomes from their empirical test. However, the authors themselves admit that their empirical test lacks generalizability due to the limited sample size. Nonetheless, Das et al. (2008) provide a rare example of a study that link safety with a competitive construct, i.e. quality outcomes.

**Future research avenues**

After Brown’s (1996) and Das et al.’s (2008) call for more safety research in OM literature, there have been a few more studies on the topic, e.g. de Koster et al. (2011) and de Vries et al. (2016). Nevertheless, a thorough search of the relevant literature yields no other articles besides Das et al. (2008) that link safety to competitive constructs. De Vries et al. (2016) do examine the links between safety and quality/productivity but find no statistically significant relation. Thus, even though more than a decade has passed, the link between safety and competitive constructs still remains mostly theoretical in both safety and OM literature.

After a systematic review of related literature, this paper aims to highlight the need for more research on the linkages between occupational safety and competitive outcomes (e.g. financial, reputational, quality, etc.) and especially more empirical tests on these linkages to answer the “surprising absence” of these empirical tests (Pagell & Gobeli, 2009, p. 281). While new attempts at theoretically testing the existing theories are highly anticipated and appreciated, replication research is another avenue to achieve such goals that this paper aims to promote.

As strong theories come from confirming and evolving ideas (Flynn et al., 1990), this paper encourages replication research on the linkages between safety and quality. Replication research is vital to scientific knowledge, as strong theories come from verifying, validating, conforming, and evolving ideas (see e.g. Flynn et al., 1990; Hempel, 1967; Hubbard et al, 1990; Popper, 1978). According to Rosenthal & Rosnow (1984), literature of un-replicated findings is of marginal value. While replication research is not a rare phenomenon in natural sciences, there is a lack of interest toward conducting replication research among OM academics (Easley et al., 2000). Thus, in addition to calling attention to research on the linkages between safety and quality, this paper also aspires to call attention to the scarcity of replication research. Das et al. (2008) is one the studies that deserve to be replicated. While De Vries et al. (2016) do not find any relation between SSTL and quality/productivity outcomes, Das et al. (2008) find some negative relation between safety disconnect and quality
outcome, yet their empirical test lacks generalizability due to the limited sample size. This limitation can be easily overcome by replicating the empirical test with a larger and more encompassing data set.

**Conclusion**

This paper aims to synthesize both quality and safety literatures and the often oversighted connection between safety and operational performance. This paper strives to call for more attention, especially empirical attention, to the linkages between safety and competitive constructs, especially quality outcomes. Despite the growing interest on occupational safety from both practitioners and academicians, the linkages between safety and competitive constructs still remain mostly theoretical. Before the linkages are well-established and corporate decision-makers are convinced of the competitive benefits occupational safety brings about, it is challenging to stop and reverse the incomprehensible increase in the number of occupational accidents and incidents.

Additionally, this paper is the author’s first attempt at an expansion of TQM to include safety, which responds to Brown (1996)’s call for safety research in OM and voices support for her proposition to include safety among the competitive priority constructs.

For practitioners, the paper helps raise awareness of the role of occupational safety as an economic opportunity instead of a regulatory cost. For procurement and tendering professionals in industries where product quality is a critical factor (e.g. healthcare equipment), it offers another indicator for a reliable quality performance.

Besides digging deeper in the linkages between safety and competitive constructs in manufacturing and production (i.e. product economy), future research could study the impacts of safety disconnect on quality performance in other segments, e.g. service and experience economies, and/or expand the definition of safety to include online (virtual) safety.

Process Mining for Six Sigma: 
Plugging into Big Data

Dietmar Stemann

Ingo Kregel (kregel.ingo@fh-swf.de)
South Westphalia University of Applied Sciences, Hagen, Germany

Karina Buschsieweke
Lana Labs, Berlin, Germany

Abstract

Six Sigma is one of the most successful quality management philosophies of the past 20 years. However, the current challenges facing companies, such as rising process and supply chain complexity as well as high volumes of unstructured data, cannot easily be answered by relying on traditional Six Sigma tools. To meet this need, based on design science, we present an approach for integrating Process Mining into the Six Sigma toolset to enable enhanced data analytics. The results of a first expert evaluation workshop provide insights into its application possibilities and ideas for future research.

Keywords: Process Mining, Six Sigma, DMAIC

Introduction

New challenges for companies in recent years include an increasing complexity of products accompanied by complex processes and supply chains (Bozarth et al., 2009). With the help of big data as the “gold” of the 21st century, digitalisation promises faster and more efficient processes and innovative products. This article focuses on using companies’ internal data for business process improvement via Six Sigma (6S).

As one of the most popular and successful process improvement methodologies and management concepts (Shafer and Moeller, 2012; Jacobs et al., 2015), 6S originated in manufacturing and was later applied to other industries, such as the service sector (Heckl et al., 2010). Three practices are critical for 6S: The role structure (belt system), the structured improvement procedure (DMAIC), and its focus on metrics (Zu et al., 2008). In this article, we do not focus on the human and organisation theory aspects of 6S. Instead, we concentrate on its data analysis aspects and the technological connection to information systems. 6S relies on a systematic, fact-based approach, including “classical” inductive statistics such as hypothesis testing or the design of experiments. Based on the new digitalisation challenges, the traditional 6S approach is confronted by limitations. For example, 6S is unable to analyse large amounts of unstructured data, which is the basis of big data analytics. In our article, we present an approach for integrating Process
Mining (PM) technologies into the 6S toolset to enhance its data analysis capabilities. Most processes in large corporations are supported by or executed in IT systems that store large amounts of data. Enterprise resource planning, customer relationship management, workflow management, and manufacturing execution systems contain valuable process-relevant data that are often not accessible under the usual improvement project circumstances. This article presents a concept that allows access to and usage of these data by integrating PM technologies into the 6S toolset.

Our research method is design science, which is increasingly being adopted in operations management (Holmström et al., 2009; van Aken et al., 2016). This method is particularly popular in information systems research and is often used there to create, implement, and evaluate innovative frameworks and IT artefacts (Hevner et al., 2004). In operations management, design science is explicitly recommended for research with high practical orientation, which matches this article’s intentions (Browning and Treville, 2018). In our article, we present the concept for including PM into the 6S methodology and assess it by using expert evaluation and a technical experiment. At the centre of the article is the concept of using PM in 6S projects by showing how it can be integrated into the define, measure, analyse, improve, and control (DMAIC) project phases. Therefore, we focus on exploratory research, which can later be followed by explanatory research.

In this article, we answer the following research question:

‘How can Process Mining be successfully added to the Six Sigma methodology?’

We start with the research background and a general introduction of PM and its characteristics and potential. We then present the concept of integrating PM into the 6S toolset and describe a variety of scenarios in which 6S projects can benefit from PM. We evaluate the concept by executing a technical experiment in an expert workshop and then end our article with a conclusion and outlook.

**Research Context**

*Research about Six Sigma*

6S research started in the late 1990s and became much more comprehensive and diverse after 2004 (Aboelmaged, 2010). Research initially focused on manufacturing and the 6S toolset, but more and more articles appeared beginning in the late 2000s addressed cultural and soft factors, such as leadership, as well as domain-specific challenges and customisation of 6S, for example, in the service and public sector (Antony et al., 2017).

The majority of 6S research remains rather practice-oriented. However, its lack of theory has already been identified and addressed in the literature (Linderman et al., 2003). Schroeder et al. (2008, p. 540) summarise the common elements from the literature and define 6S as follows:

*Six Sigma is an organized, parallel-meso structure to reduce variation in organizational processes by using improvement specialists, a structured method, and performance metrics with the aim of achieving strategic objectives.*

The meso structure integrates both micro and macro levels of analysis and is created in parallel to the existing organisational hierarchy. 6S generally is not considered a project management method only. In fact, it targets the whole organisation as a system and establishes a coloured belt system comparable to martial arts standards. We mainly focus on the black belt role in this article, as these 6S experts are intensively trained in statistical methods and typically have more project experience than green belts (Coronado and Antony, 2002). Although we keep the elements of the 6S definition intact, we aim for extending the toolset in 6S projects. Until now, the topic of PM has not been included in popular 6S books (Pyzdek and Keller, 2014) or the ISO standard for 6S (International Standards Office, 2011). Most of the elements of 6S were included in its toolbox decades
ago. In a comprehensive literature review regarding the most frequently used tools and methods in 6S literature, neither data mining and its most important methods nor PM were found (Uluskan, 2016). There are a few examples, however, for using data mining techniques in 6S projects. Zwetsloot et al. (2018) present three case studies involving data analytics experts as consultants for black belt projects. George (2019) summarises a large number of case studies where 6S already could benefit from data mining, such as applications of neural networks, artificial intelligence, and deep learning. The overall field of big data is recognised as having a very large potential for 6S while still not being extensively researched (Antony et al., 2017). Gunasekaran et al. even speculate that a new philosophy beyond 6S and total quality management (TQM) could emerge in the next few years. However, instead of thinking about a successor, we present a concept to enhance and update the 6S toolset while keeping its philosophy intact.

*Research about Process Mining*

According to van der Aalst (2016, p. 15), PM “can be seen as a means to bridge the gap between data science and process science”. The latter is regarded as the “broader discipline that combines knowledge from information technology and knowledge from management sciences to improve and run operational processes” (van der Aalst, 2016, p. 15). In their “Process Mining Manifesto”, a large number of researchers from 53 different institutions concretised this view on PM and declared it as an enabling technology for management approaches such as continuous process improvement, TQM, and 6S (van der Aalst et al., 2012). Four years later, van der Aalst et al. (2016) renewed their recommendation for future research directions to “bridge the current gap between Process Mining and Six Sigma”.

PM analyses the event logs of IT systems, which have an initiator, refer to other tasks or activities, refer to a process instance (case), and are marked by a timestamp. PM therefore can analyse and display the execution sequence of process steps, decision rules, communication paths, and processing rules, enabling us to analyse the historical data of a selected time frame and measure the real process flow, which typically includes several process loops and flaws. Algorithms for process diagnostics analyse process traces (Jagadeesh Chandra Bose and van der Aalst, 2010) to support the following three major types of PM as differentiated by van der Aalst (2016, p. 33):

- **Discovery**: Create a process model out of the event log data. A pre-existent model is not required; the model can be generated purely based on the data in order to “discover” the real process with all of its connections, potential loops, and sequence variety.

- **Conformance**: Compare an existing process model with the discovered model created from the event log data to verify or contradict the conformance of a current process model. Conformance can be used for various purposes, including checking for violations of process rules, process monitoring, and auditing.

- **Enhancement**: Use the information from event logs to find ways to improve the current process. Possible solutions are to automatically correct the current process model or to extend the model with additional data, such as throughput and processing times, frequencies, decision rules, and quality measures.

Our concept will show that all three types can be of use for 6S.

PM generally is applicable to any sector and case where its data requirements are met. Major support factors for its introduction are high-volume process executions, high complexity in the process sequences, and high cost or competitive pressure. Implementations up to today are mostly seen in the finance and accounting departments across all industries. PM in manufacturing processes is generally possible, but its rather
complex use cases are still in an early stage. Typical pilot candidates to start an initiative are order-to-cash and purchase-to-pay processes.

**Integrating Process Mining into Six Sigma’s DMAIC**

Many classical 6S projects analyse existing process models or can only rely on the input of a few workshop participants to understand the process flow. Usual data analysis is based on data reports, individual data selections, or manually performing new measurements. Analysing trustworthy existing data saves resources for the interpretation of the data and for more efficient projects compared to manual data collection. In addition, the refinement of existing process models generated out of data is much less time-consuming than building the models from scratch.

A major component of 6S is the belt system mentioned previously, which includes the green belts and black belts for typical project leaders and yellow belts for project members (Hoerl, 2001; Antony and Karaminas, 2016). When integrating PM into the 6S approach, organisations will need to determine who will analyse the PM data. There are two main alternatives: The PM knowledge can either be included in the black belt training as an additional data analytics topic, or it can be offered to 6S project managers by a separate organisational unit specialising in data analytics, as in the case studies analysed by Zwetsloot et al. (2018). We make no specific recommendation about this detail as our research to this point does not reveal clear superiority of one of the alternatives over the other.

In the following subsections, we will describe how PM can be integrated into 6S’s five structured project phases.

**Define**

As the first of five project phases, the define phase provides the basis for a successful project. The main aims are to determine the project scope and its goals, which will be important throughout the project and for the eventual calculation of the project’s benefits. Defining the right project measures is highly important for the potential effect of the project. Further instruments in this phase include, amongst others, the voice of the customer to develop the indicators critical to quality, a stakeholder analysis, and the suppliers, inputs, process, outputs, and customers (SIPOC) diagram for a first rough process step overview.

Although its strengths lie in the later project phases, PM can support the define phase by contributing first data insights via screening the available processes. With the help of a first look into the process data, the project scoping can be supported to avoid an endless project (scope too wide) or an overly limited project. Furthermore, the choice for major project goals could be verified and their target values roughly substantiated.

**Measure**

The emphasis of the measure phase in most projects lies on the data as it covers the collection of data and its planning. The project leader is responsible for contacting and considering every potentially useful data source to create a process analysis that is as complete and accurate as possible. Collecting new data is usually more cumbersome and time-consuming than using existing data. Unfortunately, existing data are often not available for all needed process aspects, or its validity cannot be trusted. Another perspective in the measure phase is the detailed comprehension of the as-is process. A typical element is to model the most relevant processes by creating flow charts or Business Process Model and Notation (BPMN) models.
PM offers another source of data for 6S projects, which, in most cases, has not been used before. Manually connecting to an SAP system and extracting timestamps at multiple points in the process is considered extremely time-consuming and could even make it necessary to contact IT consultants to create specific data queries or interfaces. PM software vendors specialise in the interfaces of common software products and can therefore deliver the needed data much faster at lower cost than the manual method. Due to the analysis of the event logs, PM typically focuses on measures such as throughput time, idle time, and waiting time. Additionally, the presented discovery type of PM can support or even replace the manual process of model creation. The model created on the data could be used for an expert workshop to verify the process and build upon it to reach a complete picture of the as-is process. Combined with the throughput and waiting time data, the creation of value stream maps is also possible. Finally, the conformance of process models can support the measurement of standardisation. PM can easily count the number of process variants, and the process experts can determine which of those are conformant to the business rules or to what extent the process standardisation already is or is not successful.

**Analyse**
Data are more important in the analyse phase where the main goal is to create causal relationships to identify which factors influence the process most significantly and, therefore, how we can positively influence its most important indicators. This work can be supported by brainstorming techniques to find potential influence factors (hypotheses) and to use the expert knowledge of the process-related employees. The most significant outcome of this phase is the transformation from many potential influence factors to the identification of the few most important factors that will be addressed later in the next phase. For this transformation, the input and experience of employees and process experts as well as the detailed analysis of all available data can be of use.

PM can offer many useful aspects based on the analysed event log data. Most PM software products can identify potential bottlenecks in the processes and visualise them in the generated process models. These automated findings can then be the basis for an expert workshop to verify and discuss the hypotheses and combine them with further findings from other sources. Validating existing hypotheses by PM data is also a valuable contribution in this project phase. The comparison of different layers of data, for example, several factories of the same company, can also be transferred to PM. The algorithms can determine whether the processes are actually being executed the same way or whether different factories deviate from the standard and receive better or worse performance results. Furthermore, with the help of the process indicators and timestamps, the most efficient process, the shortest process, and so on could be selected from amongst multiple variants to be discussed by the project team as a candidate for the future process.

**Improve**
The improve phase directly follows up on previous work. The main causes identified in the analyses now represent the requirements for improvement. Potential improvement ideas have to be developed and evaluated, followed by finally selecting the best-fitting ones for implementation. In some projects, the design of experiments allows different process configurations to be tested to arrive at the best result.

The PM enhancement especially can support the redesign of the processes; however, the data can also be used to verify potential benefits from process changes or to quantify the scope of change. If conformance is a major topic in a project, process variants can be harmonised and standardised amongst different locations, shifts, persons, and so on. In
the PM software market, advanced functionalities for simulation and forecasting are expected (Gartner, 2018). They could be used by project managers to calculate prospective effects of planned solutions and assist the selection of the best solutions regarding costs or benefits. For now, PM enables the prioritising of detected issues and making fact-based decisions on which improvement measures should be started first.

**Control**

In the fifth and final project phase, the sustainability of project benefits is the major topic. Main project indicators are measured again now to determine the exact achievement of the improvements and to calculate the project benefits. Few key measures are summarised in a process control plan for long-term process monitoring. The goal is to keep the new (higher) process performance and quickly detect significant performance changes.

PM can also assist in this phase in many ways. For the benefit calculation, the process standardisation can easily be measured again. The same applies to all the analyses in the measure phase as well as the implemented solutions in the improve phase, which now have to be controlled for changes and success. Furthermore, PM facilitates business activity monitoring, which can be used for continuously monitoring performance indicators (Janiesch *et al.*, 2011). Another useful aspect is compliance monitoring. Quality managers can monitor the emergence of new process variants or the proportion of non-regular process executions. PM can also automate or at least support recurring process audits and process certification initiatives.

**Implementation and Evaluation**

Every design science artefact needs an evaluation. We combine two design science evaluation techniques by executing an expert evaluation and discussing and implementing a technical experiment (Peffers *et al.*, 2012). Our research approach follows the work of Hevner (2007) by describing a cycle between creating and evaluating a concept. With regard to the categorisation of Pries-Heje *et al.* (2008), we are executing an ex post artificial evaluation strategy.

As company cases about the combination of PM and 6S are rare, we chose to evaluate our approach by using an expert workshop. The workshop team consisted of 12 persons with different types of expertise, including PM software representatives, statistics doctorates, experienced 6S (master) black belts, and lean experts. The workshop had two main elements, which we worked on in parallel:

- **Expert evaluation**: To receive feedback on our approach regarding how to integrate PM into 6S’s DMAIC cycle, we presented the current method draft, discussed it with the workshop participants, and proposed changes and extensions to the approach.

- **Technical experiment**: We introduced a comprehensive data set to the participants that came from a large automotive supplier company with about 10,000 employees and annual sales of about 2 billion euros. The data set contained event logs of receiving, processing, and answering claims. Together in the group, we explored the claims process using the LANA PM software to experiment with its applicability for 6S.

The analysed data already provided important input for the fictional 6S project’s define phase as it delivered a good overview about the process and its measures. The PM software created the process model shown in Figure 1 and had already annotated existing indicators. An important factor for the main goals of the project is the automatic acceptance of claims if they are not processed within a specific time frame. Main indicators for the process therefore are throughput time, claim acceptance rate, and first
pass yield. In the measure phase, the workshop participants went into the details of the PM model. All process activities were logged with timestamps and connected to potential influence factors, such as product group, location, country, division, customer, and order volume. The main process indicators could be visually analysed both via Figure 1 and inside the software when browsing through each step or following the flow. The execution counts of each step could be broken down into process variants, leading, for example, to different endings of either accepted or rejected claims. Checking for conformance was possible, as well as comparing the discovered model with others from employee workshops or work instructions to identify deviations.

![Figure 1 – Process visualisation from the LANA Process Mining software](image)

In the analyse phase of the experimental project, different attributes and their influence on the key indicators were compared to find the most important influence factors. This analysis was triggered by specific expectations of the workshop participants, that is, which factors to analyse. Alternatively, an automatic mode could already highlight the most significant influence factors. In our experiment, a clear bottleneck was identified, as more than 60% of claims were processed after more than 10 days. This delay was even worse for a single product group. At this point, the work should be continued in the classical 6S way by including more data sources, process analyses, and expert opinions to find the most significant influence factors, which will be addressed in the improve phase. A typical aspect for improvement is the optimal allocation of human resources. The PM analysis can support this allocation as it provides the processing times and quantities. In the control phase, the PM system can be used to take over some of the process control activities to create continuous process monitoring to sustain the project’s improvements.

After discussing both the approach to integrating PM in the DMAIC and the technical experiment, the workshop ended with discourse about which processes benefit most from PM. The results are as follows:
• Most activities of the process should be implemented digitally or be continuously supported by IT systems that store process data about the executions, such as timestamps, sequence of activities, and so on. Workflow management systems are a good example. If only a small section of the process is handled digitally, the benefits are very limited.

• Historical data are relevant for process analysis and improvement. PM can only deliver its full potential benefit if high volumes of historical data are available for the process analysis. Another option is the real-time PM, which is more complicated, has higher requirements for the process, and can only process new cases and not potentially large amounts of already stored data of past executions.

• If manual data collection is very complicated, time-consuming, and/or costly, PM can deliver its full potential.

Another major point of discussion centred on the aspect of data quality. A traditional element of the measure phase is the measurement system analysis (MSA) in which the project manager must validate the reliability and reparability of the measurements. The accuracy, trueness, biases, stability, and linearity of the measurements are of interest as well. The MSA can be very time-consuming, and, if the results are not good enough, the measurement system has to be significantly changed, leading to further project extensions. Regarding data quality, we agree with Hoerl et al. (2014, p. 223) on the importance of the following “building blocks of statistical thinking”: clear problem statement, process understanding, analysis strategy, variation sources, quality data, domain knowledge, sequential approach and modelling process. High-quality analysis is not achieved by just “pushing a button” to let the PM software solve every problem. The mentioned domain knowledge and process understanding let the project manager decide how to set the analysis scope and how to interpret its results. Experienced 6S trainers typically ask the following question: “Do you completely trust your data?” Without high data quality, the best algorithms and technologies cannot be successful. On the contrary, they could deliver inaccurate results, misleading projects into wrong directions (Hazen et al., 2014).

PM is a positive aspect when working on data quality because it can serve as a trigger to reflect and work on improving data, especially during the PM setup process in which insufficiencies can be identified and data generation can be optimised. Establishing PM in a process area can lead to a procedure comparable to the MSA to reach a status in which the data creation fulfils the quality requirements.

Conclusion and Outlook
The implementation results and the discussions with 6S experts show that PM is well suited to enrich the 6S toolset. The digital event logs proved to be very valuable sources for 6S improvement projects. Therefore, we recommend the integration of PM into the 6S toolset. PM supports and expedites the documentation, improvement, and control of processes, which may leave project managers with more time for improving processes rather than preparing manual analyses.

Our design science study shows strong limitations and can only mark the beginning of research about the idea to combine 6S and PM. We developed a method for integrating PM into the DMAIC cycle, evaluated and improved it with the help of an expert workshop, and finally used a technical experiment to show its general applicability. Future research should extend the analysis scope and ensure the practical relevance of the research. For this purpose, researchers could use case studies or action research to describe real cases of PM and 6S in companies.
We also see PM as a good starting point for process automation activities, as it can help prioritise the steps where the return on investment (ROI) of an automation solution is highest. A combination with robotic process automation (RPA) was recommended in a recent study by Gartner (2018) and promises a good fit with the DMAIC cycle to be implemented during a 6S project.

The impact of implementation TQM practices on Innovation in the Palestinian service companies

Ahmad Herzallah (ahirzallah@staff.alquds.edu) Ne'meh Shoqeir
Department of Business Administration- Al-Quds University (Palestine)

Ne'meh Shoqeir
Al-Quds University (Palestine)

Abstract
The purpose of this paper is to examine the relationship between TQM practices and Innovation in the Palestinian service sector. Data were collected through surveying 220 Palestinian companies.

Results derived from this study show that TQM practices (Soft TQM practices and Hard TQM practices) have positive and significant relationship with all kinds of innovation (Incremental product innovation, Incremental process innovation, Radical product innovation, Radical process innovation and Administrative innovation).

This study is the first empirical test for measuring and examining the impact of TQM practices on innovation in Palestine.

Keywords TQM, TQM practices, Innovation, service sector, Palestine.

Introduction
Quality plays an important role in the overall strategy of companies. The main challenge of global companies is to acquire a share in the global market by understanding of the needs and wants of the customers (Zakuan et al., 2010). The majority of the companies apply tools of quality to enhance the quality of their products. In respect, the world focuses on total quality management (TQM) due to its tangible results in the sustainability of companies and in achieving organizational success (Baidoun & Zairi, 2003).

The current era is characterized by constant and growing changes in all aspects, which leads companies to seek more efficiency, creativity, innovation and cast off old and traditional systems to open paths to development and continuous improvement. Thus, the concept of TQM comes in handy to develop the needed methods and procedures. The
implementation and practices of TQM are the key strategies to achieve competitive advantage, and improve performance in order for companies to remain in the market and for sustainability. Consequently, companies with all their activities and sizes apply the principles and practices of TQM (Al-Sha'ar, 2014; Bon & Mustafa, 2013).

The importance of TQM has increased on all levels globally, regionally and locally. This importance led to many production and service companies to give it great importance. Business literature show that the use of TQM by companies is based on a set of fundamental factors. These factors provide a flexible culture that supports innovation and creativity, consolidate the commitment of top management to TQM principles, focus on customers and stakeholders, personnel management and empower them to make decisions, as well as the adoption of management methods based on data analysis and facts in decision making procedures (Al-Sha'ar, 2014).

Studies show that the use of TQM concepts and practices will eventually lead to excellence in innovation. Customer care, production development, results and the adoption of a constant preventive and treatment system will definitely lead to outdo others and excel over them. Based on different studies and researches in production and operations management, creativity and innovation in all their elements refer to the creativity and innovation of the product and operation. Furthermore, Administrative innovation is considered a key factor that helps companies achieve competitive advantage (Li et al., 2001). Many studies and researches explored the impact of TQM on innovation, some of which noted that impact while some did not (Kim et al., 2012; Bon & Mustafa, 2013; Singh & Smith, 2004; Prajogo et al., 2008; Hoang et al, 2006). Over the years, service companies became increasingly important in the local and global economy. Additionally, the contribution of this sector increased not ably within the gross national product (GNP) in the majority of countries, especially in the last two decades (Bon & Mustafa, 2013).

This study aims to highlight the impact of TQM on innovation in the Palestinian service companies to contribute in developing suggestions, and solutions to improve services provision and the use of the best methods and procedures by these companies. Additionally, this study is considered one of its kind in Palestine in regards to its aim to understand the impact of TQM practices on innovation in the Palestinian service companies. Moreover, Service companies constitute a big share in the Palestinian community, as they directly influence the needs of the population and provide them with tangible services.

Although, there exist many studies on TQM, these studies focused on linking the relationship between the practices of TQM with innovation especially in the service sector. Most of the studies focused on the industrial sector. It is also worth mentioning that Arab companies in general, and Palestinian companies in particular did not apply TQM and were not particularly interested in innovation.

**Theoretical Framework**

**Total Quality Management**

The concept of TQM is a modern terminology in business adopted by many companies. Moreover, the concept of TQM was based on a set of standards and principles which encourage management to adopt these concepts. As TQM is a comprehensive concept, it
was difficult to provide a concrete definition to quality. Many experts proposed definitions to TQM based on the visions they conceived from it (Herzallah et al., 2014).

TQM is known to be a mutual partnership between all members of the organization and its different commercial operations to produce products and services with financial added values which meet and exceed customers’ needs and expectations (Dale et al., 2016).

TQM is also known to be a comprehensive approach to improve competitive advantage, efficiency and flexibility by planning every activity, organizing and understand it, as well as involving every single individual at all levels of the company (Oakland, 2014).

One can consider it a management philosophy that strives to continuously improve in all fields of the organization, and which cannot be achieved unless TQM is used at all stages from resources acquisition to customer services and after services (Kaynak & Hartley, 2008).

**Total quality management practices**

TQM practices are considered a managerial and organizational practices which are implemented continuously in a company to improve performance. The practices are not objectives but activities and operations employed by the company to reach its organizational objectives. The importance of implementing these practices is to improve the company’s success rate through improving productivity and communication, as well as achieve customers’ satisfaction, lower costs and low goods damage, and improve company’s performance to achieve competitive advantage (Talib, 2013). Furthermore, Studies differed in highlighting the elements and practices of TQM, but most recent studies adopted eight practices for TQM (Herzallah et al., 2014; Kim et al., 2012; Kaynak & Harly, 2008; Saraph et al., 1989). The key practices in TQM are as follows:

1. **Management leadership**: It is the acceptance of responsibility by managers for quality including planning total quality, allocating resources, re-designing quality, evaluating quality and participating in the efforts for improving quality (Saraph et al., 1989). It is imperative that the top management is committed to quality as decisions associated to quality are considered as strategic decisions.
2. **Customers focus**: It is the degree companies understand the necessity to meet customers’ needs and expectations to gain their continuous satisfaction (Ahire & Ravichandran, 2001). Furthermore, customers are considered one of the important elements that TQM is based on, as they are the basis for TQM activities.
3. **Training**: It is the degree to which the company provides its employees with statistical training and training linked to quality and its techniques (Kim et al., 2012). Training of employees and learning are key fundamentals of TQM, as they provide the best methods to improve the level of the individual. The more training related to TQM involve all the employees and uses statistical and technical techniques in measuring quality and developing, the more they will help achieve success in the implementation phase of TQM (Goetsch & Davis, 2014).
4. **Employees relationships**: This measures the extent of employees’ involvement in making efforts and attending meetings pertinent to quality. Also, their contribution in the activities of quality management, as well as their participation in the decisions involving quality, assuming full responsibility in matters related to
quality, commitment to high quality performance and the degree of awareness of employees in relation to continuous quality improvement (Kim et al., 2012; Saraph, 1989).

5. Data quality and report writing: It is the degree the company uses high quality data gathering and utilizing, measure quality at the appropriate time and receive the needed feedbacks of the data quality from employees and managers to resolve problems, as well as evaluate them based on quality performance (Kim et al., 2012; Saraph, 1989).

6. Relationship with suppliers: The degree to which the company relies on suppliers which results in long relationships and are chosen based on the principles of quality rather than price, as well as their ability to meet the company’s requirements and develop the products (Kim et al., 2012; Saraph, 1989).

7. Product or service design: The degree of involvement of all company departments in reviewing the designs, and in the efforts made in the clarity of the specifications. In addition to the company intent to foster productivity and highlight quality to avoid duplication in design (Kim et al., 2012; Saraph, 1989).

8. Process management: The degree to which the company achieves the conditions and steps of process management, using preventive maintenance, self-inspection of employees, use of statistical techniques and automated tests to lower the deviation of process (Kim et al., 2012; Saraph, 1989).

The practices of TQM can be divided into two parts (Herzallah et al., 2014). Soft TQM practices: These are practices that are related directly to the human element and include management leadership, customers focus, employees’ relationships, training and suppliers’ management. Hard TQM Practices: These are practices that are related directly to machines and systems and include data quality and reports, product or service design and operations management.

Innovation

Innovation is the practical implementation of an idea in a new form or new product, or the creation of new ideas without overdoing the benefit behind the idea (Schilling, 2008). Innovation can be also defined as the process of introducing a new idea, behavior, or anything new, and is viewed as new as it differs qualitatively from other existing things (Seidler-de Alwis & Hartmann, 2004).

Innovation can also be said to be the power to create a new product, service, technique or a production process and implement it, which has benefits and is of value (Schermherhon et al., 2000).

Types of innovation

Innovation is divided into different types which need different types of knowledge and which have an impact on competitors and consumers. Schilling (2008) and Kim et al. (2012) tackled different types of innovation as follows:

- Product / service innovation: It is shown in the outcomes of the company in the form of products and services. It aims to change the specifications, material and performance components of the product or service through improving on it,
developing it or producing a totally new alternative to it. Furthermore, Product innovation is the process of reaching for new ideas to create new products, services or improving products or current services to meet the needs and wants of customers and achieve competitive advantage for the company.

- **Process innovation:** It is the process through which the company manages its operations such as the techniques it uses in the production or marketing of its products and services. The objective behind it is to improve the efficiency and effectiveness of the production. Additionally, process innovation is very important when the company seeks to increase productivity and the quality of the product which is in line with TQM goals.

- **Radical innovation:** This type of innovation focuses on developing new things and totally different from existing solutions. It is deemed to be new and different.

- **Incremental innovation:** This type of innovation produces small changes or changes to the already existing practices of work performance.

- **Administrative Innovation:** It is the process that characterizes an individual when facing stressful situations, and coexists with them deeply in order to face them according to his/her own views in a new innovative way that differs from others (Bloani, 2008).

**Hypotheses of the Study**

The study tested the following hypotheses as:

- **H1:** There is a significant impact of soft TQM practices and their variables (commitment of top management and leadership, customer focus, training, employees’ relationships, suppliers’ management) on innovation (service innovation, process innovation, administrative innovation).

- **H2:** There is a significant impact of hard TQM practices and their variables (data quality and reports, service design, process management) on innovation (service innovation, process innovation, administrative innovation).

**Study Methodology**

A questionnaire was devised as a study tool to measure the objectives of the study and implement them after reviewing the previous studies and literature. The questionnaires comprised 65 questions divided into thirteen dimensions based on the Likert scale five-response categories.

The study population consisted of all general managers, executive managers, vice managers, quality management managers, production operations managers in the services companies in Palestine, West Bank which include: banks, insurance companies, telecommunication and internet provider companies, computers and information technology companies, hotels, and any company working in this sector. A complete census was used on the applicants of the population of the study within the administrative positions in the companies that include the above-mentioned managerial levels. They were chosen on the basis that they possess more knowledge, understanding and ability to evaluate more than others. Moreover, the sample comprised of 220 applicants.
Analysis and Results

Validity and Reliability of the Study Tool

The construct validity of the scale for TQM practices (soft and hard) was verified. The correlation coefficient was calculated from the average of each question of the scale with the overall average. The degree of its significance was also examined at $\alpha \leq 0.05$ on the actual applicants of the sample. The results showed that the correlation coefficient of the questions of the scale for TQM practices on the overall is statistically significant at $\alpha \leq 0.05$. The correlation coefficient was between 0.395-0.708, which indicates that the scale for TQM practices has a good degree of internal consistency.

The construct validity for the scale of innovation was also verified. The correlation coefficient was calculated from the average of each question of the scale with the overall average. The degree of its significance was also examined at $\alpha \leq 0.05$ on the actual applicants of the sample. The results showed that the correlation coefficient of the questions of the scale for innovation on the overall is statistically significant at $\alpha \leq 0.05$. The correlation coefficient was between 0.472-0.677, which indicates that the scale for innovation has a good degree of internal consistency.

The reliability of the study and its different axes was measured through Cronbach's alpha internal coefficient as an indicator for consistency on all 65 questions. The value of reliability of the TQM practice tool as a whole was 0.94, while the value of reliability for innovation was 0.91. Thus, the questionnaire is deemed to have a high level of reliability.

The data was processed using the Statistical Package for the Social Sciences (SPSS). The hypotheses of the study were analyzed at $\alpha \leq 0.05$ through the use of Person Correlation, Multiple Analysis Regression and One-way ANOVA.

Results of Hypotheses Testing and Discussion

Results for H1: A test was made on whether there is a correlation between all independent variables (soft in all its dimensions) and all the variables related to innovation (in all its dimensions) through Pearson Correlation test.

Results have showed that there is a positive relationship between all variables of soft TQM practices and all variables of innovation. As well as between all variables of soft TQM practices as a whole and all variables of innovation as a whole. The significant level was calculated at 0.00 which is less than 0.05 with a strong positive relationship as the correlation coefficient was between 0.390-0.728, which indicates that impact can be tested between these variables.

Multiple Regression test was used to test the hypothesis. The results obtained from this test have showed that there is a statistically significant impact on the variables of soft TQM practices on service innovation were the f-value was 33.253 which is significant at 0.000. The coefficient of determination was 0.437 which indicates that the variables of soft TQM practices constitute 43.7% of the service innovation. In addition, there is statistically significant impact at $\alpha \leq 0.05$ for the variables of commitment of top management and leadership, training, employees’ relationships, suppliers’ management of soft TQM practices in relation to service innovation where the t-value was, respectively, 2.741, 2.246,
2.085 and 2.101 and the statistical significance was, respectively, 0.007, 0.026, 0.038 and 0.037. These values are lower than 0.05 which indicates that there is an impact for each of them on service innovation. On the other hand, there was no impact for the variable of customers’ focus on service innovation were the t-value was 1.657 with a statistical significance of 0.099 which is higher than 0.05 and indicates that it has no impact on service innovation.

Moreover, there is a statistically significant impact on the variables of soft TQM practices on process innovation were the f-value was 32.643 which is significant at 0.000. The coefficient of determination was 0.433 which indicates that the variables of soft TQM practices constitute 43.3% of the process innovation. Also, that there is statistically significant impact at $\alpha \leq 0.05$ for the variables of commitment of top management and leadership, employees’ relationships, suppliers’ management of soft TQM practices in relation to process innovation where the t-value was, respectively, 4.306, 3.220 and 3.620 and the statistical significance was, respectively, 0.000, 0.001 and 0.000. These values are lower than 0.05 which indicates that there is an impact for each of them on process innovation. On the other hand, there was no impact for the variable of customers’ focus and training on process innovation were the t-value was, respectively, 0.483 and 1.661 with a statistical significance of, respectively, 0.630 and 0.098 which is higher than 0.05 and indicates that they have no impact on process innovation.

Furthermore, results have showed that there is a statistically significant impact on the variables of soft TQM practices on innovation management were the f-value was 27.166 which is significant at 0.000. The coefficient of determination was 0.388 which indicates that the variables of soft TQM practices constitute 38.8% of the innovation management. The table also shows that there is a statistically significant impact at $\alpha \leq 0.05$ for the variables of commitment of top management and leadership and employees’ relationships of soft TQM practices in relation to innovation management where the t-value was, respectively, 4.222 and 1.997 and the statistical significance was, respectively, 0.000 and 0.047. These values are lower than 0.05 which indicates that there is an impact for each of them on innovation management. On the other hand, there was no impact for the variables of customers’ focus, training and suppliers’ management on innovation management were the t-value was, respectively, 1.293, 1.692 and 0.213 with a statistical significance of, respectively, 0.197, 0.092 and 0.831 which is higher than 0.05 and indicates that they have no impact on innovation management.

**Results for the H2:** A test was made on whether there is a correlation between all independent variables (hard in all its dimensions) and all the variables related to innovation (in all its dimensions) through Pearson Correlation test.

Results have showed that there is a positive relationship between all variables of hard TQM practices and all variables of innovation. As well as between all variables of hard TQM practices as a whole and all variables of innovation as a whole. The significant level was calculated at 0.00 which is less than 0.05 with a strong positive correlation as the correlation coefficient was between 0.456-0.705, which indicates that impact can be tested between these variables.

Multiple Regression test was used to test the hypothesis. The results obtained from this test have showed that there is a statistically significant impact on the variables of hard TQM
practices on service innovation were the f-value was 49.625 which is significant at 0.000. The coefficient of determination was 0.408 which indicates that the variables of hard TQM practices constitute 40.8% of the service innovation. Results also have showed that there is a statistically significant impact at $\alpha \leq 0.05$ for the variables of data quality and reports and operations management of hard TQM practices in relation to service innovation where the t-value was, respectively, 2.756 and 5.206 and the statistical significance was, respectively, 0.006 and 0.000. These values are lower than 0.05 which indicates that there is an impact for each of them on service innovation. On the other hand, there was no impact for the variable service design on service innovation were the t-value was 1.622 with a statistical significance of 0.106 which is higher than 0.05 and indicates that it has no impact on service innovation.

In addition, Results have showed that there is a statistically significant impact on the variables of hard TQM practices on process innovation were the f-value was 45.239 which is significant at 0.000. The coefficient of determination was 0.386 which indicates that the variables of hard TQM practices constitute 38.6% of the process innovation. Results also have showed that there is a statistically significant impact at $\alpha \leq 0.05$ for the variables of data quality and reports and operations management of the hard TQM practices in relation to process innovation where the t-value was, respectively, 2.624 and 5.170 and the statistical significance was, respectively, 0.009 and 0.000. These values are lower than 0.05 which indicates that there is an impact for each of them on process innovation. On the other hand, there was no impact for the variable service design on process innovation were the t-value was 1.347 with a statistical significance of 0.179 which is higher than 0.05 and indicates that it has no impact on process innovation.

Moreover, results have showed that there is a statistically significant impact on the variables of hard TQM practices on innovation management were the f-value was 39.628 which is significant at 0.000. The coefficient of determination was 0.355 which indicates that the variables of hard TQM practices constitute 35.5% of the innovation management. The table also shows that there is a statistically significant impact at $\alpha \leq 0.05$ for the variable of operations management of the hard TQM practices in relation to innovation management where the t-value was 5.558 and the statistical significance was 0.000. This value is lower than 0.05 which indicates that there is an impact on innovation management. On the other hand, there was no impact for the variables of data quality and reports and service design on innovation management were the t-value was, respectively, 1.683 and 1.170 with a statistical significance of, respectively, 0.094 and 0.243 which is higher than 0.05 and indicates that they have no impact on innovation management.

**Conclusion, Applications, Limitations and Additional Researchers**

Studies show that soft and hard TQM practices are directly correlated to innovation in all its forms. According to the findings of this study, it can be affirmed that implementing TQM practices is valuable for companies and organizations which lead to innovation and in turn to sustainable competitive advantage. If Palestinian companies seek to stay in a strong competitive environment in local and global markets and compete with other international companies, they need to improve the quality standards of their products and use new methods in production and industry.
The study recommends that Palestinian companies use new methods and ways to compete in the global market. They need to investigate more, seize new opportunities for innovation and creativity as well as effectively exploit existing skills at the same time. Companies need to provide the necessary resources, keep up with the new technologies and change management through the development of innovative products (Lichtenthaler, 2009; Prajogo et al., 2008) in order to maintain sustainability in the market that is characterized by an environment of rapid development in technology.

The importance of the study stems from the focus on a vital sector in Palestine which is the service sector. This sector has an important role in increasing the socio-economic level of a country, and is a vital sector in Palestine. Due to the dynamic changes in the global economy, companies’ managers need to acquire more competencies in implementing TQM system and introduce technological innovation in their operations to keep pace with global developments and achieve the highest competitive edge. The study also contributes in guiding the companies’ managers on the key concepts of TQM and innovation. The results of this study are deemed important for decision makers in the Palestinian companies as they provide a clear mechanism to enhance the competitive advantage of the Palestinian companies through the implementation of TQM practices and supporting innovation. It also explains the obstacles that they face when applying TQM practices. This study is very important especially in developing countries such as Palestine where service companies seek to implement new philosophies to achieve their goals, improve their performance, increase their competitive edge and improve the economy of the country.

There are some limitations in this study that are important to mention. First, the selection and distribution of the study sample is one limitation as Palestine is divided into two parts: West Bank and Gaza Strip. All the participants in this study are from the West Bank and there are none from the Gaza Strip due to the political situations in Palestine and the geographical topography between the West Bank and Gaza Strip. Second, the data gathered for the purpose of this study was based on the service sector only. Future studies can expand on this study to: 1) implement studies on the challenges of implementing TQM in the service companies; 2) perform a comparative study on the degree of TQM implementation between the different service companies and industrial companies and; 3) conduct a study on the effect of implementing TQM on institutional performance for service companies.

Abstract
This study details the deployment of Six Sigma in the production and delivery system at a pharmaceutical company in Ireland. Over the past decade, teams have worked with the organization to reinforce the importance of target based manufacturing. This paper details one project with the objective to reduce cycle times for batches of products from order placement to shipment. The DMAIC framework was selected to meet the company’s quality, cost and delivery targets. After implementation, the order lead-time of products and batch paperwork were reduced by upwards of 25 percent, defects were reduced and a quicker customer response was provided.

Keywords: Lean and Agile Operations (12), Healthcare Operations Management (7), Total Quality Management, Kaizen and Six Sigma (39)

Introduction
With the volatility and strain being placed on the pharmaceutical industry today, efficient supply chains for organizations in this sector have never been more important and modeling these systems is becoming equally important (Settanni et al., 2017). Not only can inefficiencies affect sales and growth, they can also affect customer satisfaction, and in the worst cases, can potentially affect patient outcomes. Supply chain delays can cause unwanted and unintended problems downstream. For example, Einset and Marzano (2002) and Jacobs et al. (2015) showed in their studies that many organizations operate at a quality level which is equivalent to spending between 15% and 20% of their revenues...
on non-value added, wasteful, activities such as rework, inspection/testing, and losses. One way to eliminate such waste is by establishing a solid business process management and systematic supply chain improvement system using statistical and business process methods. This kind of transformation towards a standardized order process means that pharmaceutical companies have to rethink their supply chain processes and process improvement methodologies within the context of their business network. According to Alt & Puschmann (2005) pharma companies still have a way to go in adopting process improvement systems in their internal processes compared to other industries. In their view, reducing cycle and waiting times can assist big pharma in improving process efficiency and efficacy through building better relationships with their customers (Alt & Puschmann, 2005).

In this article, we will present a process improvement case where cycle time is much longer than the desired time. Using the Six Sigma methodology, along with the associated tools and techniques, we will investigate how to reduce cycle time in a particular service line and make suggestions on how to keep future problems from cannibalizing any gains made from our work. Our primary research question is whether a focused effort on cycle time reduction, using Six Sigma, can lead to performance improvements in the pharmaceutical industry. More specifically, when using well published tools such as value stream maps, fishbone diagrams, etc., and less documented tools such as the X-Y matrix, can we achieve cycle time reduction leading to less rework and/or higher quality?

**Research Motivation and Literature Review**

Six Sigma approaches and cases have been well published in the scholarly literature (Laureani and Antony, 2017). One of the most prevalent process improvement techniques for industry cases is the use of Six Sigma as a statistical measure of controlling defect rates within a system by reducing process variation. Defects can broadly be defined “as anything which does not meet customer needs of expectations” (Antony, 2006, p. 246). Brady and Allen (2006) describe Six Sigma as a structured and systematic approach to process improvement that aims to generate efficiency in the operations and efficiency of the activities in organizations by fostering an internal business orientation (Schmiedel et al., 2014; Vom Brocke et al., 2014).

According to a recent study by Takao, Woldt and da Silva (2017), Six Sigma is a rigorous and disciplined program that uses data and statistical analysis to define a problem, measure the process, improve the company’s operating performance (by eliminating defects, errors, or failures), and control the manufacturing, service, and transactional environment (Takao, Woldt and da Silva, 2017, p. 2).

**Investigating Reducing Cycle Time Using the DMAIC Methodology**

Six Sigma is also referred to as a “more detailed outline of Deming’s plan-do-check-act cycle by guiding the initiative through a five stage cycle of define-measure-analyze-improve-control (DMAIC)” (Pepper & Spedding, 2010, p. 142; Andersson et al. 2006; Andersson et al., 2014; De Mast & Lokkerbol, 2012; Pande et al. 2000). Each stage uses a set of techniques and methods in order to measure the critical issues in that particular stage. According to Pepper & Spedding, (2010, p. 143) key performance metrics are used to set “a clear focus on measurable financial returns through a sequential and disciplined manner and establishes an “infrastructure of champions” with its training style of introducing “belt” qualifications within the organization to lead the way in data-driven decision making for improvement efforts.” To achieve this, management commitment and open communication, are important for the success of a process improvement (Arora et al., 2005; London, 2005). Less support was often found with longer implementation
times of policies. While in many cases, the application of Six Sigma is explored in the construction industry, there are also select cases in the pharma industry (Nunnally and McConnell, 2007) as well as service industry (Stewart and Spencer, 2006).

The company hosting the project detailed herein is Helsinn-Birex Pharmaceuticals (Helsinn, https://www.helsinn.com/), a privately owned, Swiss-based, pharmaceutical company with manufacturing operations based in Ireland and the United States. Helsinn was listed as one of the top 1000 companies in Ireland and employees approximately 177 employees (Irish Times, 2019). Further, The Irish Times (2019) notes: “The Helsinn Group has been built on the basis of a unique business model, focused on the in- and out-licensing of pharmaceuticals, with the recent additions of medical devices in therapeutic niche areas.” One example of Helsinn’s passion towards continuous improvements is that they strive to have at least 70 percent of their workforce trained at a Six Sigma yellow belt level, or higher.

Methodology, Results, and Findings
To answer the research question, an exploratory, case study-based approach with a single case design was selected (Eisenhardt, 1989; Yin, 2014). Four criteria were adopted and applied in this case study: (1) completed Six Sigma project in the pharma industry, (2) an order management system being put into place, (3) challenges with the order management process, and (4) access to data. The researchers involved with this project were tasked with conducting a process improvement analysis of Helsinn’s Klean Prep production line due to their abnormally long cycle time from the date an order is received to the time it is ready to be shipped. Our primary metric was cycle time (in weeks), and our secondary metric was the number of times rework is completed and the percentage of rework for each step in the process. With this project came many limitations and constraints, some of which include:

**Time:** The team was limited to a one month duration to complete the project. This included gathering the data, analyzing it, and making recommendations on how to improve the process. Additionally, the team was only allowed to visit the company grounds one or two times a week, complicating and condensing the data collection and analysis process.

**Data:** While the team had access to large amounts of data, it was not easily understood what story the data was portraying. With access to ample large data sets can come ‘analysis paralysis,’ in management decision making (Bumblauskas et al., 2017).

**Industry Knowledge:** No member of the core student team had worked in the pharmaceutical industry. The manufacturing of these products from start to finish is a complicated process. Not having industry or institutional knowledge created a gap that had to be quickly overcome given the project duration and timeline.

**Regulations:** The pharmaceutical industry has intense regulations that must be adhered to at all times. This complicates decision making in order to improve a process. Great care must be taken to make ensure that these regulations are not compromised in any way. This is a unique consideration when compared to other Six Sigma case studies across other industries.

**Assumptions:** Assumptions needed to be made regarding some of the data that was collected. Bias could be introduced here, skewing results that are not desirable.

The underlying project management framework within the Six Sigma methodology is known as DMAIC, which stands for Define, Measure, Analyze, Improve, and Control. Using this approach, we were able to model ways to reduce cycle time in the Klean Prep line for Helsinn. Each stage of the process is outlined in the subsequent sections.

**Define:** One of the initial project goals the team established was to determine the cycle
time for all process activities in the Klean Prep supply chain at Helsinn. At the time of the project in 2011, Helsinn was spending roughly 13 weeks from receiving customer orders to shipping finished goods to customers. This relatively long cycle time reduced product competitiveness. Because of the nature of the pharmaceutical industry, good manufacturing practices (GMP) require certain activities to be controlled in very specific manners. Much of what seems like non-value added activity may actually be due to regulations or may be done to comply with GMP. The goal of the project team was therefore to determine where time was allocated for each activity in the Klean Prep supply chain process. Figure 1 was created to give an overview of the Klean Prep process flow. Helsinn’s material requirements, or resources, planning (MRP) system uses an item master that holds parameters for the lead-times of each order status. The supply chain manager uses this tool when scheduling the order for production. The supply chain manager takes into account the customers’ requested ship date(s) and the capacity of the production line(s). Once a ship date is determined, the supply chain manager works backward to schedule the time allocated for QA approval, production, generating a parts list and ordering materials (i.e., develops an aggregate production plan).

**Measure:** Another objective specified in the team’s project charter was to create a value stream map of the Klean Prep supply chain from the creation of a work order to approval by Quality Assurance and final shipment. The primary goal was to identify where time was being spent going throughout the process and to determine which activities have the most variability in cycle time. Figure 2 provides a fishbone, or Ishikawa, diagram (Ilie, 2010; Wong, 2011) which is a beneficial tool to help identify all the possible factors affecting the cycle time before any data collection and analysis begins.
Six categories of factors that affect cycle time were deemed appropriate for this project: material, manpower, measurement, method, environment, and equipment. The factors associated with each category represent the possible causes for variation in the Klean Prep cycle time. For example, within the environment category, the customer’s requested ship date is an issue when considering cycle time of the process. The schedule is set up to give a 13 week lead-time. Some customers will submit an order requesting delivery to be shorter or longer, depending on their time schedule. Helsinn would then adjust their time schedule to meet the customer’s demand. If the customer requests delivery after the original 13 week lead-time, Helsinn will delay ordering materials until they are needed to meet the deadline. Working in this just-in-time (JIT) fashion, it is easy to see how the cycle time can vary from customer to customer.

In the methods area, not having benchmarks was deemed to be an issue. Creating a benchmark for a procedure not only helps managers and line workers to perform a procedure correctly, but it also assists in monitoring the procedure to see if it is under control. A benchmark can lead to creation of standard operating procedures (SOP), which can be used to reduce rework and lower variance, making the process more efficient.

After assembling the fishbone diagram, an XY diagram was used to analyze important factors in varying cycle time and the impact they have on the metrics of the project. In this case, the primary metric used was the total average cycle time and the secondary metrics were (a) cycle time variance, (b) number of times rework is performed, and (c) percent rework performed in a lot. An XY diagram works by taking the input variables that are most important and cross-analyzing them with each metric, which are ranked on a scale of one to ten, with ten being the most important. The numbers inside the diagram represent the affect the inputs have on the outputs, or metrics. Figure 3 shows an XY diagram for this project.

After ranking the metrics and cross-analyzing them with the input variables, Figure 3 shows that the time materials are ordered is the largest factor in the cycle time, followed by SOPs, the schedule, and having no benchmarks in place. This can be seen in the table provided as part of Figure 3. These factors provide a good indication on what to review when making suggestions for improvements in the process. While SOPs were considered the second most important factor, it is imperative to remember that in the pharmaceutical industry these procedures must be followed at all times. These are government regulated procedures and GMPs that must be adhered to. If they are deviated from, the company could face legal action or recourse.

**Figure 3 – X-Y matrix diagram**

It is important to note that the fishbone diagram and the XY diagram are working diagrams. As time goes on, they should be updated to deter future problems. After a problem is fixed, there may be a new problem that should be focused on. Keeping an updated version of each diagram will help identify flaws in the future, making the process more efficient and easier to deal with if there is a problem later on.

**Analyze:** Helsinn’s MRP system automatically records a time stamp when specific activities occur. Time stamps from a sample of n = 33 different lots were used to determine the average length of time each activity takes in the process. The time stamps did not occur at the exact points in the original process map, so an alternative map was created that tracked the routing of the work order. The sales order process flow occurs in parallel to the work order. At certain points in the sales order data, the process actually reverses and goes upstream. This makes it difficult to track the exact cycle time for each activity in the sales order flow. As a secondary metric, the number of process reversals was calculated for each lot given. Since the cycle time was not known, there was not a way to be totally confident in which activities are the most time consuming, but where the process typically reverses can be determined.

The average total cycle time of the work order was found to be 13.15 weeks with a standard deviation of 4.5 weeks. The average cycle time for the sales order was 14.39 weeks with a standard deviation of 5.7 weeks. The sales orders and work orders run in parallel to each other. Sales and work orders are scheduled to meet a specific ship date which is specified by the customer and the supply chain planner. Figure 4 provides a box plot to illustrate high variance steps in the Klean Prep supply chain process. Boxplots are very useful for identifying quartile ranges and outliers and have been well documented.
across many industries including healthcare (Williamson et al., 1989).

Figure 4 – Work order box plot

Part of this has to do with scheduling issues and the availability of raw materials. The steps with the largest variability are 10/15 (Create the Work Order/Attach Routing) and 30 (Generate the Parts List) as detailed the figure. These steps in the process are also the ones with the longest cycle time. Figure 5 shows a value chain map of the cycle times in the work order process flow.

Figure 5 – Klean Prep value stream map

As can be seen in Figure 5, the average cycle time to create the work order and attach routing is the longest of any status. The cycle time for this step of the process is an average of 48 days with a standard deviation of 41 days. A couple of factors hinder this process. Helsinn waited one week after the sales order was confirmed to order packaging materials. The lead-time on those materials could be up to 4 weeks long. The orders must also be run through the MRP system before buyers receive a message to order materials. The packaging materials are ordered on a JIT basis. This means that they will be ordered to arrive in accordance with the production schedule, but no earlier. Buying materials in bulk can lead to discounted costs for Helsinn. The MRP system gives buyers a window of opportunity to determine whether or not they can purchase the materials together.

The lead-time between creating a work order and generating the parts list is largely
impacted by waiting for customers to confirm artwork changes. Packaging materials cannot be ordered until artwork changes have been confirmed. Artwork changes could be due to a color change on the box, moving text to another location on the package, a change of address, or any new regulatory measures on drug packaging.

The second longest part of the process is waiting to generate the parts list. This takes an average of 17 days, but the standard deviation is 22 days. This is a massive swing in variability. Helsinn’s policy, at the time, was to not commit any material to the order until all the materials were received. In this way, materials were not committed to the order until they are in the warehouse and ready to be moved to production. Once material is received, the parts list can be generated. For the secondary metric, the number of reversals in the sales order flow is examined, as shown in Figure 6.

![Figure 6 – Klean Prep sales order flow](image)

It was found that there was an average of two instances of rework in each order. In every case of reversal, the process was backtracking from either status 540 to 535 or 535 to 525 (as defined in Figure 6 and subsequently). The normal flow from status 525 to 535 is identified as “Planner Confirmed and Awaiting Customer services”. Status 535 to 540 means that the order is “Picked and Awaiting Packing List.” In 19% of cases, there is rework required on status 525 to 535. Rework on 535 to 540 occurs in 97% of cases. This rework is generally due to confirmation of changes in the sales order with the customer. Any time there is a change in the sales order it must be reconfirmed with the customer before proceeding to the next status.

**Improve: Benchmarks:** Helsinn, as of 2011, had no benchmarks set in place for each individual status. Implementing a specific benchmark for each status may serve to reduce the variability that occurs. It would also set a standard for scheduling those specific steps in the process.

**Artwork Investigation:** It was also recommended that Helsinn investigate which customers are changing their artwork frequently and which customers are stable. Once stable customers are identified, it is possible to order those packaging materials as soon as sales orders are received. This can reduce a portion of the lead-time between creation of the work order and generation of the parts list. At times, there could be up to 25 artwork changes under consideration. This can slow the process down if not enough manpower is available to tackle all of the changes at once. In 2011, there was only one employee
responsible for artwork. It would be worthwhile to investigate how many artwork changes occur in a year and to perform the cost/benefit analysis on hiring additional artwork support. Helsinn might also consider forming contracts with customers, ensuring that artwork changes are approved within a certain amount of time before the order is placed. Implementing a year-long contract period where artwork does not change can also allow Helsinn to be more confident in ordering packaging materials when sales orders are received. Exceptions should be made for regulatory changes.

**Eliminate Rework:** Sales order rework should be investigated as well. Rework occurs regularly which costs time in the sales order work flow. Since the processes are parallel, it’s impact may not be substantial enough to cause concern.

**MRP Opportunities for Change:** The actual cycle time for each status may vary from the time allotted in the Item Master parameters. If this is the case, schedules made from the Item Master will not accurately reflect the needs of each department. It was recommended that Helsinn might benefit from looking into the actual cycle time versus the [default] parameters in the MRP system. If there are discrepancies, the Item Master should be adjusted to account for the time constraints of each department. Changes to the MRP parameters can lead to adjusted schedules that reorganize time in a more efficient manner.

**Control:** If any suggestions are seriously considered, maintaining gains after implementation is critical to the success of the overall project. For this to occur, constant checks on benchmarks should be performed as to not revert back to previously identified and/or corrected problems. This could help deter future rework throughout the process, while at the same time helping to identify future problems. Thus, the process has the potential to continue to improve if the right control measures are taken. Tracking the variance over time would also help identifying future problems quickly. Keeping out in front of the problems, i.e., taking a proactive approach, will also help remedy them in a timely manner.

**Discussion, Conclusions, and Future Work**
In summary, this article details a case study derived from real data obtained from a pharmaceutical company (Helsinn) providing support for our hypothesis. With reduction in variation, rework and waiting time, better decisions can be made, and costs can be reduced. In some instances the projects executed for Helsinn over the years have yielded reductions of upwards of 25 percent of cycle time. An improvement process using Six Sigma tools and operating within the DMAIC framework was formulated to reduce the cycle times.

This is one of many projects conducted by the authors and student research teams under their supervision at Helsinn over the last decade. In one case, the Helsinn team took the results to their Senior Management in Switzerland for final decision making and action. More should be published in this area to further illustrate the importance of Lean and Six Sigma in a continuous improvement journey. Another post-project development was an impact versus effort quadrant model which uses an eight step methodical process developed by authors and a Fortune 500 organization. This should be further elaborated upon in future work. The goal of reducing cycle time using Six Sigma in the pharmaceutical industry has yielded dividends and should continue to do so for many years to come.

**Acknowledgements**
The authors would like to thank Stephen Watters, Helsinn Internal Manufacturing Senior Manager, for his review of this manuscript and the entire Helsinn team for their support.
in overseeing and supporting numerous projects over the years. We would also like to thank Allie Scott and Che-Wei Fan for their contributions to the field execution of the project detailed in this paper.

Abstract

Among Business Excellence Models that guide organizations towards high performance, EFQM is widely adopted in Europe. Given demands for better management of resources and sustainable practices, within EFQM is the principle of Creating a Sustainable Future. This study investigates whether EFQM has been effective in disseminating sustainable practices. Data from a population of recognized-for-excellence organizations by a partner of the EFQM in Spain, from 2000 to 2014, are used. The evolution of criteria on sustainability and their association with Society and Business results are examined, thus testing the premise that sustainable organizations perform well on social, environmental, and economic aspects.

Keywords: sustainability, quality management, business excellence models, EFQM

Introduction

Following the Brundtland Comission’s definition of sustainable development (WCED, 1987), several definitions of sustainability have emerged in the literature. In common, they emphasize environmental, social and economic performance, so that sustainability is about conducting business with a long term goal of maintaining the well-being of the economy, the environment and society (Hassini et al., 2012). Environmental resources are limited, so that companies need to operate in a way that minimizes their negative environmental impact (Shrivastava, 1995). In this vein, the European Foundation for Quality Management (EFQM) Excellence Model, which is the most widely adopted business excellence model in Europe, defines fundamental principles that form the foundation for achieving sustainable excellence in any organization (EFQM, 2012). Specifically, the notion of creating a sustainable future is embedded in the model, and thus EFQM addresses the institutional pressures faced by organizations to explicitly balance economic, environmental, and social impacts of their day to day activities (Edgeman and Hensler, 2001). Organizations are encouraged to consider sustainability in all stages from product/service design, material sourcing, manufacturing processes, and delivery of the final product/service to the customers, to the end-of-life management of the product after its useful life (Srivastava, 2007). Efforts to reduce carbon-footprint, how these efforts are coordinated with partners, and replicated in the
supply chain are also key features towards delivering a sustainable future. Consequently, with its focus on processes and practices, the EFQM Model can be a driver of sustainable development (e.g. Cierna and Sujova, 2015; Gorenak, 2015; del Rio et al., 2017; Pérez and Escrig, 2018), especially as it has become a global model with over 50,000 users worldwide (EFQM, 2019).

Sustainability is stressed in recognitions for excellence, since the goals of the UN Global Compact are either explicitly or implicitly covered in the criteria defining the EFQM model. Hence, the EFQM model provides a framework to promote and recognize sustainable success and guides organizations that seek to achieve excellence. Based on a standardized Recognition Scheme, trained EFQM assessors evaluate organizations according to 32 sub-criteria, which lead to scores on 9 criteria, of which 5 are ‘Enablers’ and 4 are ‘Results’. Enabler-criteria cover what an organization does and which management practices are in place with respect to each criterion (Leadership, People, Strategy, Partnership and Resources, Processes, Products & Services). While, Results-criteria cover what an organization achieves in terms of People, Customers, Society, and ultimately, Business results. Although the EFQM model does not explicitly link the sub-criteria related to sustainability and results criteria, one would expect that what recognized organizations do in order to create a sustainable future, as implied by different sub-criteria in the model, would impact their Society results and Business results scores. In other words, the triple bottom line as a concept for an overall evaluation of performance, implies co-movement between sustainability, social and economic performances.

This study identifies the implicit sustainable future orientation in the EFQM model and examines whether this orientation, which implies the adoption of sustainable practices, can explain Business and Society Results. In the remaining sections, the theoretical background and the research question that guides the investigation are summarized. Secondly, the empirical study and results are reported. Finally, the implications for practice and future research are drawn, and the paper concludes.

**Sustainability and Performance**

The Triple Bottom Line model (Elkington, 1999) entails that an organization concerned with sustainability should be responsible for the impact of their activities on social (people), environmental (planet) and economic (profit) issues. Since the development of this model, there has been a growing interest in more ethical or transparent ways of running businesses and in related concepts, such as corporate sustainability or corporate social responsibility (CSR). As Van Marrewijk (2003) or Montiel (2008) stated, corporate sustainability and corporate social responsibility might have followed separate paths, but share the same vision, so that nowadays the two concepts have become interchangeable. Indeed, both streams of literature refer to organizational activities that imply commitment to stakeholders and accountability of economic, social and environmental issues while managing operations (Aguinis and Glavas, 2012; Larran et al., 2016; Mehralian et al., 2016). Moreover, as Asif et al. (2011a) highlighted, sustainability also requires the adaptation of business strategies to emerging stakeholders’ requirements.

As several authors recognized (e.g. Husted and de Sousa 2017; Mendes and Dias, 2018), Stakeholders Theory implies a managerial decision-making that accounts for the demands of all stakeholder, rather than a focus on shareholders, so that value is generated and sustainable results are achieved. Hence, organizations engaging in sustainable practices are likely to operate consistent with the expectations of their stakeholders, which potentially results in competitive advantage and higher performance.
(Porter and Kramer, 2006; Mehralian et al., 2016). Accordingly, there is a business-case for sustainability (e.g. Carroll and Shabana, 2010). Despite conflicting evidence on the business case for sustainability (Brammer et al., 2006), a meta-analysis by Orlitzky et al. (2003) concluded that there is positive association between business performance and key elements of sustainability. Sustainable practices were reported to impact customer’s perceptions of differentiation and quality (e.g. Aguinis and Glavas, 2012), which are likely to affect business results. Peršič et al. (2018) also found that the adoption of ISO 26000 can positively influence financial performance. In the specific context of Spanish organizations, Muñoz et al. (2012) observed benefits of having standards of socially responsible management for business and environmental performance. Moreover, Mendes and Dias (2018) concluded that sustainable approaches based on quality management and socially responsible practices improved financial and operational performance, as well as the quality of working-life. In summary, sustainable practices can benefit businesses and society.

The EFQM Excellence Model as enabler of change towards sustainability
How can sustainability be integrated into management practice has been subject of ongoing research, with some concluding that, where quality-related initiatives are in place, social responsibility is easily promoted (e.g. Van Marrewijk, 2003, Tarf, 2011). In fact, quality management has evolved from customer-focused to stakeholder-focused (Mellat-Parast et al., 2014), and when addressing the quality management and social responsibility nexus, Ghobadian et al. (2007) observed that both are rooted in a common philosophy that can lead to non-financial and financial benefits. Hence, current quality management recognizes the impact on society of what an organization does, and account for the need to balance and fulfil different stakeholders expectations (Mehralian et al., 2016; Mendes and Dias, 2018). Similar to the Malcom Baldrige National Quality Award that specifies social responsibility and various stakeholders’ interests within its assessments, the EFQM Excellence Model is a useful platform to guide organizations in placing sustainability into practice.

The EFQM Excellence Model
The EFQM Excellence Model is a non-prescriptive quality management framework that facilitates the understanding of the relationships between what an organization does and the results it achieves. It provides a systematic structure, which allows organizations to thoroughly review their management practice and can guide them towards sustained success (Bou et al., 2009; de Menezes and Escrig, 2016). The current framework, as per EFQM (2012), is based on nine criteria, as depicted in Figure 1.

![Figure 1. EFQM Excellence Model criteria](image-url)
The “Enabler” criteria cover the actual organizational practice, while the “Results” criteria cover what is achieved. The RADAR logic of the assessments reflects the dynamic nature of the Model and provides a structured scheme for systematically reviewing the nine criteria. Therefore, the EFQM model indicates the areas that managers should focus their attention in order to improve performance and, as illustrated by the arrows in Figure 1, the model accounts for the feedback-loop from management practices to results and learning (Zwetsloot and van Marrewijk, 2004). When an organization applies for EFQM recognition, its practices are assessed against the model in Figure 1, so that points are allocated to each sub-criterion by trained assessors based on evidence. Recognition for excellence can be given at three levels (300+, 400+, 500+) depending on the score obtained (maximum score =1000). Recognition is valid for two years, after which an organization (or unit) would need to apply for reaccreditation.

**Sustainable practices embedded in the EFQM model**

Anninos and Chytiris (2012) noted excellence and sustainability are linked. Since society and the environment can be stakeholders (e.g. Garvare ad Johansson, 2010; Siva et al., 2016), Stakeholders Theory informs not only social responsibility, but also the EFQM model, which states that excellent organizations “achieve and sustain outstanding levels of performance that meet or exceeds the expectations of all their stakeholders” (EFQM, 2012: 2). Considering that sustainability can be reached when an organization recognizes the concerns of its main stakeholders and develop strategies to satisfy their expectations, the EFQM model can be used to address stakeholders’ demands in pursuit of sustainability (Asif et al., 2011b). Indeed, embedded in the model is the concept of Creating a Sustainable Future, accordingly “excellent organizations have a positive impact on the world around them by enhancing their performance whilst simultaneously advancing the economic, environmental and social conditions within the communities they touch” (EFQM, 2012: 5).

The EFQM model’s Creating a Sustainable Future is a transversal concept, as is manifested through distinct sub-criteria in the model (EFQM, 2012; del Rio et al., 2017). The adoption of the EFQM model can raise awareness of sustainability, and enable related practices as part of a quality management approach to be developed, continuously assessed, and refined. According to EFQM (2012), Creating a Sustainable Future is an orientation that underlies the following sub-criteria, i.e.: 1a.Leaders are role models for social responsibility; 1c.Leaders engage with external stakeholders; 1e.Leaders manage change effectively to ensure the sustainable success; 2c.Integrate the concept of sustainability in the core strategy; 4b.Finances are managed to secure sustained success; 4c.Buildings, equipment, natural resources are managed in a sustainable way; 5b.Products and services are developed to create value to customers in a responsibly way.

Considering guidelines on these sub-criteria, organizations adopting the EFQM model develop their own practices to integrate sustainability in their vision, mission and values. They preserve the environment, collaborate with customers, suppliers and other partners, and promote the integration of their business activity in society through sponsorship of socio-economic or cultural projects. In doing so, their actions confirm that the EFQM model is a basis for the practical implementation of social responsibility (CEG, 2018). Several case studies (e.g. Pedersen and Neergaard, 2008; Avlonas and Swanninck, 2009; Asigil, 2010) also support the view that social and environmental concerns can be integrated into everyday practice via the adoption of the EFQM model. For instance, Pedersen and Neergaard (2008) observed how management commitment,
a driving force in the EFQM Model, is also a prerequisite to addressing environmental management, and developing dialogues with stakeholders, ethical programs or codes of conduct. Pérez and Escrig (2018) concluded that the greater the maturity in the adoption of the EFQM Model, the greater is the development of sustainable practices. Yet, these studies have not addressed the triple bottom line.

**The EFQM model enables measurement of social, environmental and economic results**

As per del Río et al. (2017), creating value regarding the triple bottom line is in the essence of the EFQM model, for the impact of the implementation of sustainable practices can be identified in Results on economic status, social and environmental benefits. In fact, Kok et al. (2001) highlighted that results criteria in the EFQM model include the core of corporate social responsibility. While being economically viable is in the EFQM criterion that assesses Business results, social and environmental responsibilities are included in the criterion assessing Society results (Cierna and Sujova, 2015; del Río et al., 2017). Business results considers the key elements in the organizational policy and strategy, and focuses on internal measurements of achievements regarding the planned-performance, i.e. financial indicators and performance indicators on key processes. Society Results accounts for the general impact on society and on the local community, both in the socio-cultural and environmental dimensions. It specifies that excellent organizations “achieve and sustain outstanding results that meet or exceed the needs and expectations of relevant stakeholders within society” (EFQM, 2012: 19). Hence, recognized for excellence organizations demonstrate: involvement in community, support for education, health, sports, efforts towards reducing noise, pollution and other damages from its activities, as well as policies towards preserving and maintaining resources (e.g. reduction of packaging). Following recognition, organizations can benefit from its reputation.

**Sustainability approaches can influence performance**

Although the EFQM model, Figure 1, does not specify the relationship between having an orientation that creates a sustainable future, as embedded in its concepts, and results criteria, a positive association is expected. First, as reported above, the literature on the business case for corporate sustainability underlines that sustainable practices can impact dimensions of performance. Secondly, since the EFQM model is a tool to assess how enablers influence results, a correlation between Creating a Sustainable Future and results is envisaged. In fact, different studies on the EFQM model support relationships between enablers-criteria and results-criteria (e.g. Bou et al., 2009; Escrig and de Menezes, 2016). Specifically, del Río et al. (2017) and Calvo et al. (2018) concluded that there is positive associations between EFQM-enablers and Society results.

A sustainability orientation is reflected on how leaders are agents of change. As such, they behave ethically and responsibly, scan social and environmental data, focus on stakeholders when designing the organizational strategy. In addition, within Creating a Sustainable Future, managerial commitment is assessed by investments in resources that do not harm the environment, guiding clients on responsible use of products, and identifying improvements in products and services according to the expectations of customers and other stakeholders. Hence, having a sustainability orientation may imply savings due to efficient use of resources (financial, material, information, infrastructures), as well as reputational gains. Moreover, the RADAR scheme in the EFQM model, as a continuous improvement methodology, facilitates that a sustainability orientation is carried out systematically in order to ensure progress. According to Anninos and Chytiris (2012) excellence entails self-improvement,
progress based on adaptation to new situations via continuous self-assessment and improvement of results. RADAR promotes a corporate behaviour that enables organizations to systematically address emerging stakeholders’ demands and integrate sustainability into their operations. EFQM therefore enables sustainable practices to be implanted in routines and processes, and ensures the fulfilment of an organization’s responsibilities towards society (Mehralian et al., 2016). Consequently, we explore the following research question: Can an orientation towards creating a sustainable future impact Society results and Business results as predicted by the EFQM model?

The Study
The data are from a population of organizations awarded EFQM recognition by the Club de Excelencia en Gestión (CEG), a partner of the EFQM in Spain. The dataset contains 2,069 observations corresponding to recognitions from January 2000 to September 2014 obtained by 1,350 organizations. For each unit, the data include the level of recognition and their dates of issue and expiration; the size, the activity and the location of the unit assessed; and the scores on each sub-criteria, which are only available when a unit was recognized for excellence (total score ≥300). Given the availability of scores, we restricted the sample period to the last 8 years, for which there are 5 or more organizations recognized for excellence in the year. This leads to an unbalanced panel with 147 observations and 110 organizations: the maximum number of time-measurements per organization is 4, with only 25% of the sample having more than two sets of assessments (recognitions) in the period; and the number of organizations recognized in a year varies from 5 to 50.

If there is an orientation towards Creating a sustainable future, it can be inferred from the correlation between the scores in the 7 sub-criteria that reflect this concept in the EFQM model. Considering the number of sub-criteria and yearly sample sizes, it is assumed that the correlations between pairs of sub-criteria does not vary significantly with time, and the data are pooled so that factor models can be estimated. Using Stata 15, principal factor and a maximum likelihood estimations imply that underlying the sub-criteria there is a single common factor: only one eigenvalue is greater than 1; a measure of the amount of variance in a sub-criteria that is not explained by the common factor is such that it varies between 16% to 45%, and is on average 25%; in addition, if a two-factor model were estimated, the first factor accounts for 95% of the variance, and the second factor is rejected by a likelihood ratio test. Considering the estimates based on maximum likelihood one-factor model, scores on this orientation are predicted for each organization at each year when it is recognized for excellence. This measures EFQM’s Creating a Sustainable Future orientation, which is the independent variable in this study. The dependent variables are the actual scores on Society results and Business results achieved at recognition.

Figures 2 and 3 illustrate the association between dependent and independent variables. We note the difference in scale and identify an outlier in Figure 3, which is excluded from the analysis that follows. Further preliminary analysis of this subsample also highlighted that most organizations are in the services sector, but there is variation in size (number of employees). In addition, when the dependent variables are plotted for organizations that have more than one recognition in the period, it can be seen that their starting points (intercepts) vary, which is consistent with the three levels of recognition in the sample. Given these observations, random effects models (Results\(i_t = \beta_1 \text{Sustainability Orientation}_i + \beta_2 \text{size}_i + \alpha + u_{i+} + \epsilon_{i+}\)) that control for the size of the organization, using a binary variable that indicates whether the organization is small or medium, were estimated using Stata 15. The results are summarised below.
Tables 1 and 2 summarize the estimated models for Society and Business results, respectively. It can be seen that having a sustainability orientation is positively associated with both types of results (P-value=0.00). Based on the variance of the error terms, the intra-class correlation ($\rho$) is computed and shows how much of the variation in the data is due to the year in which recognition was awarded. In both models, this value is greater than 0.05, thus justifying the treatment of the data as separate panels. The fit statistics, Chi-Square and R-Square indicate that a significant proportion of the variance in Results are captured. Society results vary with the size of organization (p-value=0.04), but this is not the case with regards to Business results. In all, both models imply that an orientation towards Creating a Sustainable Future can benefit the organization and society.

A limitation of this study is the sparseness of the data, which is due to the fact that most organizations in the dataset have not achieved recognition for excellence. Indeed, this confirms what is stated on EFQM’s website: “All organisations strive to be successful, some fail, some achieve periods of success but ultimately fade from view, and a few achieve sustainable success, gaining deserved respect and admiration.” (EFQM, 2019). Future research may therefore engage with other EFQM partners and build a database with a larger population and additional years, as the data also demonstrates that with time the number of recognitions increase.

Summary and Conclusions
This paper contributes to the literature addressing the integration of sustainable practices into management systems and its findings support Zwetsloot and van Marrewijk’s (2004) statement that the basis for sustainability can be constructed on the experiences of business excellence models. Organizations that have been awarded an EFQM recognition exhibit a sustainability orientation displayed in the use best practices implicit in several enablers sub-criteria. Given the performance indicators within the Society results criterion, recognized for excellence organizations track social and environmental impact, in addition to economic performance. Yet, small and medium organizations differ in Society results, and this corroborates the findings from previous analysis of organizations awarded EFQM recognition (e.g. Escrig and de Menezes, 2016). As Ascigil (2010) argued, a potential explanation is that closeness to the local communities in which they operate is greater in SMEs, thus the pressures are more immediate, require rapid response and proactivity, as well as resources that may not be available in SMEs.

Scholars such as Kok et al. (2001), Pedersen and Neergaard (2008) or Asif et al. (2011b) stress that the EFQM Model focuses on the needs of stakeholders, but only to the extent that there is a direct relationship with the economic responsibility of the organization. This study confirms that the EFQM model incorporates the triple bottom line: economic growth, respect for the environment and social progress, and thus integrates the tree pillars of sustainability. This is encouraging, since sustainability has
been one of the trends and topics of interest highlighted in the different versions of the EFQM model. In addition, the positive correlation with both types of results indicates that EFQM has been effective in guiding companies on what sustainability means, providing approaches to its achievement and ensuring coherence between the apparently conflicting responsibilities that organizations assume to its shareholders and society.

Acknowledgments
The authors appreciate the financial support for this research from the Universitat Jaume I (Ref. UJI-B2017-21) and Ministerio de Ciencia e Innovación of Spain and FEDER (ECO2015-66671-P) (MINECO/FEDER). The authors are also greatly indebted to the CEG for providing the data; without its support this study would not have been possible.

Abstract

Over one million organisations have a Quality Management System (QMS) certified to the ISO 9001 standard; however, the system requires a lot of resources and its value has been questioned. The purpose of this paper is to investigate how different types of uses of QMS correlates with management perceptions of QM in terms of respect, cost, and strategic importance. The paper is based on a survey within eight organisations and shows that a compliance-orientated QMS usage will more likely lead to a view on quality management as costly, and of little respect, than a business- or improvement-oriented QMS usage.

Keywords: Quality Management Systems, Quality Management, Value-adding QMS

Introduction

Today, more than one million companies and organisations globally are certified in accordance with ISO 9001 (ISO Survey, 2017). In organisations’ Quality Management (QM) work, a significant amount of time and focus is given to the Quality Management Systems (QMS) (Elg et al., 2011), thus it is important that QMS adds value to the organisations (Lenning & Gremyr, 2017). The interest in QMS has further grown by its potential to support implementation of sustainable development efforts through integrated management systems, or by improving environmental management systems based on learnings from QMS (Siva et al., 2016). This potential has, however, not fully been exploited and Allur et al., (2018) suggest that increased formalization and bureaucracy, induced by a certified QMS, is a reason stated for cases in which QM is perceived as hindering rather than supporting implementation of sustainable development efforts. Even with a focus on QMS per se, i.e. not as a support for an environmental management system, QMS have been subject to critique for providing limited value in its support for quality improvements, hindering creativity, and being disconnected from actual practice (Pokinska et al., 2006).
At the same time, evidence suggests that QMS provides a critical and well-established infrastructure with potential to create value and support continuous improvements (Lenning & Gremyr, 2017). To achieve as much value as possible, one critical factor is to have managements’ support and appreciation of QM work overall (Beer, 2003; Joiner, 2007; Kaynak, 2003; Lakhal et al., 2006). The purpose of this paper is to investigate how different types of uses of QMS correlates with management perceptions of QM in terms of respect, cost, and strategic importance. Drawing on the various ways of operationalizing QM proposed by Maguad (2006), this study investigates three types of QMS usage: QMS as support for developing the quality of an offering, QMS as a tool for daily management, and QMS as a tool for standardization and documentation. The study focuses QMS that are certified to ISO 9001, and correlations between the three ways of using QMS and managers’ view on QM.

The main contributions of this paper to the existing body of research on QMS are: to describe three different ways of using a QMS; to detail and nuance the understanding of why QMS are perceived as non-value adding by focusing ways of working with QMS and not QMS overall; and to add to the research evaluating QMS impact mainly on financial performance by also studying possible impact on management’s perception of QM. In the following a background to QMS usage and three ways of using QMS is provided, followed by a method chapter, findings, discussion of the findings, and finally conclusions drawn.

**Theoretical Background**

Born with the ideas of Deming, Shewart, Juran, and Ishikawa, soon four decades ago, QM has evolved to become a management philosophy and approach (Hackman & Wageman, 1995). QM has been presented to be based upon three pillars, namely; principles, practices and techniques (Dean & Bowen, 1994); the principles being customer focus, continuous improvements, and teamwork.

The ISO 9001 management system standard, being a QM tool and a common basis for a QMS, has become universal (ISO Survey, 2017). ISO 9001 is argued to have potential to contribute to quality improvements (Sousa & Voss, 2002) and improved operational performance (Kaynak, 2003). However, the value and the effect of a QMS is argued to depend on different factors such as QM maturity, implementation strategy, and people involvement and certification audits (Pokinska, 2010).

The type of motivation for implementing a QMS is also argued to influence the performance of the system. Organisations focusing on real quality improvements achieve higher benefits from their QMS implementation in e.g. quality and operational improvements, compared to those organisations that implement and seek certification of their QMS for external motives, for example image or customer requirements (Boiral & Amara, 2009; del Castillo-Peces et al., 2018; Pokinska et al., 2002; Sampaio et al., 2009). Thus, a QMS implemented based upon external requirements, tends to focus more on compliance control, and less on organisational efficiency (Alič & Rusjan, 2010). Therefore, to achieve the possible benefits from a QMS a change in practise, and commitment from all members in the organisation are required while it is argued that there are only a few internal or external benefits from the standard i.e. ISO 9001 itself (Pokinska, 2010).

In the following three different ways of working with QMS will be outlined. The three ways draws on Maguad (2006) who argued that quality in the 21st century could be categorised based on three different orientations; business management oriented, improvement oriented, and compliance oriented. However, it is argued that all three
orientations must coincide in order for an organisation to be successful in their QM work (Maguad, 2006).

**Quality Management Systems as a tool for daily management**

Maguad (2006) argued that business management-oriented quality demands an integrated deployment of strategy, and attention to critical success factors e.g. vision of the business, markets, and core processes. It also requires involvement from top management and every employee in continuous improvement efforts (Maguad, 2006). On an overall level, Sadikoglu & Zehir (2010) studied relationships between TQM practices and multiple performance measures and revealed that all TQM practices studied e.g. training, employee management, continuous improvement, information & analysis were significantly and positively correlated with measures on employee performance, innovation performance, and firm performance.

Regarding use of QM tools, one aspect that has been in focus is that the explicit potential of the tool to support a perceived and contemporary need is critical. To support QM tool usage it is necessary to have a structured deployment, which depends e.g. on training (Lee, 2004), and that training should be offered just-in-time when needed so that employees directly can practice what has been taught (Bunney & Dale, 1997). Furthermore, if tools are introduced when a team or department has a defined need, these tools are better understood and used in applications compared to tools deployed as a group e.g. as a part of a company-wide improvement program. In other words, a perceived benefit from a tool appears tightly coupled to it being deployed and used in a way that directly supports the daily activities in an organization.

Narrowing down to QMS as a tool for QM, it has been shown to have effects not only on effectivity, product and service quality, but also on employees and employers e.g. related to health and safety at workplaces (Levine & Toffel, 2010). Furthermore, Levine & Toffel (2010) show that after being certified firms experienced a growth in both sales and employment considerably quicker compared to firms that were not certified; thus the authors argued that managers should consider an ISO 9001 certification as valuable.

**Proposition 1:** If QMS is used as a support for managing the organisation, management will likely show respect for QM, not view QM as cost-driving but rather view QM as being of strategic importance.

**Quality Management as a support for developing the quality of the offering**

To achieve customer satisfaction and ensure sustainable organizational success it is argued that emphasis should be on continuous improvements. This improvement-oriented view on QM promotes an integrated approach for process improvements, involves the whole organisation and has wide range of applications e.g. on service and support operations (Maguad, 2006). In a study of customer-interacting service employees, Coo and Verma (2002) found that the employee’s perceptions of the implemented QMS had an impact on service quality i.e. reliability, responsiveness, assurance, empathy and tangibles (Parasuraman, Zeithaml, & Berry, 1988), and in turn firm performance. Coo and Verma (2002) further argue that one success factor to these perceptions were strong leaders that were involved in promoting QM.

In e-commerce it has been argued that knowing how to improve loyalty and increase repeated purchase is important to stay competitive (Honore Petnji Yaya et al., 2011). Honore Petnji Yaya et al. (2011) show in a study of customers using online banking that service quality was a key forecaster of both satisfaction and loyalty. All dimensions of service quality; that is reliability, responsiveness, assurance, empathy and tangibles
(Parasuraman et al., 1988) had positive effects on loyalty and satisfaction. Hence, it can be assumed that if QMS is perceived to impact the product/service quality and hence have effects on satisfaction, this will be noticed by management and lead to positive views of QM.

**Proposition 2:** If QMS is seen as supportive of the development of the quality of the organisation’s offering, management will likely show respect for QM, not view QM as cost-driving but rather view QM as being of strategic importance.

**Quality Management Systems as a tool for documentation and standardization**

A focus on providing documentation, developing procedures and ensuring consistency is argued to result in a compliance-oriented approach to QM (Maguad, 2006). Implementing a QMS standard like ISO 9000 drives standardization and how such standardization impact an organisation is argued to depend on three variables; what is standardized, how is the implementation done, and to what extent are activities standardized (Poksinska, 2007). First, if there is a low motivation for implementing a QMS it is argued to result in that organizations only fulfill the minimum requirements in the ISO 9000. Fulfilling only the minimum requirements may result in that the implementation of a QMS focuses only on describing the existing work practices i.e. standardizing present practices instead of practicing the standard (Poksinska, 2007, 2010). Second, if the result of a standardization is positive or negative is also affected by how the standard is implemented i.e. if the standardization is done with employee involvement (enabling), supporting changes of deficient practices or if the standard is implemented top-down (coercive), where management want to discipline work. Finally, the level of standardization need to be right and independent of the person performing the work. Poksinska (2007) argues that a person’s interest in his or her job is reduced if there is a high level of standardization.

In a study on experiences from the implementation and certification processes in small organizations (Gustafsson, Klefsjö, Berggren, & Granfors-Wellemets, 2001) concluded that there is risk to describe i.e. document, everything in detail. Moreover, documentation created as part of implementation and certification of a QMS was reported to be time- and resource consuming. Poksinska, et al. (2006) found in a study of ISO 9001 in small organizations that QMS were perceived as a tool for handling documentation, not a tool for managing processes. Implementation of ISO 9001 was perceived as a bureaucratic and something that increased paperwork, which was a demotivating factor. Findings also pointed towards problems to find an ideal level of standardization of work instructions. Work instruction and procedures should not be too general to be able to provide support for users, neither too detailed to limit employees’ freedom in performing their work (Poksinska et al., 2006).

**Proposition 3:** If QMS is used as a tool for documentation and standardization, management will likely show little respect for QM, view QM as cost-driving, and not view QM as being of strategic importance.

**Methods**

**Research instrument**

The study was based on a survey instrument containing 43 questions, developed through a literature review, input from senior practitioners as well as researchers, and input from previously validated questionnaires. In specific, this paper draws on a set of items focusing the main function of the QMS (Poksinska et al., 2006), and management’s perceptions of QM (Elg et al., 2011) (see Table 1).

10 = Fully agree |
| …show little respect for QM in our daily work (little respect) |  |
| …regard QM as a costly activity (costly) |  |
| …acknowledge the strategic importance of QM (strategic) |  |

Sample
Eight large-sized Swedish organisations (> 1000 employees) participated in the study. Each participating organisation identified 30-50 respondents on different hierarchical levels. The respondents within each organisation were chosen among employees that had dedicated time and responsibility for QM work. The total number of responses were 249 (response rate = 81%), the number of respondents per organisation ranged from 16 to 51. For this paper the subset of questions used in the analysis focused management perceptions of QM and overall view on the QMS, these questions were only asked to respondents with management responsibilities and resulted in a subset of 108 respondents.

Data collection
The survey was administered by e-mails, including a customized invitation letter for each organization and a link to the survey (using the web-based tool SurveyMonkey). The survey was open for one moth per organization, including two rounds of reminders.

Data analysis
Since the analysed statements are jointly exhaustive, answers in which no alternative was chosen were considered to be missing values. After excluding rows containing missing values, 108 of the original 249 observations remained. Of these, nine had rows containing the answer “no opinion”. Since this answer cannot be interpreted as an ordinal value, these observations were excluded as well, resulting in a sample of 99 observations.

Spearman’s rank correlation coefficient was used to evaluate the monotonic relationships between the ordinal variables.

Findings
On an overall level, the data shows that the respondents to a large extent agree with all statements regarding the function and use of the QMS in their organisation (see Table 2).

It appears that QMS as a ‘tool to handle documentation’, ‘tool for standardisation’, and as having ‘significant impact on how the organisation works’ are the three statements where most respondents to some extent agree and in other words recognise their way of working with QMS. For statements where there is a group of respondents not agreeing at all, the three other statements stand out. The statement for which most respondents do not agree is that QMS is ‘a tool that supports efficient management of our organisation’, followed by QMS as ‘a tool that help us to fulfil our customer’s needs’, and QMS as ‘a tool for managing our quality work and improve the quality of our products/services’. As QMS and activities related to designing, implementing, and maintaining the system is a large part of what a QM function does, it arguably will influence how managers view QM overall. Figure 1 shows the correlations between the level of agreements on the statements related to the function of QMS, and management’s view on QM in terms of respect, cost, and strategic importance.
First, proposition 1 focuses on a business management-oriented use of QMS, relating to two functions of QMS: impact on work, and efficient management (Table 1). Although the correlations are small, these two functions of QMS correlate negatively to management viewing QM as costly and with a lack of respect, on the other hand there is a positive correlation to viewing QM as being of strategic importance. Hence, the data points in the same directions as outlined in proposition 1.

Second, proposition 2 encompass the statements on QMS as a tool focused on customer needs and a tool impacting product/service quality; these two constitute what this paper refers to as an improvement-oriented use of QMS. In the same way as the statements underlying proposition 1, the statements of ‘customer needs’ and product/service quality’ correlates positively to management acknowledging the strategic importance of QM. Moreover, there are negative correlations with QM being viewed as with little respects, and as a costly activity. Looking at the correlation values, these are largest for the statement regarding ‘customer needs’, which might depend on larger variation in the responses.

Last, and third, proposition 3 refers to a compliance-oriented use of QMS and concerns documentation and standardization. Again, the correlations are small, but the results are mixed as compared for the other two propositions. The statement focusing QMS as a tool for documentation, displays correlations supporting parts of proposition 3, i.e. positively correlates with little respect for QM and a view of QM as being costly. However, the statement on documentation does not correlate with QM being seen as strategic. Moving to the other statement on a compliance-oriented QMS use (‘standardization’), the correlations do not support proposition 3. The use of QMS as a tool for standardization negatively correlates with all three views on QM, i.e. does not appear supportive of a view on QM as costly or QM being little respected. However, it does have a negative correlation with QM being viewed as strategic (as outlined in proposition 3). Again, the correlations are small and further investigation is needed.

Discussion
To support improved QMS usage and increase the perceived value added by a QMS, there is a need to move beyond the broad conception of QMS usage and move towards a more detailed analysis. This paper contributes to research on QMS by outlining three different ways of using QMS rather than studying QMS usage overall. Drawing on Maguad (2006) three types of QMS usage are described as either business management-, improvement-, or compliance-oriented.

First, the business management-oriented use of QMS is operationalised by QMS ‘significantly impacting the way an organisation work’, and ‘is a tool that supports efficient management of an organisation’. As assumed in proposition 1, these functions appear to support that management will likely show respect for QM and not view QM as cost-driving but rather view QM as being of strategic importance. This is in line with previous research by e.g. Bunney and Dale (1997) establishing that deployment of QM tools will be more successful if the tools are perceived as closely connected to, and potentially can improve, current work practices.

Second, the improvement-oriented use of QMS is based on QMS as ‘a tool that help us to fulfil our customers’ needs’, and ‘a tool for managing our quality work and improve the quality of our products/services’. The proposed impact of these functions is supported, i.e. ensure respect for QM, not viewing QM as costly but as strategic (proposition 2). Hence, using QMS to fulfil customer needs and improve the quality of the product or service will positively impact managements’ perception of QM overall. Previous research has shown that improved quality of the product/service lead to increased customer
satisfaction and loyalty (Honore Petnji Yaya et al., 2011; Parasuraman et al., 1988); thus, if QMS is used in a way that can be linked to improved quality and customer satisfaction this will likely impact managements perception of the value added by the QMS.

Third, in relation to proposition 3 that QMS is used as ‘a tool for documentation’ and ‘standardization’, would be correlated with management showing little respect for QM, viewing QM as cost-driving, and not viewing it as strategic the results are more mixed. A focus on documentation is as stated by e.g. Allur et al. (2018) perceived as bureaucratic rather than a respected and value-adding activity, however a certification is still of value e.g. as a qualifier in certain business relations (Boiral & Amara, 2009; del Castillo-Peces et al., 2018). This might be a reason that the documentation focus does not appear to have the anticipated negative correlation with management viewing QM as strategic value. Moreover, a standardisation-focused use of QMS does not appear to reduce respect for QM, neither seeing it a costly. Perhaps this can be linked to Poksinska’s (2007, 2010) notion of practicing the standard rather than standarise current practices. In other words, if standardisation is done with an improvement approach rather than one of pure documentation, it will likely be perceived as beneficial. This is also linked to the function of QMS as having ‘impact on work’, which is classified as a business management-oriented QMS usage. If this is practiced and QMS is allowed to impact actual practices, it will likely mean that QMS is used to standardise and at the same time improve existing work practices.

Overall, the findings supports literature pointing to challenges of QMS in terms of focus on compliance rather than organisational efficiency (Alič and Rusjan, 2010), and sometimes not being relevant for actual practice (Poksinska et al., 2006 ). However, by distinguishing QMS usage in the three orientations presented above, this study indicates that documentation focus is what might be the cause to many negative perceptions of the value of QMS. On the other hand, many respondents fully agree that QMS is ‘a tool that help us to fulfil our customers’ needs’, which has a relatively high correlation with management viewing QM as strategic. Contrary to the view of limited value from QMS, this paper supports e.g. Poksinska (2007) and Lenning & Gremyr (2017) in that there is potential value of QMS, and that this perceived value will increase if QMS usage is mainly business management- and improvement-oriented, although wisely documented and standardised processes are also required to maintain a certified QMS.

The data set underlying this paper is limited in size and the correlations established are small, more research would be needed to enhance the trustworthiness of the findings. This research could be either empirical or conceptual.

Conclusions

Based on an extended view of QMS, this paper has elaborated on three types of QMS use: business management-, improvement-, and compliance-orientated use. It is shown that the way organisations use QMS influence management’s respect for, and view of, QM in terms of it being costly and/or strategic. For a business management- and improvement-oriented use the propositions based on previous research is supported, i.e. theses ways of using QMS correlates with management viewing QM as respected, strategic, and not cost-driving. For a compliance-oriented use of QMS, earlier research suggests this to be the reason for many of the negative perceptions of QMS and leading to a view of QM as costly, less respected and of less strategic importance. However, for a compliance-oriented use of QMS the findings are somewhat contradictory to the anticipated proposition. It is suggested that a perception of limited value of QMS is mainly due to a focus on documentation whereas work on standardization, which is also part of a compliance-oriented QMS use, does not carry similar negative implications. In summary,
this study highlights how the perceived strategic value of QM can be increased through a deliberate design of an organisations ways of using QMS.

Exploring QMS Audit Practices in the Digital Era

Felipe Martinez (felipe.martinez@vse.cz)
University of Economics, Prague, Czech Republic

Abstract

Quality auditors are essential for Quality Management System (QMS) development, and communication is necessary for its performance. The digitalisation of the economy, especially Industry 4.0. (i4.0), introduces several digital elements all over the supply chain. This paper presents a preliminary exploration of the influence of digitalisation in internal audits practices. The research enquires QMS auditors about the implementation of current Information and Communication Technologies (ICT) in their practices. Then, it explores the importance of i4.0 and new technologies for the companies on which the auditor performs its activities. Finally, it investigates the implemented technologies based on QMS auditors’ recommendations.

Keywords: Industry 4.0, New Technologies, Information and Communication Technologies.

Introduction

A certified Quality Management System (QMS) requires an internal audit (ISO 9001, 2015) and this certification is the minimal business requirement for several industrial organisations (Govindan, et al., 2010). Quality audits facilitate the compliance of the standards (Hernandez, 2010) and the auditors influence the efficiency of the QMS implementation (Phillips & Kluse, 2012). Furthermore, the audit strategy requires communication for its performance (Kymal, 2016).

The digitalisation of the economy, especially Industry 4.0. (i4.0), introduces several digital elements all over the supply chain (Sommer, 2015). This new industrial paradigm requires the integration of the different aspects of an industry (Rüßmann, et al., 2015; Germany Trade & Invest, 2014) and quality practitioners have an essential role in this new industrial revolution (Ranganath, 2017).

Therefore, this paper presents a preliminary exploration of the influence of digitalisation in internal audits practices. The research enquires QMS auditors about the implementation of current Information and Communication Technologies (ICT) in their practices. Then, it explores the importance of i4.0 and new technologies for the companies on which the auditor performs its activities. Finally, it investigates the implemented technologies based on QMS auditors’ recommendations.

Quality Audits and Industry 4.0
Audit belongs to the requirements for the development of a Quality Management System (QMS) (ISO 9001, 2015). The clause 9.2 of the norm stipulates Internal Audit as a systematic, independent and documented self-assessment process that procures evidence
of the QMS and objectively assesses its fulfilment (ISO 9001, 2015). The external audit complements this evaluation in its element of independence towards the organisation. Companies overtake the effort of a quality audit to obtain the ISO 9001 certification, which in several cases is the minimal requirement to develop business within a sector (Govindan, et al., 2010). Furthermore, organisations obtain significant benefits from the implementation of these standards (Swann, 2010) including the enhancement in their organisational knowledge (Wilson & Campbell, 2016).

Quality audits have relevance to the business, and it goes beyond the efforts of compiling documents of evidence the QMS fulfilment. The audits are a source of improvements (Lenning & Gremyr, 2017) and knowledge (Wilson & Campbell, 2016). The audit practices provide to the business evidence-based possibilities of improvements using the corresponding knowledge. Furthermore, the audit facilitates the compliance of the standards to obtain respective certification (Hernandez, 2010). Therefore, the role of auditors is essential for QMS. Specifically, auditors influence the implementation of QMS (Phillips & Kluse, 2012).

A significant component of the quality audit strategy is communication (Kymal, 2016). The compilation of documents and the general evidence to assess the QMS of the organisation requires a communication strategy that allows the auditor to obtain the corresponding data for the evaluations and possible additional suggestions for improvements. Chapter 7.2 of the standards contain specifics about this matter (ISO 9001, 2015). Relevant documents reduce the subjectivity of the assessment (Montoya Quintero & Cogollo Florez, 2018) and a better communication strategy facilitates the comprehension of the vast documentation of a QMS and other systems (Kanon, et al., 2017).

The introduction of the concept Industry 4.0 (i4.0) offers organisations a new manufacturing paradigm (Baur & Wee, 2015) with several digital elements all over the supply chain (Sommer, 2015). Approaches such as smart factories (Rashid, et al., 2011) or the industrial application of the Internet of Things (IoT) (Islam, et al., 2015) complement the understating of this new era of manufacturing. The i4.0 includes new technologies such as cyber-physical systems, big data, real-time connectivity, among others (Lasi, et al., 2014).

The primary requirement of the implementation of this new industrial paradigm is the integration of the different aspects of an industry (Rüßmann, et al., 2015; Germany Trade & Invest, 2014). Furthermore, the most relevant driver of the digitalisation of the economy is the Internet. There is increasing constant use of the Internet around the world (Internet World Stats, 2018) through emails, social media and other technologies (Haigh, et al., 2015).

Then, this new industrial paradigm requires the integration Quality practices that correspond with the digital changes faced by organisations. QMS audits are an essential part of any industry (Govindan, et al., 2010; Swann, 2010). Therefore, QMS auditors have an important role within this new industrial revolution (Ranganath, 2017) and since communication is essential to the QMS audit practice, this search explores the implementation of Information and Communication Technologies (ICT) in the QMS auditors practices. Additionally, it investigates the introduction of digitalisation in their practices. The aim is to explore current practices in respect of digital tools. This understanding provides information about the areas on which auditor requires knowledge enhancement, and it also opens the discussion about the role of audits in a digitalised economy.

Methodology
This paper presents a preliminary exploration of the influence of digitalisation in internal audits practices. The literature review offers a vast understanding of the QMS auditors' practices and their importance to implement and develop the QMS in an organisation or to obtain a particular certification such as ISO9001. In the other hand, the digital transformation of the industry, or i4.0, develops a new paradigm for industrial organisations. Then, this research requires to approach the QMS auditors to start the development of the knowledge regarding the QMS practices in the i4.0 world.

The selected research design implements an online survey in summer 2018 (Bryman & Bell, 2015) among internal auditors related to the Czech Society for Quality (CSQ). The survey explores the ICT appropriation of the auditors for QMS activities and personal use within the last five years. The survey also enquires about the use of digitalisation as a tool or solution within the QMS activities in the same period. The implementation of a seven-level Likert scale facilitates the assessment of ICT usage. The range starts at "I don't use/I don't have" towards "actively use it for Personal and Work purposes". Personal use has less score that the usage at Work.

The CSQ is the appropriate source of QMS auditors. It is the nongovernmental institution dedicated to disseminating the QMS knowledge in the country among other management systems (Czech Society for Quality, 2019). The CSQ educates and certifies QMS internal auditors, and it also develops the external auditors for certification activities. Then, the research identifies internal auditors trained at CSQ and CSQ accredited internal auditors with current activities in the industry. Additionally, the certification process requires the identification of the current internal auditor at the organisation.

The captured data offers the opportunity to implement statistical analysis (Bryman & Bell, 2015) of different aspects of the internal auditors' digital knowledge and digital quality improvements from the last five years. The study includes a descriptive analysis of the QMS auditor's population and the relationship between personal use and work use of ICT tools. Furthermore, the data offers information about the importance of digitisation for QMS auditors.

This research explores the current QMS audit practices in the Czech Republic. Moreover, the Czech economy reports the highest industry contribution of the GDP within European Union and the country is considered technically advanced and the fastest growing economy in the EU (CZSO, 2017; Growth Lab, 2017). Therefore, research on the industry in the Czech Republic provide relevant information for the development of QMS practices in other countries. Furthermore, although the response rate of the online survey is low, the findings provide preliminary assumptions that required a qualitative approach such as focus groups to understand the reasons behind these findings (Bryman & Bell, 2015; Mayring, 2000). Additionally, this low response rate might evidence a weak implementation of new technologies in QMS practices.

Findings
The survey respondents are QMS auditors with knowledge, experience and often implementing audits. The population structure concerning the educational level of QMS auditors is similar to that of the country (OECD, 2014). The majority of QMS auditors completed secondary education (92%), and half of them (48%) received a university degree with less having above level of formal education (14%). The analysis of training taken by all respondents illustrates that they acquired their knowledge about QMS audits at specific courses on audit (54%), QMS (7%), Lean management (19%) or Six Sigma (20%). Furthermore, the auditors realise their activities in 2018 (87%) two up to five times (67%) in the Czechia (66%) and also out the country (34%). The experiences out of the
country include at least one audit (38%) and more than five (21%). Additionally, the respondents report intensity of one audit per quarter (31%), per month (30%), per semester (19%), per year or more (11%) but also per week (9%).

The implementation of digitalisation in QMS practices still low. One-third of the respondents (33%) indicate an extent of use of digitalisation in their auditing activities between 21% - 40% and less than a third (27%) between 41% - 60%. The 20% respondents indicate a lower extent of use (0% - 20%), the 14% of respondents state a high extent of use (61% - 80%) and 6% of respondents report reports the highest extent of use (81% - 100%).

Moreover, more than half of them recognises the importance of digital elements in their practices. Specifically, 45% of the respondents distinguish that digitalisation has several items with applicability in QMS practices, 33% identifies a lot of elements for implementation while 12% declare that digitalisation is per se the new only element for the QMS practices.

Furthermore, one-third of respondents (30%) acknowledge that digitalisation is a current issue to be included in the QMS practices. Other 11% of the respondents allocate digitalisation as an issue in the next year. The next third (36%) expects digitalisation to be an issue in two or five years from now. Besides, 9% of the respondents expect digitalisation to be an issue in about ten years, and 14% of them argues that digitalisation is not and won't be an issue for QMS practices.

The respondents (34%) express a high use of communication technologies for work and personal reasons when someone asks for it. Moreover, an important group of respondents (23%) do not have or do not use ICT. The active personal use of ICT (17%) complements the less active users (14%). The less use of ICT for Work purposes (14%) is similar to the active use of ICT for work and personal matters (14%). The lowest usage of ICT (6%) corresponds to work issues when someone asks for it.

The communication technologies with the most extensive use among the respondents are telephone (18%), email (18%) and SMS (16%). The technology of file sharing indicates 11%. Modern platforms of communication such as LinkedIn (9%), WhatsApp (5%) or Facebook (8%) represent less usage among the respondents. Additionally, the highest intensity of ICT use is found among traditional technologies while new technologies obtain their highest concentration among personal use or even not use.
Furthermore, the companies for which the auditors perform their activities promote learning and knowledge about relevant topics of digitalisation (38%), some of the topics in the field (29%), some specific initiatives at work (15%) or the support is unlimited (14%) with just few organisation without support (5%).

Moreover, there is a lack of strategies to develop or implement digitalisation within QMS. The larger group of companies (39%) uses some digital elements with implementation in QMS internal audits, but a similar group (35%) uses fewer elements of them in QMS audits. Some firms (12%) have digitalisation as an integral part of the strategy, and others (8%) uses several elements of them in QMS audits. The lowest representation (6%) do not consider digitalisation as part of their strategy.

During the last year, the suggested implementations from QMS auditors do not apply digital elements (39%) or the solution has up to 20% of digital elements (35%). In other cases, the implementation has between 21% - 40% (7%), 41% - 60% (7%), 60% - 81% (9%) or 80% - 100% (2%). Additionally, the QMS auditors’ recommendations prompt the inclusion of new technologies in improvements such as general automation (22%), electronic communication (22%), big data (19%), simulations (14%), robots (14%), smart machines (7%) or additive manufacturing (2%).

Conclusion
The preliminary findings open several questions on respect the reasons behind the lack of digitalisation among the QMS practices. The digital transformation of the economy, especially i4.0, requires the digital integration of the entire supply chain (Sommer, 2015) and quality is an essential part of it (Kymal, 2016; Hernandez, 2010). Moreover, this research shows that the integration of QMS practices is low. There is still a lack of inclusion of digitalisation in the firms' strategies, but also the recommendations and solutions from auditors offer low involvement of digitalisation. Furthermore, the auditors recognise a low involvement of digitalisation in their practices. Since QMS audits are a source of improvements (Lenning & Gremyr, 2017) and knowledge (Wilson & Campbell,
2016), auditors must take an important role in the digital transformation of their organisation providing possible solutions with higher use of new technologies.

A suggestion for this leadership role in the digitalisation of the organisation is the use of new ICT in their current QMS practices. Documentation is essential for QMS audit (Montoya Quintero & Cogollo Florez, 2018; Kanon, et al., 2017). Current technologies facilitate the work with documents throughout real-time reports, file sharing or even paperless initiatives (Henderson, 2016; Vidyarthi & Coffey, 2016).

This research also shows that the organisation are willing to support the creation of knowledge about digitalisation. However, their strategies lack the digital element. Then, the efforts to learn about digitalisation might lead to information without real application in the organisation. The role of the QMS auditor as a knowledge creator in the organisation (Wilson & Campbell, 2016) is essential to facilitate the implementation of new technologies and digital solutions. QMS auditing might become the most important driver of the transformation, or it also can become its main obstacle.

The current situation illustrates that the solutions or recommendation of the QMS auditors contains a lower level of digital elements. Then, future research must concentrate on the reasons behind this absence of digitalisation. Which, so far, might be the lack of knowledge of the auditors about the possibilities of new technologies in their processes or the resilience of the organisations on the digitalisation of the industry. In both cases, the auditors have an important role in the success of digital implementation.

Abstract

Modern drone technology offers untapped potential for increasing productivity and safety in factory operations. Yet, only a few factories have experimented with indoor use of drones and there are no field-tested guidelines for how evaluate such applications. We engaged in a design science project with a manufacturer of sanitary products. The purpose of our study was to develop grounded technological rules that can be used to identify, select, test and implement profitable drone applications in factories. The developed prescriptive knowledge help managers, engineers and consultants to make informed choices when exploring the potential of drones in manufacturing environments.

Keywords: Drone technology, Manufacturing operations, Design science

Introduction

Industrial applications of unmanned aerial vehicles (UAV), commonly known as drones, have grown quickly (Panetta, 2018). The oil, gas, and petrochemical industries for example use drones to inspect hard-to-reach equipment, detect hazardous gases, and site surveillance. The construction industry is using drones to inspect complex infrastructure assets such as bridges and buildings. To date however, industrial drone use has been almost exclusively outdoors and few firms have experimented with ‘in factory’ applications. Proponents argue that drone technology has untapped potential (e.g., higher productivity, improved safety) in factory operations, but how do we evaluate the quite different challenges and opportunities for indoor drones (Floreano and Wood, 2015)?

Current indoor manufacturing applications are limited to supporting inventory recording, factory planning and inspection. For example, drones are used for cycle counting in large warehouses (Hoffmann, 2017), for taking photos of current factory layouts (Melcher et al., 2018), and for internal inspection of confined spaces such as tanks, silos, furnaces, chimneys, boilers, and pipelines (Maghazei and Netland, 2018).
Are drones simply another form of advanced manufacturing technology (AMT)? Or, because of their versatility (e.g. they have multiple formats and can be paired with various complementary technologies like simultaneous localization and mapping (SLAM), motion capture, thermal imaging, material handling, etc.), do they follow different technological ‘rules’? In this paper, we use a design science approach, informed by the AMT literature, with a cooperating firm to study the process of drone application detection, testing and evaluation. To do so, we use the “context, intervention, mechanism, and outcome” logic (CIMO) defined by Denyer et al. (2008). From this, we develop grounded technological rules that can be used in manufacturing to identify, select, test and implement practical drone applications.

Theoretical background

In order to address the research objective, we follow a management engineering approach focusing on ‘engineering a solution’ rather than applying of existing insights (Groop et al., 2017). That said, our fieldwork is deeply informed by knowledge from the existing AMT literature, in particular categorizing three distinct phases of technology adoption: evaluation, implementation, and measuring effects of AMT in different organizations and contexts (Maghazei and Netland, 2017).

The first phase, AMT evaluation, is mostly concerned with the economic justification of different technological options. It comprises three parallel and interacting elements: (1) choice and technical feasibility, (2) financial justification, and (3) strategic commitment to gaining competitive advantage from any AMT investment (Langley and Truax, 1994, Ramasesh and Jayakumar, 1993). Such evaluations are inevitably complex and often contested processes, due to the difficulty of establishing tangible (e.g. quantifiable and often financial) and non-tangible (e.g. non-quantifiable and often non-financial) factors (Saleh et al., 2001). Technological innovations that are completely new to organizations add more degrees of uncertainty (Wang et al., 2008).

The second phase, AMT implementation, is associated with unpredictability due to the innovative nature of the process (Boer and Krabbendam, 1992). Although some AMT failures are due to lack of investment in infrastructure (Boyer et al., 1997), many AMT implementations fail due to insufficient organizational preparation (Voss, 1986, Chung, 1990). Successful AMT implementation requires both technological and organizational preparations, rather than “just installing a new piece of equipment” (Boer and Krabbendam, 1992, Zammuto and O’Connor, 1992, McDermott and Stock, 1999). Changing organizational routines remains a determinant of success in adoptions of technological innovations (Edmondson et al., 2001). Organizations that prioritize the development of human factors are likely to achieve more benefits from the implementation of new technologies (Small and Yasin, 1997, Co et al., 1998).

Concerning the third phase, measured AMT benefits are frequently debated (i.e., are AMT worth the investment?). Different forms of AMT are reported to improve flexibility, direct labor costs, product changeover costs, process variability, work-in-process inventories, and product quality (e.g., Swink and Nair, 2007, Braglia and Petroni, 1999, Udo and Ehie, 1996). There is also (an increasingly important?) reputational benefit that can be realized from publicity about automation and newsworthy articles in trade presses (Meredith, 1987b, Swamidass and Kotha, 1998). However, few organizations have been able to achieve all the promised effects of AMT adoption (Swink and Nair, 2007, Udo and Ehie, 1996, McDermott and Stock, 1999).

While the existing literature on AMT provides a useful starting point, it does not offer a sufficient basis for evaluating the application of drones in manufacturing. This is in part, as discussed above, a consequence of drone functionality (i.e., versatility, variety of flying
Research methodology
Design science is driven by research questions targeting field problems or exploring new opportunities (Denyer et al., 2008, van Aken et al., 2016). It is a well-suited method for developing “field-tested and grounded technological rules to be used as design exemplars of managerial problem solving” (van Aken, 2004, p. 221). Technological rules (or design propositions) aim to produce prescriptive knowledge by linking interventions with intended outcomes through generative mechanisms in order to solve field problems (Romme, 2003). The justification of research products are primarily focused on pragmatic validity, which can be guaranteed through field-testing (Denyer et al., 2008).

To apply design science research, we followed the CIMO logic introduced by Denyer et al. (2008). The CIMO logic explains in which context, what intervention and mechanisms can produce certain outcomes. The context is the research environment that consists of a mix of social and technical factors (Denyer et al., 2008). Contextual layers include individuals, interactions among individuals, physical settings, and the wider infrastructural systems (Pawson et al., 1997). Interventions are alternatives in the hands of managers to improve existing entities or to realize new entities (Denyer et al., 2008). Generative mechanisms describe what happens and will be triggered after interventions in a given context, which can help us understanding why this happens (i.e., causality). Expected outcomes are effects from the interventions, such as improvements in human conditions and the effectiveness of organizations.

Field tests
We engaged in a design science project with a leading Swiss manufacturer of sanitary products (henceforth called “the company”) in order to develop technological rules through experimenting with drone applications. First, we collected data from the company through observations and informal interviews in order to develop a long list of potential drone applications. Second, we asked for the feedback of top managers from the company through a survey about the feasibility and scalability of each application. Third, we analyzed the collected data in order to prioritize and select the application for experiments. We also conducted interviews with six company managers to evaluate and prepare for the experiment. Fourth, we planned the implementation, assessed the risks, and prepared the production area for the experiment. Fifth, we conducted the experiment with the help of a drone service provider. Sixth, we summarized our findings after the experiment by debriefing the project with the drone service provider, and a follow-up meeting with 12 managers and employees of the company who were involved in the experiment.

In the company, we identified several potential applications of drones. We selected two applications in the area of maintenance for experiments, namely the visual inspection of metal silos and the thermography of injection molding machines. Visual inspection of silos allows the company to identify metal degradation and corrosion early. The alternative technologies for the visual inspection of silos can be ladders, scaffolding, and man lift cranes. The thermography of injection molding machines allows for mapping heat losses, thus improving isolations and reducing downtimes of the machines. The alternative technologies for the thermography of injection molding machines are using mounted cameras in ceiling conveyors or handheld cameras and ladders. We used manually controlled drones for the selected applications during the first experiments in the company. Figure 1 shows pictures from the field test.
Simulation
In the next phase, we used the learnings to develop a simulation model for using autonomous drones for machine inspection. The objective of the simulation was to examine the feasibility and technical requirements of using autonomous drones in factories following a certain flight trajectory and conducting a certain operation, such as inspection. To do so, we used RotorS, a modular drone simulation framework, developed by Furrer et al. (2016) (see Figure 2). It allowed us to use different controllers and state estimators to simulate our use case in the same production site that we conducted piloted drone experiment. RotorS simulator is developed for autonomous flights in Gazebo that is an open source robot simulation software.

![Figure 2 – Snapshots from Gazebo simulation software using Firefly hexacopter.](image)

Simulation can potentially reduce the risk of trial and error and allows for experimenting with technologies that are not yet commercially available by analyzing near-misses (Denyer et al., 2008, Furrer et al., 2016). In fact, implementing an autonomous drone for indoor application has technological complexities, namely localization, obstacle detection and avoidance algorithms, control algorithms, and failsafe systems. The development of an autonomous drone system is costly and still under research. Moreover, implementing a potentially high-risk application can increase the disturbance to the system in case of failures, and “[m]anagers are understandably reluctant to have entire operational systems subjected to manipulation and experimentation when the outcome is uncertain” (Groop et al., 2017, p. 16).

Solution design and discussion
Technological rules can be built on existing artefacts, yet with innovative combinations in order to address emerging field problems (Arthur, 2009, Groop et al., 2017). We base our technological rules on the technology adoption of AMT literature, namely evaluation, implementation, and measuring effect while following the CIMO logic. In the case of
adopting drone technologies, evaluation mainly incorporates the analysis of context in terms of both the type of *drone application* and the *manufacturing environment*. The implementation of a drone application in a manufacturing environment is mostly concerned with the type of interventions that organizations implement and associated mechanisms that those interventions trigger. Measuring the results of a drone application corresponds to the success or failure of adopting drones to achieve intended outcomes.

*Context – Drone applications*

We classify the type of drone applications into *prevalent, progressive, and prospective* according to the degree to which manufacturing companies are using, experimenting or researching them. Based on the current state of drone technology and mounted sensors, we argue that a combination of following technological features determine the type of drone application: indoors vs. outdoors, flight time, payload, flight reliability, flying beyond visual line of sight (BVLOS), and the level of autonomy. Evidence shows that outdoor applications are currently more prevalent in manufacturing environment. Indoor applications of drones with between 10 to 30 minutes flight time, and sensors below ca. 5 kg with acceptable quality, and limited levels of automations are mostly progressive. Drone applications that need long flight endurance above 30 minutes, use heavy and precise sensors above 5 kg, fly BVLOS, and need high autonomy with machine learning algorithms are mostly prospective.

*Context – Manufacturing environment*

We classify the manufacturing environment into *ready, receptive, and resistant* towards the use of drone technology. Our classification for manufacturing environment is mostly based on AMT and organization science literature and our evidence. What determines the type of manufacturing environment is associated with the *physical characteristics* of organizations, and the *potential productivity gains* from adopting drones. The physical characteristics includes: area, height of ceilings, noise sensitivity, density of workers under drone flights, risk of damage to equipment in the case of drone failures, presence of hazardous, chemicals and gases, and number of moving objects in the air such as robot arms, cranes, lift trucks, automated storage and retrieval systems (AS/RS).

Evaluating the productivity gains from adopting drones includes both financial and non-financial benefits. Firstly, organizations measure the degree to which drones can financially add value, for instance in the case of inspection, through reducing the size of inspection teams, increasing the speed, and reducing machine downtimes. Secondly, organizations measure the frequency of the operations that will be carried out by drones, for instance, some inspections by drones have to be conducted weekly/monthly as part of regular preventive maintenance or they are only carried out during overhaul maintenance. The financial benefits should be compared with the cost of drone procurement, training, and spare parts. Non-financial benefits are associated with increasing the safety of workers, efficient data collection, and publicity, to name a few.

Yet, multiple factors can influence the degree to which manufacturing organizations are *ready, receptive or resistant* to adopt drones. For example, one of the factors that makes a manufacturing company *ready* for the adoption of drone technology is firm’s technology level and readiness for automation (Jimenez et al., 1992, Meredith, 1987a). Dimnik and Johnston (1993) discuss social dynamics, personal beliefs and motivations of manufacturing managers to use new technologies, which promote championing behaviors of AMT adoption by the theory of reasoned action. Championing includes behaviors toward experimenting with new technologies with a limited scope in real-life
settings (familiarization) as well as convincing others about the benefits of innovating with new technologies (promotion) (Dimnik and Johnston, 1993).

There are multiple reasons for why organizations are resistant to adopt drone technology. Oliver (1997) explains such a resistance with institutional isolating mechanisms either as a function of organization’s unwillingness, or as a function of organization’s inability to acquire and imitate resources such as a new technology. In terms of unwillingness, top management is reluctant to adopt drone technology because it can contradict with company’s ‘low-tech’ culture, or poorly fits with cultural belief system and norms, or is inconsistent with physical characteristics of organizations (Oliver, 1997). In terms of inability, a company can be unable to adopt drone technology because of the lack of skills, know-how, proximity to knowledge sources, and capabilities that are tacit, unique, or path dependent (Oliver, 1997).

**Intervention and Mechanisms**

We selected our industry partner for the experiment from the receptive class of manufacturing environment. The main reason was that ready organizations were among those who have already experimented drone applications in their settings, and were often reluctant to engage in a research project for experimenting drone applications. Obviously, resistant companies were not open for experiments with drone technology. We explain the summary of defined interventions and mechanisms that each intervention can trigger in Table 1.

**Outcomes**

Using drones for the visual inspection of silos increases the frequency of inspections, reduces the hazards of workers who operate in high altitudes, and reduces the cost and setup time of using expensive technologies such as man lift cranes. Using piloted drones for the thermal inspection of machines provides a better overview of the equipment in hard to reach areas, is faster in collecting several thermal images compared to humans climbing ladders, and can be used in multiple production areas flexibly compared to ceiling conveyors. Autonomous drones can also increase the frequency of inspections besides the benefits from piloted drones, as well as reducing the cost of training and drone pilots.

Nevertheless, there are technological and organizational limitations for using drones in a manufacturing environment. For example, high quality sensors are often heavy, which increases the size of drones or decreases flight times. Moreover, the application of drones requires organizational preparations such as training pilots, defining new safety measures, and integrating drones into working environment. Noisy operations and privacy issues are also challenging.

| Organization | Receptive | Prevalent (Inspection of metal silos) | • Invest in drones  
  • Train pilots  
  • Document best practices and know-how | • Evaluating both financial and non-financial benefits and return on investment can facilitate mainstream adoption of drones | • Increase the frequency of inspection  
  • Increase safety  
  • Increase the efficiency of inspection |
Conclusion

The industrial applications of drones are growing and manufacturing industries have begun to evaluate the use of drones as a potentially new form of AMT. We develop and present technological rules for drone applications in a manufacturing environment. The proposed solution design assists managers, engineers, and consultants making informed choices when exploring the potential of drones in specific manufacturing settings. The application of drone technology in manufacturing operations is facing multiple challenges that holds many industries back from adoption. This study represents an overview on what drones can offer, how they can be implemented, and why they are viable alternatives for certain operations.

Limitations

The application of CIMO logic for empirical OM research is scarce, thus its application virtually involves new challenges. Groop et al. (2017) provide caveats for using CIMO logic in an OM design science research. Firstly, small changes in the context may affect the feasibility of outlined interventions. For instance, in our study, many physical limitations in our experiment can be non-existent in the other manufacturing environment, thus restraining the feasibility of defined interventions. Secondly, the implementation of outlined interventions in an operational system can trigger unpredictable mechanisms resulting in undesirable effects. For example, unexpected failures of drone experiments and disturbance in manufacturing operations can influence the trust and commitment of top management for drone adoption. Thirdly, observing unintended consequences can stimulate design researchers to modify outlined interventions or developing new interventions. For example, our interventions for autonomous drones were developed after observing the consequences of piloted drones. Having these caveats in mind, clarifying and exemplifying the boundary conditions relevant to the context of empirical
research and technological rules can increase the external validity of designs (Busse et al., 2017, Groop et al., 2017, Whetten, 1989).

A second limitation is that we could not run a full-fledged test on autonomous drones due to the infancy of the technology. In this study, we mitigated this limitation by experimenting with simulation. We used simulation for the use of a new technology that is not yet commercially available, but has high potentials in the future of manufacturing operations. This helps scholars to examine the use of technologies that are not available in the market, to explore the use cases that are not prevalent for benchmark analysis, and to interact with the companies that are reluctant for field experimenting. Combining methods can also increase the quality of research in OM (Boyer and Swink, 2008, Singhal et al., 2008).

Abstract

Nowadays, manufacturing companies have been facing a complex phenomenon of technological advance, often named Industry 4.0, that is reshaping companies’ strategy and organization, products and services, supply chains and operations. At the best of our knowledge, the academical panorama lacks an exhaustive literature review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems. Accordingly, this paper carries out a systematic literature review with the aim of mapping the publications and systematizing the often-fragmented literature on this field to propose directions of future inquiry that could inspire scholars and support practitioners.

Keywords: Digital Strategy, Digital Transformation, Literature Review, Industry 4.0

Introduction

Nowadays technologies progress like a dense avalanche of advancements pouring into the environment (Brynjolfsson and McAfee, 2014). The rhythm of growth has been exponentially hastening in recent times indeed, and this has been provoking shocks in the realm of management (Westerman et al., 2014; Brynjolfsson and McAfee, 2017; Venkatraman, 2017). This complex phenomenon, often named Fourth Industrial Revolution or Industry 4.0, is reshaping companies’ strategy and organization, products and services, supply chains and operations (Porter & Heppelmann, 2014). The concept of Industry 4.0 (I4.0) was initially introduced in Germany in 2011 (Lu, 2017), referring to the integration of physical objects, human actors, intelligent machines, production lines and processes across organizational boundaries, with the aim of realizing a system in which all the processes are integrated and information is shared in real time (Hozdić, 2015).

This wave poses an important challenge to companies that more and more are required to deal with the opportunities offered by the digital technologies which are at the core of
the Fourth Industrial Revolution. Aware of both the limited financial resources as well as of their level of digital readiness, companies need to make some strategic choices, selecting and exploiting the set of digital technologies that better fit with their own context (Hess, 2016).

In other words, to remain competitive companies are called to strategically govern the digital change by formulating and executing a clear strategy to keep pace with the new digital reality (Matt et al. 2014). Since the beginning of the 2010s, a large proliferation of papers on this subject matter has been observed, but often in a quite fragmented fashion and using an ample variety of terminology. At the best of our knowledge, the academic panorama lacks a complete and exhaustive literature review on how companies can strategically govern the digital change provoked by technology advancements and occurring in business systems. To date indeed, the newness of the topic and the wideness of the combined domains blur the knowledge on the company ground and torment researchers and experts across their affairs by creating overlaps between words and meanings, constructs and definitions, and by fostering useless varieties of vocabulary, and diverse perspectives on the same objects and phenomena.

Accordingly, this paper carries out a systematic literature review (SLR) on this field, with the aim of charting the map of the publications and systematizing the often-fragmented literature on this field into a comprehensive body of organized knowledge, underlining the different perspectives and proposing some directions of future inquiry that could inspire scholars and support practitioners.

In pursuance of these targeted objectives, the SLR has been guided by the following research questions:

- **RQ1**: Which are the perimeter and the current state of the art in the field of research?
- **RQ2**: Is there a way to frame and organize the knowledge belonging to this field?
- **RQ3**: Which are guidelines to drive future researches on this field?

Findings of the research contribute to systematize the often-snippered literature on how to govern the change provoked in companies by digital technology advancements. Results of the literature review show that the field under investigation may be framed into four blocks, namely: Digital Transformation Strategy; Digital Transformation Execution; Leadership & Culture; and Models. Hence, our review will depict the nature and the main contents of these blocks, to what extent they are intertwined, and which are the levers managers may employ to govern the change. Along this line, in the final part of the paper, a discussion on the current detected gaps is carried out, and some avenues of future researches are spelt out.

**Methodology**

Towards achieving our aim and answering the research questions, a systematic literature review on how to strategically govern the digital change provoked by technology advancements occurring in companies has been carried out. The field under investigation, which concerns the process followed by companies to strategically select the most prominent digital technologies and then drive their implementation within the companies, revolves around two main key areas. From one side the opportunities offered to the companies by the set of digital technologies and the Fourth Industrial Revolution, and, from the other side, the strategic process they have to follow to govern within the company this change. Accordingly, two different groups of keywords have been selected to carry out the literature review on the ISI Web of Science Database (core collection):
• Group 1: it contains the keywords to intercept the papers referring to the Fourth Industrial Revolution (i.e. "Industry 4.0"; "Industrial Revolution"; "Smart Factory"; "Smart Manufacturing") and the ones referring to Digitalization or Digital Transformation (i.e. "Digital*").

• Group 2: it contains the keywords related to the investigation of how firms can strategically cope and manage these digital technology advancements which is the baseline of the studied field. The focus has been given to the governance of this kind of transformation ("Strateg*"); "Transformation*"; "Change"; "Roadmap"; "Cultur*").

We combined a) the terms belonging to group 1 and group 2; and b) the terms belonging to group 1 with each combination of two terms belonging to group 2. a) and b) where searched respectively in titles and topic (i.e. abstract, title and keywords). In this way, we were able to capture most of the papers covering the field under investigation.

The queries that were accomplished on the 12th of March 2019, returned 10,114 results at first, reduced to 508 by applying some basic filtering options proposed by ISI as the research area (i.e. Management, Business, Operations Research Management Science), the English language, and the document type. Duplicates have been subsequently removed. The application of these criteria provides us with 459 papers, that were subsequently analyzed by the authors.

Consequently, in order to check the pertinence of these papers with the field under investigation (e.g. how to strategically govern the digital change provoked by technology advancements occurring in companies), we read the abstracts of these articles and we excluded those articles that were not pertinent, and 168 relevant articles remain. The reading of the full articles made it possible to identify the 59 most pertinent articles.

At the end, after 16 papers and 8 books have been added via a snowball process, the final dataset was composed by 83 contributions. It may be argued that the final database is made up in most part by ISI ranked journals (i.e. the queries searched on ISI-WoS Database), while the snowball process added mostly practitioners’ articles. We believe that this balance is valuable, bearing in mind the topicality and the hype of the theme discussed.

Finally, all the selected articles have been carefully mapped in a structured spreadsheet with different dimensions, namely: - the field, - the topic and the purpose of the article, - the construct/s under investigation and its definition (when provided), - the description of the theoretical ground, - the methodology, - the main findings. The analysis of this spreadsheet made it possible to develop a framework that organizes the contributions of the literature on the field and sheds some light on the state of the art on the theme as well as on gaps and avenues for further researches.

**Field of research**

Giving a general overview of the papers, the overall counter of publications per year on the field has been growing exponentially and the curve has just reared in the last three years (max[1996-2015]: 5; 2016: 8; 2017: 10; 2018: 28). The mounting interest around the topic witnesses its relevance and renews the necessity of this work.

The large part of the publications empirically test their arguments on real cases (Figure 1), interviews and surveys, secondary data analysis or action research, but the analysis of the papers also shows the presence of a consistent set of papers (i.e. “Opinions”) which expound findings without the backing of a proper scientific methodology – and this principally happens with the articles dealing with strategical matters.
The deep analysis of the papers shows that the articles on the field are quite fragmented and they deal with different aspects of the phenomenon, thus making it difficult to get a clear picture of it. To try to systematize the variety of these contributions, we develop a framework meant to integrate the different dimensions that shape the research field on how to govern the transformation provoked in companies by digital technology advancements. This framework (see Figure 2) is composed of four blocks.

The first two blocks – Digital Transformation Strategy (DTS) and Digital Transformation Execution (DTE) – constitute the backbone of the field and describe the process of digital transformation process (DT) triggered by the injection of digital technologies into companies. The second two blocks instead revolve respectively around the technical skills, Leadership and Culture companies need to be equipped with to be successful in the change process, and the Models literature supplies to comprehend these kinds of transformations. In this view, these latter two blocks sustain the field’s backbone providing knowledge and tools to the people enlisted in the digital transformation process.
The Digital Transformation

The backbone of the field describes the process of governing the transformation of the company triggered by the injection of digital technologies. This process may be broken down into two diverse blocks, referring respectively to its strategical conception (i.e. Digital Transformation Strategy) and its execution (i.e. Digital Transformation Execution). More neatly, inside the concept of Digital Transformation there is one set of papers that concern Digital Transformation Strategy (DTS), where a company needs to explore the opportunities offered by technology (Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Konlechner et al., 2018) to select which to invest on (Mithas et al., 2010; Ardolino et al., 2018; Ghobakhloo, 2018; Pappas et al., 2018; Ross et al., 2018) and how to organize and control the strategical change (Tichy, 1983; Bharadwaj et al., 2013; Andriole, 2017; Davenport & Westerman, 2018). DTS papers conceptualize the path to be executed, argued in the second group of papers, which instead deal with the practical deployment of strategy into actions to transform the business model (Ross et al., 2016; Gobble, 2018) or with the management of the business-system-technology integration (Woodard et al., 2013; Agarwal & Brem, 2015; Teubner, 2018; Gastaldi et al., 2018). Consequently, as Digital Transformation Strategy lies in abstraction by the very nature of strategies, as its operations are made in the land of representations and models of reality (Gavetti and Levinthal, 2000), it has concrete effects on reality only through the Digital Transformation Execution (DTE) block (Gavetti and Rivkin, 2007). The proposed distinction comes out by the analysis of the aim and main constructs presented in the analyzed papers and will be clearly described in the subsequent sections.

Digital Transformation Strategy

Papers within this block deal with how to strategically address the opportunities and risks that originate from digital technologies, planning the company journey towards being digitally transformed (Singh & Hess, 2017). In order to refer to this concept, authors often employ different labels (i.e. digital transformation strategy, digital strategy, digital business strategy). A part from the different labels, the common features, which delimitate the boundary of the concept, relay on the fact that it governs the digital transformation: a) by defining objectives and priorities to provide directions (Mithas et al., 2010; Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Ardolino et al., 2018; Ghobakhloo, 2018; Konlechner et al., 2018; Pappas et al., 2018; Ross et al., 2018); b) by organizing the structure to enable the execution of digital initiatives (Agarwal & Brem, 2015; Hess et al., 2016; Sia et al., 2016); and c) by gauging progress to reroute efforts or investments when required (Sebastian et al., 2017).

Moreover, authors who use the label digital business strategy (Mithas, 2010; Kettinger, 2011; Bharadwaj et al., 2013; Grover and Kohli, 2013; Markus and Loebbecke, 2013; Mithas et al., 2013; Woodard et al., 2013; Sia et al., 2016) emphasize the integration between information technology (IT) function strategy and business strategy, which has its root in the need to achieve a peaceful and effective co-existence between IT and business strategy, thus suggesting a juxtaposition of their purposes and plans (Henderson & Venkatraman, 1992).

Beyond the definition of the concept of DTS, papers show that firms might craft their digital strategy to achieve two main objectives:

Value Propositions. A company can transform its value proposition to elevate “the performance implications of IT strategy beyond efficiency and productivity metrics to those that drive competitive advantage and strategic differentiation” (Bharadwaj et al., 2013). Ross et al. (2017) draw how companies use to pursue either a Customer
Engagement Strategy, whether they decide to focus on boosting their customer experience (Lanzolla & Giudici, 2017; Haenninen et al., 2018; Kotarba, 2018; Subramaniam et al., 2019), or a Digitalized Solution Strategy, if they bet on R&D chances to innovate their value proposition by combining products, services and available data (e.g. new smart and connected product, platform, analytics service-based) (Woodard et al., 2013; Porter and Heppelman, 2014; Echterfeld and Gausmeier, 2018).

Processes. A company, pursuing an Operational Excellence Strategy (Ross et al., 2017) may decide to transform its processes. The matter is how to invest on the redesign of the way activities to deliver value propositions are performed, taking advantage of technology to generate more outputs employing less inputs (Zuehlke, 2010; Erol et al., 2016; Dremel et al., 2017; Sanders, et al., 2016; Szozda, 2017; Gastaldi et al., 2018; Kaidalova et al., 2018; Mittal et al., 2018). Moreover, authors sustain companies are required to consider adapting their processes whenever a change in their value propositions occur (Benner, 2009; Ross et al., 2016; Dremel et al., 2017; Lanzolla and Giudici, 2017; Ross et al., 2017).

Digital Transformation Execution

Digital Transformation is the product of the execution of a Digital Transformation Strategy (i.e. Digital Transformation Execution - DTE), where strategies transform the reality towards their exploitation by mean of actions (Gavetti and Rivkin, 2007; Ross et al., 2016). Accordingly, the overall subject matter of the second block is how to exploit the strategetical transformations of value propositions and/or processes by leveraging on technologies (Day-Yang, L. et al., 2011; Gastaldi et al., 2018; Wagner et al. 2018; Weill and Woerner, 2018). Comparing to the previous block, here the knowledge is much more fragmented due to the absence of a referential theory and also because researches mostly and simply describe use cases of technology and how they have just been implemented (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018). Despite the complexity in navigating the knowledge of this block, the analysis on the research aims and the findings of each paper contained into the dataset allowed us to identify three patterns on DTE, regarding Industry 4.0, Lean Management and Project Management.

DTE & Industry 4.0. As salient detail, the contributions referring to the construct Industry 4.0 (i.e. The Fourth Industrial Revolution) mainly focus and prioritize the digital transformations of manufacturing operations and supply chains, and the way an Operational Effectiveness strategy (Ross et al. 2017) may be executed. (Hozdić, 2015; Lee, et al., 2015; Lu, 2017; Bienhaus & Haddud, 2018; Yin et al. 2018).

DTE & Lean Management. Going inside the contributions referring to the digital transformation of Supply chains and Operations, we notice a niche of contributions inquiring the relationship between Lean Management (LM) (Womack and Jones, 1997) and Digital Transformation, and we can outline two outlooks. On one side, Bortolotti et al. (2014) claim the effective execution of a Digital Transformation cannot avoid laying on already efficient and streamlined processes. This is the reason why tracking LM may lead to an operational readiness to change (Sanders et al., 2015; Mrugalska and Wyrwicka, 2017; Besser Freitag et al., 2018). On the other side, Kolberg and Zühlke (2015) overturn the concept, arguing that LM is enabled by Digital Transformation, because technology is broadening the chances for manufacturing and service companies to reinforce their efficiency by solving problems in ways afore unthinkable.

DTE & Project Management. Indeed Digital Transformation Executions are often described as a package of digital coordinated projects, (Erol et al., 2016; Goelzer and
Fritzsche, 2017; Dremel et al., 2017; Singh & Hess, 2017; Bertoncel, 2018), and this opens a question on the role of Project Management in the Digital Transformation process, although few publication refers explicitly to the issue (Schüritz et al., 2017; Teubner, 2018).

Leadership & Culture
The third block considers the academical interest on the impact of the organizational and cultural variables into a Digital Transformation (i.e. DTS and DTE). Compared to the rest of the papers, this block presents a dissonant peculiarity on the methodologies employed by scholars, that is the preponderance of hypotheses tested by surveys and statistic techniques, while case studies are the rule in the other papers. In this niche of knowledge results figure out two main topics discussed by scholars: technical skills, leadership, and cultural background requirements.

From the analysis, these requirements seem a prerogative to make a Digital Transformation effective, mainly for two reasons: first, they must to be fostered whatever the DT will be (Ross et al. 2016; Sia et al., 2016; Westerman, 2016; Dremel et al., 2017); second, it is “difficult, rather impossible, for a network of typical manufactures to achieve them in a short run” (Ghobakhloo, 2018)

Technical skills. Some publications claim that a Digital Transformation to survive in time without having a negative impact on performances need people to be equipped with some technical skills (Weizi et al., 2016). These are required to understand, deploy and manage the opportunities offered by technologies and the dynamics of the change their introduction involves Sia et al., 2016; Davison and Ou, 2017; Ross et al. 2017). Such skills are hybrid skills (Weizi et al., 2016; Schwarzmueller et al., 2018), for example, the ability to perceive week signals of disruption (Bertoncel, 2018) or to handle the analysis and conversion of big amount of data to make decisions above valuable information (Davenport and Patil. 2012; McAfee, Andrew, et al., 2012; Schallmo et al., 2017).

Leadership. Literature maintains the central role leadership plays in the Digital Transformation process, and in particular the interaction between leadership and technology advancements that is baptized as e-leadership (Avolio et al. 2014). Weizi et al. (2016) divide the construct of e-leadership in two layers, where at micro level it deals with the abovementioned skills requirements, and, at a macro level, e-leadership challenges the redesign of company’s governance to allocate responsibilities to tackle a DT. On this account, the analysis on the dataset pinpoints a stream of research on the relationship between Chief Information Officers and Chief Executive Officers (Weizi et al., 2016; Hansen et al., 2011; Oberer & Erkollar, 2018), and the opportunity/possibility of introducing a new referential profile the Chief Digital Officer – CDO to supervise the DT (Singh & Hess, 2017).

Cultural Background. Some contributions address the theme of which kind of organizational culture is more suited to engage a Digital Transformation. From the analysis, two significant features emerge: agility and innovation (Ross et al., 2017; Dremel et al., 2017). In particular, Schwarzmueller et al., (2018) state “organizational culture should be transformed to a culture of involvement, in which decisions are taken together, a culture of innovation, that ensures agility based on the acceptance of suggestions, and a culture of training, in which staff is constantly developed (Patterson et al., 2005).” Furthermore, other authors hint companies need to pursue openness to change (Ghobakhloo, 2018) to adapt more quickly and shorten adaptation time to new working habits (Weizi et al., 2016), and, eventually, create a culture of decision making based on data instead of experience and intuition (McAfee et al., 2012; Dremel et al., 2017).
Models
The Models block collects the contributions which provide knowledge on the opportunities offered by technology advancements and on guidelines companies may follow to implement a Digital Transformation. They are divided into three different groups: Frameworks, Roadmaps and Methodologies, and Assessment Tools.

Frameworks. As defined in the introduction of the paper, Digital Transformation is a consequence of the technological evolution which companies wrestle along their journey. Literature maintain diverse publications that try to build knowledge around this phenomenon (Porter & Heppelmann, 2014; Rometty, 2016; Westerman et al., 2014), inquiring how technologies progress, and/or their social impact, and/or the types of mutations they are provoking on companies (Brynjolfsson and McAfee, 2014; Porter & Heppelmann, 2015; Weill and Woerner, 2015; Brynjolfsson and McAfee, 2017; Venkatraman, 2017).

Roadmaps and methodologies. In this group are contained all the contribution referring to methods (i.e. standards and steps) (Bibby & Dehe, 2018; Mittal et al., 2018), guidelines, roadmaps and tools (Westerman, 2016; Andriole, 2017; Gobble, 2018) which a company could use for architecting and standardizing its Digital Transformation (Liu, Day-Yang et al., 2011; Porter & Heppelmann, 2015; Matt et al., 2015; Erol et al., 2016; Parviainen et al., 2017; Dremel et al., 2017; Ghabakhloo, 2018; Weill and Woerner, 2018). Methodologies can be applied to any type of digital transformation, and their focus ranges from the entire company to a specific project. Literature is rich of anecdotal cases of successful integration of technologies towards a digital transformation (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018), but a thorough reference methodology to handle the problem of Digital Transformation still lacks (Nwaiwu, 2018).

Assessment tools. This stream of papers provides contributions on instruments which support managers or companies in measuring and evaluating the degree of technological integration into company’s processes. This results in a seminal provision to position companies into a reference system that can better drive the digital transformation process (Plomp and Batenburg, 2010; Bibby & Dehe, 2018; Heavin & Power, 2018; Kontic & Vidicki, 2018).

Conclusion
Although this is a preliminary review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems, some contributions to both research and practice have been provided. On the academic side, the paper systematizes the knowledge on the field and provides a framework to orient future researches. On the managerial side, our research offers some insights on the strategic aspects of the digital transformation that endeavour and supports organizations and managers that are tackling the challenges offered by the new digital era.

The paper has also some limitations, that can drive further developments. Results maintain that literature on the field is still in its infancy, suggesting that future research should go more in depth in comprehending how digital transformation can be developed and executed. The performed queries are more focused on the digital strategy conceptualization rather than its exploitation. So, additional research could be performed through a wider sample to validate and enrich the considerations addressed on Digital Transformation Execution subgroup.

Abstract

The purpose of the paper is to identify the issues and challenges to employing blockchain technology for different operations context. The paper analyses five cases to identify drivers and barriers to adopting the technology. Our findings suggest that interoperability and platform dependency can limit the wide-scale deployment of the technology. Additionally, trust in rule-based software automation and consensus among supply chain actors can inhibit effective adoption. In summary, the paper finds that care should be taken when applying blockchain, since there are many situations where its implementation is not feasible or not beneficial.

Keywords: Blockchain, Challenges, Limitations

Introduction

Blockchain has emerged as a technology that can provide visibility, traceability and transparency in business operations, which will lead to better accountability. The potential usefulness of the technology has been reported in many sectors such as: energy (Adoni et al., 2019); health-care (McGhin et al., 2019); digital supply-chain (Min, 2019); retail (Morkunas et al., 2019); financial services (Tapscott and Tapscott, 2017); and transportation (Lei et al., 2019). The key properties of this technology that makes it a valuable proposition to handle heterogenous transactions in different sectors are discussed below and these have been reported in the pilot studies undertaken by technology providers such as IBM (2017), Capgemini (2017) and in academic research.

- **Immutability**: The transactions recorded in a blockchain cannot be tampered, deleted and revised, i.e. the process and information stored in each block is irreversible, thus providing an accurate view of the activities. However, the
authenticity and quality of the information will depend upon the author and source.

- **Distributed:** The blocks and corresponding chain is stored among all the entities in the network participating in the transactions, which increases visibility of the information. However, access restrictions may apply depending on the nature of the information and the rules associated with the creation of blocks.

- **Decentralised:** The transactions occur based on automated rules set in the network (mainly through a process of consensus), which eliminates the need of a central authority, i.e. this potentially will lead to faster transactions, and eliminates the risk of the data being held centrally in a server (as in contemporary information systems). However, as the size of the chain increases the processing time to create or retrieve a block will increase.

- **Automation:** Most processes in the network, i.e. creating a record, processing transactions, are executed automatically by the software codes deployed in the network. The cryptographic verification process ensures authenticity of the transactions and makes the process incorruptible, i.e. devoid of errors (if the software codes do what they are meant to or agreed upon in a suitable manner). It is worth highlighting that the process of rule creation and revisions is a grey area and will depend on the context and purpose of using the technology.

- **Single Unified Ledger:** This helps in aggregating all the records in a single network, i.e. provides the actors with high-level as well as low-level view of all the transactions, linked-information efficiently, thus reducing the information and cognitive overload to some extent. Employing blockchain analytics to provide such a view can be complex and inefficient, due to size of the chain and automated access rights imposed by automated rules.

The existing literature has focussed mainly on the advantages offered by the technology in different business sectors. Though, the merits offered by the technology are demonstrated through pilot projects undertaken by technology providers, it is necessary to understand the challenges to large-scale adoption of the blockchain and readiness of businesses to deploy the technology.

**Issues and challenges identified from the literature.**
The literature gathered from various business disciplines, information systems and computing science was systematically reviewed to identify the potential challenges associated with the adoption of the technology from a business perspective. Though, the emerging technology has been tipped to transform businesses in a ‘positive way’, the key issues associated with the technology (usage, implementation and deployment) and organisation needs (value of using the technology, skills and expertise) are yet to be understood and discussed comprehensively. Table 1 will present the key challenges that can be potential barriers towards the wide-scale adoption of the technology in business domain (in-particular global supply-chains which are increasingly becoming complex). A quick review of the table highlights: the need to understand that will aid in managing and implementing the technology (skills and expertise); agreement between various businesses adopting the technology on the automated rules (process and author), and operational software platform; assessing the long-term benefits of the technology (i.e. consider its efficiency to process multiple transactions and viable integration with the existing operations and processes).

**Review of industry pilot cases**

Blockchain is considered as a valuable solution in different areas because it can record transactions in a secure, transparent, decentralised, efficient, and low-cost way (Schatsky & Muraskin, 2015). It can simplify the transmission of information to eliminate the commonly conflicting layers found in supply chains, making information more reliable,
timely, highly visible and incorruptible. The purpose of this section is to present different instances in which blockchain has been implemented to investigate the themes identified in the literature review and to understand the requirements to leverage the potential of this technology. The five cases selected are looking at the food industry, energy, disaster relief, housing and banking. The findings stemming from the review of the pilot cases is summarised in Table 2.

- **Food Supply Chain.** The food supply chain is an excellent example of the potential value of blockchain. Freshness of food, especially meat, is a significant health concern. That was the motivation behind Provenance (Provenance, 2019), a company that has implemented blockchain to provide more certainty and transparency in the food supply chain. The purpose is to allow users/companies to know more about the origin, travel and destination of food. Talking about meat that can allow users to trust the “kill” dates in their meat products, thereby ensuring freshness. In fact, the company implemented a similar idea in Indonesia, in which they used blockchain to track tuna from the moment it was caught until it reached the consumer (Safaryan, 2017). That way, it was possible to add traceability to the supply chain and ensure consumers about the journey of their product. The potential of blockchain in this setting is not only to increase traceability though. It can allow to support commodity management to reduce duplication of certificates and paperwork, allow marketplace creation by connecting suppliers and customers, increase data sharing among different members of the supply chain through collection of information from different sensors at different stages, increasing access to capital investments, and enhancing payments (Noel, 2018).

- **Energy.** Introducing a fully decentralised energy system is another potential venue for blockchain. The technology available nowadays allows people to be not only consumers of electricity, but also producers. Blockchain has the potential to support transactions among customers with different roles. Elektrify is a good example of the use of blockchain to allow these interactions (Electrify, 2019). In fact, a project between Busan City, Nuri Telecom, Pusan National University, Busan City Gas, and Korea Industrial Complex Corporation tries to exploit this possibility, to improve power generation and distribution in the region (Marley, 2019). This would also facilitate the creation of a micro-grid in regions of the country, which is a project currently pursued by Korea Electric Power Corporation (KEPCO). Beyond that, also in Korea, Swytch, is partnering with Chuncheon to use smart meter and blockchain technology to incentivise and provide benefits for companies and people looking to reduce carbon emissions (SmartCitiesWorld, 2018). On top of that, blockchain can also be used to allow metering, billing and clearing processes (PwC, 2016), which shows the reason this technology is very promising for other countries as well.

- **Relief and disasters.** Collaboration and cooperation are very complicated in situations in which a disaster has affected a region because of the multiple number of organisations involved. Governmental organisations, non-governmental organisations, charities and civil organisations try to provide support for the affected people, but it is complicated to provide a honed response because of the duplication of efforts and the centralised systems used by these organisations. The U.S. government realised that blockchain could be effectively used to enhance collaboration. Blockchain can be used to create a decentralised system through improved information sharing exploiting its traceability, transparency and immutability (Akilo, 2018). In that way, organisations could have more clarity about
the activities of the other stakeholders, helping guide their activities. Moreover, this would allow to pool resources and introduce a coordinated response. This benefit, however, would not be only for the organisations. Transparency and traceability would allow donors to increase trust in NGOs and charities and ensure a more efficient response to the victims. From that perspective, blockchain can allow to provide support for donations and financial transaction in disaster settings (Phil, 2018).

- **Housing.** The housing industry represents an area with huge potential for the implementation of blockchain. A very interesting example comes from the intersection of housing and public policy. The Kenyan National Housing Fund provides government-funded housing for families in need. However, the scheme has been criticised because of fraudulent activities and corruption (Aki, 2018). The use of blockchain would allow to ensure the transparent distribution of houses because blocks cannot be altered once these have been added to the chain. The notoriously porous land registry database would be recorded using blockchain to ensure that houses go to the people who need them. Additionally, funds would be more difficult to embezzle, and bribes would be reduced considerably (Sharma, 2018).

- **Banking.** The most notorious application of blockchain is related to cryptocurrency. Looking at financial services, blockchain has an incredible potential to improve transactions. The We.Trade platform from HSBC in collaboration with another 9 banks is a clear example (Finextra, 2018). HSBC has been at the spear point of the use of blockchain to improve financial transactions. In 2018, the bank was able to perform the first trade finance transaction using R3’s Corda scalable blockchain platform, in the situation of a Cargill shipment of soybeans going to Malaysia from Argentina (HSBC, 2018). The purpose of this test was to use a shared application instead of applications in multiple systems, which reduced the transaction time from days to less than 24 hours. This outcome showed the feasibility of trade digitisation and emphasised the potential to reduce fraud risks in letters of credit, and introducing more efficient procedures (Ganesh, Olsen, Kroeker, & P, 2018).

**Research Agenda**

An important contribution of this research is to convert the themes identified in the literature and illustrated through analysis of cases, into possible directions for future research. We identify four research questions that demand attention, if blockchain is to be seen as a valuable technology for operations management.

- **Interoperability.** Research on blockchain focuses on the benefits and the characteristics, but often overlooks the technical requirements and implications. For example, each actor in the system must possess the required expertise and equipment to effectively share data. Therefore, research should investigate the minimum technical requirements and how big a challenge it may be to bring organisations to the required standard. Additionally, when discussing cases in which individuals also read or write data, this becomes even more complex.
Table 2: Summary of the business cases

<td>Energy</td>
<td>The decentralised system requires similar technology for users/producers and organisations to record/update.</td>
<td>Highly complex system with multiple nodes in which a single platform across all users/producers would be required.</td>
</tr>
<tr>
<td>Disasters</td>
<td>There is a varying level of technological proficiency and resources among actors, particularly donors.</td>
<td>Multiple platforms should be integrated, and databases consistently prepared.</td>
</tr>
<tr>
<td>Housing</td>
<td>Technological requirements for data collection and recording need to be defined. The expertise to implement blockchain would be essential.</td>
<td>Different branches of government need to interact through the integration of different systems.</td>
</tr>
<tr>
<td>Banking</td>
<td>Technological proficiency would need to be consistent across actors.</td>
<td>Multiple platforms should be integrated into a single platform.</td>
</tr>
</tbody>
</table>
• **Platform dependency.** As with information technology, the extent to which blockchain delivers benefits is affected by the data in the system. This means the platforms used, the way in which they are used by actors and the level of expertise of these actors are all important. In particular, the way that data are captured and communicated could be crucial. For example, if objective data are captured using a standardised approach, the data will be more trusted than data input manually, with implications throughout the lifetime of these data. Research should seek to understand data management, platforms and readiness for blockchain implementation.

• **Trust in rule-based automation software.** Rule-based systems, whether electronic, economic or otherwise, are important in enabling business. Trust in such systems, however, is greatly affected by the source of the rules. Whether blockchain rules are set by regulatory bodies or by individual companies and whether they can be modified by individuals or not can affect the trust and hence the adoption or success of blockchain. Research should investigate the behavioural aspects in particular, to understand how and when blockchain can command sufficient trust to be adopted.

• **Consensus among supply chain actors.** The adoption of the technology will require an understanding and agreement between all the actors (for example, supply-chain entities) participating in the blockchain network. This will require have an agreement on the rules set-up within the network, using a platform provided by a technology provider, which will require integration with the existing processes, and participating in the transactions (i.e. willingness and mindset to use the technology). The consensus between the firms will be driven by the potential benefits offered by the technology to the individual firms and the awareness/expertise of the managers about this new and complex technology. The consensus within firm will be driven by the organisation culture to take risks i.e. adoption a technology whose benefits are yet to be validated through long-term usage and technical complexities involved to integrate with existing process in the firm, which will require persuading the management and updating the skill-set of the relevant employees throughout the processes involving technology adoption, deployment and maintenance. Research should understand and investigate various consensus factors within and between firms that will lead to wide-spread adoption of blockchain and eventually make it scalable.

**Managerial Implications**

Operations Managers in a variety of business contexts may find blockchain being offered as the silver bullet that will solve all problems. Examples, including the cases discussed in this research, demonstrate the breadth of applications, from supply chains for consumer products, to government contracts and from energy to banking. Blockchain can be applied in almost every business context. Before leaping into the unknown, however, managers should question whether it should be used in their specific context. This research outlines four key questions that should be considered before deciding that blockchain offers the appropriate solution.

• **What kind of expertise is required?** Implementing a blockchain based solution requires both strategic and technical expertise. The former is to evaluate and
decide on the most appropriate implementation of technological possibilities. The latter must be updated as the technology will evolve, and its complexity increases. This complexity is particularly clear in cases such as the energy one, in which the number of actors contributing energy (and data) is enormous. Ensuring that all of these actors are appropriately connected and that the sources of data are integrated, as well as being certain that the system will remain suitable over time, represents a considerable technical challenge.

- **Who has the right to input data?** Assuming the required technical expertise and strategic decision making are in place, one of the key challenges is platform governance. Consider, for example, the case of the food supply chain, in which traceability depends on the information in the system, how it is input and how it is communicated. If false data are input, these will be stored and transmitted through the whole system. While using blockchain should give confidence that fish have been caught legally or food safety standards have been maintained, this confidence would be unfounded if an actor in the supply chain has deliberately or inadvertently supplied inaccurate data. It is essential, to be sure that the right people have the right access and use it appropriately for blockchain to be useful.

- **Who will decide the rules, and can they be modified?** Access rights are among the aspects that should be defined in the rules of a blockchain system. For example, in a smart contract, it is important that access is restricted to those affected by the contract and that decisions are made when rule-based conditions are met, e.g. once payment is made by one party, the ownership of a property is transferred to that party. Managers should be aware of which actors can decide the rules, for example, in a supply chain, will suppliers have any say and, should the members of the supply chain make changes, will there be ongoing implications? Moreover, should the situation change, the original rules may no longer be relevant, but if they cannot be changed, blockchain may not be appropriate. For example, if a buyer and seller change their agreement, so that a higher amount is payable at an earlier date (or vice-versa) it is possible that blockchain would limit flexibility and prevent changes.

- **What level of transparency is good for business?** Blockchain provides potential benefits in terms of transparency and traceability. An important consideration, however, is whether this is always desirable. In most business contexts, holding back some operational details can be very important. For example, knowing which sources of supply are used or how efficient equipment is can affecting negotiating positions between buyers and suppliers. The transparency offered by blockchain can be of benefit between partners in a supply chain, but managers must consider whether too much transparency may be involved. Consider, for example, a situation where a supplier also supplies competitors, who therefore have access to information. Or an alternative situation in which the agreement with a supplier ends and their access to their own data is restricted. Neither of these situations suggest that the benefits of blockchain should always outweigh the costs.
Conclusion
The limitations of the blockchain technology has received less attention, leading to an inaccurate impression that it can address any challenge pertaining to transparency, reliability, effectiveness, efficiency, accuracy, decentralized information storage and distributed information. The paper contributes to theory by developing the understanding of the key challenges of blockchain implementation and proposing a research agenda (Figure 1) that warrants further investigation to understand potential realistic solutions for addressing these challenges. For operations managers, the paper offers a useful starting point to reflect on several key questions that are likely to impact intra-firm relationship, inter-firm relationship and key decisions pertaining to benefits of adopting blockchain (i.e. both short and long-term). However, the key question for the managers is ‘If blockchain is the solution, what is the problem’.

Abstract

To address food insecurity and achieve efficient food recall, many technologies have been investigated in recent years. One of the most promising technologies is Blockchain, which already been successfully used in financial aspects such as bitcoin, is attracting interests from food supply chain management. As blockchain has characteristics such as decentralization, security, immutability, smart contract, it is therefore expected to improve sustainable food supply chain management and food traceability. This paper uses content analysis methods to carry out a comprehensive systematic literature review in blockchain adoption within food supply chain. We proposed four propositions and five potential challenges.

Keywords: Blockchain, food supply chain

Introduction

Food systems are complex and keep changing over time (Wognum et al., 2011; Yakovleva, 2007). Customers have growing concerns of food security and quality, and an increasing demand of food supply chain transparency. From the food safety survey in 2018, more than two-thirds (68.3%) of participants worry about food fraud problems (Fortune, 2018). According to the World Health Organization (WHO, 2015), almost 1 in 10 people get sick due to foodborne disease each year. Food hazards can cause more than 200 diseases by bacteria, chemical and other contaminations, the foodborne and waterborne diarrhoeal diseases can kill about 2 million people annually including children (WTO 2015). Food crisis ranks the seventh risk in terms of impact by the World Economic Forum in 2018 (WEF, 2018). The most well-known food scandals include Sanlu milk scandal in China (2008), horse meat scandal in the UK (2013), outbreak of E.coli of Romanian lettuces in America (2018) which are only a piece of the food recall iceberg. In 2018, there were 1935 recalls reported, according to US Food and Drug Administration (FDA 2019).
Moreover, globalisation and outsourcing make food system even more complex with more suppliers and companies involved (Christopher et al., 2011; Roth et al., 2007). The longer geographical distance of food supply chain from producers to consumers has also became a challenge to maintain food quality and to achieve fast food recall when necessary. It is not just customers who have doubts, food companies also suffer economic loss from product recalls, which can cost on average $10M for a food company for one recall (Tyco Integrated Security, 2012). Indirect losses and further damages on brand reputation and sales are countless. Within a complex food supply chain, efficient traceability system can make significant contribution in food recall. It can isolate certain products and ingredients from the root of the problem in fast speed to prevent further loss.

Blockchain, as a decentralized platform that not only allows peer to peer direct transaction, eliminates middlemen, but also validate information by cryptography and records history permanently has drawn a lot of attentions, is believed to be a compromising solution to improve traceability and revolutionise the modern food supply chain (Kouhizadeh and Sarkis, 2018). The primary aim of this paper is to investigate how blockchain has been used in the food supply chain area, and how this technology can help to address food security issues. This paper applies a literature review method and expects to answer the following research questions:

Question 1: What are the researches have been carried out upon blockchain’s adoption in food supply chain management (FSCM)?
Question 2: What benefits can blockchain bring to the FSC?
Question 3: What are the challenges of blockchain’s adoption in FSC?

Previous researches have introduced a few integrations of blockchain and FSC, with the application of Internet of things (IoT) (Tian, 2016; 2017), by applying case studies (Verhoeven et al., 2018), or Survey (Hackius and Petersen, 2017). The studies presented both benefits and challenge of blockchain adoption. However, no literature review has been carried to explore this topic in a systematic manner. Therefore, this paper is trying to fill the gaps, by collecting and summarising related papers, and giving a deeper analysis of the literatures to answer the questions mentioned above. The structure of the following chapters is as follows: the second chapter is a literature review on the background of the key concepts, third chapter is the research methodology and review processes, the propositions and discussions are in the fourth and fifth chapter, while the final chapter is the conclusion to summarize the whole research.

**Literature review**

**Food supply chain**

Food supply chain is defined by Folkerts and Koehorse (1997, p. 11) as “a set of interdependent companies that work closely together to manage the flow of goods and services along the value-added chain of agricultural and food products, in order to realize superior customer value at the lowest possible costs”. Compare to the other industries, food products have more vulnerable value chain, and require more attention over handling processes (Aung and Chang, 2014; Ting et al., 2014; Yu et al., 2013). The natural feature of changing quality all the time make keep food safety and quality a challenge (Aung and Chang, 2014). Outer environments such as temperature and transports can also contribute to affect products quality and freshness. Besides, complex food supply chain also means higher risks of products failure, which includes food borne disease, food poisoning, low quality food, counterfeit products, or mislabelling and undeclared ingredients after producing (Lin et al., 2018; Ting et al., 2014; Tyco Integrated Security, 2012). Food security is a shared responsibility in a supply chain, and requires efficiency and closer partner collaboration to maintain the value chain and eliminate products failure.
Modern centralized food supply chain heavily relies on the central powers to control information flow, which can be the threats to the transparency, information equality and trusts (Tian, 2016; Tian, 2017). Lack of transparency can lead to certain risks include: information inequality between stakeholder (Mao et al., 2018), bribery (Tian, 2017), information fraud, etc. Therefore, a single failure can lead to the disruption of the whole supply chain (Tian, 2017). For certain products, such as organic, kosher, vegan or fair trade products, it is even harder for consumers to know the products and information authenticity. Even laws and authority verifications have been helpful, deep concerning and lack of trust of food industry and food quality still remind.

Blockchain

The concept of the decentralized peer to peer ledger was introduced by Nakamoto in 2008. It has been successfully applied in financial area such as Bitcoin, and it triggers huge interests in multiple areas including, supply chain, property, voting, etc. The fundamental technology of blockchain has a few main features: decentralization, immutability, security and smart contract.

- Decentralization
  Decentralization eliminates the central powers and address information inequality by allowing direct transaction between users. Users have equal power to examine transactions, to keep copies of records and to access entire transaction history. In food supply chain, from the raw material suppliers to customers, products information can be recorded along the whole supply chain and ready to be retrieved upon on demand. For example, the end users, consumers, can obtain the detailed information on the products include authenticity and origins, etc. Producers can also monitor their suppliers to make sure raw material quality meet requirements. Therefore, decentralised supply chain can eliminate information inequality and build trust.

- Security
  Data security can be achieved by blockchain consensus algorithm. Transactions are examined by users to define computer calculations. When decentralization eliminates central power on the network, it also prevents a supply chain breakdown because of a single point failure will not lead to the failure of the whole network, which can reduce the chance of hacking. Technically, hacking can only be achieved when the majority (at least 51%) of users are taken over, which will take a considerable amount of energy/time. Therefore, the more complicated blockchain network with more users, the more difficult for the hacking behaviour to happen. When applying into food supply chain, blockchain can keep records and data safe, and eliminates the risks of hacking and data stealing.

- Immutability
  Blockchain ensures the records are original and authentic by its immutability feature. This means history data cannot be altered without warning other users, which can prevent the human intervention on records. This feature makes blockchain as a powerful proof to investigate for accountabilities under food crisis and food recall. It can prevent any stakeholders change history and escape from responsibilities. It is also an evidence for ensuring producing process especially for products such as organic, halal, fair trade, etc., immutable records can provide customers buying confidence. However, immutability cannot always guarantee the raw information authenticity, it can be considered as a strategic tool to encourage stakeholders to take responsibilities for their information.

- Smart contract
  Smart contract is a digitalized program which operates automatically when certain agreements are met. The use of smart contact can significantly speed up transactions and enhance trust, save time and labour. For example, in 2014, Maersk have found that over 30 people and organizations have got involved when shipping a container of roses and
avocado from Kenya to Netherlands (Park, 2018). It also took 34 days include 10 documents processing days to finish a whole shipping activity, which is also not include missing paper caused delay and time extension (Park, 2018). As the smart contract based on the agreement of all partners, therefore, no single user can make changes. In another word, it can replace “the letter of credit” and protect the partnerships. For instance, the payment can be sent to producers automatically once the products arrived to warehouse.

**Traceability**

Traceability has many definitions so far, the earliest definition was by International Organization for standardization (ISO 8402, 1994): “the ability to trace the history, application or location of an entity by means of recorded identifications”. More precisely, “food traceability is part of logistics management that capture, store, and transmit adequate information about a food, feed, food-producing is correct animal or substance at all stages in the food supply chain so that the product can be checked for safety and quality control, traced upward, and tracked downward at any time required. (Bosona and Gebresenbet, 2013, p.35)”.

From the definition, record-keeping is an important element for building good traceability. It not only allows companies to have a clearer view of the supply chain, make better decisions and avoid potential quality risks by providing precise records; but also gives the ability of tracing backward and tracking forward along the supply chain during food recall, which can improve the speed of isolating and finding certain products from certain suppliers (UN global Compact, 2014). For sustainability purpose, traceability is also a way to monitor environmental impacts, therefore, encourage companies to be more sustainable. By demonstrating the resources and products flow, customers have better knowledge and trust on the buying products. Traceability can be the added value to the food products, and be used as a marketing tool to attract more customers and enhance customer trusts. (Dabbene et al., 2014; Golan et al., 2004). The record keeping can also be used as a strategic tool to encourage suppliers to provide quality products (Aung and Chang, 2014; Golan et al., 2004).

Traditional traceability system largely relies on paper-based system or internal computer system, which can be time consuming and incapable for other stakeholders (Aung and Chang, 2014). Traceability can also differentiate companies from success and failure during food recall by accelerating recalls and saving unnecessary costs (Golan et al., 2004). FDA reports that it can take averagely 57 days for a recall, or even up to 10 months sometimes (McCallister, 2017; O’Donnell, 2017). The slow products recall can lead to deep concerning of food safety and damage company brand image. Technologies include Radio Frequency Identification (RFID), barcodes, smart tags, Wireless Sensor Network (WSN) and DNA based techniques, can provide more efficiency but can be expensive.

Blockchain is considered as a compromising solution to achieve efficient traceability. The early research by Tian (2016) proposed a conceptual framework which integrates blockchain and IoT, and suggested the benefits, include improving efficiency and transparency. There are also many pilot studies that provide the practical implication. The real world pilot study was carried by Walmart tracing mangoes (Yiannas, 2017). Compare with traditional traceability system, mango tracing time reduced from nearly seven days to 2.2 seconds by using blockchain.

**Methodology**

In order to answer the research questions, this research adopts a literature review method. There are several review papers on blockchain and SCM, however, none of them have a specific focus on food supply chain (Wamba et al., 2018; Wang et al., 2018). These
papers provide the foundation of this research. Fink (2005, p3) defined literature review as “a systematic, explicit, and reproducible design for identifying, evaluating, and interpreting the existing body of recorded documents”. This paper adopts a content based literature review on the application of blockchain in FSCM. This paper not only thoroughly reviews blockchain, but also considers some practical applications, and aims to provide a more precise and integrated understanding of blockchain and its influences.

This literature review applies six-stage refinement process suggested by Durach et al. (2017): define research question, set inclusion and exclusion criteria, determine searching databases, apply criteria, synthesize relevant literatures, and report findings. Research questions have been provided in the introduction. Therefore, research keywords are blockchain and the food supply chain. Web of science, Scopus and Ebsco are the three online bases that applied for relevant academic literature searching, as the three databases have a wide range of resources, and have been used extensively in SCM research. Peer-reviewed journal articles are seen as a way of high quality communication between research fellows. However, in this paper, due to the early stage of blockchain and the limited published articles, other resources such as conference papers, grey papers, consulting reports, third party reports that can provide more updated information are also considered. The initial search came out 57 results in the three databases.

Removing the duplicated papers and applying inclusion & exclusion criteria (Table 1), the number of useful papers reduced to 23 in the final process (Diagram 1). The final 23 papers are categorized and evaluated by content analysis method (Table 2), which is a systematic and objective research method that been used to quantify phenomena, documents or communications (Seuring and Gold, 2012).

Descriptive analysis is the first insight into all the papers, and suppose to provide a basic view of the selected papers. Among the selected papers, due to the young age of technology, the earliest paper (1 out of 23) was released in 2016, and eight papers in 2017, and the 14 papers were 2018 and onwards. The time trend shows that blockchain tends to gain an increasing research interests in food supply chain area. This also explains well that 13 out of 23 papers are technology and innovation related conference papers. Papers are focusing on different aspect of food supply chain, however 12 out of 23 of the papers focusing mainly on traceability. Papers mainly adopted conceptual framework (13 out of 23), and pilot cases (6 out of 23), three theories (3 out of 23) and survey (1 out of 23) respectively.

Finding and discussion
Blockchain is believed can address the inefficiency in current traceability and enhance trust during food recall (Yiannas, 2017). Galvez et al. (2018) suggested that blockchain is a powerful tool to avoid food fraud and to improve traceability efficiency includes time and costs saving, risks reducing, and increasing trust. Similarly, Caro et al. (2018) agreed the ability of blockchain on providing transparency and auditability by built blockchain traceability systems. A pilot study of blockchain based mango tracing system was launched in 2016 by Walmart and IBM. By current traceability system, it took almost 7 days to collect all the information of mango movements, and required every stakeholder to contact with each other to get to know the required details (Yiannas, 2017). By blockchain, the time to contact and wait for response from other stakeholders can be eliminated. The movements of mangoes are recorded by each stakeholder along the supply chain, and ready to be checked anytime. The trace time reduced from nearly 7 days to 2.2 seconds by blockchain (Yiannas, 2017).

- Proposition 1: Blockchain can positively improve food traceability
  
  In the centralised supply chain, leading companies tend to choose selected information to open up to the public, which can cause the lack of transparency and trust issues within a supply chain, especially for certain products such as Halal, organic, etc (Tieman and Darun, 2017). Besides of companies themselves, even authorities can contribute to cover up unlawful hazards. For example, the China Sanlu milk scandal did not get exposed on the first place due to the cover up by company managers and local authorities (Barboza, 2008). Information credibility is questioned in centralized food supply chain (Hua et al., 2018). Blockchain, as a decentralized platform, allows authorised users have equal powers to have a copy of history and access it directly without central power intervention, which can prevent any large powers over the information flow and provide transparency along the supply chain, may be the solution for information inequality.

  Information fraud is another major concern within centralized supply chain, where transparency and visibility remain low. Companies can erase or change history to escape from taking responsibilities or hiding the truth (Biswas et al., 2017; Caro et al., 2018; Tian, 2016; Tian, 2017). By blockchain, once transactions are validated and are added on the blockchain, the original records stay permanent and can be retrieved anytime (Tian, 2017). In 2016, Walmart and Tsinghua University traced pork in China from-farm-to-fork. The finding shows that blockchain can improve information authenticity, reduce information errors and gain trust (Yiannas, 2017). This pilot case suggested that the
digitalization of records and documents not only can save time from manual paper check, but also eliminate risks from information fraud.

- Proposition 2: Blockchain can address food supply chain information asymmetry and information fraud

Many studies have combined blockchain technology with IoT, and suggested that blockchain can help to manage IoT and make supply chain more efficient (Galvez et al., 2018; Leong et al., 2018; Lin, et al., 2018; Tian, 2016; 2017). IoT such as RFID, WSN, connects objects and provides intelligent, reliable and high speed information exchange. Information such as temperature and humidity can be captured automatically by IoT sensors in near real-time, which is significantly important for food products, as the quality is closely related to the external environment (Lin et al., 2017; Tian, 2016). The automation by IoT can increase the efficiency of monitoring and reduce human intervention and errors (Lin et al., 2018; Tian, 2016; 2017). By combining with smart contract, once anything goes wrong such as losing temperature control, the digitalized program can be triggered automatically and send register users warnings, which can prevent further damage (Caro et al., 2018; Lin et al., 2017; Tian, 2017). There are a few blockchain pilot studies that have incorporation with IoT, such as WWF using smart tagging combine blockchain to prevent illegal tuna fishing in Fiji; Belagricola uses IoT and smart contract to track grains and ensure the quality (Leong et al., 2018).

- Proposition 3: Blockchain can positively integrate with the IoT management in a food supply chain

By using blockchain, food supply chain is found to be more sustainable by efficient products management and fast food recall. When products information is updated on blockchain in near real-time basis, stakeholders can have the awareness of products situation immediately. For instance, Walmart realized that fresh products such as mangoes can wait to be checked up to four days in the border (Yiannas, 2017). In this case, Walmart can accelerate the products checking process and give mangoes more shelf lives. The improvement of information transparency can improve the supply chain efficiency and eliminate unnecessary products wastes. Depends on the information, companies can make more accurate customer demand forecasting based on the point of sales data (Wang et al., 2019).

- Proposition 4: blockchain can reduce food wastes

The references also suggest following challenges:

**Lack of deep understanding of the blockchain technology**

Public still has not enough knowledge of blockchain, even many people working within the SCM area still having troubles to fully understand about blockchain potentials (Hackius and Petersen, 2017; Galvez et al., 2018). Verhoeven et al (2018) suggested that many companies tended to choose blockchain as a solution before diagnosing company issues, which show a lack of deep understanding of blockchain true potentials. For instance, Verhoeven et al (2018) suggested that in Walmart’s pilot study of tracing mangoes, the tracing speed increase by blockchain should due to the eliminating of manual validation process rather than change to an efficient platform. Leong et al (2018) also suggested that different stages of the supply chain might have different requirements on technology adoption.

**Technology scalability issue**

The second challenge is called the “scalability trilemma” by the founder of the smart contract platform Ethereum -- Vitalik Buterin (Perboli et al., 2018). It is hard to achieve decentralization, scalability and security at the same time, only two out of three can be achieved at one time (Ometoruwu, 2018; Perboli et al., 2018). Scalability determines how
large the capacity the network can be. Currently, Ethereum can process 15 transactions per second, while other platforms such as Visa can process 45,000 transactions per second (Coindesk, 2019). Mining process can ensure high degree of decentralization and security; it can also cause slow speed of validations when a large number of transactions are happening. For vast global food supply chain, the scale can reach about Petabyte per year by assumption (Pearson et al, 2019). Pearson et al (2019) assumed that blockchain is more likely to happen in niche areas in a food supply chain, where the blockchain potentials are necessarily needed. Different stages of the food supply chain may have different requirements for blockchain adoption (Leong et al, 2018).

Raw data manipulation before uploading to blockchain

Although, blockchain can provide a robust way to keep records, many studies have concerned about raw data manipulation, for example by tempering with IoT sensors (Galvez et al., 2018; Lin et al., 2017). It is also possible to make damages on products without notifying blockchain users (Kshetri, 2018). In this case, third parties such as governments and certifications can get involved by making regular checks to ensure raw data authenticity (Tian, 2017; Leong et al., 2018). Meanwhile, the immutable recording can also encourage stakeholders to take responsibilities for their products and information. It is hard to require all stakeholders within a food supply chain to adopt blockchain.

It is difficult for all stakeholders get involved due to the different levels of knowledge and infrastructures. The implementing and infrastructure mentioning fee can also be the barriers (Leong et al., 2018; Pearson et al., 2019; Perboli et al., 2018). Perboli et al (2018) suggested that implementing fee of blockchain can be highly sustainable and can be paid back by saving on the costs. They also suggested that replacing the system partially by blockchain is more reasonable. It is also important for developers to make blockchain easy to use and to deploy with low initial costs (Leong et al., 2018; Pearson et al., 2019).

Regulations/laws need to be updated

By examining the external environment factors for blockchain implementation, Tse et al (2017) suggested that third parties also gain benefits from blockchain. Many countries and authorities have showed their interests and supports (Tse et al., 2017): China has published Blockchain White book and launched blockchain related projects (Tse et al., 2017); ISO Blockchain (TC307) was also working on developing a global blockchain standards (Pearson et al., 2019). However, there is no strict blockchain policy in food supply chain area so far. As Leong et al (2018) and Pearson et al (2019) suggested that policies and rules need to be developed to protect users and company secrets. It is a challenge to invite all stakeholders on board before some completed policies and rules are being launched.

Contributions and limitations

This paper, to our knowledge, is the first to investigate how blockchain engage into food supply chain specifically. The paper provides a fundamental and comprehensive understanding of blockchain and its potential impacts, which will not only can be a useful guide for new researcher in relevant area, but also can provide some deep insights for practitioners such as company decision-makers. By identifying and analysing the most related papers, this work lays a solid ground for future research on this area, and points out some research directions. This paper also gives technology adopters a better understanding of blockchain, and explains them some possible adoption challenges and reminds them to use blockchain fit right into the issues.

Despite from the contributions, the author also would like to point out some limitation and future research areas. First of all, due to the immaturity of the technology, the paper is based on very limited number of theory-based researches with several pilot case studies,
which may lead to research bias. The big success of Bitcoin may cause a “hype” of blockchain and potentially lead to positive perspectives. In this case, the future research can focus on blockchain implementation in the real world and provide more empirical evidence. Secondly, food supply chain is complicated and various. This paper bases on the food supply chain in general, which can remind the future research to focus on specific food products and present more precise findings.

Abstract

This study investigates the application of current Industry 4.0 technologies as measures to counteract risk factors within companies and supply chains. Drawing on a database of more than 300 Industry 4.0 projects all around Germany, this study not only empirically explores which technologies and risk factors are currently relevant among practitioners – but also evaluates the applicability of various technological solutions for the purpose of mitigating existing supply chain risks.

Keywords: Industry 4.0, Risk Management, Digitalization

Introduction

Rapid technological developments in the fields of data generation, processing and storage left a mark on society and economy during the last decades. This extends to huge improvements of artificial intelligence and algorithms for data analysis. These technologies have also become increasingly employed in supply chain- and production processes (Tjahjono et al., 2017; Xu et al., 2018). This development can be tied to various drivers and motivations on the side of decision-making instances. While many projects are initiated for image or hype reasons, Industry 4.0 technologies often also serve as measures to deal with existing challenges and risks within companies or supply chains.

On the other hand, new technologies and their application raise new challenges for practitioners as well – regardless of the branch. For example, Guha and Kumar propose that the application of Internet of Things (IoT) and predictive manufacturing in healthcare supply chains raises risks related to data security, high costs of implementation and hidden problems/costs even after successful implementation of projects (Guha and Kumar, 2017). While this is a problem with extensive practical implications beyond the healthcare sector, scholars have just started to explore the possible interrelations and
mutual effects between supply chain risks and digital technologies. While there are few conceptual works using illustrative examples to outline possible relationships (e.g. Ivanov et al., 2018), the literature lacks exploratory empirical investigation of these phenomena. To the best of our knowledge, this is the first attempt at integrating insights from empirical, multiple cases of projects in order to extend the debate on digitalization and supply chain risks. Thus, the study aims to answer the following research question: How are industry 4.0 technologies employed to address various sources of supply chain risks within production and supply chains and which factors impact this relationship?

This study expands the work of Schlüter et al. (2017) and Ivanov et al. (2018) by investigating how technologies behind Industry 4.0 can affect supply chain risk using a large sample of 300 Industry 4.0 projects in Germany. In particular, the study addresses three main objectives:

- Analyse the supply chain risk factors that practitioners address through the use of specific Industry 4.0 technologies;
- Evaluate the benefits practitioners associate and aim for with the implementation of different technologies;
- Evaluate additional factors that influence the relationship between supply chain risks and Industry 4.0 technologies.

The paper is structured in six sections. The following section 2 briefly discusses the state of the art, while section 3 and 4 describe the methods and data used. Section 5 presents the main findings, while section 6 concludes with several theoretical and practical contributions.

**Literature Review**

The literature on supply chain risk management provides numerous models and frameworks for types and sources of risks as well as mitigation strategies (Chopra and Sodhi, 2004; Kersten et al., 2007; Rao and Goldsby, 2009). However, little is known on the interdependencies of these supply chain risks and Industry 4.0 applications as of yet (Ivanov et al., 2018). Current literature in this stream is only emerging at the moment and contains fragmented and mostly conceptual insights. Recent studies contain a strong focus on big data technologies and put the emphasis on outlining potential application areas of these technologies in supply chain operations, e.g. Kuo and Kusiak (2018) on the use of big data in customer research and manufacturing and Roßmann et al. (2017) on big data for demand planning and return management. These studies also point out potential risks associated with the implementation of Industry 4.0 technologies, such as data manipulation, safety and security (Guha and Kumar, 2017; Roßmann et al., 2017), risks due to different levels of technological maturity between supply chain partners (Roßmann et al., 2017), coordination complexity and information disruption risks (Ivanov et al., 2018) and hidden costs after implementation (Guha and Kumar, 2017). They do not evaluate applications of Industry 4.0 technologies for the purpose of addressing existing supply chain risks in detail, though. Other authors focus only on potential new risks of Industry 4.0 implementations, without addressing the interdependencies with existing risks being reduced at the same time (Tupa et al., 2017).

Overall, current literature mostly just covers risk management regarding Industry 4.0 by analysing potential new or intensified risks, but not by evaluating the role of Industry 4.0 applications as measures for mitigating existing risks. This perspective is only addressed by studies pursuing conceptual analysis of potential benefits or motivations for projects in that field. In this regard, current literature lacks empirical evidence based on cases of Industry 4.0 implementation and associated risk factors. This study aims to
address this research gap and to explore the relationship between supply chain risks and Industry 4.0 technologies based on cases from Germany.

Methods
In order to explore risk factors associated with Industry 4.0 empirically, a multiple case study design is employed in this study. For this purpose, the study draws on insights from 300 cases of Industry 4.0 applications in Germany. These cases are based on the well-known ‘platform Industry 4.0’, created and managed by the German Federal Ministry for Economic Affairs and Energy in cooperation with the Federal Ministry of Education and Research (Federal Ministry for Economic Affairs and Energy, 2018). This platform was set up with the objective to transfer learnings and best practices from the implementation of Industry 4.0 projects across German companies. In this regard, the platform provides standardized categories with pre-set possible data fields for each case, namely company size, region, product examples, value creation, application example and development stage. Moreover, for every project, several leading questions are answered. These questions include insights on challenges, benefits, approach adopted for the implementation of Industry 4.0 and lessons learnt. This database of cases was selected for several reasons. First, the cases presented on the platform represent the current state of the art of Industry 4.0 implementation in Germany. Second, the database is comprehensive and representative since it includes projects from various regions within Germany, different types of companies, industry applications and technologies employed.

Therefore, by using the 300 cases, this study can develop first empirical insights on risk factors associated with the adoption and implementation of Industry 4.0 projects. The analysis of cases in our approach followed a five-step procedure, as shown in Figure 1.

![Figure 1 – Steps and applied methods](image)

Data Overview
Several cases have been excluded from the initial database of 359 cases. Reasons for exclusion included missing key information concerning the technology used, benefits, risk factors, etc. A final dataset of 300 cases with complete information was used for further investigation.

This dataset can be described in terms of several characteristics. First, the majority of the cases are located in Baden Wuerttemberg, North Rhine-Westphalia, Bavaria and Lower Saxony – which are the four largest federal states of Germany. Nevertheless, all federal states are represented through companies with use cases, making the sample representative for the whole of Germany. 43 percent of the companies participating in the platform rank among the Small and Medium-Sized Companies (SME, 1-250 employees).
Companies of the other three size categories (250-5000, 5000-15000, >15000 employees) are represented similarly with approximately 20 percent each. Third, the 300 cases entail a strong focus on production processes, since nearly two-thirds apply to ‘manufacturing industry’ and more than half of the cases state ‘production and supply chain’ as the part of the value chain in question.

With regard to the technologies used, the case description includes a wide range of names for different technologies. Based on appropriate literature (e.g. Schlüter and Hetterscheid, 2017; Oztemel and Gursev, 2018), we identified 56 basic technologies or technological components relevant within the scope of current applications of Industry 4.0. Of these, 46 occurred within the examined cases. Due to the broad range of basic technologies and the size of the overall database, we aggregated the technologies into the following twelve higher-order technological groups, presented in Table 1.

<table>
<thead>
<tr>
<th>Technological group</th>
<th>Examples</th>

Findings
In this chapter, we analyse ex-post benefits connected to the Industry 4.0 applications described in the use cases as well as ex-ante challenges mentioned by the practitioners. In both cases, we compare the perspectives of providers and users of Industry 4.0 solutions to examine if these may diverge significantly. Through the analysis of benefits, we conceptualize variables with positive impact on current supply chain risks: these variables may reduce the exposure to existing risks factors in supply chains. The challenges extracted from the case analysis are conceptualized as potential risk factors that practitioners want to address by the use of Industry 4.0 solutions. After highlighting...
benefits and risk factors associated with the technologies, the study examines relationships between benefits and technologies as well as between technologies and risk factors, also taking into account the distinction between technology users and providers.

Benefits - Positive impact on supply chain risks
In the fourth phase, we aggregated all benefits identified within all cases and used a bottom-up approach to cluster them substantially. As a result, we derived a total of 14 higher-order categories regarding fundamental opportunities and desired benefits of Industry 4.0. Figure 2 shows the frequency in absolute numbers for all of these categories respectively. It is conspicuous that the accessibility and visualization of data – which means real-time knowledge about conditions and ongoing processes on the shop floor level – is prevalent among the achieved benefits of Industry 4.0 applications. Making own production more flexible and adaptable to volatile demands and increasingly individualized customer needs is another frequent topic.

Supply chain risk factors
In the following phase, we aggregated all identified risk factors and used a bottom-up approach to cluster them substantially. As a result, we derive a total of twelve higher-order categories regarding fundamental risk factors addressed by applications of Industry 4.0, which serve as mitigation measures in this context. Figure 3 shows the frequency in absolute numbers for all of these categories respectively. The results show that the susceptibility to errors and high costs of already existing, often manual and therefore labour intensive processes is by far the most common risk factor among the examined cases. Following next are the inflexibility and high latency of the existing production system in confrontation with a high diversity of variants as well as an increasing individualization of customer needs.
With 35 indications each, two risk factors within the scope of IT are also mentioned quite frequently. First, many companies face a fragmented landscape of IT systems and experience difficulties linking existing systems to one and another, or integrating new systems into the existing infrastructure. Second, the control layer or the decision-making personnel in general lacks knowledge about current conditions and ongoing processes on the shop floor level, especially regarding machine statuses, order progresses and unpredictable incidents like machine malfunctions.

Figure 4 shows the relative shares of the six most frequent risk factors within each of the four different enterprise sizes, divided into provider and user perspective.

It is notable that, compared to the provider side, on the user side much larger shares of all types of companies state increasing complexity, insufficient inflexibility and high latency of the existing production system as prevailing risk factors. This may indicate insufficient insights into customer needs on the provider’s side. Alternatively, state-of-the-art applications of industry 4.0 may not be particularly suitable to mitigate this risk factor from the providers’ perspective. The opposite applies for ‘fragmented system landscape’, which is more of a core topic to providers of all sizes than it is for users.
Exploring interrelations between technology, benefits and risk factors

Our data set also allows further insights by examining relationships between the different case characteristics like employed technologies or addressed risk factors. Figure 5 shows the proportionate composition of assigned benefits for each technology respectively, from the perspective of Industry 4.0 providers.

Figure 5 - Benefits accompanying specific technologies, provider perspective

While some technologies like additive manufacturing seem to have only a limited scope of application, i.e. predictive maintenance and cost reduction, there are also technologies like big data, cloud computing, software solutions and sensors that have a very broad spectrum of intended benefits, including all six most frequently mentioned ones. This versatility is likely a main driver for the intensive deployment of these technologies as seen in Figure 5.

In Figure 6 we show the proportionate composition of assigned benefits for each technology respectively, this time from the perspective of Industry 4.0 user. Interestingly, this perspective diverges significantly from the provider perspective in some cases – which indicates different understandings, experiences and expectations regarding the respective technologies and goals of its implementation.

Figure 6 - Benefits accompanying specific technologies, user perspective
While big data and software solutions are still utilized for all six most frequently mentioned benefits, for cloud computing and sensors this is no longer the case. Technology users so far do not associate cost reduction with the implementation of sensor technology, while cloud computing is not utilized for automation/economics of scale and error reduction. On the other hand, the benefits of technologies like human-machine-interfaces and additive manufacturing are perceived as more versatile, utilizing them for benefits that are not considered in the provider perspective so far.

Another interesting aspect is how providers and users perceive technology by the means of its ability to address the twelve identified risk factors. Figure 7 shows which technologies were applied in order to address the twelve risk factors respectively from the providers’ point of view.

For almost all risk factors, software solutions are the most used technology, tailed by (big) data management technology and cloud computing. These three technologies cover almost more than 50 percent of the solution approaches, thus dominating the field. What is also worth mentioning is the extensive application of machine-machine-interfaces to address insufficient supply chain collaboration as well as additive manufacturing to counteract quality defects.

Figure 7 - Technologies addressing specific risk factors, provider perspective
Figure 8 shows, which technologies users implemented to address the twelve risk factors that companies are facing. In comparison to Figure 7, we see the perspectives of providers and users significantly diverging.

First, there are no cases in the database of users concerning the risk factor of cybercrime, indicating that this issue is often ignored or perceived as a merely potential risk, not worth addressing through specialized technological applications. Second, there are differences between the providers’ and users’ perspectives for the remaining eleven risk factors. While software solutions, big data and cloud computing are still deployed most frequently, they no longer make up the majority of applied technologies for all risk factors. This is most apparent for quality defects, which is not addressed by either software solutions or cloud computing. Furthermore, while providers greatly consider machine-machine-interfaces in order to address insufficient supply chain collaboration, users do not consider this at all as of yet.

**Discussion and conclusion**

This study put forward the following research question: How are industry 4.0 technologies employed to address various sources of supply chain risks within production and supply chains and which factors impact this relationship? Through our examination of 300 cases of Industry 4.0 technology implementation across Germany, several key insights emerge. Technologies employed in Industry 4.0 projects tend to reduce exposure to current supply chain risks, such as demand-side risks (volatile demands, increasingly individualized customer needs) and operational risks such as errors caused by manual processes or malfunctions of machinery. Our insights also suggest that the perspectives of technology providers and users tend to be very different regarding benefits and risk factors. Moreover, the results showed how some technologies seem to be more versatile as means of risk mitigation, and how users’ and providers’ assessments diverge in this regard. Yet, these technologies may also pose additional risks to supply chains, namely inflexibility, high latency of the existing production system, increasing complexity, integration with current IT systems and lack of adequate knowledge and skills of key personnel. Based on this work, these new risks should be evaluated to enable trade-offs and interdependencies of risk factors.
With this, our study contributes to the emerging literature on supply chain risks and digital technologies with an empirical investigation of opportunities and risk factors based on ongoing Industry 4.0 projects in Germany. The findings also entail some important implications for managers. First, managers can employ specialized software solutions since they are ever-present in mitigating different types of risk factors. Cloud computing can be employed to address insufficient supply chain collaboration and therefore managers can design integration projects around the use of the cloud technology. In addition, purely digital, often location-independent, easily adjustable applications like cloud- and software solutions present numerous opportunities for supply chain risk reduction and are quite popular among practitioners. Second, technology providers and users can enhance their communication in order to balance their diverging views and experiences, in particular concerning the risk of cybercrime. The user side often disregards cybercrime, which is mostly addressed as a key risk factor by providers of Industry 4.0 solutions.

The study presents also several limitations, which open avenues for further research. First, the database inherits the limitation and biases of secondary data. In order to account for this, these insights need to be further explore based on primary data, such as expert interviews. Second, the study adopts a bottom-up perspective on supply chain risks, building on the constructs found in the cases description. The next step is to compare the higher-order constructs with literature on supply chain risks in order to develop a more comprehensive image of supply chain risks and digital technologies. Moreover, this study presents a good starting point for exploring new risk factors accompanying Industry 4.0 solutions and examining trade-offs with the mitigation of existing ones.

Abstract

Smart product development (SPD) in industry 4.0 facilitates decision making during different activities involved in development process. Contextual evidence shows such activities are influenced by several factors; however there remains little understanding on factors influencing SPD from industry 4.0 in Indian context. Present study aims to identify and develop perception based prediction model to investigate critical factors influencing SPD. Two dimensions extracted viz. “technological” and “strategic” factors have significant positive impact while out of five identified critical factors three have significant positive impact i.e., technology & innovation, system integration and collaborative engineering. Thus, increasing quality of industry 4.0 can be accomplished with proper integration of technologies.

Keywords: Critical factors, India, Industry 4.0, Smart product development

Introduction

With the advancement of digital technologies and a paradigm shift to industry 4.0 manufacturing industries have been found to be in major transformation towards adopting smart manufacturing (Feeney et al., 2015). This new industrial trend affects organizational structure and customer’s demand (Gilchrist, 2016) which resulted into development of complex and smart products with new capabilities thus influence product life cycle that is somewhat different from conventional product development approach (Nunes et al., 2017; Ahmed et al., 2019). Industry 4.0 is an integration of “intelligent systems, machines, production and processes to form a well-defined network” (Kagermann et al., 2013, cited in Ahmed et al., 2019). It is a concept that involves combined components of “cyber physical systems (CPS)”, “internet of things
“IoT” with cloud based models as disruptive technologies (Wang et al., 2015; Dalenogarea et al., 2018). It produces new types of products with intelligent systems embed in it. Despite the recognition of the term “smart” as extensively used by many organizations and researchers, still today there is no consensus of consistent definition. The concept of “smart product” is a network based integrated approach that spans entire manufacturing process and control production stages/processes autonomously (Nunes et al., 2017). It is characterized by its computation and data-storage facilities and its way of interaction with other objects. From developing economy like India manufacturing industry resembles high priority sector in terms of wealth creation and employment generation. However, such development initiative is still in its concept phase and has got immense potential to bring positive effects in terms of cost, quality, productivity, time, flexibility and innovation. Traditional product development approach consisting of multiple processes and sub-processes that interferes decision making information and knowledge capture (Ahmed et al., 2019) and hence real time decisions cannot be taken (Wasim et al., 2013). This becomes an imperative for development of frameworks for smart products so as to offer unprecedented customer insights. In-spite of several advantages in combining industry 4.0 and SPD, majority of the Indian industries are in state of dilemma with respect to its adoption and implementation. Contextual evidence indicates that factors that influence traditional product development approach may not be same as in case of smart product development. Thus the purpose of this paper is to identify the critical factor dimensions that affect smart product development from Indian industry 4.0 perspective. Accordingly the following objectives have been considered.

**Objectives:** (i) To identify and predict the influence of critical attributes or indicators on SPD; (ii) To identify critical factor dimensions and its influence on SPD.

**Hypotheses Development**

*Technology and Innovation*

With high-technology development influenced by innovation facilitates product design and development process. Such innovation led technological development engenders substantial changes in existing market that leads to successful product development. Quality of the product can be improved with technology intervention as organizations are moving towards digitalization in context of industry 4.0. Development process of smart product entails diffusion of advanced technologies and equipment, advanced production procedures with upgraded software and databases. Thus it is expected that ‘technology and innovation’ would increase the process flow by focusing on process innovation. Accordingly the following hypothesis is proposed.

H1: Technology innovation has positive influence on smart product development

*Collaborative Engineering*

Collaboration, in terms of human interface perspective, aids towards execution of series of activities which provides channel for team. Collaborative product development from
engineering perspective is a technology oriented process that is used to design innovative and improved products by exploring new markets so as to gain competitive advantage (Büyüközkan and Arsenyan, 2012). From the literature it is evident that collaborative process is followed in many industries those are involved in complex product and service development including research and development (Feller et al., 2005). Collaborative engineering also focuses in handling problems in relation to partner selection and evaluation which is critical for product development success. Thus following hypothesis is proposed.

H2: Collaborative Engineering has positive influence on smart product development

**System Integration**

Pertaining to SPD from Industry 4.0 perspective, SI refers to cyber physical systems that interconnect physical systems and communication infrastructure (Baheti et al., 2011). Integration of cyber technologies make products internet enabled that generates lots of data and communicates with other interconnected products. These facilitate product development process which can be achieved in cost effective and effectual manner. With system integration approach flexible operations could be performed by adjusting combination of standardized modules that speed up the product development process and reduces time to market. Thus following hypothesis is proposed.

H3: System integration has positive influence on smart product development

**Sustainability**

Sustainability is considered to be a critical attribute that strategically addresses the risk management in product development. With reference to environmental perspective issues pertaining to sustainability related to smart products focuses on reducing wastes, resources and energy thus moving towards green products. Reducing series of activities pertaining to traditional product development approach would eventually make the process efficient and eliminate any special causes of defects which ultimately lead to product development success. Moreover, economic sustainability facilitates agility and smooth flow in smart product development with objective to maximize profit and minimize costs. Thus the following hypothesis has been proposed.

H4: Sustainability issues have positive influence on smart product development.

**Lean Operating System**

Lean implementation is initiated by cyber physical system (CPS) which results in elimination of wastes by maximizing productivity. Such implementation produces products at low production costs, with good quality, better accessibility to market and customer satisfaction. Lean aspects of product development include knowledge based engineering focusing on smart technology, mistake proofing, and continuous improvement as core enablers for process development (Khan et al., 2013). Knowledge based platform proposed in work of Ahmed et al. (2019) demonstrates the influence of
advanced lean technology in product development process using knowledge-based engineering. Thus the following hypothesis is proposed.

**H5:** Lean Operating System issues have positive influence on smart product development.

**Methodology**
In order to address the research objective the present study adopts qualitative and quantitative approaches. A comprehensive search on related literature has been conducted to identify critical attributes of SPD in context of industry 4.0. To carry out qualitative based approach a semi-structured questionnaire was prepared in understanding the contextual attributes and accordingly an in-depth interview is carried out from ten manufacturing organizations where respondents were from top management and managers who have got experiences of working in domain of product development. Criteria for selecting respondents were such that they should have atleast served for minimum of eight to ten years as senior manager category with respect to design, R&D, marketing aspects of product development. Organizations involved in manufacturing products that includes consumer based household appliances and intelligent medical devices are considered in this study. Overall five critical attributes have been finalized to be taken into consideration from industry 4.0 perspectives. With identification of critical attributes of SPD attributes a structured questionnaire is developed and respondents were asked to give their opinion for each attributes on 5 point Likert scale ranging from “5= strongly agree” to “1= strongly disagree”. A structured questionnaire was sent to around 250 organizations, out of which 200 organizations responded. Out of 200 questionnaires received 35 found to be with missing data thus total 165 questionnaires were taken into consideration for further data analysis. Overall 165 respondents’ opinion is finally captured for data analysis. SPD is taken as dependent variable in terms of product development success considering operational performance measures. To establish link between predictor and dependent variables proposition have been drawn considering literature and contextual understanding (Büyüközkan and Arsenyan, 2012; Hermann et al., 2014; Kiel et al., 2016; Jianfan et al., 2017; Mrugalska and Wyrwicka, 2017; Kamble et al., 2018). Thereafter, a step-wise multiple linear regression modelling is performed to study the influence of all the five models on SPD. Secondly, factor analysis with PCA (principal component analysis) is done on five attributes to extract and identify the critical dimensions. Third, the extracted critical dimension is further subjected to regression analysis to predict and understand the relationships between extracted factor dimensions and dependent variable (SPD success). In this study SPD is taken as dependent variable which is measured by both operational and quality performance.

**Data Analysis and Results**
This research is exploratory in nature. From quantitative perspective firstly a step wise multiple linear regression modelling is executed which shows all five models are statistically significant with positive and significant impact on SPD. The data being
captured were further subjected for corroboration to see whether it could be analyzed through factor analysis or not. Accordingly, we performed the following analysis: (i) Correlation Analysis: Correlations were high among the practices; (ii) stepwise regression model of critical attributes on SPD (iii) Bartlett’s Test of Sphericity: Found to be significant (p < 0.05), this shows the acceptability of data; (iv) Kaiser Meyer Olkin Test (KMO): KMO test has been found to be 0.752, which is well above cut-off range; (iv) cronbach alpha: overall is 0.791, F1 is 0.823 and F2 is 0.696. Therefore based on analysis it can be concluded it is appropriate to conduct factor analysis (Meyers, 2006; Pallant, 2007). Before conducting factor analysis we performed univariate and multivariate statistics of the variables and discovered no apparent outliers (Jun et al., 2006). To further confirm the existence of normality we conducted two tests i.e. Kolmogorov-Smirnov and Shapiro-Wilks tests, which shows p value to be greater than 0.05 and therefore revealed normal distribution.

**Note:** Dependent Variable is Smart Product Development (SPD); TI: Technology and Innovation; SI: System Integration; CE: Collaborative Engineering; LOS: Lean Operating System; SUST: Sustainability
Factor analysis is performed on five critical indicators as identified from review of literature and contextual understanding based on qualitative study. We conducted factor analysis on explanatory variables/indicators with objective to determine minimum number of factors that accounts for maximum variance in data. The factors were extracted using principal component analysis (PCA with varimax rotation). The objective of deploying PCA is to reduce the number of variables (Jolliffe, 2002). PCA is used to “extract maximum variance from the data set with each component thus reducing large number of variables into smaller number of components” (Tabachnick and Fidell, 2007), which facilitate easier interpretations. Table 3 exhibits rotated component matrix which shows all the five variables having factor loading of more than 0.5 and further could be reconfigured into two factor dimensions as being extracted. Factor dimensions extracted are labeled as “Technological” (F1) and “Strategic” (F2).

The overall reliability analysis shows Cronbach’s alpha to be 0.791 which validates the reliability of the study. Further reliability analyses show Cronbach’s alpha values for factor dimensions F1 and F2 to be 0.823 and 0.696 respectively, which validates the reliability of the factors being extracted. Regression analysis is performed on two extracted factors. The model explains the variance ranging between 46.8% to 53.5% i.e. the predictors explains the variance in the dependent variable well which is more than the standard 40%. Durbin- Watson index suggests that there is no problem of autocorrelation in data. F-value and VIF indicates that overall model has no multicollinearity problem.
Overall, analysis (Figure 1) indicates the importance of technological factors which can be regarded as critical dimension for SPD. It is expected that from industry 4.0 perspective, IoT could have capability to offer transformational solutions for solving the complex digital issues in complex digital environment. In our opinion smart India in future would add value to realisation of industry 4.0 by deploying cloud manufacturing / manufacturing-as –a- service (Maas) which is gaining importance in manufacturing industry. Cyber-physical systems resemble a significant technological enabler for smart product development.

**Findings and Discussions**

The stepwise regression analysis reveals that attributes like technology and innovation (TI), system integration (SI) and collaborative engineering (CE) have significant positive impact on SPD whereas attributes like lean systems (LS) and sustainability (SUS) have insignificant impact on SPD. The impact analysis of technological innovation indicates that Indian industries are moving towards digital manufacturing where product development process will be executed through organised application of scientific knowledge and is consistent with Hecker (2005). With intervention of advanced technologies it is also likely that developmental process is driven by innovations that add value to the products which facilitates market demand. Here, SI resembles critical significance of cyber physical systems (CPS) where organizations would be able to generate large chunks of production data for real time analysis and decision making. Perception of respondent’s towards SI also confirms the rapid move of manufacturing organizations to adopt IoT (internet of things) based approach where objects/ entities are virtually interconnected with lots of data being generated. CE approach also shows the significance of concurrent engineering management on the developmental process of SPD. As SPD from industry 4.0 perspectives is in its stage of infancy thus it would take some time to apply lean systems management and to develop a sustainable framework. Although TI, SI and CE models have been found to be statistically significant however impact of TI, SI found to be strong and CE to be moderate. This shows the lack of prominence in teamwork and human resource
practices. Exploratory factor analysis extracted two factor dimensions which are referred to as constructs namely “technological” and “strategic” factors respectively. Based on analysis performed, automatic linear modelling shows that both technological and strategic factors have significant impact on SPD which is interesting and thus exhibits paradox. The paradox itself gives an impression that strategic factor alone could not significantly impact SPD when acting alone but can significantly influence when combined effect of each technological attributes (TI, SI and CE) is deployed which shows complementarity effect with other resources. The results indicate that Indian industries with respect to Industry 4.0 anticipate better digital adoption with reduced operational costs and productivity improvement. The significant influence of strategic factor indicates the importance of triple bottom line (3BL) with lean initiatives as critical strategic components towards successful SPD initiatives. The perceptual measures from technological perspective expected to exhibit digital automation with integrated sensor systems as one of the most implemented technologies. The results obtained based on analysis gives an overall impression that increasing quality of industry 4.0 can be accomplished with proper integration of technologies and strategy. The integrated application of technological and strategic factor dimensions indicates that when products embed with advanced technology it increase intelligence and play strategic role. From lean initiatives the results indicate the possible dominance of design engineers to hide unwanted and irrelevant features and reduce environmental impact of product. Findings exhibit an overall impression that strategic/ intelligent product information is likely to be utilized as part of user-centered design process, where industrial designers can take advantage of smart product’s life cycle management. Overall the perception based findings show that advances in semantic and sensing technology can change approach of user interaction with products which eventually leads to product development success.

**Contribution of the Study**

In this study attempt has been made to analyze the perception of Indian organizations which are involved in product development in order to measure the impact of factor dimensions on SPD in terms of expected implementation benefits. Since the concept of smart product development from industry 4.0 in Indian context is in its stage of infancy and the scarcity of literature available in the said context clearly shows the prominence of the present study and its contribution. Results demonstrate the emergence of two constructs (technological and strategic) which are positively associated to expected benefits in terms of SPD success. The main contribution of this paper is identification of emerging constructs (herein referred to as factor dimensions) of SPD and how these factor dimensions are seen in emerging economy context like India, since most of the studies have been done from developed nations perspective. In this regard the present study showed how technological and strategic factor dimensions are associated with projected benefits of SPD. The designated approach using quantitative model for industries 4.0 gives industries the opportunity to learn regarding solutions from techno-strategic aspect which may be deemed to be a novel contribution from Indian context since Industry 4.0 is still in concept development phase.
Conclusions
In this paper the current industrial development on smart products from industry 4.0 in Indian context has been represented. The attributes and factor dimensions influencing SPD gives a preliminary overview regarding developmental process based approach for smart products. SPD from industry 4.0 perspective in Indian context being relatively new thus there is always a possibility of high degree of uncertainty and technological know-how for real time implementation. Hence, present study would be beneficial for its application based findings which could be taken up by the industries as partial guidelines to undertake implementation procedures from both technology and strategic perspectives.

Practical Implications
Results derived from this study can be beneficial to operations manager and industry policy makers to execute decisions at all levels from strategic, tactical and operational aspects. From operational perspective the results exhibit which attributes are critical for successful implementation of SPD. Considering the present industrial scenario the results would provide partial guidelines to the industries who wish to adopt the strategy of industry 4.0 and think which attributes should be considered. Accordingly based on competitive priorities industries can develop and design their implementation strategies. On other hand industrial policy makers can use the findings of this study to initiate policy level decisions as to what technology and strategic dimensions need to be considered during developmental phases of smart products in order to achieve competitive advantage. For example technological attributes like TI, SI and CE could be strong trending patterns followed by strategic attributes like lean systems and sustainability. Results and findings derived from this study can be beneficial to operations manager and decision makers to design their implementation strategies.

Limitations and Future Scope
In this study five critical attributes of SPD have been considered and there is a scope to explore more number of attributes from industry 4.0 perspective. From statistical perspective the study has some limitations since we considered perceptual measures based on respondent’s opinion from industry 4.0 context, thus there may be possibility of respondent’s bias. Secondly, there is a scope to increase number of respondents to generalise the findings. Future research can incorporate multiple variables and attributes along with control variables for advanced statistical learning. Furthermore, advanced prediction modelling could be initiated in future to investigate the role of contextual variables. Researchers can even think of bringing design management aspects into the entire process flow methodology to make smart products highly flexible and quality oriented.

Abstract

The diffusion of digital additive technologies has enhanced manufacturing flexibility but also opened questions on how such technologies could affect practices in the production space. Addressing these timely questions, we adopt a sociomateriality perspective and comparatively explore how different digital manufacturing machines—characterized by increasing degrees of manufacturing—affect the use of space and time. We qualitatively observe and compare 45 digital manufacturing machines sampled across 4 types and 14 companies in two countries (UK and Italy) within the motorsport industry. A model emerges where the imbrication between machine time and space mediates the relationship between machine flexibility and performance.

**Keywords:** Digital Manufacturing; Sociomateriality; Flexible manufacturing.

Introduction

The recent paradigmatic shifts towards digital manufacturing—represented by the disruptive diffusion of additive manufacturing machines (AM)—are dramatically changing business and innovation models, shrinking supply chains, and altering the global economy (d’Aveni, 2015; Holmström et al., 2017; Khorram Niaki and Nonino, 2017), thus representing a pivotal phenomenon within the so-called “Third Industrial Revolution” (Anderson, 2012; Rifkin, 2008).

Research in operations management has been thoroughly investigating the evolution and innovation of manufacturing technologies (Holmström and Romme, 2012; Jiang et al., 2017; Mellor et al., 2014; Reeves et al., 2011; Wagner and Walton, 2016). Extensive research on flexible manufacturing systems and advanced manufacturing technologies has shed light on several compelling effects, especially in terms of influence on organizational, operational, and economic performance, as well as their overall linkage.
to operations strategy (Cagliano and Spina, 2000; Swink and Nair, 2007). In this vein, the adoption of new digital technologies in manufacturing—which are able to provide additional degrees of manufacturing (Eyers et al., 2018)—is currently attracting increasing scholarly attention, thus creating a sort of “hype” regarding its potential advantages. However, both in the literature and in the practice, it is still unclear what are the rising complexities and potential pitfalls associated with the implementation of such technologies. For instance, new technologies are often wrongly considered as “plug-and-play”, while executives and managers tend to underplay the complexity of additional factors influencing their effective implementation—see among others Adidas’ efforts to scale-up its 3D-printed soles to mass production (Tepper, 2017).

Despite scholars are developing novel frameworks to understand and implement digital technologies in manufacturing (see for instance Mellor et al., 2014), when investigating the concept of manufacturing in the production floor, the operations management literature has mainly adopted an “Euclidean perspective”: a positivist approach where time and space are conceptualized as finite, tangible, and objectively measurable resources. This specific view has overlooked the more subjective and relational aspects of human agency, as well as the critical interaction between humans and machines/technologies, which are more often than not influencing business performance (Leonardi and Barley, 2008). The relation between human and material agencies within organizations and across organizational boundaries has recently been gaining increasing attention (Balogun et al., 2014; Carlile et al., 2013), especially in management and information systems literature (Boudreau and Robey, 2005; Cecez-Kecmanovic et al., 2014; Leonardi, 2012; Orlikowski, 2000, 2005). Recently, the interdependence between individuals and technologies—which shape each other’s development, affecting organizational social space, and actions over time (Leonardi, 2013; Pentland and Rueter, 1994)—has been overall defined as imbrication. From this perspective, technologies and human agents become mutually intertwined, embedded (Barad, 2003; Leonardi, 2012), thus mutually influencing and jointly enabling the development of organizational practices (Leonardi and Bailey, 2008). The constitutive imbrication of technologies on individuals’ actions gives the resulting practice a social character, which has been analyzed using the so-called “sociomaterial perspective”, or in short “sociomateriality” (Leonardi, 2012; Suchman, 2007). To date, and despite the pivotal importance of human and material agency in their conversation, operations management and innovation management scholars have seldom considered sociomateriality and its paramount implications. This would be particularly compelling when considering the evolution of manufacturing technologies and introduction of new digital technologies (such as AM) within the innovation process—see for example the consideration on the importance of adopting a “socio-cognitive sensemaking” in Nambisan et al. (2017: 228). The operations management literature has investigated the relationship linking technology adoption with manufacturing, in turn influencing firm performance; however, it has massively overlooked the role played by the “imbrication” between the agency of the machine and the human operators, which involves key dimensions such as space and time.

We believe the adoption of this new scholarly perspective would help understand why organizations that are currently implementing new, high-potential, flexible technologies are still facing challenges in effectively integrating these technologies and in turn failing to obtain superior business performance and a sustainable competitive advantage. In our study we purposefully aim to develop a first attempt at opening the “black box” of innovation relative to the relation between varying levels of manufacturing of (digital) manufacturing machines and the “subjective” dimensions of human agency related to
time and space in the production floor. Hence, we address the following question: “How do flexible (digital) manufacturing machines influence organizational manufacturing practices in terms of space and time?”. We respond by extensively collecting and analyzing qualitative data from the British and Italian motorsport industry, an innovation-driven empirical setting where firms have extensively adopted a broad range of (digital) manufacturing technologies—including AM.

With this study, and in line with the sociomateriality perspective, we extend the boundary conditions of the sociomaterial perspective from IT technologies to flexible machineries and investigate how those also affect the space and time within organizations, and ultimately performance. In addition, we show how different degrees of technological flexibility enable their adaptation in different spatial contexts and through time, shaping the development and evolution of different organizational practices. Ultimately, we advance an overarching model connecting technological adoption of digital machines to manufacturing, imbrication, and firm performance. In this model, great exposure and reflection is given to digital transformation as enabler of flexibility and moderator of the relationship between flexibility and imbrication.

**Theoretical background**

*Manufacturing flexibility and the dimensions of space and time*

Manufacturing flexibility has been considered as one of the major competitive levers for manufacturing firms operating in increasingly uncertain environments and turbulent markets (Gerwin, 1993; Sethi and Sethi, 1990; Slack, 1983; Upton, 1994). Such flexibility allows to rapidly change production outputs, to develop new products more quickly and more frequently, as well as to respond more rapidly to competitive threats (De Toni and Tonchia, 1998; Oke, 2005). In their literature review Jain et al. (2013) underline its complex and multi-dimensional nature: on the one hand, manufacturing flexibility represents a general ability to adapt/change, while on the other hand, the proactive adoption of flexible solutions can support the organization in gaining competitive edge, by raising customer expectations and putting competitors under pressure. Therefore, the role of flexibility of production systems has heavily attracted operations and innovation scholars’ attention throughout the last 30 years (Browne et al., 1984; Buzacott and Yao, 1986; Cagliano and Spina, 2000; MacDuffie, 1995; Myint and Tabucanon, 1994; Slack, 1987).

To date, research on the evolution of manufacturing technologies has mainly focused on flexible manufacturing systems and advanced manufacturing technologies (Kotha and Swamidass, 2000; Swink and Nair, 2007). Such literature has traditionally identified and analyzed compelling implications for supply chains (Slack, 1983), operation strategy (Gerwin, 1993; Upton, 1994)—such as opportunities for mass customization (Da Silveira et al., 2001)—and wider influence on performance at different levels (Gupta and Somers, 1996; Swamidass and Newell, 1987)—i.e., from operational to organizational. One key insight emerging from the literature is that it is impossible to obtain disruptive results from the stand-alone adoption of flexible technologies, without the support of design-manufacturing integration (Swink and Nair, 2007), and the appropriate combination of “soft” elements and strategic orientation (Cagliano and Spina, 2000; Nambisan et al., 2017). This is paired with the relatively scant understanding on the relationship between manufacturing flexibility and another key competitive criterion: innovation (Bolwijn and Kumpe, 1990; Oke, 2013). In fact, due to its possible limitations and pitfalls on organizational performances, it has been argued that companies pursuing manufacturing flexibility should develop the specific innovation capabilities that enable them to enjoy a significant improvement in organizational performance (Camisón and Villar López,
2010). Yet, it is still not clear yet what are the microfoundations (i.e., interactions, routines, co-creation opportunities) which favor the emergence of such key capabilities.

Furthermore, and perhaps more importantly, when considering a specific manufacturing configuration (e.g., the adoption of a series of new production machines), the literature has underlined the importance to understand the right context of application and its related flexibility features. The classic “product-process” matrix developed by Hayes and Wheelwright (1979, 1984) provides useful guidelines to position different technologies along several degrees of flexibility, ranging from production lines (characterized by a standardized structure with high volume, low variety, and high rigidity), cellular-based manufacturing (where flexible systems play a key role), to job shops and individual projects (featuring higher adaptability and opportunities for customization, but limited efficiency). Recent reviews on manufacturing flexibility (Jain et al., 2013; Mishra et al., 2014), underline a common orientation in the field towards a positivist, number-driven, engineering-oriented approach (i.e., often supported with granular quantitative analyses and measurement) to identify critical holdups and suggest changes for sizeable process optimizations. Taking this approach, scholars investigating manufacturing have mainly focused on “space” and “time” dimensions by adopting a Euclidean perspective (i.e., where time and space are conceptualized as finite, tangible, measurable, objective resources), and have treated them as mere operational factors that characterize a manufacturing/service process and its performance implications.

![Sociomateriality Perspective](image)

**Figure 1 – Conceptual model emerging from the literature review**

However, we argue that the traditional quantitative approach has so far foregone the opportunity to develop a more complete understanding of how manufacturing tools and machines can influence the use and cognitive understanding that agents hold of time in a more subjective, intangible, and nuanced fashion. In fact, “softer” dimensions are hardly considered in the main frameworks available in the literature (Jain et al., 2013; Mishra et al., 2014).

This has affected our understanding in two inter-linked ways. First, instead of passive tools and assets, manufacturing technologies (particularly the digital ones) can play an “active” role and influence space, time, and human interactions (Nambisan et al., 2017). Second, routines—intended as repetitive patterns of interdependent organizational
processes or actions that utilize resources to achieve outcomes (Pagell et al., 2015; Parmigiani and Howard-Grenville, 2011)—have been merely considered in terms of performance implications, rather than a substantiation of human-machine interaction, due to the lack in the operations management literature, of a behavioral and socio-cognitive understanding of individual actions. In the case of manufacturing flexibility, scholars have long searched a deeper understanding of how machines influence the creation of new routines in the shop floor, not only considering in their flexibility as an operational feature, but also as a socio-cognitive quality connected to the human-machine interaction (Feldman and Pentland, 2003; Howard-Grenville, 2005; Patel, 2011). Responding to a recent call by Pagell et al. (2015) to follow researchers in other fields and begin to explore routines from a more “micro” (Felin et al., 2012; Teece, 2007) and behavioral (Gavetti, 2005; Gino and Pisano, 2008) perspective, the sociomateriality perspective has recently opened new avenues for investigating this influence and offers a lens to observe and comprehend the interactions between human agents, and machines.

**Methodology**

To answer this question, we collect and analyze qualitative data from the motorsport industry, a cutting-edge empirical setting where firms have traditionally experimented with a broad range of manufacturing technologies, and have an advanced experience, compared to other industries, in innovative machines such as AM. Our study adopts a qualitative methodology (Gioia et al., 2013) that is well suited for our study’s exploratory scope and fully consistent with the sociomateriality perspective. We qualitatively analyze and compare 45 digital manufacturing machines sampled across 4 types and 14 companies in the iconic motorsport industry in two countries (UK and Italy), by conducting semi-structured interviews with relevant actors in each company. Reliability of data has been assured through triangulation and use of additional archival materials.

**Findings**

**Space-machine imbrication**

Despite traditional manufacturing and innovation literature often considers machines as passive set of tools or—more in general—assets that human agents leverage and manipulate for their goal, the collected evidence suggests instead that all manufacturing machines play an active role in shaping the operational space where innovation and manufacturing takes place. Our first order-constructs point to a reshaping of the interactive space around the machine. For the observed projects, we noticed that when a new machine entered the production space, the adoption was associated with the (re)design of a specific layout of operational space where human agents were involved to optimize routines and collective procedures. This interactive space represented not only an intangible discourse between human agents, but often translated—particularly for more flexible machines such as AM—into an opportunity for setting up dedicated areas, such as R&D labs, customer trial rooms, and other spaces for idea generations via multiple actors’ interacting with the machine). The use of space revolved around the work of the technological equipment that—when possible; the experimentation with the machine was aimed at gathering new knowledge via processes of search, trials-and-errors. In such instances, it was common to even see either some of the design activities to be moved to the production floor where the experimenting machines were located or—when size of the machine allowed—the positioning of a flexible, digital machine to be placed in the offices dedicated to design.
Evidence showed that custom-made product-specific machines were clearly less associated with these types of initiatives. Interviewees suggested that this was due to the manufacturing rigidity of such machines (e.g., lines for specific products).

Instead, flexible machines tended to play a more dynamic role in shaping the virtual and physical space around them, thus creating opportunities for interaction, knowledge exchange, and experimentation. This was systematically associated to the co-presence of partners and customers within the interaction space, thus making the production plant where the machine operated a connection point between the production facilities of multiple stakeholders involved in the co-development project. As CNC machines and AM offered a broad and not fully understood range of possibilities, companies that used such technologies enjoyed the opportunity to upgrade the understanding of their functioning, and thus enlarged their types of manufacturing applications. Among other less notable aspects, the space was specifically designed (or modified) to facilitate the access and exit of customers and partners, in order to maintain a good level of discretion about their involvement, particularly towards other customers and partners which could be competitors. By showing careful attention to such space design, the focal company aimed at obtaining a high level of trust from each partner.

Evidence suggests that machine adoption also corresponds to a shift in the innovation practices performed around the machine space. In advancing this observation it is necessary to include two additional reflections. First, the increasing level of flexibility (usually associated with more digitized machines) corresponded to more significant changes in such practices—this, however, might be related to the fact that newer tools embedded possibilities and features that by definition disrupted those formerly established by the adoption older machines. Second, and perhaps more importantly, the emergence of new practices was associated with a different perception of space, where the spatial areas bent to incoming needs of flexibility to embrace more fluid and unstructured experimentation activities. Our observations started with affirming that a space of active experimentation called for the needs of partners being present in the same area to conduct their co-development activities. Simultaneous presence transformed the space in co-working spaces, with desks and/or working tables that were used for meetings and experimentation between workers and with business partners. In such areas it was often possible to retrieve artefacts of such practices and interactions: sketches, blueprints, guideline documents, and instructions. Such material artefacts had both a functional utility insofar they indicated ways of utilizing the machine to more unaware users. Yet, they also demonstrated, with their visible and tangible presence, the amount of reasoning and thinking that had been going into the engagement with the machine. Another key element that was common to find in the proximity of the machine was advanced manufacturing samples. These were usually purposefully left to impress possible visitors or (perhaps narcissistically) showcase the potential of the machine. Such elements, however, had also a more profound function. As increasing level of manufacturing allowed potentially an infinite number of applications and operations, such artefacts were used to demonstrate through material evidence the firm’s creative capability and its skills in exploiting and exploring the machine potential.

AM machines were in most cases placed at the center of the room, or in a highly visible position where it is impossible not to notice them once inside the space—they represented a sort of “totem” within the manufacturing space, an object which was regarded with a sort of admiration, respect, and curiosity (probably due to their untapped potential). Such machines could be observed from all sides, by simply walking around them. Visiting the machine with new partners often followed patterned rituals, where the problem-solving value of the machine was described by using a specific narrative of time.
Time-machine imbrication
Beside space, time-machine imbrication emerged as another prominent element from our observation. Within this domain, time was conceived not only—in a more objective and positivist form—as a measurable and systematic repartition of human activities, but also as a subjective, cognitive construct which resided in the human agents’ mind, took different forms, lead to different understandings, and consequently affected the practices on the shop floor in different ways.

We identified a set of ways in which time (e.g., sequencing, length) was reshaped within practices involving the machine. To gather a more precise understanding of the machine usage, we asked our informants a series of question aimed at understanding (1) how many hours of work actors dedicated to the design and first set-up of the new machine; and (2) how many hours they spent to understand its functioning and exploring its possibilities before considering the machine as fully integrated in the manufacturing processes.

This distinction was critical to identify whether the imbrication was concentrated in the planning or in the execution of the manufacturing process, or both. In addition, as imbrication with these machines might involve human agents from different organizations, inquiring into such aspects also provided insights about the temporal evolution of the relations between the human agents and the machine. Specifically, we asked our interviewees to quantify the hours spent in interaction with other members of the organization, or other partners such as the equipment suppliers or the customers. We collected values for each machine and averaged them across machine types. Then we asked executives and operators to provide narratives of such phases. Our data collection highlighted that the intensity of human interaction with the machine was strongly influenced by the machine’s degree of manufacturing. Throughout all our observations interviewees consistently affirmed that for machine that were intrinsically more flexible, human intervention was higher in the phases that did not strictly follow defined procedures or routines.

As custom-made, product-specific machines and machines for standard ‘off-the-shelf’ products did not offer any major opportunity for significant variation within the manufacturing process—unless the machine underwent a structural re-engineering—they required instead an intense human intervention while designing the machine itself, as the equipment came with a high level of customization.

Instead, evidence pointed to a quite different scenario for the application of more flexible machines (i.e., milling machines and 3D printers), as this latter equipment came in rather standard models, but provided higher space for flexible applications. Hence, while the design phase was relatively standardized, and left little space to customization, once the machine was set up the possibilities of experimentation benefitted from an experienced and continuous interaction with the machine.

All in all, we notice how the different levels of machinery flexibility corresponded to different timings in the interaction process with the equipment. While customized, task-specific machines (i.e., machines for standard, “off-the-shelf” products and custom-made, product-specific machines) led to more intense interaction in the machine design and set-up phase, standard flexible machines (i.e., CNC milling machines and AM machines) required a more intense interaction later-on in the testing and operational phase. Practices enabled by highly flexible machines were often described as more “fragile” and prone to hold-ups. Hence, and despite such devices allowed a certain level of automation, human agents felt compelled in monitoring more often their activity.

The overall refocusing on the experimentation phase created a relevant shift in the timing of the innovation development, as the machine constraints and utilization paced
the project timing and deadlines. However, as such machines were used as collaborative devices in multi-partner experimentation, the alignment of the partners was also constrained by the timing of the machine. In other words, the firm that deployed the machine ended up indirectly influencing the timing of the third parties involved.

Ultimately, the time-machine imbrication carried significant implications on a more subjective and cognitive level. The adoption of more flexible and technologically sophisticated machine corresponded to the adoption of new narratives of time within the organization. Concepts like “speed,” “responsiveness,” “reaction time,” became part of the core value proposition that the companies’ embraced, particularly when proposing their services or potential collaborations to third parties. This is overall not surprising, as technological adoptions are often justified with aspirational upgrades in efficiency and effectiveness, particularly in innovation-focused domains. However, in our cases such types of narratives held substantial implications in the way time was envisioned and activities were scheduled. Despite (as we reported) more flexible machines entailed the systematic extension of the experimentation phase (due to extensive set-up time, integration or multiple actors, and exploration of diverse operational possibilities), this narrative of time and “speed” was associated with an average reduction of estimated experimentation time in a range between -10% and -20%. This means, for example, that a new design project that formerly was expected to last around 10 weeks with prior machines and technology before was now expected to take between 8 and 9 weeks. Still, such estimates often fell short to deliver on the original planning. This was not necessarily a negative thing in terms of quality of the output, as products developed with superior manufacturing flexibility did embed an added value in terms of innovation and performance, but timing remained an unfulfilled promise in the relation with third parties. Yet, the partners’ direct involvement in the collaborative project allowed them to better appreciate the nuances of the process and the superior returns that an extended experimentation entailed, and thus reasonable delays were seldom considered an issue, and they hardly terminated the partnership in future instances.

Furthermore, and perhaps more interestingly, particularly with AM machines the design and engineering of a component became a key element of each project. More recently, with the advent of hard-materials in AM (e.g., through metal, graphene powders) the companies were able to manufacture more and more “functional prototypes.” These are components which, despite their prototypical nature can be deployed (within certain limits) in finished products such as race cars, rather than just being used for mock-ups and wind-tunnel models. The diffusion of functional prototypes blurred the boundaries between experimentation and production phases, and actors involved in the process struggled to more objectively divide the two. This reconceptualization of time and project sequencing made former project development and current ones less comparable, thus contributing to interpreting the adoption of new machines as a paradigmatic shift in the manufacturing operations.

Discussion of findings
Moving from the original empirical model, we advanced in our theory section, Figure 2 provides an elaboration of how our empirical investigation unpacks the role of imbrication in the relation between manufacturing and firm performance (in our case considered as product and process performance, given the nature of our inquiry). While the literature gives extensive explanation of the relation between manufacturing and performance (Grawe et al., 2011; Youndt et al., 1996), as well as sociomateriality and performance (see Orlikowski and Scott, 2008b for a review), little is known on the
imbrication between digital manufacturing machines (i.e. flexible machines) and social practices.

Figure 2 – Final model based on empirical evidence

In our model the concept of imbrication, which is traditionally ascribed to sociomateriality (Leonardi, 2012), acts as a mediation between manufacturing flexibility and firm performance, thus leading to a mediation model. The level of manufacturing flexibility increases the level of imbrication across multiple dimensions, such as space and time. In terms of space, we showed how more flexible machines trigger a reshaping of the interactive space around said machines, as for example, the undertaking of a more radical change in the layout of a shop-floor, the inclusion of experimentation spaces, or the creation of show-rooms dedicated to the creation and display of related artefacts (notes, instructions, advanced samples). At the same time, more flexible machines re-shape innovation practices in the machine space by calling for a co-present involvement of multiple actors, and a new set of interactions and routines in relation to the machine itself. Increasingly, manufacturing flexibility has also an effect on innovate practices over time. Not only the time of the practices involving the machine undergo a significant reshaping (e.g., superior experimentation and monitoring; all partners align to the time constraints of the machine), but also there are significant cognitive implications. Specifically, a new narrative of “speed” and “responsiveness” is embraced by all the actors that utilize more flexible, and ultimately more efficient and better performing, machines. although the systematic underestimation of the temporal variable by previous studies, the positive effects of the adoption of flexible machines and the development of dynamic social practices can be seen in the increasing average quality of the product/process, thanks to iterative activities with third parties, but it can also be undermined by the necessary increasing experimentation phase in the producing process.

This brings systematic underestimation of the development time, but at the same time by involving the third parties in extensive experimentation phases, the average quality of the product/process increases insofar partners see possible delays as necessary costs to achieve superior outcomes. Ultimately, this strengthens (rather than foregoes) partnerships. Further, functional prototypes make it harder to distinguish experimentation from production (thus requiring a new way to reconsider project time and compare them
to older ones). Still, the possibility to apply components born in prototyping processes to final products reduces the complexity of the production process by eliminating the intermedia production phase that create final parts from prototyped ones, thus ultimately enhancing product and process performances altogether.

The digital component plays, by any mean, a key role in our model. As a first premise, it is important to acknowledge that the great majority of modern manufacturing machines (no matter how operationally flexible) embed a digital component, such as data transmission systems for digital commands through project specs. Arguably, the digital technology can be, thus, considered endogenous to (and embedded in) the technological adoption, and one of the very enablers of manufacturing (see dotted arrow in Figure 2). This said, it is also important to notice that the level of digitization can also present significant variations across firms, and it might depend on the firms’ engagement with the digital technologies—e.g., the level of digitization of each machine (different machines can have a more or less prominent digital component) and, perhaps more importantly, the level of digital transformation that each firm has embraced in its productive process and complementary/supporting technologies. In these regards the digital component play a pivotal role to positively moderate (and thus enhance) the relation between manufacturing and imbrication.

Digital solutions are based on strings of data which are—by definition—mode loosely coupled and modular than physical artefacts (Baldwin and Clark, 2000; Ulrich, 1994). Digital interface can be more easily aligned common standards and it is therefore easier and more efficient to recombine the layout of a manufacturing space, if the different machines can be easily connected to common data protocols. Digital solutions allow superior level of process flexibility, thus becoming an enabler of time reshaping across projects. In addition, Digital solutions, despite powerful and influential, are naturally intangible and immaterial. This intangible nature makes them more apt to be imbricated—and it is not by chance that such phenomenon was first of all observed in the domain of information systems, where the digital (often online) component is largely predominant (Leonardi and Barley, 2008).

Finally, digital component of manufacturing machines is an enabler of manufacturing and at the same time a moderator of the relation between such flexibility and opportunities for imbrication. Jointly, despite the role of manufacturing flexibility as a key aspect to enhance firm performance in terms of product and process innovation is beyond the scope of our study, we believe that scholars and practitioners should also consider the mediation effect of imbrication across time and space in the domain of innovation and manufacturing in affecting said relation.

Conclusions
Our study attempts to adopt sociomaterality in operations management and innovation management studies. This endeavour complements the traditional Euclidean aspects of manufacturing (offered by different types of manufacturing technologies) with the novel sociomaterial dimensions of imbrication of space and time—two facets of process and product innovations which carry relevant implications for firm performance. In addition, our research contributes to the broader conversation on sociomaterality by providing insights on dynamics happening in the (more) physical context of manufacturing, where current technological disruption is underpinning non-trivial dynamics between digital and manufacturing innovations.

Abstract
The main objective of this article is to evaluate the motivational factors that induce and those that block the adoption, use and appropriation of digitalization in Brazilian apparel SMEs. It is considered of interest to focus the study on the technologies of the so-called "Industry 4.0". The methodological approach is based on a multiple case study. In this sense, 5 Brazilian apparel SMEs were selected and a semi-structured questionnaire was applied. In general, it can be said these are still in the early stages of the digital transformation process.

Key words: Digital transformations, Brazilian apparel SMEs.

Introduction
The technologies that were previously considered novels, such as computers, internet, mobile devices, and even social networks, now they could be considered mature technologies, that is to say, they have already established themselves and become essential in the vast majority of the companies. It is considered of interest to focus the study on the technologies of the so-called "Industry 4.0", such as artificial intelligence, cloud computing, big data analytics, production internet, among others. A characteristic of these new technologies is that they have found a place in the entire value chain of the enterprise and, by generating disruptions, open the way to the incorporation of new products, services and business models.

Based on extensive interviews and analysis Berman & Marshall (2014) try to explain how the next digital transformation will result in a paradigm shift from one that is customer-centricity to an everyone-to-everyone (E2E) economy. For these authors “E2E is characterized by hyper-connectedness and collaboration of consumers and organizations across the gamut of value chain activities: co-design, co-creation, co-production, co-marketing, co-distribution and co-funding”. They conclude that the next
future, all organizations that will survive in their marketplace will operate in ecosystems
of converging products, services and industries.

The main objective of this article is to evaluate the main motivational factors that induce
and those that block the adoption, use and appropriation of digitalization in SMEs.

Some of these new technologies are presented next: Computer-aided manufacturing
projects CAD/CAM; Integrated engineering systems for product development and
product manufacturing; Digital automation without sensors; Digital automation with
process control sensors; Digital automation with sensors for product and operating
conditions identification, flexible lines; Remote monitoring and control of production
through systems such as MES and SCADA; Simulations/analysis of virtual models
(Finite Element, Computational Fluid Dynamic, etc.) for design and commissioning;
Collection, processing and analysis of large quantities of data (big data); Incorporation
of digital services into products (“Internet of Things” or Product Service Systems);
Additive manufacturing, rapid prototyping or 3D printing; Use of cloud services
associated with the product.

Among the obstacles that companies face when adopting or using new technologies, it
is possible to verify the internal obstacles, such as lack of knowledge or interest, lack of
financing and lack of qualified human resources; within the external obstacles, it is
noticeable the lack of infrastructure or of suppliers of technological products and
services, little mature technology, and an insufficient training system. Also, when
measuring the levels of adoption, the use and appropriation of the benefits of new
technologies, technological convergence (such as digitization of most areas of a
company) add a degree of complexity to this analysis.

The adoption of these emerging technologies in Latin America, and particularly in
SMEs, is low. Given this scenario, a study is proposed about the process and the
motivations of those that have adopted these new mechanics.

To this end, a survey will be carried out for a total of 20/30 Argentine companies. This
survey will be semi-structured interviews with open and closed questions, and the
companies will have to focus on a set of new technologies that will be previous decided.
The definition of the sample will be non-probabilistic, because SMEs will be selected
from which they will know a priori that they have already incorporated, are in process,
or are in a position to incorporate some of the new digital technologies. It is estimated
that companies in the manufacturing sector are the most likely to meet the required
conditions. Likewise, knowing that all new digital technologies have the potential to
affect all the links of the company's value chain, it is proposed to focus on the following
areas: innovation and product design, production, logistics of entry and relationship
with suppliers, marketing and relationship with customers.

The present project will be carried out simultaneously among different Latin American
countries, in order to later elaborate a comparative study among them. The final
objective of the work is the generation of policy proposals for the incorporation of
digital technologies in SMEs.
Small and medium-sized companies in the Brazilian textile / clothing (T&C) chain

Small and medium-sized enterprises represent 99% of establishments in Brazil (6.4 million), which account for 52% of formal jobs (SEBRAE, 2017).

The textile industry can be divided into three main segments: production of chemical fibers, production of basic textiles (yarns, fabrics and knitwear) and production of ready-made articles (clothing, home and technical-industrial articles), it is included in the industrial stages of the sector the production of natural fibers, which are of agricultural or agricultural origin (IEMI, 2017).

The textile and clothing industry is particularly important in Brazil because of its breadth, relevance of the value of production and its ability to generate jobs. There are 33 thousand companies that together totaled R$ 120 billion in 2016, equivalent to approximately 5% of the manufacturing industry and they also generated 1.62 million jobs, corresponding to 10.6% of the total industrial and the generation of US$ 473 million in wages. That is to say, it is a sector with a strong social impact (IEMI, 2017).

In addition to that, concerning the textile and clothing industry, they are the 2nd largest employer in the manufacturing industry; 2nd largest generator of the first job; 4th largest manufacturing park in the world; 5th largest textile producer in the world; 2nd largest producer and third largest consumer of denim in the world; the fashion week, which is considered one of the five largest in the world, is proving how decisive the sector is for the Brazilian economy and is increasingly strengthening the competitiveness of this industry (IEMI, 2017).

The T&C chain in Brazil is pulverized; as the number of employees is measured, the number of personnel employed, the production volumes and revenues obtained, are increasing. However, by examining the average per company, as the final link is taken, the indicators of generated jobs, volumes produced and revenues obtained per company fall, which, according to the IEMI (2017), shows the reduction in the average producing companies with respect to yarn and fabric producers.

It is possible to visualize the structure of the textile and clothing chain in Brazil. In addition, some companies can present a vertical structure, having more than one link in the chain, such as weavings that have finishing functions (dyeing, stamping or laundry) and confections that also have wholesale and retail stores.

Textile and / or apparel companies are present in all Brazilian states. In the Southeast region there are 49% of the personnel employed, followed by the South region with 29%, the Northeast region with 17%; Central West region 4% and the North region with only 1% (IEMI, 2017). Based on the analysis of occupations available in the RAIS (Annual Social Information Report) of the Ministry of Labor and Employment, it is indicated that between 1997 and 2005 there was an increase of approximately 12% in the total number of employees in the sector. Although there is an increase in the number of male employees, the workforce in the sector is female, of which 75% are financially responsible for the whole family (IEMI, 2017).
Methodology

The methodological approach is based on a multiple case study. According to Yin (1998), the main characteristic of this case study method lies in the fact of its being generalized to theoretical propositions, and not to populations and universes. The generalization to theoretical proposition is exactly the subject intended by this work, which makes of the case study the ideal instrument to attain the goal. In this sense, 5 (six) Brazilian apparel SMEs were selected, due to their outstanding importance in this industrial segment. A semi-structured questionnaire was elaborated and applied to the main executives of the industrial area of the companies.

Main questions

The main questions that are guiding this research are the following:

- What are the different projects, investments or contracted services related to new digital technologies?
- Is it possible to identify the most common technologies to the company that would fit the concept of new digital technologies and the main functions of the value chain of the company that are of interest for the impact of the new digital technologies?
- Has the company implemented any project or hired any service among the following new digital technologies?
- What are the main motivations to implement the project / investment or hire the technology service?
- What are the relevant elements on how the decision was made to invest or contract services in new digital technologies?
- How was the implementation process? What were the main problems or obstacles that should have been overcome?
- How were the projects funded? Did they use external funding sources? (Assess availability and ease of access to external sources of funding).
- What were the main benefits so far? Is your company evaluating or planning to implement any project or contract any service on any of the new digital technologies in the near future?
- How much has your company spent with resources to implement the new project or make use of the services that are contracted? What are the problems or obstacles you face?
- Is the company receiving or expecting to receive any kind of public or private support for the evaluation, design or implementation of the project / investment?

Our main hypotheses that support this research are the following:

- In general, SMEs are in the stage of adoption of some technologies regarding the third industrial revolution (computing, automation, consumer Internet, etc.);
- A low adoption or preparation for the deployment of the new technologies of Industry 4.0;
On the other hand, we can point out some implications of these hypotheses:

- Finish measuring what you already know
- Measure only opinions about industry 4.0;
- Increase complexity if it is necessary to evaluate the automation and use of digital (traditional) technologies across all areas of the company.

Barriers / Obstacles to the adoption and use of new technology:

Internal to the company:
- Lack of knowledge;
- Lack of interest;
- Lack of funding;
- Lack of qualified HR;

External to the company:
- Lack of infrastructure;
- Little mature technology;
- Small number of Technological products and services suppliers;
- Insufficient training system;

Case study

Company A

Company A is a medium-sized company (with 178 employees and annual revenues of US $2 millions, producing lingerie items (bras and panties).

From the point of view of new digital technologies, the company stands out because it has already made significant investments in the purchase of sensors and applications to monitor the notes in real time, directly from the smartphone, aiming at greater production efficiency, production predictability and operations history in the factory floor. Such investments include consulting services (Senai Cetiqt) software and hardware. Also in the sphere of product design the company hired a supplier specialized in 3D tool that streamlines the process of creation and design.

The main motivations that led company A to invest in these new technologies are basically summarized as follows: 1.) Search for improvements in the efficiency of a function or process; 2. Cost savings; 3. Facilitating the development of new products.

Regarding the main barriers, the company stands out: 1.) Difficulties of the operators in the use of these new technologies. For example, many seamstresses had the treadmill, even without sewing equipment (need for training in these technologies and breakdowns with "cultural barriers" in the company); 2. Problems in communication infrastructure (WIFI).
Company B

Company B can be considered a small company (52 employees and revenues, under US $ 2 millions / year) that operates in the segment of knitting and printing.

In terms of new digital technologies the company has already invested in an application to program and select prints of the fabrics and devices to implement the digital stamping operation. In addition, he had already invested in digital marketing (e-commerce). As to the reasons for such investments, the company stated that the main reason was the pursuit of higher productivity (higher costs and better production processes) in its factory operations. In addition, the companies also sought to improve the relationship and minimize customer response time ("being able to serve customers 24 hours a day").

The main problems faced are the difficulty of adjusting the calibration of the robot in the factory operation to obtain better results in comparison to the manual activities.

In terms of new investments in the near future Company B is evaluating the possibility of investing in "virtual and augmented reality".

Company C

Company C is medium-sized (122 employees and revenues of about US $ 3,800 thousand / year) and produces lingerie articles (panties and bras). Regarding the incorporation of digital technology, the company invested basically in the following freights: 1.) Digital marketing with actions of e-commerce; 2.) Integrated management software and ("ERP Sistextil") electronic data exchange (EDI); 3.) Software for automation in the cutting operation.

The main digital transformation projects currently being conducted by the company are as follows:
1.) Cloud Computing ("Sistextil" application); 2.) Printing 3D. (this is in negotiation with software supplier yet).

Regarding the main factors that motivated the company to adopt such innovations, the following stand out: 1.) Speed in customer service; 2.) Scale gains in production; 3.) Monitoring market trends for (increased use of the Internet and social media). According to its leaders "the company must be prepared for these changes ...".

On the other hand, the following difficulties were identified for the adoption of other innovations of digital transformation: 1.) Infrastructure of information and communication weak or insufficient. 2.) Suppliers of technological products or services missing.

Company D

Company D is a company that produces articles of feminine, masculine fashion and accessories for clothes. It is a medium-sized company with gross annual sales of US $ 10 millions, employing 76 people. As for the recent investments in innovations, we highlight the implementation of a Customer Relationship Management (CRM) system.
Regarding the motivations that led the company to invest in the new technologies stand out the search for greater agility in its operations and reduction of expenses in the allocation of the logistics warehouse. In this sense, the company achieved a significant efficiency gain reflected in the reduction of the warehouse's operating cycle from 8 to 5 days.

On the other hand talking about the difficulties or main obstacles to the implementation of these new technologies, the company highlights the lack of greater knowledge of the technology itself, besides the lack of qualified human resources for its implementation.

**Company E**

Company E is a large company with 500 employees and gross sales in the order of US $ 53 millions / Year. It operates in the textile segment - Knitwear (Dyeing and Dyeing) and its main product are fabric rolls.

The company's main investment in the digital transformation process is a Company Loom Monitoring System. The main motivation for this investment was to monitor the efficiency of the Company's production machinery (looms). In addition, the company also stated that other factors were important in deciding this investment: 1.) Improve the efficiency of a productive function or process and 2.) Improve the relationship with the customer.

On the other hand, regarding the factors that made the implementation of technology difficult, it is important to mention the weak and insufficient information and communication infrastructure.

**Some Conclusive Remarks**

The digital transformation in emerging economies as the Brazilian one is not so easy, nor is it a rapid process. Specially talking about Brazilian apparel SMEs this phenomenon must be considered in a medium/long term perspective.

The requirements to develop a digital transformation in this case depend on how well the barriers regarding enterprise culture, legal policies, technological infrastructure and information technologies are jointly tackled among government, scholars and companies.

In fact SMEs can leverage their business significantly if they invest in the new technologies required by the digital transformation process. The gains relate both to increasing operational efficiency and to expanding its markets.

It is known that traditionally larger firms are at a higher level of competitiveness both on the domestic and international market. The clear differences in terms of the evaluation of competitiveness in favor of larger firms appears through the emphasis on determining factors such as production technology, the quality of the management staff, financial possibilities, effective marketing, research and development. Such discrepancies between large firms and SMEs suggest that there a great gap in
competitiveness as between the SME sector and large companies. One potential way of overcoming the lack of competitiveness of small and medium-sized enterprises is to create the conditions for SMEs to invest properly in new digital technologies.

In general, it can be said that SMEs in the textile / clothing sector in Brazil are still in the early stages of the digital transformation process. The innovations carried out by most of the SMEs analyzed in this study concentrate their investments in the relationship with the customer and in digital marketing. Some exceptions occur in companies that also invest in product design and design using the capabilities of new digital technologies.

Abstract

When introducing production control solutions, most textbooks focus on a to-stock, repetitive context. In response, we extend the classical match and dice game, which focusses on a repetitive context, in order to teach complexities that emerge in a non-repetitive context, such as the emergence of direct and indirect load, and to introduce appropriate production control solutions (e.g. ConWIP and COBACABANA). A field test is used to prove the playability of our game and assess its teaching effectiveness using post-game scores and self-assessment. Both give support to our game and highlight that it helps specifically average students to understand complex knowledge.

Keywords: Match and Dice Game, Customization, Kanban

Introduction

The complexity of Operations Management (OM) does not rest upon individual operational issues themselves, rather it is a result of their interrelationship; and this interconnectedness of phenomena must be manifest in the material that is taught to students of the discipline (Hill, 1987). For example, the success of production control methods is contingent on the environment to which they are applied (Jonsson & Mattsson, 2003; Sousa & Voss, 2008; Tenhiäälä, 2011). Consequently, production control techniques, such as Kanban, should not be abstractly taught in themselves but grounded within the context from which they derive, since this determines their applicability (Hill, 1987; Thürer et al., 2016). A major contingency factor used in the production control literature is the position of the so-called Customer Order Decoupling Point (CODP; Hoekstra & Romme, 1992),
also referred to as the inventory/order separation point (Hopp & Spearman, 2001) or the order penetration point (Olhager, 2003). The CODP marks the border between to-stock and to-order production. It also marks the degree of customization that can be realized (Amaro et al., 1999; Stevenson et al., 2005) since highly customized orders are typically not repeated and thus cannot be kept in stock. Most textbooks teach some content on the CODP and the different production modes it creates. However, when production control solutions are introduced most textbooks remain in a to-stock, repetitive context. Yet production control techniques for this context, such as the use of Kanban containers for inventory control, cannot be directly applied to shops that produce a high variety of products, such as small and medium-sized make-to-order companies (e.g. Hines et al., 2004, Thürer et al., 2012, 2014a). While contingency factors are introduced, how to solve these contingencies is neglected.

For over 20 years, it has been accepted in the academic literature that if a Kanban system produces orders that are not interchangeable, then a card acquisition process takes place (Chang & Yih, 1994a,1994b; Bonvik et al. 1997) that makes it necessary to allow for more cards at downstream stations compared to upstream stations (Gstettner & Kuhn, 1996). But is this really taught to students? Surprisingly, while there exists a large body of theory and alternative solutions (see e.g. Thürer et al. (2016) for a review of alternative card-based control systems), there is no evidence that this is routinely taught to students. This means students remain ill-prepared for practice since a significant portion of firms in practice are actually small and medium sized make-to-order companies and since customization plays a significant role in firm success (Spring & Dalrymple, 2000).

We have found that most textbooks do not discuss complexities that arise if systems such as Kanban are used in non-repetitive contexts. One reason for this may be the complexity of the emerging phenomena itself. Appropriate methods to teach complex phenomena are simulation and experiential learning. While experiential learning allows students to make sense of real-world phenomena by reflecting on experience (Itin, 1999; Moon, 2013; Beard & Wilson, 2018) and transforming this experience (Kolb, 1984), simulation allows the teacher to act as a sense-giver (Weick, 1995) controlling the experience of the students.

While the largest group among OM games arguably focuses on production control in manufacturing (Lewis & Maylor, 2007), all of the simulations for teaching production control systems that we could identify assume a repetitive context (e.g. Cox III & Walker, 2004 and 2005; Ashenbaum, 2010; Lambrecht et al., 2012; Manikas et al. 2015; Heikkilä et al., 2016; Hübl & Fischer, 2017; Rachman & Ratnayake, 2017 and Wake & Urquhart, 2018); i.e. the same product is produced over and over again. In fact, most follow the classical match and dice game originally introduced by Goldratt & Cox (1984, see chapters 13 and 14). The match and dice game models a production line in which each upstream station replenishes the inventory at its downstream station whereby the output of each station is dependent on a random event (a dice throw). While this illustrates the effect of variability and dependent events, the proper working of the game relies on the assumption that matches are interchangeable. But this assumption is rarely discussed, nor are the consequences of violating this assumption. So, the question remains: How can we teach the complex phenomena that emerge when production control systems are used in non-repetitive contexts? In response, we extend the classical match and dice game and assess the performance of our newly designed simulation in teaching practice.

Theoretical Background
Gamification has been used to teach managers and students for approximately 100 years (see, e.g. Cohen & Rhenman, 1961; Robinson & Robinson, 1994). A summary of
different forms of gamification is provided in Lewis & Maylor (2007). In this study, we focus on a physical simulation, which means that we seek to construct a small, simplified version of a complex real-life problem – the so called ‘game’ – to help students (or managers) to understand its complexities (Fripp, 1993). As a basis for our development, we first outline the content to be taught and summarize our expected learning objectives. The content are two complexities and two alternative solutions.

**Complexity I – Customized Products Prohibit Producing in Advance of Demand**
If the same item(s) are always produced, then these items can be stored in an inventory decoupling point, typically referred to as a ‘supermarket’ in the Kanban literature (Ohno, 1988). This allows demand to be satisfied instantaneously; the Kanban system functions as an inventory replenishment system signaling via Kanban cards that ‘an item X was used, please replenish it’. But when each item differs, items cannot always be stored in advance and simply withdrawn from the supermarket to satisfy demand (Amaro et al., 1999).

**Complexity II – Card acquisition leads to Indirect and Direct Load**
When each item differs, the need for the item must first be propagated upstream from station to station until it reaches the first station where the need can be met – the CODP. In other words, a job must acquire a card from each station downstream from the CODP, and only then can processing of the job start. Acquiring means that a Kanban card is associated to this and only this specific order until the order is complete (Chang & Yih, 1994a and 1994b). During this card acquisition process, the kanban card signals ‘an item X will be used, please create it’. Once a job has acquired a card for all operations in its routing, the actual processing of the order can start. The order is released, and the job moves downstream from station to station, being processed at each one in turn. After job completion at a station, the corresponding Kanban card can be used for a different order. So, a Kanban card remains associated with an order from release to the first station in the routing until completion at the corresponding station. But only when the order has arrived at a station does the corresponding Kanban card represent direct load. Before this point the card represents indirect load, which is the load associated to a station that is yet to arrive at this station. Since the indirect load increases the further downstream a station is positioned in the typical routing of jobs, downstream stations require looser or slacker limits on the number of Kanban cards (Gstettner & Kuhn, 1996; Oosterman et al., 2000).

**Alternative Solutions – Kanban’s Decentralized Card Acquisition can be Centralized**
The decentralized card acquisition process executed when using standard Kanban without adaptation may lead to severe blocking in the material and information flow (Bonvik et al., 1997; Thürer et al., 2018). It also complicates control of the system, since: (i) the last station, which has the loosest limit exercises the control; and, (ii) order prioritization is decentralized. Both can be resolved by centralizing Kanban’s card-acquisition process; for example, by combining Kanban with Constant Work-In-Process (ConWIP; see e.g. Spearman et al., 1990; Hopp & Spearman, 2001) as in Bonvik et al. (1997) or through Control of Balance by Card Based Navigation (COBACABANA; see e.g. Land, 2009; Thürer et al., 2014b), which centralizes the whole card acquisition process.

**Expected Learning Objectives**
Our analysis suggests two main complexities that arise when Kanban systems are used in a non-repetitive context. These complexities are neglected in most standard textbooks. The same holds for the solutions. Most textbooks only cover simple push methods, with
infinite work station loading being the main control exercised by local priority rules. While ConWIP is sometimes taught, this is mainly due to it arguably being simpler than Kanban. Meanwhile, COBACABANA is widely neglected although it has the potential to significantly improve performance compared to ConWIP and Kanban (Thürer et al., 2014b). Within Bloom’s (1956) taxonomy we mainly focus on the cognitive domain, specifically comprehension. Table 1 summarizes the expected learning objectives.

| Alternative Solutions: Kanban’s Decentralized Card Acquisition can be Centralized | 5. Utilize ConWIP and COBACABANA. |

### Design of the Game

**Required Materials and Set-Up**

The basic infrastructure of our new game follows the match and dice game. We model simple production lines where each line consists of 4-6 players. Sheets of paper are used to represent the output buffer of a player, the products and the Kanban cards. The Kanban cards should be of a size such that five fit on the planning board described below. This planning board can be a simple A4 sheet of paper. Note that the use of sheets of paper is arbitrary and any other material (e.g. bowls and matches) could equally be used. Finally, we do not use a die so as to exclude the effect of variability in the output rate and to isolate the effect of customized products. Hence, the output rate and processing time are fixed. The game takes approximately 45 minutes for one modelled line.

### Execution

There are three primary learning styles: visual, auditory and kinesthetic (Protzman et al., 2016). Visual learners prefer pictures with written materials. They also prefer lists and make mental maps of activities and tasks. Auditory learners prefer to talk out loud and repeat things to themselves. They prefer to discuss ideas that they do not understand in a group. Kinesthetic learners learn from experience. They can remember how to do things they have only done once. They need practical, participatory experiences where they can handle materials. All three types need to be considered when executing the game. First, the visual learning style is supported by use of a Powerpoint presentation synchronized with the execution of the game. The presentation summarizes the simulation, the structure of the production control methods and the results step-by-step. Second, the auditory learning style is supported by letting students discuss the results, guiding the discussion through a set of open-ended questions. Third, the kinesthetic learning style is supported by the simulation; all students actively participate in the simulation. In total, three experiments will be executed.

As a baseline, we start with a ‘classical’ Kanban system, as illustrated for five stations in Figure 1, and the scenario where all products are interchangeable (Experiment 1). There are arbitrarily five Kanban cards allowed in each Kanban loop. The teacher takes products
from the output buffer of the last station (finished goods), which frees up Kanban cards. The player at the last station (Station E) then goes to the previous station (Station D) and takes products from the output buffer before finishing the products and putting them in his/her output buffer. The Kanban cards of the previous station are freed when the player at the last station takes parts from the previous station and attaches his/her Kanban cards. This triggers production, and so on.

**Figure 1 – Baseline Kanban System**

**Complexity I: Customized Products Prohibit Producing in Advance of Demand**

We then change the scenario, stating that we now produce highly customized products (Experiment 2). This means products are now no longer interchangeable. We ask the students to set up the simulation as for the baseline experiment, but they should soon recognize that customized orders cannot be held in stock. Students learn that if orders are highly customized one must shift the CODP and always wait for demand before the production process can occur. This addresses our first learning objective – students can explain why customized products cannot rely on traditional Kanban.

**Complexity II: Card Acquisition Leads to Indirect and Direct load**

We now trigger the first customer order. Students discover that a card must be acquired at each station until the order reaches the first station, since demand created downstream cannot be fulfilled instantaneously or directly from stock. This addresses our second learning objective – students can describe the card-acquisition process. To facilitate this card-acquisition process, we ask the students to put all Kanban cards on a centralized planning board. Thus, instead of each student independently deciding which order to process, we introduce a centralized release function executed by the first player in the line. Kanban cards no longer remain in the loop of the station, rather they are attached to the order at release and move with the order until completion at each station. This establishes a centralized loop between each station and the first/gateway station.

It is important that production at each stage is synchronized. This means each station completes its order, detaches the card sending it back to the planning board and moves the order at the same time. After four rounds the first order reaches Station E with one card (from Station E) attached to it and the steady state is reached. At the steady state, four cards are taken from the planning board and attached to the order, and four cards are received (one from each station) from the shop floor and put on the planning board. We now let students continue for some rounds until they have internalized the feedback loops. We then stop and ask them to observe the distribution of available cards on the planning board and assigned Kanban cards on the shop floor. This is illustrated in Figure 2.
As an example, take Station E: Where are all of the cards of Station E? We explain to students the difference between direct load, represented by the card directly queuing at the station, and indirect load, represented by the cards at the three upstream stations. It arises since it takes longer for cards from station E to actually reach Station E than, for example, for cards from Station B to reach Station B. This addresses our third learning objective – students can explain what is meant by direct and indirect load.

We next ask whether we can release more than one order. Students will observe that this is not possible since there is only one card from Station E on the planning board. Hence, Station E imposes the limit for the whole system, although we designed the system to have five orders at each station. As a result, the limit on the number of cards should increase the further downstream a station is positioned to ensure that the direct load at each station remains at five orders. This addresses our fourth learning objective – students recognize the consequences for the workload limits.

As an example, take Station E: Where are all of the cards of Station E? We explain to students the difference between direct load, represented by the card directly queuing at the station, and indirect load, represented by the cards at the three upstream stations. It arises since it takes longer for cards from station E to actually reach Station E than, for example, for cards from Station B to reach Station B. This addresses our third learning objective – students can explain what is meant by direct and indirect load.

We next ask whether we can release more than one order. Students will observe that this is not possible since there is only one card from Station E on the planning board. Hence, Station E imposes the limit for the whole system, although we designed the system to have five orders at each station. As a result, the limit on the number of cards should increase the further downstream a station is positioned to ensure that the direct load at each station remains at five orders. This addresses our fourth learning objective – students recognize the consequences for the workload limits.

Alternative Solutions: Kanban's Decentralized Card Acquisition can be Centralized
We now explain to the students that the centralized Kanban system represents the COBACABANA system as outlined in Land (2009). We then ask: is there a simpler solution to control the number of jobs in the system? A single card loop from the customer to the first station of the line (the release function) could be used. We explain that this is ConWIP, which neglects direct and indirect load. We ask about the minimum number of ConWIP cards in the system, which is equal to the number of stations, and let students simulate the ConWIP system (Experiment 3). While students will find the execution of the ConWIP system easier, they should also observe that only 1 or 2 players are actually processing orders while the remainder watch. We now explain that ConWIP cannot be applied if processing time variability or routing variability is high, since it does not control stations. Moreover, the routing length is restricted since the number of ConWIP cards increases with the routing length. This addresses our fifth and final learning objective – students can utilize ConWIP and COBACABANA.

Field Test Results
Different assessment methods could be identified in the literature; for example, the use of self-reported data on whether learning outcomes improved, either directly from
students themselves (Arenas-Márquez et al., 2012; Costa Santos et al., 2012; Piercy et al., 2012; Yalabik et al., (2012); Scholten & Dubois, 2017) and/or from teachers (Léger et al., 2012; Scholten & Dubois, 2017), and final test scores (e.g. Arenas-Márquez et al., 2012) or pre/post implementation scores (e.g. Manikas et al., 2015). In this study we use both self-assessment and test scores. However, our game teaches new knowledge which is not part of an existing curriculum. So, we cannot assess pre/post implementation scores but only assess post implementation scores. We can also not use a problem-based assessment (see, e.g. Bamford et al., 2012) since it focuses on an uncontrolled environment where a basic requirement is that the problem is not fully defined. In contrast, our simulation provides a controlled learning environment.

The game was conducted in December of 2018 in a class in China as part of an introductory course on production control systems. A total of 41 students participated in the game and 10 production lines were simulated. Lines consisted of either 4 or 5 students on a team. The differing line sizes were necessary due to the layout of the teaching facility. After the game a questionnaire was given to each student. All questions were in both English and Chinese. Students were free to answer in any of these two languages.

Assessment & Self-Assessment of Teaching Effectiveness
Table 2 summarizes the questions used to assess whether learning objectives were met together with the percentage of given right answers. The percentage of right answers compares favorably with those obtained in post-tests in other studies in repetitive contexts (e.g. Manikas et al., 2015). A major issue is the low score observed for drawing a ConWIP system. It may originate from a confusion of terms, since students assume ConWIP cards to be Kanban cards. In fact, 8 students drew a Kanban system.

<table>

<td>Indirect load arises at a work station when producing customized goods because:…</td>
<td>71%</td>
</tr>
<tr>
<td>4. Recognize the consequences for the workload limits</td>
<td>If a production system for customized orders has six work stations and a limit of 7 Kanban cards at the first station, what will be the actually imposed limit at the last station?…</td>
<td>90%</td>
</tr>
<tr>
<td>5. Utilize ConWIP and COBACABANA</td>
<td>Can you outline the loop structure of a ConWIP system?…</td>
<td>46%</td>
</tr>
<tr>
<td></td>
<td>When utilizing a COBACABANA system:…</td>
<td>78%</td>
</tr>
</tbody>
</table>

A seven-point Likert scale was used for student self-assessment. Table 3 summarizes the questions and the average score. Our third learning objective – explain what is meant
by direct and indirect load – received the lowest score, which overlaps with the test results given in Table 2 above. Still, we considered it adequate since direct and indirect load are highly complex conceptualizations. So, to a certain extent the low score was expected. For practice it is important that most of the students were aware of its consequences in terms of workload limit applied. The high score for our fifth teaching objective - utilize the ConWIP and COBACABANA alternatives to Kanban – supports our conjecture that the low score for the ConWIP related question in Table 2 is due to a confusion of terms.

</tbody>
</table>

**Engagement, Comments and Discussions**

The questionnaire also contained general questions: Can you think of more effective ways to learn the material you acquired with this game? Did you enjoy the game? To what extent? Do you think the game can be improved? If yes, how would you improve the game? And, Any further comments?

In terms of more effective ways, two students mentioned the inclusion of practical examples and one student suggested a better link to the course textbook. All answers would better fit under improvements. Meanwhile, 34 out of 41 students enjoyed the game, ranging from “so, so” to “normally” and “very much”. The majority of the students actively participated in the game, but a major problem was the large number of lines used in class (10 production lines) which led to students waiting while we were explaining the game to the students at other lines. Overcoming this issue was one of the major suggestions to improve the game. Students suggested the use of videos or letting students teach each other. The latter would also help to overcome the language barrier, given that the course is taught in English to a native Chinese audience. Developing strategies to more rapidly teach the game in different linguistic contexts is one of the main future research issues.

**Conclusion**

A major contingency factor that determines the applicability of production control techniques is the position of the so-called Customer Order Decoupling Point (CODP). While this is widely recognized in the literature and most textbooks teach some content on the CODP and the different production modes it creates, most textbooks remain in a to-stock, repetitive context when introducing production control solutions. However, production control techniques for this context, such as the use of Kanban containers for inventory control, cannot be directly applied to shops that produce a high variety of products, such as small and medium-sized make-to-order companies. While contingency factors are introduced, how to solve these contingencies is neglected. We therefore asked: How can we teach the complex phenomena that emerge when production control systems
are used in non-repetitive contexts? In response, we extended the classical match and dice game, which focusses on a repetitive context, and integrated a strategy to teach two complexities (i.e. customized products prohibit producing in advance of demand and card acquisition leads to indirect and direct load) and two solutions (ConWIP and COBACABANA). We then used a field test to prove the playability of our game and assess its teaching effectiveness. We used two different approaches: post-game scores and self-assessment. Both give support to our game and highlight that it helps specifically average students.

Using Virtual Reality to teach warehousing operations: the Leclerc Drive Case

Aurélien ROUQUET (aurelien.rouquet@neoma-bs.fr)
NEOMA Business School

Abstract
While increasing volumes of knowledge are becoming available on the Internet, the challenge remains of providing students with unique experiences in the classroom through experiential teaching methods. The stakes are all the greater since student numbers are growing with the massification of higher education. One way to provide experiential learning for large numbers of students is to use Immersive Virtual Reality technology. The paper provides feedback on a virtual reality application developed at NEOMA Business School that enables students to visit a logistics warehouse owned by the retailer Leclerc while remaining in the classroom.

Keywords: experiential, virtual reality, warehousing

Introduction
Since Freud made his celebrated statement, people often describe teaching as an “impossible profession.” However, recent upheavals in the educational system mean that the statement has doubtless never been as true as it is now, and for two major reasons. First, all knowledge is immediately available: everything that is said can instantly be verified. Thus, there is every chance that when a teacher makes a mistake in the classroom, one of the students will point it out after checking on Google. Second, it is increasingly impossible for teachers to keep their students’ attention for any length of time. When a teacher speaks in the classroom, many students are no longer able to concentrate for more than a few minutes...

How can teachers overcome these two new disruptions? The answer lies in pedagogical innovation. One challenge is to develop educational strategies that provide less theoretical, lecture-based, “experiential” learning (Kolb, 2014). According to Legendre (2007), experiential learning is “a learning model that advocates participation in activities set in contexts as close as possible to the knowledge to be acquired, the skills to be developed, and the attitudes to shape or modify.”

Experiential learning encourages knowledge retention and involves students more actively in the learning process. It enables a learning process involving, to use Schön’s (1984) expression, a dual reflection: “reflection during the action and reflection about what is put into action.” Experiential learning takes place during class time, using practical work, advanced learning sessions, questioning, the application of content worked on beforehand via distance learning, simulations or business games, group work, traditional case studies, exercises, virtual or actual projects, professional experience (internships or voluntary work), etc.

The benefits of virtual immersive reality in experiential learning
While a range of tools is available, one recent technology is particularly appropriate for experiential learning: virtual immersive reality. Virtual immersive reality consists of photographic or video images of professional or entertaining scenes. These images are
used to create a 360° digital reconstruction of the scene, in which users, equipped with a headset, feel immersed, included in the photo in the middle of those being photographed, or standing next to the people in the video who are speaking to them. Virtual immersive reality can thus enable students to visit a location (even if it is small, dangerous, or inaccessible) while remaining in the classroom, to experience a learning situation, or to be immersed in an environment relating to the discipline being studied. Using a smartphone and a passive virtual reality headset, students can be propelled into a 360° environment chosen by the teacher. Learners will use their critical skills in the environment to analyse the context and take decisions as appropriate for the exercise.

In 2016-2017, NEOMA Business School initiated its Learning Experience approach. This is part of the school's pedagogical approach, focused on experiential learning and action learning. The School's first initiative in this area was to use immersive virtual reality to develop an application that immerses our students in a retail store. The approach, designed to improve marketing courses covering sales outlets (merchandising, organization, etc.) has been proposed to over 2,000 students since 2016.

We developed our second virtual immersive reality application for our operations and supply chain management courses. Ultimately, NEOMA’s aim is to produce a library of teaching content that will immerse students in a wide range of organizations to work on their agility and "critical awareness". Our library of immersive content will enable students to benefit from a variety of educational experiences and to make connections between these experiences. It will also provide learners with a variety of contexts that would not otherwise be possible due to the temporal, spatial or organisational constraints of their curriculum. Finally, the system will enhance the value of the teacher, who must provide learners with the means to go back and forth between theory a.

The Leclerc Drive case study: an application to a logistics warehouse tour
The application immerses students in a logistics warehouse: a drive-through warehouse operated by the supermarket chain Leclerc. Drive-through stores are a retail format that appeared in France in the year 2000, and which are both stores and logistics warehouses. Their development has been remarkable, and in 2017, there were more than 4000 drive-through stores in France. Unlike a supermarket, where customers choose their purchases in the store, in a drive-through store, customers order their shopping on Internet, and then drive to the store, where the shopping is loaded into their car boot, after being prepared by the staff.

The case plunges students into the largest drive-through store in France (in 2018): the Leclerc store in Saint-Brice Courcelles, near Reims. As a logistics and supply chain management (SCM) consultant, the students’ mission is to discover how the Drive operates, and then to provide Leclerc senior management with recommendations to help the store absorb the rapid increase in customer orders. Specifically, the students:

1. Visit Leclerc Drive in Saint-Brice Courcelles, either in immersion (ideally) or in 360°
2. Model the physical and information flows through the Drive, in groups. To do this, the students:
   a- Draw the store building with its different areas
   b- Locate the drive-through store within its upstream and downstream supply chain environments (suppliers and customers respectively)
   c- Draw a diagram of the physical and information flows through the Drive from supplier to customer
3. Prepare a critical analysis of the drive-through store with their group. The students analyse the marketing and logistics choices made when designing the Drive, and then imagine how the store could be rethought to cope with the increase in customer orders.

4. Present their analysis using a five-minute slideshow, including the key issues identified and proposed improvements for each of the key issues they have identified (objectives, means, expected results, budget required).

**Case study design**

We designed the case study in partnership with the retailer Leclerc. The project took almost 18 months, divided into 5 phases. The first phase of the project was to define the learning objectives. In the case of the application, four objectives were defined, classified according to the Bloom taxonomy. Specifically, the goal was that after the case study, students would be able to:

- Schematize the logistic process of a drive;
- Explain the link between physical flows and information flows;
- Analyse the decisions taken with regard to marketing and logistics;
- Design a Drive according to different constraints from those of Leclerc.

The second phase of the project was to define a script for the application (figure 1). The script identifies the different areas of the Drive that the students would see in the application, and in particular where they would watch videos of employees working (V1, V2, etc.) and where they would watch 360 panoramic pictures (P1, P2, etc.). During this phase, we wrote the text that each Drive employee would say during each video, to help students reach their learning objectives.

![Figure 1: Script of the VR Application](image)

The third phase consisted in shooting the application at the Leclerc Drive. During this phase, the Drive employees rehearsed what they would say and do. After the rehearsal, 3 days of shooting were organised at the Drive, using a 360° camera (see figure 2).
The fourth step of the project consisted in developing the smartphone application. During this phase, the application was tested technically, debugged, and several versions were released. In parallel, the videos, which had been shot in French, were translated into English, to enable the application to be used with a larger audience. During this technical phase, we designed a first draft of the teaching material (teaching scenario, slides, etc.).

Finally, we tested the application with two classes. Using their feedback, we made improvements to the application and the teaching scenario. Finally, we launched the case study in September 2018, since when it has been used by more than 600 students in three-hour classes.

**Learning from the case study**

The results of this initiative have been extremely positive. First, the students learn fast. They feel more involved and quickly learn the concepts associated with managing physical flows in warehouses. This is mainly because they are not on their smartphone, but in their smartphones when they use the application! Second, they appear to retain what they learn. As the experience is new and unfamiliar, they do not forget the concepts studied. In addition, their understanding is more complete. In this nonlinear, immersive approach, they learn about the system as they would in real life. Finally, the students are captivated by using the very latest technology. In this “attention economy,” the system benefits the teacher while making the learning process enjoyable: the era of edutainment (educational entertainment) has begun.

Using virtual reality, however, requires care. Indeed, using any technology involves paying particular attention to the UX (user experience). In the case of immersive virtual
reality (IVR), the brain is subjected to a unique exercise and needs to be provided with an environment of the highest quality: the brain will see and hear an experience that the other senses do not perceive directly. In rare cases, either because of the poor quality of the immersive environment, or because of the student’s personal reaction to this type of experience (as with forms of transport sickness), a few students may feel the effects of motion sickness during virtual immersion. According to a US Navy study in 2015, up to 40% of users may feel motion sickness when using VR. This phenomenon is of course directly related to the type of experiment and the user’s profile.

In the case of immersive virtual reality, particular attention must be paid to:

- the quality of "navigation" during the IVR experience, avoiding complex or unnecessary movements,
- short immersion times to limit exposure to the smartphone screen’s light and visual accommodation effort time,
- the quality of the images, to avoid tiring the user with blurred or poorly edited images.

![Students using the VR application in class](image)

**Figure 3: Students using the VR application in class**

**Proposal for the EUROMA session**

During the EUROMA session, we will present in more detail the case study’s design and use in the classroom. We will also give participants the opportunity to use the application and experience the Drive-through immersion as the students do (see figure 3). We will supply Homido headsets for participants to test the application using their own smartphone. Finally, we will stress that the interest lies not in the technology but in its educational uses. Without a thoughtful pedagogical approach, finely crafted goals, and a carefully constructed scenario, immersive virtual reality will simply become a passing fad. Moreover, as highlighted by Figure 4, we use the technology coupled with traditional techniques: a marker and flipchart sheet to draw the warehouse. Such
techniques keep the students focused on reality and help them really work together, which is crucial.

Figure 4: Students drawing the Drive warehouse with a marker and a flipchart sheet

Abstract
The UK government’s objective to increase accessibility to the rail system for users presents challenges for the management of day-to-day operations. This research reports on the development of a virtual-reality-based learning tool (game) to facilitate continuous improvement of rail service management in respect of accessibility. Application is via two modes, a journey planning tool for users and a training tool for customer-facing rail staff. The tool aims to identify issues pertinent to the management of rail operations and promote the staff discussion of accessibility management. Provisional results and demonstrator will be presented at conference.

Keywords: Service Improvement, Virtual Reality, Learning

Introduction
One aim of the Department of Transportation’s Accessibility Action Plan Consultation (Department for Transport, 2017) is to improve railway accessibility for individuals with Less Visible Impairments (LVIs). In context LVIs are conditions that limit an individual’s ability to utilize rail services that are not immediately visible (or obvious) to the casual observer, for instance, developmental conditions such as Autistic Spectrum Disorder (ASD). Furthermore, with aging populations the number of potential rail users with LVIs such as mild cognitive impairment is likely to increase and they in particular will require modification to service provision. This is an issue for standardized high volume, low variety, operations management where operations are normally geared toward the majority of users (without LVIs) and there is currently little academic research on how this can be achieved. Facilitating rail access for individuals with LVIs would enable them to take a more active role.

This research involves the Rail Safety and Standards Board (sponsors), technology and operations management academics, LVI experts, and a Train Operating Company (TOC) with the aim of improving access for those with LVIs through two routes:

- enabling users to prepare for, and be better supported during, rail journeys
- developing a learning capability for customer-facing rail staff to improve their ability to provide appropriate customer service for users with LVIs.

The project will assess the effectiveness of Virtual Reality (VR) technologies and gamification to improve the quality of service and travel experience for users with LVIs, and the ability of customer-facing staff to manage operations in respect to those with LVIs. The research focuses on two specific LVIs, mild cognitive impairment (MCI) / Pre-Dementia and ASD, where the use of VR technologies and gamification as a therapeutic aid has provided superior results over traditional methods (Mesa-Gresa et al., 2018; Fleming et al., 2017).

It is envisioned that a gamified VR environment will aid MCI and ASD users to plan, practice, and thereby more effectively execute rail journeys and facilitate improvement of staff/LVI interactions, accessibility, and customer service.

**Literature Review**

Gamification remains a nascent area of research and, as such, has not been definitively characterized. An oft quoted definition is that of Deterding et al. (2011) which focused on the use of game elements, such as badges and missions, in non-game contexts. Other authors e.g. Mora et al. (2017) go beyond this to include factors that are aimed at changing behaviour, levels of motivation, or engagement in organizational initiatives and the improvement of users’ experiences. It is within these broad approaches that the application of gamification in this research resides, where the virtual environment will include gamified elements in order to motivate users to engage with the process of journey planning.

Authors argue that to achieve a successful gamified outcome requires a process perspective in order to enhance behaviour through a persuasive design approach (Werbach 2014). Persuasive design itself can be characterized in three elements which can achieve the targeted behaviour (Fogg, 2009). The design must provide the user with sufficient motivation, they must have sufficient ability to complete the tasks required, and there must be an effective trigger which motivates the desire to achieve the behaviour. Thus the use of gamification should consider what behaviours are desirable and therefore should be rewarded in some context. Importantly for this to be achieved the process to be gamified must have some intrinsic value to the user, without this the use will have no motivation to engage or further deepen that engagement through gamification. As such gamification can be considered a potential motivational design solution (Deterding,
Therefore to achieve behavioural changes design should attempt to ‘provide the user with arguments for specific behaviour and suggest actions’ for the users as part of gameplay (Tromp et al. 2011). In the context of this research the gamified approach should encompass game elements that influence users towards explicit goals; where both the behaviour and explicit goals are apparent to the user. In more specific terms, gamification should motivate and enable potential rail users to plan for their journey (something that is not straightforward for those with ASD or MCI) and provide customer-facing rail staff with a mechanism to gain insight into, discuss, and develop service improvements. In broad terms design should consider functional and practical requirements, constraints, and non-functional requirements. These include primary tasks that provide meaningful content for the user, computer-human interaction which moves the user toward the goal or behaviour through feedback, a credible system that is persuasive in terms of the desired behaviour, and social support which can influence the user’s progress towards the desired behaviour (Oinas-Kukkonen and Harjumaa, 2009).

Examples of serious games and gamification to promote knowledge sharing are becoming more common as gamification becomes recognized as, “…a process of making activities more game-like…” and, “… focus[ing] on the crucial space between the components that make up games and the holistic experience of gamefulness” (Werbach 2014). It is the aim of this research to apply the learning capability as a serious game to promote discussion and knowledge sharing between customer-facing staff through the lens of the requirements of rail users with LVIs. In the context of this study it is important to make the distinction between the use of a serious game and the gamification of the process of improvement. Deterding et al. (2011) developed a 2x2 matrix where gamification involves the use of game elements in parts of a designed process whereas a serious game involves the use of a game without necessarily including it in a wider process. This research combines this design thinking to use a serious game, as an intrinsic, explicit and critical part of the process improvement process. Hence the process improvement process is gamified through the use of a serious game. This approach is an example of gamification because it is possible to be engaged in both game design and gamification, “without conflating the two” (Werbach, 2014).

VR is broadly defined as an experience that gives a person a sense of reality and a feeling of presence in a synthetic environment that is normally computer generated and different from one’s surroundings in reality (Steuer, 1992). Due to advancement in optics and tracking, there is a variety of affordable Head Mounted Displays (HMDs) which allow the users to be fully immersed in a VR environments (Liagkou et al. 2019). Typical examples are the Oculus Rift, the HTC Vive, and Playstation VR. Oculus and HTC HMDs offers 1080 by 1200 pixels and a refresh rate of 90 Hz and both of the devices offer controllers and their one implementation for tracking, PSVR is a cheaper alternative but is broadly widely used due to the integration with the Playstation 4. Other cheaper alternatives include the Google CardBoard VR, and Samsung Gear VR which are heavily dependent on the user’ mobile phone.

Previous research has shown promising results in terms of the use and effectiveness of VR as a therapy tool for people with different LVIs such as Autism Spectrum Disorder (ASD) (Bernardes et al., 2015). VR also offers several advantages over traditional therapy and staff training methods, namely that VR offers a risk free environment, the ability to easily customize and develop highly controlled experiments (Maples-Keller et al., 2017) while having high ecological validity, meaning that the skills acquired during VR interventions could potentially be transferred to real life (Mesa-Gresa et al., 2018).
Theoretical Framework
The theoretical basis of the research is that the use of the gamified learning environment can facilitate the elements of the SECI framework.

![SECI Framework](adapted from Nonaka and Toyama, 2003)

Figure 1: SECI Framework (adapted from Nonaka and Toyama, 2003)

The provision of customer service for those with LVIs requires an understanding of their particular needs, this however is not a straightforward proposition due to the individual nature of their requirements. Consequently it is necessary to have some means of capturing their needs and communicating them to the organization as a whole. The development of organizational knowledge is characterized by the SECI framework (Nonaka and Toyama, 2003), Figure 1. In this context it is necessary to transfer the knowledge of individual requirements to the organizational context and then to transfer that knowledge within the organization itself.

The gamified VR environment aims to enable customer-facing staff to better understand the requirements of those with LVIs and stimulate discussions on how customer service can be improved. It is argued that the game and its feedback will allow those with LVIs to plan their journey and particularly highlight the elements of their decision process that will affect it. In this sense, under the SECI framework, individuals with LVIs can to some extent socialize their individual knowledge which can then be absorbed as individual knowledge by customer-facing staff. This knowledge can then be externalized by promoting discussion between customer-facing staff who have undergone the training and other individuals in the organization. In this way the initial learning and
knowledge can be spread within the organization. Subsequently customer-facing staff would combine their individual knowledge, and experience with customers with LVIs, to identify customer-service improvements and standardized approaches (where appropriate) that can be used across the organization as a whole. This is particularly important in the context of rail operations which are geographically dispersed and staff do not necessarily have significant contact between different geographic locations. Individuals at different locations, who had undergone the training, would then internalize what they had learned, apply it in practice, and then begin the cycle again (socialization) by sharing their individual experience. It is the approach of this research to test whether this process can be facilitated by the use of a learning game.

In summary gamification and games can be used to create learning environments and motivate users to participate in that learning. This learning can be facilitated in the subject group, those with LVIs, by the application of VR technologies. Further it is argued that such an approach can be used to educate customer-facing staff and subsequently begin a cycle of organizational learning, the ultimate outcome of this research.

**Methodology**

Gamification utilizes gaming associated elements in non-game contexts (Deterding et al., 2011). This research will develop a gamified learning environment to help engage users with LVIs and customer-facing staff in planning, practice, execution and discussion of such customers’ journeys. A generic new product development methodology (Tidd and Bessant, 2013) was used and modified using the recommendations of other educational game developers (Fripp, 1993), see Figures 2 and 3.

**Figure 2: Generic new product development methodology adapted from Tidd and Bessant (2013)**

**Figure 3: Game development methodology applied in this research**

Stage 1, Prototype definition: requirements gathering interviews and focus groups were conducted with experts in ASD, MCI, and customer-facing TOC staff identifying areas which affect the planning and execution of journeys for people with LVIs.

Stage 2, Conceptual design: a VR environment, based on a medium-sized UK railway station, was developed incorporating desirable game elements identified through literature review and consultation with a professional game developer. The design was reviewed by experts in the needs of those with LVIs on an iterative basis.

Stage 3, Prototype and Pilot: the prototype is under development at the time of writing. Development will involve periodic review by subject matter experts. Pilot studies will constitute live testing of the gamified VR environment with individuals with LVIs, including standardized pre- and post-test questionnaires designed to evaluate usability, game experience, workload, and presence, and individual feedback on the perceived system usefulness. Every questionnaire is aimed at subjectively measuring a different aspect of the developed prototype, where the System Usability Scale questionnaire (SUS) (Brooke, 1996) will measure the overall usability of the prototype, the Game Engagement Questionnaire (GEQ) (Brockmyer et al., 2009) will measure user engagement in the gamified aspects of the prototype, the Presence Questionnaire (PQ) (Witmer and Singer, 1998) will measure how immersed users felt in the VR environment developed for this prototype (i.e. VR train station) and finally the NASA-TLX Questionnaire (Hart and Staveland, 1998) is used to measure the mental and physical workload experienced by users during their use of the prototype. User responses in these questionnaires will be important to further refine the VR game in Stage 4. In addition to questionnaires, objective in game user performance metrics will be recorded such as task completion times, head movements (i.e. where a user is looking in the VR train station in a given task) and in game choices (e.g. answers given by users to challenges in the VR game, avatar choice, number of attempts in completing a given task). This data will be used to further improve the prototype and measure its effectiveness in quantifiable measures when used as a training tool by users with LVIs. Objective and subjective measures will potentially highlight common user preferences and behaviors when faced with different problems in a VR train station. These findings will be particularly important for staff training. Staff testing will involve a debriefing session assessing perceived system
usefulness and identifying system, service, and training improvements in order to meet
the needs of users with LVIs.

Stage 4: Refine, rework and review: production of the final design based upon user
feedback, and methods for commercialization, implementation in the participating TOC,
and making the prototype publicly available. This may include distribution of the game
as an Android App on the Google Play Store, where more in game objective data will be
collected in order to continuously improve the prototype.

**Brief Overview of game environment**
The learning capability will have gamified features so that it becomes an engaging and
fun experience for passengers and frontline staff to use. The learning capability will also
focus on the movement of passengers with LVIs through railway stations, and their
interactions with augmented information (i.e. using Augmented Reality (AR)) to provide
passengers with additional information that is not necessarily available in the physical
space of rail stations to benefit future designers of such spaces.

Based on the user requirements outlined by experts, a gamified VR system will then
highlight how the physical environment (i.e. rail station) presents difficult challenges to
people with LVIs. Unlike people who have physical impairments that are visible, and
readily evident to others, people considered by this project have impairments not readily
visible. Therefore difficulties they have in being in environments (i.e. rail station) –
normally geared toward the majority who do not have such impairments – are not readily
understood (Smith, 2009).

In designing the game, a number of design considerations for users with the two LVIs
that this research focuses on were taken into account, including presenting users with a
choice from different avatars which can be motivating for users (Silton, 2014; Bejan et
al., 2018) (see Figure 4), use of animations and encouraging language that were found to
help attract user attention (Bozgeyikli et al., 2016), use of bright and contrasting colors
in the user interface of the game to increase usability for elderly users (Siriaraya and Ang,
2014) and due to previously reported difficulties that ASD users face when dark colors
are used in VR systems (Bozgeyikli et al., 2017), finally short and literal instructions were
used throughout the game to avoid any user confusion especially due to the fact that
difficulties in language processing are kin to the LVIs addressed in this research (Faria et
al., 2016; Bozgeyikli et al., 2016).

![Figure 4: In-game avatars](image)

The game consists of three different levels, where level 1 acts as a training level for
users to become more familiar with the gameplay, interface and devices used in the game.
This first level allows users to look and move around the train station from the point of
entrance up until boarding the train without facing any challenges (Figures 4 and 5).
Level 2 then presents one challenge per task, where challenges address potential problems that users with ASD or MCI can face during journey planning in a train station, e.g. tickets machine is broken, the stairs are busy (Figure 6).

Level 3 finally presents a repetition of the challenges in level 2, as task repetition in VR environments is considered to be beneficial for users with ASD and MCI given its potential in honing brain skills (Hamadani et al., 2018). Additional challenges are also presented in this final level in the game, that in some cases require users to solve problems that are normally stressful in real environments and may require a lot of movement in a train station in order to be solved (e.g. sudden changes in train platforms, train delays).

Following the completion of all three levels of the game, users are then able to play any of the three levels again in no specific order, along with an option that allows users to freely explore the VR train station without any tasks or challenges.

**Contribution**

In addition to addressing the agenda set by government (Department for Transport, 2017), that highlights lack of confidence to travel as a major issue for people with LVIs, this project will present a novel approach to continuous improvement through increasing the understanding of supported rail passenger journeys in a high volume environment, a topic that is currently largely unexplored. It is also expected that assessing the feasibility of supported approaches to achieve improved access to rail services and the use of VR environments as training for customer service and accessibility will represent a shift from the current focus on simulating symptoms to the facilitation of improved coping mechanisms for users.

For frontline staff, VR gamification will offer a novel approach to continuous improvement. The approach will use interactive VR (e.g. video with questions, information, tasks and challenges relating to LVIs). This will enable frontline staff to better understand and empathise with people with LVIs and be more able to identify and
develop innovative solutions to LVI accessibility problems, without necessarily having direct contact with people with LVIs. This proactive and asynchronous approach has the potential to encourage LVI related improvements more quickly and effectively if compared to traditional methods (e.g. questionnaires, focus groups). Currently there are limited uses of virtual tours of this kind for passengers and limited feedback from LVI passengers, or potential LVI passengers, regarding their concerns about travel which makes this approach novel; it has the potential for the remote identification of improvements directly from passengers without the need for them to physically travel and will directly identify ways in which LVI passengers’ experience can be improved. In addition built environment engineers will be able to use the resulting dataset to improve ergonomics and journey experiences for such rail users.

A demonstration of the VR game and preliminary results will be given at the conference.

Abstract

The paper studies a case teaching method that tackles companies’ actual business problems of their current environment. The Real-life case method allows students to devise solutions novel to the case company, guided by their instructor and a company representative (the protagonist) in a live case setting. The method is also compared with traditional Harvard cases. The Real-life case method is evaluated by a survey and identified to bring additional value particularly in increasing students readiness to face real business problems in the field, understand the concepts of the course and becoming more confident with the taught subject in general.

Key words: Live case study, industry collaboration, learning-by-doing

Introduction

What makes high performing companies share their core business-critical information with a group of undergraduates? Why do the same companies keep paying for this year after year? These questions manifest the uniqueness of the teaching method under investigation. The paper will study an application of case-based teaching developed in the focal university, which is titled here Real-life case. This method builds on actual business problems that real companies face in their current environment and allows students to devise solutions that may be – and often are – novel to the case company itself. The students are guided by their instructor in a live case setting where they interact with relevant stakeholders to analyse and develop future scenarios together with the protagonist (focal character from the case company). The case method gives students the opportunity to attain managerial competences in a “real-world” setting including interaction with stakeholders This approach has gained popularity in the focal university in the form of “real-life challenges” and is also used as “Real-life” cases globally in business schools. The method is compared with the Harvard case teaching method that builds on Socratic principles to stimulate discussion, debate and critical thinking through
using descriptions of decision-making problems faced by an organization/individual. One of the goals of the case method, in general, is to bridge university education with practice through building students’ skills that will be relevant when working on complex real-world phenomena after graduation (Steiner and Laws, 2006). The research aims to study Real-life case as a possibly effective method to reach these goals.

Harvard case method has become a commonly approved way of delivering parts of standard business curricula. Despite being useful in many settings, it has shortcomings particularly in terms of how effectively a carefully prepared written report can simulate an actual business problem within a company. Live cases are an application of case teaching, which aim to provide even better resemblance of real-life circumstances in actual organizations and stakeholder groups’ perspectives (e.g. Roth and Smith, 2009; Steiner and Laws, 2006). They should provide a more thorough representation of the dynamics intertwined within companies’ decision-making processes. In live teaching cases, students have even more freedom to develop the case, construct a problem and devise a solution (Steiner and Laws, 2006). The Real-life case studied here take these ideas even further through deeper co-learning among the students, the focal company and the instructor.

This study aims to analyse Real-life case as a way to deliver engaging, high impact education that is tightly linked to company practice. A key goal is to capture the essence of this method to enable other educators to replicate it in suitable contexts. One of the core aspects is to define the roles of parties participating in delivering Real-life cases, because these differ considerably from many other forms of case teaching. Further an explicit comparison of Harvard, instructor-led live case and Real-life case will be carried out to identify the value that these methods can bring to the participants.

The research questions (RQs) are:

RQ1: What kinds of roles do parties play throughout co-teaching Real-life cases?
RQ2: What kind of value do Real-life cases deliver to each party, and how does this compare with the Harvard case method and author-led written case?

Literature background

Different case methods in business school education

Business school education faces a challenge by the ever-changing managerial requirements in work-life. Accordingly, instructors need to provide education relevant for work-life, which often means a rich use of various teaching cases (e.g. Miller and Maellaro, 2016). Variety in both case content and teaching style provides students with a broader perspective on ways to apply knowledge in different real-life scenarios (Druckman and Ebner, 2018). The value of teaching cases is traditionally seen in the decision-making process, although the case method can offer a multitude of value to different participants when the delivery is amended. Concepts behind case methods vary and can be interpreted in many ways depending on the instructor, but the categorization used in this study is based on the following: strategic orientation, structure, relevance for the case itself, participation role of the student (Steiner and Laws, 2006), complemented by the role of the protagonist.

This paper focuses on three case study approaches: (1) Harvard case, (2) author-led written case and (3) Real-life case (see Table 1). In the second method, the instructor provides a written case in the classroom with all the information relevant to the case, similar to the written case description in the Harvard method. In the third method, students are guided into a live case setting where they interact with relevant stakeholders to analyse and develop future scenarios together with the protagonist who is a practitioner.

*Live case method as a way of delivering experiential learning*

Business school education should be influenced by the epistemology of the field: rather than simply allowing students to acquire knowledge, they should be engaged in a process that transforms some of their beliefs, values and ways of working (see Kolb, 2014). Fulfilling this likely requires a thorough learning process, where students are exposed to real-life business situations where they interact with relevant stakeholders and construct knowledge from this process (Yardley et al., 2012). Learning and knowledge creation requires reflection on the experience and conceptualization of key events (Kolb and Kolb, 2009), where the instructor’s help is crucial.

Live case teaching is a method that can help students acquire several types of work-life skills required in future practice. This is achieved in closer partnerships among universities, companies and university students (Roth and Smith, 2009), which requires different types of course designs but also new roles from the instructor, students and partner companies. Live teaching cases (Cameron et al., 2012) amend live cases by introducing a practitioner/protagonist to deliver the case description in-person in the classroom. This requires the development of close relationships between the university and companies as well as between the instructor and practitioner. However, the learning results that the students can reach from this experiential learning approach are more relevant to practice but also more durable (Elam and Spotts, 2004; Miller and Maellaro, 2016; Druckman and Ebner, 2018).

**Research methods**

The original purpose of the case method is to enhance learning by fostering better thinking (Lundberg et al, 2001). We argue that offering case variety, especially in case teaching methods, is important for developing students’ managerial competences. The Real-life case method offers an extension to the more traditional Harvard style case, which focuses strongly on decision-making whilst the Real-life case focuses on a larger spectrum of outcomes, such as managerial recommendations, insights into business operations and interaction with the protagonist. The Real-life case method gives students the opportunity to attain managerial competences in a “real-world” setting including interaction with stakeholders. This approach has gained popularity in the focal university in the form of “real-life challenges”.

---

*26th EurOMA Conference Operations Adding Value to Society*
For this study, an undergraduate course was analysed in a Northern European global top-50 Business School (ranking based on 2018 Shanghai Ranking in Management). Three teaching methods with similar goals were compared on the course: a collaborative Real-life case, instructor-led written case and a traditional Harvard case called “Leitax (a)”. The Real-life case aimed to improve participants’ interaction with the learning materials and context, in a co-learning setting.

The data set considers both qualitative and quantitative data from a questionnaire with students (23 individuals) responding to questions concerning the three case methods. It focuses on how useful the case methods are for learning to apply concepts to a real-life situation. The data was analysed primarily through content analysis methods (Miles *et al.*, 2014) and comparison of variances.

**Findings**
The findings of the study centre on the roles and value of the Real-life case method. Figure 1 provides a summary of the roles in different phases of the process. From the instructor’s viewpoint, significantly more time in the preparation phase is needed because the case company and protagonist must be engaged early enough to allow content creation and preparation and secure availability during the lecturing times. In Real-life case, the instructor is also expected to take new roles such as coaching the protagonist in their preparations, facilitating classroom interaction not only with students but with students and protagonist and between them. The approach calls for flexibility, good communication and facilitation skills, not forgetting an ability and willingness to direct and lead the conversation when needed.

*Roles of participants in the Real-life case compared to those in other case teaching*

Table 2 assesses the three studied case study approaches through the different participating roles: (1) Student, (2) Protagonist, and (3) Instructor. University graduates need to possess a broad set of managerial competences that include: personal (i.e. self-regulating work, ability to develop oneself), interpersonal (i.e. working within interdisciplinary teams), informational (i.e. critical thinking, analysing information) and actional competences (i.e. decision-making, making things happen). Emphasis on decision-orientated cases, such as the traditional Harvard case, limits the development of students’ managerial competences. In the author-led written case, the student can gain considerable experience in knowledge and secondary experience. Harvard methods allow students to act in a classroom setting without the real-world challenge and stakeholders, which makes the learning experience somewhat scarce in actual business dynamics. In practice, real-world challenges do not take place in an isolated setting. Finding solutions to real-world challenges requires a broader set of managerial competences than traditional written format cases can offer. To create value through learning, student interaction with the case context and reflection on the experience are required.
Figure 1 – Key activities in the Real-life case process from the viewpoint of Instructor, Protagonist and Student.

Testing the approach: Value of Real-life cases compared to other types of cases

Data were collected from course participants immediately after completion of each case study and before starting the following case study. The data consisted of scores of the questionnaire described in the research methods section, with a 5-point Likert scale (1=strongly disagree, 5=strongly agree) being utilised for all items. Table 3 presents the analysis of participating students’ perceived value of the different case methods used in teaching during a course.

Table 3 – Mean (and standard deviation) of students’ perceived value of case methods post case study.

</tbody>
</table>

Note: (1=strongly disagree, 5=strongly agree)

The Real-life case method is associated with feeling more confident with the subject in general as a result of the case, the case helping students understand key concepts of the course and feeling confident in tackling related real-life problems. Overall, the Real-life case was considered more value adding by the participating students. Although there were some exceptions, the author-led JEQ case was considered overall as the most satisfying case and was thought of as equally intellectually stimulating as the Real-life case.

Based on our experiences, critical differences between real-life case and other forms of case teaching relate to preparation time, level of uncertainty and learning experience (Table 4).
### Table 4 – Differences of Real-life case compared to Harvard method, from the instructor’s perspective?

<table>
<thead>
<tr>
<th>Changes compared to Harvard case method</th>
<th>Reasoning</th>
</tr>
</thead>
</table>
| Instructor’s preparation time increases | Identify a fitting case company and protagonist.  
Plan schedule and get solid commitment from the protagonist.  
Agree on the scope of the case and student assignment.  
Support protagonist’s preparation e.g. writing the case brief by giving guidance and feedback (often iterative). |
| Uncertainty increases | **Protagonist**: depth of business knowledge, presentation skills, ability to answer questions, willingness and courage to share the (ugly) truth.  
**Case design**: estimation of student workload during the scoping phase, ease of applying course theories, students’ ability to relate (vs. instructor’s ability to understand the problem).  
**Teaching/learning interaction**: time usage in class both during the brief and student presentations, role of instructor vs. protagonist in giving feedback. |
| Learning experience increase | Unique case with no predefined right answer, i.e. honest opportunity to invent something novel.  
An appropriate amount of pressure due to the real client.  
Opportunity to experience how complex and messy situations are in real-life; problem definition alone can be tricky. |

It is particularly intriguing to evaluate the value of the proposed Real-life case approach. There are several factors which may help explain why the Real-life case method is an excellent case study approach for participants’ to gain value as learning and other value. First, a Real-life case involves the participation of a partner company, with a real-life challenge, changing variables and a deadline to meet. The challenge is not hypothetical, and students receive information directly from the real-life protagonist, rather than reading past accounts. From a students’ point of view:

*I would choose [real-life] case studies instead of theoretical approach, because cases make it easier to understand concepts and real-life examples are more interesting than plain theoretical frameworks. Also, cases help you to remember learnings.* (Student N.N. of the studied course)

Second, the dimension of the Real-life case as a learning experience is much deeper with the potential access to a large amount of real-life information from the partner company. From a student’s point of view:
Case studies are one of the best ways to support active learning by motivating students to implement their prior knowledge with the course material more deeply. I personally prefer this style of learning than just memorizing the materials to the exam. Case studies are real and broad enough to test students problem-solving skills. (Student M.M. of the studied course)

On a downside, it is equally possible that the partner company is not willing to disclose enough information for a successful case. In some cases it is difficult to check whether the protagonist is willing to share all relevant data and prior checks and promises might not realize in the classroom for a variety of reasons. Therefore, it might be reasonable to consider formal contracts and Non-Disclosure Agreements. Third, the Real-life case takes a different form every time it is taught, depending on the partner company, their challenge at hand and the current business environment in general. This way students do not get familiar with certain case types and generally accepted outcomes and decisions for the cases. Finally, a Real-life case scenario requires all the participants to get involved in addressing the challenge provided by the partner company. The sense of commitment towards the case is much higher when real-life stakeholders are involved and regular opportunities for face-to-face engagement are organised.

While it is important to note the relatively small sample size and focus only on a one-time teaching setting, the results of this study indicate that the use of a Real-life case contributes positively to increase the spectrum of case teaching methods and offers participants added value through real-life interaction.

Discussion
Contributions
The paper contributes primarily to the body of knowledge of teaching innovations in general and case method in particular. It offers novel insights on how case study teaching can be made more relevant to students and yield additional benefits to the case company in addition to the students and the instructor. The Real-life case builds on the live (teaching) case method (e.g. Elam and Spotts, 2004; Roth and Smith, 2009; Steiner and Laws, 2006) taking it even further to provide experiential learning that closely resembles real-life circumstances in companies. The method enables students to acquire capabilities around critical thinking, self-regulated working, project management, collaboration and other highly relevant work-life skills that the Harvard case method may not fully support. The paper is an initial attempt to explicate the roles and additional value of Real-life case method and is limited to the context and data set of the study. Future research is encouraged to explore how the method could be applied in other contexts and to compare it with alternative teaching methods.

Limitations of Real-life case method
It is important to identify possible shortcomings and risks related to Real-life cases, in addition to the many opportunities. First, the context of education should be considered carefully before the possible application of the method. Real-life cases require skills in scoping and designing the education process from the instructor, while students need skills in tackling difficult challenges and fuzzy problems. Further, first-year undergraduates may struggle due to having little understanding of the field or in case if lacking the motivation to engage in a somewhat challenging learning experience. Second, there are additional risks in relying on a company protagonist to deliver the case live in class, particularly related to reduced possibilities for the instructor to control delivery. As
a result, some company protagonists may take more time in delivering the case or experience other challenges due to a lack of teaching experience. Accordingly, the authors suggest selecting the protagonist carefully and prefer a person with whom the instructor has prior experience. On the positive side, a Real-life case is always delivered for the first time and has good chances of success through thorough preparations. On the other hand, the Harvard case method seems to require experience of delivering the particular case several times to realize the full value potential.

Abstract

This paper presents the development and pilot testing of a board game for education and training in Industry 4.0. The game main goals are to improve participants understanding of I4.0 design principles, of the relationships among technologies-equipment-departments and to enable them to experience the transition process towards I4.0. Three pilot tests of the board game were carried out. Participants indicated the game is successful in improving their understanding of the link between I4.0 principles and company’s objectives as well as of the I4.0-related technologies. Overall, the board game was a suitable learning tool to foster I4.0 education.

Keywords: Industry 4.0, Gamification, Education.

Introduction

The recent disruptive technological advancements and their industrial applications such as factory digitalization, smart objects lead to the expectation of an unfolding fourth industrial revolution, coined as Industry 4.0 – I4.0 (Lasi et al., 2014). In this context, researchers have been discussing education and training requirements for this new paradigm (Abele et al., 2015; Paravizo et al., 2018). To address this need, we developed a board game connecting key concepts and technologies related to the transition process towards I4.0. As such, we had to integrate a conceptual body of knowledge in I4.0, define a learning strategy and develop a learning tool.
Many researchers have discussed the core characteristics of I4.0 and what it can mean for the development of industry (Kagermann, Wolf-Dieter and Wolfgang, 2011; Hermann, Pentek and Otto, 2016; Qin, Liu and Grosvenor, 2016; Roblek, Meško and Krapež, 2016). One proposition by Hermann, Pentek and Otto (2016) claims that designing and developing factories towards I4.0 depends on 6 design principles to succeed. They provide a systematization of knowledge, aid the understanding of what should constitute I4.0, support practitioners in developing solutions and, in an academic perspective, are the foundation of the design theory. Within the context of this paper (and more broadly the research project conducted by the authors) we have adopted Hermann, Pentek and Otto (2016) proposition of six design principles: interoperability, decentralization, virtualization, real-time capability, modularity and service orientation.

In line with (Qin, Liu and Grosvenor, 2016) we consider interoperability as the ability to employ different machines and equipment to perform the same task (even if they are from different vendors), fostering the creation of intercommunication and trusted networks which enable I4.0 development. Decentralization is related to the capacitation of local actors (companies, professionals or machines) to make decisions with more flexibility, employing specialized knowledge, aiming to achieve a decentralized self-organization (Roblek, Meško and Krapež, 2016). The virtualization principle is highly related to the achievement of a virtual twin that gathers the data collected across the factory to virtual plant model, supporting operations’ control, simulation and optimization (Schuh et al., 2011). Real-time capability is linked to the responsiveness of companies’ operations which is enabled by the continuous data flow and analysis leading to impact throughout the company roles and functions (Verrière and Quenedey, 2012). Modularity is related to the development of modular, flexible systems, that are able to adapt to changing factors by incorporating or replacing production modules, which could also benefit from an interoperability standpoint (Qin, Liu and Grosvenor, 2016). The service orientation principle is enabled by I4.0 ability to collect and analyze large amounts of data, in real-time, which facilitates the provision of product-service systems (Demirkan and Spohrer, 2016).

After selecting the six principles as a basis, an ongoing literature review pointed towards other key concepts associated to I4.0, Internet of Things (IoT) and Cyber-Physical systems (CPS). The former being considered as a key enabler of I4.0 through the multitude of sensors and communication routines possible (Kagermann, Wahlster and Helbig, 2013) and the latter regarded as the integration between physical process and computations interacting in closed feedback loops (Lee, 2008).

As the design principles were made to achieve the full potential of I4.0, the lack of knowledge on how to work within this new context can lead to unnecessary risks and worse results, be it on the economic, environmental or social spheres. From these design principles, we can derive that the increased integration of technology will lead to a decrease in direct control for the leadership, and, as proposed by the authors (Hermann, Pentek and Otto, 2016), this is a positive effect directly related to decentralization and real time capability, which can contrast with traditional thinking.

Regarding the learning strategy, among the many developments and innovative approaches designed for improving teaching and learning of many subjects, the use of games – both virtual and physical – is increasingly popular (Connolly et al., 2012; Qian and Clark, 2016). As key advantages, games have a positive effect on motivation and place the learner in a more active role, in comparison to more traditional methods, and have been increasingly used as learning tools (Qian and Clark, 2016). Regarding topics on sustainability and circular economy researchers have employed both digital learning environments and board games (Despeisse, 2018; Whalen et al., 2018). Furthermore, the
benefits of educational games in industrial engineering education have also been discussed (Braghirolli et al., 2016).

Considering the lack of active tools to facilitate the learning of I4.0, this paper reports the development and initial tests of a board game for I4.0 developed to bridge this gap. In the next sessions, we summarize the methodology, detail the board game (BG i4.0) development process; the preliminary tests performed and conclude highlighting the potential benefits and shortcomings of this board game.

**Methodology**
The development of the board game can be divided into three steps: content, game development and testing.

The first step was building a body of knowledge and identifying the most important concepts about I4.0. After the evaluation of the most cited articles, we have selected the six design principles proposed by Hermann, Pentek and Otto (2016) for their scientific impact and practicality, since these principles can be translated into industrial decisions. The rest of the literature was not discarded, with many other articles being used to select key technologies, understand their relation and enhance the concepts present in the game.

After the definition of an initial body of knowledge, the main learning goals of the BG i4.0 were defined as:

- Understanding the design principles of I4.0 that enable achieving its potential;
- Understanding the relationships among the I4.0 design principles and industrial developments. These developments represent technologies, machines, production methods and industrial departments;
- Enabling participants to experience the transition process towards I4.0 (i.e. I4.0 is not something that is simply bought and installed in the company).

The second step was realizing the development of the board game, following game design and gamification theories (Werbach and Hunter, 2012; Schell, 2014). A board game was chosen as the medium for such educational resource due to its tangible and social aspect. An initial analysis of several commercial games of wide renown (e.g. Settlers of Catan, 7 Wonders, Puerto Rico, Project Gaia) served as inspiration to the BG I4.0 design process especially due to their gameplay mechanics, such as resource management, and aesthetics.

The third step was testing the game and collecting feedback for further improvements. These tests have been divided into two types: workshops – focusing on the development of the game; pilot test – for testing of the current prototype. The workshop and pilot test and their results are further discussed in their own section.

The tests results are then used to review both the game content and the mechanics. This interactive approach during the workshops allowed for direct input from the participants while the iterative approach between pilot tests allowed to infer on the current functioning of the presented prototypes and external feedback.

**Selection of game and gamification elements**
Following the game element hierarchy for gamification devised by Werbach and Hunter (2012), the main dynamics (high-level, abstract elements of the game) of the BG I4.0 are related to constraints (resolving trade-offs and facing limitations) and progression (players strive to grow and develop their companies). Regarding the mechanics (basic processes of the game) of the BG I4.0, the main ones are related to resource acquisition, turns, challenges, competition and win states. The components (specific implementations of game mechanics and dynamics) of the BG I4.0, that were devised to enable the learning goals are detailed on Table 1.
Table 1 – Game components and their relationship to the learning goals of the BG I4.0

Overview of the BG I4.0 gameplay

The BG i4.0 is played in teams (usually two people per team) which are in charge of an existing factory with basic equipment, technology and departments. At the beginning of the game each team receive two random objective cards that mimic strategic planning directions which they should strive to achieve by the end of the 3 rounds of the game.

During each round, players can use resources and money to buy developments (machines, equipment and technologies), hire workers or advance in competencies development tracks. By the end of each round, players produce goods (based on the productive capacity of their factories) and thus earn money to subsidize the next round of investments. After the third round, players count how many Victory Points (VP) they got...
which depends on the goals they achieved, the developments and design principles, the number of workers they have, how far along the competencies track they got and their money.

Victory points attempt to reward players for achieving improving their factory results according to their objectives; these points emulate predicted success factors in I4.0. They reinforce the idea of not implementing technology for its own sake, but according to the company’s strategic objectives. At the end of the game, the team with the most VPs wins.

After finishing the game session, a collective discussion of the underlying concepts of I4.0 and their application in the game is conducted to deepen participants understanding of I4.0 and clarify any doubts and questions they may have. During this discussion, facilitators emphasize that the VPs are not the end goal (since they try to translate a set of complex, intertwined decisions in a simplified way), so the main takeaway are the discussions and learning had throughout the game.

Validation Workshops
In the course of developing the BG i4.0, we conducted several internal and external tests and workshops. The internal workshops focused on the game design, discussing content, mechanics and overall experience to improve and refine the game. The external tests focused on pilot testing the most current version of the game to gather insight from participants and assessing gameplay performance and participants’ learning. Table 2 provides an overview of the workshops and pilot tests and Figure 1 shows these workshops.

The final list of components that are part of the current prototype includes individual (teams) game boards, a central board (market), workers’ pawns, objective cards, developments (machines/technologies) cards, money tokens, rules leaflet, events cards, a competencies development tracks board and a website with the additional resources for participants.

![Figure 1 – Validation workshops and pilot tests of the BG i4.0](image)

**Pilot Tests**

The pilot tests were structured in such a way that participants answered a brief questionnaire before the session and another afterwards. The first questionnaire aimed to get an overall understanding of participants perception of their own knowledge of I4.0 and its related concepts. The second questionnaire inquired participants of their background, if they felt the game helped them in achieving a better understanding of I4.0 and related concepts, as well as usability aspects, their familiarity with boardgames in general and had an open-ended question so participants could freely comment on their overall experience. All participants consented to take part in the study.

In this section, we are going to present results from the pilot tests (in terms of teams’ performance) and responses from the feedback questionnaire. Figure 2 shows the evolution of money (revenue) accrued by teams in each phase of the game, in the three pilot tests (PT). Figure 3 shows the distribution of the VP each team got in the three PTs.
Figure 2 – Evolution of the money received by each team throughout the phases of the pilot tests. Pink – Phase 1, Orange – Phase 2, Blue – Phase 3.

In total, in the 3 pilot tests held, 18 unique participants took part in the BG I4.0. One of the participants of the pilot test three did not answer the pre-questionnaire and was taken out of the response pool. Thus, the final respondents’ sample is 17. In the post-pilot test questionnaire, participants were asked about their perception on the learning of the I4.0 topic they experienced through the game. The questions were presented as 5-point
Likert scale, ranging from “Completely agree” to “Completely disagree”. An overview of the answers for this question is shown in Figure 4.

![Figure 4](image)

**Figure 4 – Participants answers for the I4.0 understanding questions.**

In the feedback questionnaire answered after the pilot test session, participants were prompted to comment on the positive aspects of the game and the areas in which it could be improved. These comments were analysed following the general inductive approach for qualitative data analysis (Thomas, 2006). Out of the 17 comments written by the participants a total of 57 segments were coded to 1 of 20 codes which were divided in two main categories (positive and “can improve” aspects). An overview of the 8 most recurrent codes (accounting for 71% of the segments coded) is provided on Table 3.

**Table 3 – Participants’ comments analysis overview**

**Discussion**

Regarding team’s performance shown in Figures 2 and 3, it is possible to see that their income at the end of each game phase can vary significantly. Despite being a strong factor influencing teams’ performance, money is not the only factor for winning the game. For
instance, in the pilot test 3, the winner team was not the richest. Additionally, the money received in the third phase of the game, for 7 out of the 12 teams, counterintuitively, decreased. This could be due to teams’ increased investments that enable future higher incomes or technological infrastructure, but not in production elements that use that infrastructure. The VPs distribution shows, on average, that roughly 53% of teams’ VPs were obtained for achieving objectives, advances and for the money left at the end of the game, which is in line with the learning goals of the BG I4.0.

As shown in Figure 4, the most undisputed questions are those related to the “understanding the need for aligning the I4.0 principles to company objectives” and “increased understanding of the I4.0-related technologies”, with 88% and 94% of the participants indicating they agree or completely agree, respectively.

Furthermore, from participants comments, the most recurrent topics highlighted were related to an overall good impression of the game (17,3%), to the understanding of general I4.0 aspects (13,4%). Some areas of improvement indicated in participants’ comments were related to the duration of the workshop (9,6%), too short for the game as it is, and the need for an overview of I4.0 concepts before the game (7,6%). Some examples of participants’ comments in these categories are: “The evolution structure is very good; the game is thrilling and fulfils the goal to increase learning” – Pilot Test 2 participant; “I loved the depth on the theme that the game had” – Pilot Test 1 participant. “Maybe the duration of the game didn’t allow a deeper discussion of the correlation between the objectives, advances, developments and resources” – Pilot Test 3 participant; “Concepts need to be presented for longer time for them to be completely absorbed”.

Conclusion
Novel approaches for education and training in the field of operations management and engineering are increasingly popular. We report the development of a board game for teaching the design principles of I4.0. Throughout the design workshops the board game evolved significantly. The inputs received in the pilot tests are the last input for guiding the final improvements of the BG I4.0 that are already underway. The final version will be available for being used in a variety of contexts.

The iterative and interactive development of the board game for I4.0 education enabled the research team to identify and address a series of issues in terms of gameplay and mechanics. Overall, in the pilot tests, the game achieved its main learning goals of improving participants understanding of I4.0 principles, the relationships among the technologies, machines and departments and the transition process of I4.0.

Future applications of the final BG I4.0 in different contexts (technical courses, universities and companies) will be necessary to validate the final version of the game and provide further insight in the Industry 4.0 education particularities.

Enabling problem-based education in collaboration with manufacturing companies

Staffan Andersson (Staffan.andersson@mdh.se)

Erik Flores-Garcia

Jessica Bruch
Department of Innovation and Product Realization, Mälardalen University, Sweden

Abstract

A focus on problem-based education is crucial as students need to complement academic knowledge with real-life projects. Several concepts in problem-based education have been tried over the years with focus on preparing students for working life. This paper aims at creating a list of recommendation on how to enable learning in problem-based education. To do so, we collect data in a problem-based course at Mälardalen University in Sweden. The resulting list of recommendations contributes with guidelines on what to do, and what to avid to successfully enable learning in problem-based education.

Keywords: Problem-based Learning, Production System Development, Education

Introduction

Problem-based courses has been on the agenda as an opportunity for real-life situated learning for many years (Brown Sr. and Brown Jr., 1997). Literature claims that problem-based learning is an important enabler of the way Operation Management (OM) students transition to working life, yet executing this type of courses places strains on actors compared to traditional courses at universities (Brown Sr. and Brown Jr., 1997; Nielsen, 2004; Bennis and O’Toole, 2005; Bak and Boulocher-Passet, 2013; Gorman, 2018). Therefore, the purpose of this paper is to present a list of recommendation to enable learning in problem-based education with real-life manufacturing company student projects. This paper analyses problem-based education from the perspective of three actors, students, companies and facilitators in an OM university course for engineering students. To reach this, we formulate the following research question: how can challenges in problem-based education be approached to enable learning in OM course? For the purpose of this paper, problem-based education means that students gain professional experience in a real-life setting to improve abilities to solve complex interdisciplinary problems and to learn how to communicate and collaborate with companies (Brown Sr. and Brown Jr., 1997; Nielsen, 2004). Teachers in problem-based courses has a facilitating role rather than exclusively giving lectures (Gorman, 2018), subsequently teachers are referred to as facilitators in this paper.

In problem-based courses, facilitators and companies experience challenges in time-consuming preparations starting months before the course starts, including the demanding phase of defining and scoping student projects, and setting up schedules (Gorman, 2010,
The actors, having intense interactions throughout the student project, are interdependent which requires the facilitator to manage the collaboration between companies and during the course (Nielsen, 2004; Bak and Boulocher-Passet, 2013; Gorman, 2018). Assessing the problems and challenges associated with problem-based leaning is an open issue in preparing students for working life (Bak and Boulocher-Passet, 2013). Contributing to existing problem-based literature, this paper presents three novel contributions by a list of recommendations providing, firstly approaches to managing problem-based courses, secondly present what to avoid in problem-based courses. Finally, the contributions are based on data collected from a course in OM.

**Problem-based education in literature**

In the review of problem-based education by Gorman (2018) indicate that the facilitators require a longer period of preparations for the course, for instance by undertaking a solicitation phase. Finding challenging and new student projects requires redoing the solicitation phase each year which is time-consuming compared to standardised lectures in other courses (Gorman, 2018; Konrad, 2018). Several contacts with companies need to be established, especially as the rate of accepted student projects from companies can be as low as 60% (Gorman, 2018). However, well-established industrial contacts are likely to come back for several years with new student projects easing up the workload for the facilitator. The student projects are scoped to include both the industrial partner’s criteria, academic requirements and to make sure that the student projects are attainable for the time given in the course. Preparations are also made to ensure that student groups are formed and assigned to a case (Bak and Boulocher-Passet, 2013; Gorman, 2018).

According to Gorman (2018), the actors involved in a field-based course, students, company and facilitators experience challenges and benefits from participating in courses with real-life student projects. Companies that are unable to sustain the level of involvement and support required for the student project is risking the student project to miss the intended project or learning goals (Bak and Boulocher-Passet, 2013). Nevertheless, the learning experience from a student and academic perspective is still valuable (Gorman, 2018). The student projects ambiguity is considered to be a risk in that students can experience that the project is overwhelming and require more time than the course stipulates (Bak and Boulocher-Passet, 2013). A rigours project selection process done by the facilitator give the students direction on how to approach the student project. With further guidance on standardised documentation, grading and continuous facilitation, these risks can be limited. Facilitation can include supporting student groups to narrow the scope and clarify goals of the project (Gorman, 2018).

In problem-based education, the facilitator experience a risk in student projects as course ambiguity can results in an intense level of student group supervision, resulting in time-consuming activates (Bak and Boulocher-Passet, 2013). A release of time and resource of the facilitator can be achieved when student projects are self-managed and supported by the facilitator. Thereby being a learning opportunity in project management (Gorman, 2018). Furthermore, facilitators perform a tedious company solicitation and promotion, which requires business area acquaintance and contacts (Bak and Boulocher-Passet, 2013). Approaching companies on-site and creating groups of industrial partners as a long-term strategy can minimise the risks involved with solicitation. Indeed, resource shortage in the course can be addressed by increasing the credit scope of the course (Gorman, 2018). Finally, from a company perspective, there are risks associated with course participation as the resources required are challenging to estimate, especially in regards to the requirements of academic courses and expectations of student skills (Bak
and Boulocher-Passet, 2013). Generating a schedule and assigning supervisors, often experts, is challenging in a problem-based student project. The facilitator carefully communicating expectations to the company, such as course outline and schedule, can limit the aforementioned risks (Gorman, 2018).

**Methodology**

The purpose of this paper was fulfilled by analysing course evaluations and performing observations before, during and after a problem-based course. Initially, a literature review was conducted by searching databases such as Scopus and Emerald Insight with keywords like; ‘teachings and learnings AND organisational management’, ‘Field-based education’ and ‘problem-based education AND organisational management’. Data was collected from problem-based course industrial excellence at Mälardalen University (MDH) in Sweden from year 2018 by observations, investigating course evaluations, facilitator’s self-evaluation as well as conducting field studies by writing notes when visiting companies. The data was analysed in a seven-step process including both individual analysis as well as joint analysis sessions, see Figure 1. The purpose of step one through three was for the authors to individually analyse the data in terms of categories, perceived course dynamic based on the categories and to identify interrelationships of the aforementioned. Finally, in step four through six the authors compared results, presented an initial set of recommendation and supported findings with literature. The analysis was scrutinised iteratively to ensure reliability in the list of recommendation.

![Figure 1 - Analysis Process](image)

**Mälardalen University**

MDH is a public university college in Sweden, located in the cities of Eskilstuna and Västerås. MDH has a student body of 16 000 students in undergraduate programs ranging from two to five years of education. In the field of OM, MDH is concerned with education and research necessary for developing new products, services and production systems in a technically leading, economically viable, and environmentally sustainable way. MDH offers its production engineering students problem-base courses related to the development of production systems. In addition, students of this program take OM courses that help contextualise the development of production systems during their education. This program requires all production engineering students to pass the problem-based course industrial excellence. In this course, students meet twice a week for three-hour sessions during 16 weeks. On average 20 students, in their fourth or fifth year of education, attend the course every year. Student composition includes diverse nationalities with about a third of students from abroad and students with different background (product or production specialisation). Course industrial excellence has been
Problem-based education at Mälardalen University

The problem-based course industrial excellence includes collaboration with five to six companies ranging in size from small to large manufacturing companies. The aim of this course is to give students a deeper understanding of how to apply knowledge from the field of OM and improve industrial processes. The course includes three tasks: understanding the competitive priorities reflected in a production system, analysing the steps involved in the development of a production system, and proposing an improvement to a production system based on Discrete Event Simulation. In addition, students analyse literature in areas manufacturing strategy, production system development and discrete event simulation in OM individually, and participate in a four student project during the course. Company representatives and course facilitators select and define a project and a schedule of at least three on-site student meetings is decided. In this project, student teams visit a company on at least three occasions to understand the problem, collect data and clarify or present partial results.

During the execution of the course, course facilitators provide lectures, supervisions, and feedback supporting students in their project. Students visit the company continuously and the companies are expected to support the students throughout the course. Furthermore, the facilitator require the students to present project status in set milestones as well as facilitating the projects and company collaboration.

At the end of the course, student teams submit an academic report to course facilitators and companies, and present their results to other student teams and companies. Collaboration with companies occurs in three phases including preparation, execution, and follow up. These phases occur prior, during, and after course industrial excellence respectively, and include different activities for each of the actors involved in the course (i.e. students, companies, and facilitators).

Analysis of problem-based education
This section describes the activities of the three actors in course industrial excellence (i.e. students, course facilitators, and companies) during the preparation, execution, and follow-up phases. In addition, this section presents a classification of strengths, weaknesses, opportunities, and strengths as perceived by students, course facilitators, and company representatives according to Osita et al. (2014). Correspondingly, strengths are characteristics of the course that gives it advantages over other courses to prepare engineering students for real life problems. Weaknesses are characteristics of the course that places the course at a disadvantage relative in preparing engineering students for real life problems. Opportunities means elements in the environment that the course could exploit to its advantage in preparing engineering students for real life problems. Finally, Threats are elements in the environment that the course could cause trouble in preparing engineering students for real life problems. In Table 1 - 3, the SWOT’s are presented by abbreviations, thus only S, W, O and T are seen in the table. Each activity can contain one or all of the SWOT’s depending on its analysed impact on the course.

Preparation phase
For the facilitators, the preparation phase consumes a generous amount of time and effort, similar to that of companies. Initially, visiting companies to find projects entails several meetings with company representatives that are either known by the facilitator, or new companies. As some visits ends without a project being formulated, this activity requires several iterations. However, time spent on visits ensure that the students projects are offered for five years in its current form.
tailored to the course and that the projects are indeed a real issue for the companies. Facilitators and company representatives analyze that these projects may be achieved within the duration of the course. Evaluation of student projects is a time-consuming, but the benefits are front-loaded activates and, the companies are able to see the project from a new angle by iterating cooperatively with the facilitator. The activities in the preparation phase are on the other hand, experienced as demanding and time-consuming. For instance, taking time off daily operations to define a student project, collect data, and later supervise students and evaluate results of the student project. Time spent on the preparation activities ensure clearer problem definition, purposefulness of visits and a manageable student project as well as student in-depth problem solving. Additionally, the iterative approach of defining the problem together with the facilitators is a learning experience regarding the company’s ability to form student projects, see Table 1.

**Execution phase**
The role of the facilitator comes with challenges in managing the diversity in student
projects as well as addressing company-student collaboration issues. Time spent on this effort have benefits in academic results, solution fit to companies as well as in evaluating students. A set of course milestones support facilitating the student projects in a structured and controlled manner. Preparing students for the project creates a common view of the project, and how to approach the problem but also how to communicate with companies. Preparation by lectures and, especially, the individual assignment give the student a preconception of the topic at hand. The individual assignment, being a literature review on a topic related to the project, is demanding but the knowledge is useful for both project execution and report writing, see Table 2.

Students report that course industrial excellence is challenging and time-consuming when compared to courses that do not include a problem-based approach. For instance, “the workload was very high”, and “[the course is] tough, but the experience could not be provided anywhere else”. In addition, students report that the course is worthwhile as it leads insights about problems faced by manufacturing companies, and collaboration with companies in solving problems. Working closely with the companies is identified as an opportunity to learn about problem-based projects and how to manage, re-define, and execute the projects at companies. However, contact persons at the companies can be difficult to contact due to hectic schedules. Presenting results to a company provide students with communications skills and students “have learned how to communicate results directly to a company [...]”. Companies can however, fail to attend the university presentations and focus on on-site presentation at the company. Student report benefits in learning self-management and group work, “You learned to plan and work on your own and in a group” and to manage project setbacks, “I learned how to make the best out of a situation”. Furthermore, defining and adjusting the problem is a challenging task for students, but it is nonetheless an opportunity to learn about how production system-related problems are managed in real-life. Additionally, the opportunity to meet and learn about future employers is expressed as a strengths of the course, for instance, “I would recommend it [the course] for learning about simulation and get company contacts”, as one student said. Finally, students express that “the teachers [facilitators] helpt us a lot” and “the course was structured and planned” giving the students an opportunity to focus on project delivery.

From an academic perspective, students found that the assignments in the course add to the demand and time limitations of the course. However, improvement in writing and presenting complex problems in an academic way are identified as important learnings from the course. For instance, “I learned a lot about manufacturing strategy, production system development and discrete event simulation. [...] I learned to manage my time better and where my flaws are when delivering and finishing assignments, that is very valuable to me”. Additionally, thesis preparation and managing a project are perceived as major learning outcomes. Student’s experiences show that there is “a lot of time spent on writing” in the course, but the assignments contributed to the student’s “improvement on writing a literature review and connecting it to analysis” and to “learn how to write a report and prepare for thesis”. The assignments furthermore contributed to learning by “[...] discussions among the group and teachers [facilitators] to get insight and perspective”. For details, see Table 2.

The company’s participation is planned to minimise the companies time in the course by only having three mandatory student meetings. This does however require the companies to make preparations prior to the meetings. Companies experience that the planned meetings are controllable, but some projects require adjustments and, the supervisor need to add more time to the project. On the other hand, the opportunity to evaluate students as future employees or potential thesis workers is seen as a major benefit
when collaborating continuously with students in several course activates. As a result, master theses can be developed as a continuum on the student’s project, allowing the company to continue working with the students that performed satisfactorily. Finally, the execution phase provide the company with insights on student ability to understand and solve complex production system problems, see Table 2 for details.

<table>
<thead>
<tr>
<th>Activity</th>
<th>SWOT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confirm student projects with companies</td>
<td>S – Securing final projects and ensure that resources are in place&lt;br&gt;W – Time-consuming task due to many projects&lt;br&gt;O - Increase collaboration with companies, companies learn about academic viewpoint in project (also Gorman, 2018)</td>
</tr>
<tr>
<td>Act as student project facilitator</td>
<td>S – Quality in student project execution is increased&lt;br&gt;W – Many issues have to be addressed in project groups (also Gorman, 2018)&lt;br&gt;O – Gain insight on student project management and ability to adjust projects that are off-track (also Gorman, 2018)&lt;br&gt;T – Time-consuming task</td>
</tr>
<tr>
<td>Supervision for individual and group assignments</td>
<td>S – Set deadlines facilitates report and assignment deliveries, progress can be monitored&lt;br&gt;O – Support students in project execution&lt;br&gt;T – Due to many project, each student project have specific challenges and prerequisites that need consideration/suppor</td>
</tr>
<tr>
<td>Solve student project group dynamic issues</td>
<td>S – Ability to combat issues hands-on as they arise&lt;br&gt;W – Time-consuming, each student project is different&lt;br&gt;O – Learn from issues to develop course/project outline</td>
</tr>
<tr>
<td>Solve issues related to company-student collaboration</td>
<td>S – Issues can be managed instantly – adjusting project etc.&lt;br&gt;W – Time-consuming (also Gorman, 2018)&lt;br&gt;O – Show companies and students that they are supported&lt;br&gt;T – Issues can be difficult to manage</td>
</tr>
<tr>
<td>Grading of individual assignment and student project</td>
<td>S – Teach students how to write and read articles – preparation for report and thesis&lt;br&gt;W – Each project is unique, hence a common grading system is not entirely possible&lt;br&gt;O – Identify good students for future thesis or PhD positions</td>
</tr>
<tr>
<td>Meet students 3 times for: Workshop, interviews and complementary data collection</td>
<td>S – Time spent is limited and controlled, little time needed for supervision&lt;br&gt;W – In some projects, more time is needed to form and support student project&lt;br&gt;O – To get to know students and evaluate them&lt;br&gt;T – Supervisor might become unavailable on predetermined times due to daily operations</td>
</tr>
<tr>
<td>Provide feedback to students</td>
<td>S - To follow student project and address issues, gain insight on student project&lt;br&gt;O - Learn how students work and perform, gain insight on novel student project solutions&lt;br&gt;T - Might be considered time-consuming (also Gorman, 2018)</td>
</tr>
<tr>
<td>Provide additional data for student project</td>
<td>S – Support project for better execution and results&lt;br&gt;W – Can be time-consuming, expertise might be needed&lt;br&gt;T – Time and experienced personnel might not be available for a one-case problem-based courses</td>
</tr>
<tr>
<td>Participate in final presentation of student project</td>
<td>S – Gain insight on project results, gain novel knowledge on current issues&lt;br&gt;W – Can be challenging to interpret academic results&lt;br&gt;O – Find potential candidates for employment – based in project execution&lt;br&gt;T – results might not reach expectations, or be too far from initial problem statement</td>
</tr>
<tr>
<td>Active participation in student project</td>
<td>S – Effective groups, collaborative learning experience, learn self-management&lt;br&gt;W – Can be time-consuming due to group meetings and company visits&lt;br&gt;O – Learn how to work with problem-based project on academic and company approach (also Gorman, 2018)</td>
</tr>
<tr>
<td>Deliverables for Supervision and milestones</td>
<td>S – Deliverables ensure that sub-targets are met, and finally the report&lt;br&gt;W – Students feel pressured to deliver continuously throughout the course&lt;br&gt;O – Learn about problem-based project, and managing deadlines&lt;br&gt;T – Students might skip supervision due to high workload, thus lose learning opportunities</td>
</tr>
<tr>
<td>Write an individual assignment on provided subject (in PSD)</td>
<td>S – Learn about topics relevant for project&lt;br&gt;W – A lot of reading and writing is expected&lt;br&gt;O – Become a better academic writer, preparation for full report&lt;br&gt;T – Students can experience high demands for a passing grade (also Gorman 2018)</td>
</tr>
<tr>
<td>Adjust problem for student project</td>
<td>S – Opportunity to collaborate with companies and gain insight on how to limit and adjust projects (also Gorman, 2018)&lt;br&gt;W – Challenging to balance academic and industry expectations (also Gorman, 2018)&lt;br&gt;O – Learn much about production system projects and problem-based projects in production companies&lt;br&gt;T – Overwhelming amount of information can complicate this task&lt;br&gt;S – Learn to present results in a scientific way, preparation for thesis&lt;br&gt;O – Can view report to be “too academic”.&lt;br&gt;W – Companies can view report to be “too academic”.&lt;br&gt;O – Learn from feedback from company and facilitator on how to improve on writing and problem-based investigation&lt;br&gt;T -Students can experience these tasks to be demanding and time-consuming</td>
</tr>
<tr>
<td>Deliver individual assignment and student project</td>
<td>S – Learn how to present, and communicate, complex project results to both companies and academia (also Gorman, 2018)&lt;br&gt;W – Academic presentations can be considered too stiff and complicated for companies&lt;br&gt;O – To get feedback from both academia and companies on project management&lt;br&gt;T – Students can experience company presentation as a daunting undertaking</td>
</tr>
</tbody>
</table>

Follow-up phase
Taking time in the follow-up phase to speak with participating companies give valuable feedback to the facilitator in regards to updating the course curriculum as well as to form closer relationships with the companies in both research opportunities and in preparation for next year’s edition of the course. Feedback from companies is a valuable contribution on how to manage the partnering companies, student-company relationships and future versions of the course structure. Course evaluation from companies and students are indeed of high value in problem-based courses, as the learning environment need to be improved each year to enable students to focus on learning and collaboration rather than surrounding issues. Companies add current industrial issues to the curriculum, but also gain up-to-date knowledge on ongoing research in related areas. The final report and results contributes to the company with an outside perspective on the defined problem. However, as there are only a few points in time for collaboration, the companies might experience that the results does not match the initial student project. Nevertheless, continuous collaboration with the university and learnings from earlier student’s projects can increase the possibility of valuable end-results from the project when planning for next year’s student project. Additionally, student theses can spring from close collaboration. Details of the analysis can be seen in Table 3.

Table 3 – analysis of Follow-up phase in problem-based education

<table>
<thead>
<tr>
<th>Activity</th>
<th>SWOT</th>
</tr>

</table>

Contributions and Discussion
This study contributes to previous research by providing a list of recommendations on how to enable a problem-based course, to do so we focus on three distinct points in time, preparation, execution and follow-up. This paper provide insight on outstanding challenges that hinders problem-based education. Furthermore, actions have been identified that can be taken to avoid the aforementioned challenges.

A novel contribution presented in the paper shows that the preparation phase in general is a prerequisite for successfully enable learning in problem-based education (Bak and Boulocher-Passet, 2013; Gorman, 2018). Efforts in this phase ensure that students can focus on problem solving, problem solving and achieving academic goals. Gorman (2018) suggested that this phase should be in focus, however, we present the novel finding
that company data collection is necessary to ensure that the student projects can get a short start-up and focus on problem solving. We presented that the individual assignment in course industrial excellence support the students in learning about subjects related to OM in general, but manufacturing strategy, production system development and discrete event simulation specifically. Additionally, the individual assignment prepare the students understanding of the company’s context, which contribute to their ability to understand the current challenges. This paper suggest that the companies should be presented with a clear understanding of the course schedule and curriculum (Nielsen, 2004; Bak and Boulocher-Passet, 2013; Gorman, 2018) but going further, we suggest that a predefined set of student company visits should be decided. Three company visits during the course have been proven as a success factor for enabling students to focus on learning and problem solving and the companies to be able to manage the timeframe for the project. Finally, we contribute with a course structure consisting of a set of milestones throughout the course. The milestones gives the facilitator an opportunity to determine student project status and address issues in student group or student-company collaboration, whereas students have clear deadlines and can get support from the facilitator. In Table 4, a complete list of recommendations and what to avoid is presented, thereby answering the RQ: how can challenges in problem-based education be approached to enable learning in OM course?. The list contains all actors, but the focus is on what approaches are required from a facilitator’s perspective in relation to the course actors.

<table>
<thead>
<tr>
<th>Challenges</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Focus on long-term collaboration with companies</td>
<td>Keeping the company satisfied with student group performance, in delivered results and overall student and facilitator collaboration experience</td>

</tr>
<tr>
<td>What to Avoid</td>
<td></td>
</tr>
<tr>
<td>Giving companies leeway on timeframe</td>
<td>Companies can ignore students and prioritise daily operations</td>
</tr>
<tr>
<td>One time company projects</td>
<td>Companies on long-term collaboration learn how to scope projects and knows how to priorities project and reap benefits, simplifying the solicitation process.</td>
</tr>
<tr>
<td>Using last-minute project</td>
<td>Usually ill-defined, poorly scoped and companies have not realised the required time needed for project execution</td>
</tr>
<tr>
<td>Company secrecy</td>
<td>Students cannot use or present results in the course</td>
</tr>
<tr>
<td>Letting students create groups</td>
<td>Can have a negative effect on company-university collaboration due to low performing groups</td>
</tr>
</tbody>
</table>

**Conclusions**

The purpose of this paper was to present a list of recommendation to enable learning in problem-based education with real-life student projects. This have been achieved by a list of recommendations and what to avoid in problem-based education stemming from a thorough analysis of course industrial excellence at MDH. Indeed, the preparation phase was identified as the most challenging for company and facilitator, but the reword in learning outcome and manageable student projects for all actors is worth the time of preparations. This paper would have benefited additionally by collecting data on how companies prepare the student project to understand the underlying reasons for engaging...
in problem-based education. Additionally, an investigation of other courses in problem-based education, outside the production system development area, would have given an opportunity to compare data and verify results to strengthen our findings. For future research, we recommend additional courses in problem-based education to be investigate, and that companies should be more thoroughly investigated in order to understand how to engage them in problem-based education.

Enhancing Operations Management Learning Environment Through an Educational Big Data Analytic

Tarek Taha Kandil (egysms3@yahoo.co.uk)
Faculty of Business Administration Helwan University - Egypt

Abstract

The teaching and learning modularity in the higher education environment of business and management studies are of the view that there has to be a linkage between institutional work-experience and classroom educational instruction. The teaching value of supervised industrial work-experience has become an important component of well-planned teaching environment of the operation management studies in most universities. Recently, Higher education teaching models opened new line of teaching and learning researches relating to the analysis of teacher and student engagement and experiences within the learning management systems (LMSs). The framework proposed in this paper may be used for further studies in this area; for example, to study lecturer behaviour patterns as well.

In the current paper, Author presents a case study conducted at the High Colleges of technologies in The United Arab Emirates for four academic years started from 2015 to 2018, where the High colleges of Technologies HCTs used both the institutional work-experience and classroom educational instruction as a two mood of delivering the operation management modules. The obtained results are demonstrated using visual analytic techniques, and evaluated in order to detect trends and deficiencies in the use of the LMS by teacher, experts and students.

Keywords: Big Data Analytic, Management Learning Environment, learning management systems.

Introduction

The significant amount of data extracted from these platforms provide fundamental information that can aid both teachers and students in improving their educational goals. One of the main problems of data relating to the activity generated by users through the use of learning management systems (LMSs) is the large volume of data available in the teaching and learning environment, and the different formats of these data, particularly for the management of unstructured data (Azmi & Singh, 2015; B. Daniel, 2015; Elhoseny, Elhoseny, Riad, & Hassanien, 2018). The present study aims at designing and implementing an analytical framework based on educational big data technologies, the present study defines the following steps to design the framework (Bogarin, Cerezo, & Romero, 2018; B. Daniel, 2015; B. K. Daniel, 2019):
• Data pre-processing, by studying the data to be extracted from the LMS and its storage in a big data platform.
• Data analysis and identification of pattern recognition techniques that may provide value in the educational context.
• Presentation of the obtained results according to suitable visual analytics techniques and tools (Elhoseny et al., 2018).

The authors have considered data processing guided by e-learning analytics in the high college teaching and learning environment, both are learning analytics and visual (Elhoseny et al., 2018; Fathema, Shannon, & Ross, 2015). And it also aids the present work in data processing for discovering connections among students, teachers and the learning process, with the purpose of creating recommendations in the educational environment. The author proposes and analyses of the LMS data extracted from user events generated during four final complete academic years in all courses for the three learning modalities at the HCTs, amounting to 120 GB of data. The present paper evaluates whether the results obtained by applying a big data analytical framework to these LMS data aid in detecting tendencies and anomalies in the use of these platforms in any learning modality. Several on-campus degrees have been offered since 2001, and within the past five years, the HCTs have consolidated its teaching and learning offer with several degrees which teaching operation management in online and blended modalities. The present study uses The Sakai LMS1. Which has been considered as a resource management and collaborative platform for all of the training modalities (Elhoseny et al., 2018; Fathema et al., 2015; Grover, Chiang, Liang, & Zhang, 2018).

Related work
Using the LMS as an essential methodological tool in educational environment is the standard and generating new needs and fields of study to aid in the design of new analytical framework through the knowledge obtained from the LMS data. It provides a large volume of data, while also generating the need for intelligent tools integrated within the LMS that aid in their interpretation and provide feedback of this information. The identification of the student behaviour helps in developing new teaching methodologies that aid and improve both student and teacher performance by means of analysing the data provided by the LMS and other tools such as surveys (Huda et al., 2018; Kumar, Shankar, & Saravanaguru, 2019).

Recently the educational data produced by LMSs have increased considerably. Therefore, the current framework the new challenges faced by higher education institutions analysis techniques for LMS data must evolve and adapt. The Big data analytics offer the opportunity to reach a higher level in the use of LMS. Thus, it is possible to convert complex, unstructured data into actionable information, thereby aiding in identifying useful data and transforming it into valuable information for higher education institutions. Furthermore, the literatures demonstrated the benefit of applying big data techniques in higher education, such as, in which the student learning patterns were searched based on data extracted from forum tools integrated in massive open educational online courses (MOEOCs) (Huda et al., 2018; Limongelli, Lombardi, Marani, Sciarrone, & Temperini, 2016; Lochner, Conrad, & Graham, 2015; Miller, Ganster, & Griffis, 2018).

1 https://sakaiproject.org/.
Therefore, lecturers can make specific remarks based on the classification, while students can quickly find the required content. Then, a big data-based analysis and monitoring tool that implements a scoring system for students in the LMS. The score of the teaching and learning classrooms represents the student participation in learning activities, and low scores usually imply poor student achievements. Finally, demonstrated that interactions (Nakamura, de Oliveira, & Conte, 2017; Rodriguez & Da Cunha, 2018; Shin & Kang, 2015) with learning environments can be modelled and measured effectively. The framework evaluated the behaviour of students attending videoconferences by measuring their level of attention based on face and eye observation, using an attention-scoring model (Simović, 2018; Sin & Muthu, 2015; Zaharias & Pappas, 2016).

Our work extends this research line on the adoption of big data for analysing LMS data. The present study present a framework based on big data technologies to analyse large volumes of data from events generated in the use of every learning tool available in the Sakai LMS for the three main training modalities: on-campus, online and blended (De Mauro, Greco, Grimaldi, & Ritala, 2018; Grover et al., 2018; Kumar et al., 2019; Rodriguez & Da Cunha, 2018).

Figure 1 – Big data architecture for acquiring and storing Sakai data.
The proposed framework - on big data for analysing Sakai data

Data storage

In order to store the original working dataset in the Sakai LMS and extract it to a big data storage platform, a deep study related to the relevance of such tables with respect to study the student behaviour patterns were found to include the most important information for our study: Sakai_User, Sakai_Session and Sakai_Event. Among these data are session id, event id, event date, and context (the course in which the event occurred). Relationships exist among these three tables, so it is possible to query session and event data for any user. Once the data sources have been selected, the data are anonymized in order to protect personal information such as names and emails. Next, the data need to be transferred from the Sakai database to big data storage. To this end, a big data solution based on Azure HDInsight has been adopted, using its Hadoop distributed file system (HDFS) implementation. The tool used to transfer data from the Sakai database is Sqoop (Shin & Kang, 2015; Simović, 2018; Sin & Muthu, 2015; Zaharias & Pappas, 2016)

Methodology

The present study performs a quantitative analysis using HiveQL, which is the ad-hoc query system for Hive. With this analysis, we are able to calculate the following information items.

- Tool ranking: This analysis studies the tools that are used more by each student in each session. A session is defined as the time lapse for which a student is connected to the elearning platform. For each tool, we analyse the most-used events per tool. Moreover, during this process, we analyse the correlation between events in a session. This correlation will be used and analysed together with the Apriority algorithm. The purpose of this correlation process is to determine which events are related during the same session, in order to determine student behaviour patterns. Therefore, the Pearson correlation coefficient is calculated by means of a Hive function (Gorur, Sellar, & Steiner-Khamsi, 2018).
- Event ranking: This process analyses the events carried out by a student in each course, in order to identify not only the most frequent events in each course, but also the absence of certain events. It is aimed at detecting courses with high or low activity, along with a global ranking of events occurring in each training modality.
- Event trends: The intention of this query is to analyse the timeline related to events of interest in the e-learning platform (for example, an event for connection to Sakai), in order to identify certain significant cyclical patterns. By using the time series analysis technique offered by Hive, it is possible to identify periods with high or low activity in the e-learning platform (De Mauro et al., 2018).

Conclusion

---

These values are obtained using the methods provided by the MapReduce API and the capability of HDFS and Hive to handle this algorithm in a distributed manner (Fathema et al., 2015; Lochner et al., 2015).

The framework proposed in this paper may be used for further studies in this area; for example, to study lecturer behaviour patterns as well. It can also be employed in other fields, such as smart cars, to identify good (or poor) driver behaviours, or smart homes to study the energy usage of inhabitants.

**Limitations and Recommendation:**
The framework proposed can also be employed in other fields to identify good (or poor) driver behaviors, or smart homes to study the energy usage of inhabitants.

Abstract

A usual management task in organizations is decision-making, and some of the most important decisions made by business leaders involve ethical components. Our behavioral-ethics-field research explores the business students (BS) subconscious influence in the ethical decision-making processes applying cases reporting ethical dilemmas. A questionnaire with neutral or non-neutral images acting as subliminal stimuli was administered to 30+30 BS trying to find out about the ethical maturity level in decision-making processes and the subconscious influences in these decisions. Cognitive biases and BS metacognitive strategies were identified when non-neutral images were present. The effects of subconscious in BS ethical decision-making are discussed.

Keywords: Business students, Ethics education, Business Ethical decision-making biases

Introduction

After so many corporate scandals in the global economic scenario, research on ethical behaviour has progressively growing within the business general area. Ethical decision-making (EDM) has increasingly gained significance in the management literature (Tenbrunsel and Smith Crowe, 2008) and now a broad and consistent body of research exist, either with a theoretical or an empirical approach. Business scholars and social psychologists nowadays are dealing with the emotive, instinctive, and intuitive reactions importance in EDM process (Dane and Pratt, 2007) and it seems that these intuitive and emotional processes (the moral intuition expression) deeply and firstly influence the decision maker in such contexts (Provis, 2015). In contrast, conscious and rational processes (the moral reasoning expression) in such situations may instead occur in a later phase to offer a ‘rationale’ or a ‘sense’ for behaviors and decisions undertaken (Haidt 2001).

Findings of Damasio (1995) clearly point to the fact that emotions are part of the decision-making process and they are necessary to make the decision choice itself. Other studies show
a link between emotional intelligence and decision-making process (Lumina, Scott and Bulent, 2011) as well as a relation of decision-making process and analytical-intuitive style of decision making (Sarmány-Schuller, Kuračka, 2012). Murphy and Zajonc (1993) studied the influence of subliminal stimuli in the ethical decision. Other author’s evaluation addressing influence of subconscious in EDM in business find that under pressure, emotions rather than rationality affect the process of decision-making and without them, the decision would take a long time (Baron, Zhao and Miao, 2015).

The ethical decision-making in business, either as an intuitive process (moral intuition) or a traditional rational approach, might generate a conflict in a business strategic decision, between adding value and causing no damage. In fact, unethical behaviour might be a very attractive short cut to organisational success despite practice codes, regulation and social pressure (Bazerman and Tenbrunsel, 2011; De Cremer, 2010).

While the motivation for taking the most strategic decisions in business originates from various sources (such as competition, social responsibility, lost opportunity cost, sustainable policies, effect on resources, return on investment, image and brand impact, stakeholders, international policy), the final decision still resides with the main organizations’ decision-makers. These deciding managers seek and evaluate information and alternatives before concluding. However, do the unconscious thoughts of those individuals affect the EDM process when dealing with complex decisions, delaying the aware conscious experience?

Rather than deriving from conscious deliberation or cognition, the EDM is often drawn almost automatically. It is like an instinctive impulsion, rather than a reasoned or calculated inclination. This type of impetus is consistent with large bodies of research on the prevalence of powerful, instinctive drives whose origins (be they psychological, genetic, epigenetic, evolutionary, or environmental) tend to elude consciousness (Dijksterhuis and Aarts, 2010; McManus, 2016; Zeni, Buckley, Mumford and Griffith, 2016).

Ethical decisions involve learning and knowing what is correct or incorrect, and only then does a sustained decision addressing the circumstances in evaluation arise. However, the correct thing is not as easy to find as the business ethics literature appears to state. So, how to increase the next generation of managers’ consciousness towards sustainability and business ethics? Can ethics be taught and learned? EDM is an extreme learning-goal to achieve in BS formation because there is a latent BS tendency to instil a certain level of non-rationality into their decision-making when facing real business situations and it is deeply influenced by priming, subjectivity, and bias in one’s memory and feelings (Huang and Ho, 2018). Thus, cognitive biases resulting from BS subconscious influence the EDM processes.

In literature, the extent to which subjective feelings (as the ones related with political ideals aversion/sympathy) influence managers and EDM moral judgements remains unclear. This constitutes a gap, which we address. This, along with the significance of EDM education in Business Schools, and the importance of subconscious in EDM of business students, who will be future managers, makes room to the following research questions:

**RQ1. Are BS able to apply moral principles to business ethics issues in sustainability or corporate responsibility?**

**RQ2. Do subliminally presented stimulus influence ethical decision making in BS?**

With these questions in mind, the purpose of our exploratory research is to identify biases in BS perceptions (under subliminal stimuli) and ethical decisions towards business ethics and sustainable operations in cases reporting ethical dilemmas. The chosen analysis tool utilized is an adaptation of the one developed by Brenner and Molander (1977).
Literature review

Ethics in business world

Ethics is an “inquiry into the nature and grounds of morality where the term morality is taken to mean moral judgments, standards and rules of conduct” (Hunt and Vitell, 1988). It deals with what is morally correct and incorrect. In business, ethics embraces not only the moral values and responsibilities of the profession itself, but also the existing values and expectations of the larger society (Michael, 2006). Considering business ethics (BE) all decisions should be made, taken and defended based on underlying moral philosophy and these moral philosophies present guidelines that allow both, conflicts resolution and the optimization of mutual benefit of people living in groups (Ferrell and Fraedrich, 1991).

The ethical decision-making process consists of (i) ethical awareness, (ii) ethical judgment, and (iii) ethical action (Lumina et al, 2015). The first step involves recognizing the ethical nature of the situation at hand, a task that activates specific parts of the brain associated with emotional processing. Awareness will more likely arise if prompted by social environment, ethical language “framing” the situation, or the potential for serious harm to others. As with awareness, neuroscience research is finding that ethical judgment is a unique form of decision-making. Cognitive biases often block an ethical judgment, impairing how to gather facts, how to think about consequences, how to evaluate integrity, and how use intuition. Unconscious biases affect how to valuate different people (e.g young/old, black/white), and emotions while necessary for ethical judgment can interfere with good decision-making when they overcome the rational ability (Lumina et al, 2015; Robert et al, 2015; Vykinta et al, 2013). Managers should use these cues to promote ethics.

Doug Wallace and John Pekel (2006) explain that attention to business ethics is critical during times of fundamental change – times much like those faced nowadays by businesses, either non-profit or for-profit. In this context, values that were previously taken for granted are now strongly questioned and many of these values are no longer followed. Consequently, there is no clear moral compass to guide business managers and leaders through complex dilemmas about what is right or wrong. Nevertheless, ethics in the workplace should be part of decision making of both leaders and staff. Perhaps, most important, attention to ethics in the workplaces helps to ensure that when leaders and managers are struggling in times of crises and confusion, they retain a strong moral compass.

The business world today and its related scientific and technical professions have a special responsibility both in this regard and in operations under a TBL approach. In fact, the knowledge and technologies that are developed have huge impacts on natural environments, economies, and on the empowerment of citizens and societies. Moreover, their efforts to succeed in a highly competitive, global context and the attained achievements continue to produce both positive and negative effects, at present, as well in the future.

Numerous issues are threatening businesses – from financial crises, to climate change from local land issues to financial lobbying. Companies face difficulties to set appropriate strategies and operations for sustainable innovation in an environment of tough competition. Moreover, several issues can cause a breakdown in business ethics, such as lack of integrity, organizational relationship problems, conflicts of interest, and misleading advertising. Thus, companies need guidance on how to evaluate the implementation of a strategy, both for disclosure purposes, for strategic planning and for sustainable business managing.

An ethical culture might support sustainable growth by adding value to a brand, whereas failure in ethics may cause social, economic and environmental damage, undermining the
company’s long-term development. Thus, ethics must be embedded in business models, organisational strategy and decision-making processes. Despite business people awareness of the requirements for ethical decision rules and moral behaviours, some contexts are sufficiently compelling for almost anyone to engage in unethical behaviour (De-Cremer, 2010). Short-term gains, incentives and temptation may promote an ethical dilemma in the decision and decision process of an individual (Tenbruse and Smith, 2008). Despite codes of practice, regulatory oversight and ever-increasing public pressure, multiple control and monitoring systems, the decision-making process in many firms routinely ignores ethical considerations (Bazerman and Tenbrunsel, 2011). This can undermine the wider economy, the society values and cause irreparable damage. Therefore, the resulting massively profitable entities, despite their impressive initial results, may turn out to be unsustainable.

Applying ethics to business and to operations management is a particularly vital endeavour, as this field provides one of the few forces that can serve as a counterweight to profit seeking and self-interest by balancing the ways in which managers’ act, the policies they approve and the role companies play in society (Brenkert 2010). This is, therefore, an attempt to ensure that the operations function is taking a forward and progressive sustainable approach, not damaging the consumer or the society and ensuring an economic welfare. This is far from being a simple, easy and peaceful task.

Moral Decisions and the Subconscious Effect in EDM
Moral decisions abound in organizations: builders choose between durable and cheap materials; salespeople choose to reveal or conceal available discounts; and accountants decide when creative becomes deceptive. The adverse effects of unethical-decisions upon individuals, organizations, businesses, and society are substantial: employees lost jobs, retirement funds, and health benefits; stockholders lost share value; consumers' corporations boycotts increase; and suppliers lost significant business.

Corporations’ scandals such as the Volkswagen’s emissions or the Facebook scandal drew attention from public to unethical business conduct and heightened the interest in EDM, raising obvious questions about the basic, underlying causes of these corporations’ decisions. Research on EDM in operations-management (OM) is incipient. EDM is a very complex process and even though some influencing factors have already been recognized (such as gender, culture, and organizational aspects), an effort to identify all factors that contribute to ethical decisions in corporations – and which may be relevant in OM – is not readily apparent in the literature, which constitutes another knowledge gap.

Master’s Business-Students (BS) are the future generation of managers and constitute an important group with strong potential impact on the everyday business practice. Therefore, it is essential to identify on BS, (a) the ability to draw up and defend arguments on specific business ethical decisions; (b) the potential barriers to these decisions; and (c) the factors that may short-circuit the EDM process through reductions in moral issue recognition, minimization of moral judgments or the feeling of no obligation to act upon a moral issue.

Some authors argue that Ethics-Education in-Business-Schools could improve the students’ moral reasoning, which is an essential driver of EDM (Almeida and Silva, 2016), and foster the ability to ethically evaluate questionable situations, and to make ethical-decisions, by taking appropriate actions (Baker, 2017). However, as we state earlier, EDM is a very hard achieving learning goal due to the influence of priming, subjectivity and individual’s memories that involuntary bias the decisions (Huang-and-Ho, 2018). This irrationality further generates a dilemma in decision-making in ethically questionable issues
because such decisions are associated with an individual’s empathetic and emotional responses towards the situation.

In addition, biased beliefs frequently lead to wrong decisions, discriminatory action, and inhibit emotional, ethical and cognitive development. Such beliefs also serve as perceptual screens that constrict thoughts, limit experience, and diminish the possibilities of constructing useful meaning about real circumstances (Greene, 1995). The process of making meaning which supports the EDM regarding ethical issues, is a situation that it is limited by previously associated positive, negative or neutral connotations (moral, social, cultural, political, or environmental values, among others) held in one’s mind (Almeida and Silva, 2016). To propose problematic business situations in a class, which raise strong ethical issues vs economic development importance, provides dissonance (Jarcho, Berckman, Elliot and Lieberman, 2011), and contradiction (Newark, 2018) if a quick decision regarding the problem is requested to the students. Such dissonance is an internal imbalance that causes students to seek new understandings to restore cognitive equilibrium (Piaget, 1970).

Our interest in finding dissonances and contradictions amid a BS ethical decision-making process comes from the established view, that behavior, in general, and decisions, in particular, are directed by goals (Dijksterhuis and Aarts, 2010) that if not well defined or not, they could be triggered by underlying factors. The concept is simple: goals drive persons to pursue required end states, such as improving life quality, the accomplishment of a duty or find an answer for a dilemma. Research on goals has highlighted the intentional, conscious search of end states. For a long time, it was nearly contradictory to propose that goal pursuit may well occur outside of consciousness since all decision-making process were placed at the level of consciousness. Still, some authors have demonstrated that goals can be inevitably activated by environmental/external cues and then shape behaviours and decisions without any apparent intent or awareness (Bargh et al., 2001). Also, such nonconscious goal pursuit and the related decision-making process are widely considered to be an example of a class of mental processes not reachable to conscious awareness (Dijksterhuis and Aarts, 2010).

Based in the literature review about understanding the nonconscious goal pursuit and EDM process (Bargh, Gollwitzer and Ettingen, 2001; Carlson, Tanner, Meloy and Russo, 2014), two most common proxies could be identified: (i) explicit behaviors known to be driven by the goal in question, and (ii) reaction to goal-related words or images in a lexical decision task. While such proxies are enough for underpinning that a nonconscious activated prime trigger a hypothetical change in behavior (response and decision making), they are less useful for identifying which specific goal, from a potentially large set of possibilities, was activated by a congruent or incongruent environmental stimulus, such as vivid situation (Craigih, 2004), visual threats (Liu et al, 2018), or any stress-leading condition (Janak & Tye, 2015). In Business, individuals do differ noticeably in their ability to recognize and deal with managerial and ethically divergent questions, a difference that has been linked to variability in perceived arousal (Barrett, Quigley, Bliss-Moreau, and Aronson, 2004), emotional awareness (Craig, 2004), and emotional intensity (Herbert, Pollatos, and Schandry, 2007). According Schnall, Abrahamson, and Laird (2002), individual differences in the perceptual abilities influence the way people experience emotions that trigger the making of decisions.

Ethical Business Teaching in Business Schools and its impact in BS
Ethics involves learning what is correct or incorrect, and then make a sustained decision addressing the correct thing. However, the correct thing is not as easy to find as the business
ethics literature appears to state. So, how to increase the next generation of managers’ consciousness towards business ethics and sustainability? Can ethics be taught and learned?

Business schools are important drivers of the economy, government, business and the whole society (Vilas-Boas and Leandro, 2014). Consequently, business schools should pay attention to the world’s important issues as their graduates play an important role as initiators and managers of the global society (Araç and Madran, 2014; Vilas-Boas and Leandro, 2014). Accordingly, business schools have the intellectual capital, creativity and entrepreneurial vision to contribute to powerful solutions that are globally needed (Maurizio et al, 2013).

The business world not only has a financial crisis issue, but it also struggles with problems such as resource depletion, deforestation, climate change, wealth/power distribution, poverty, hunger, social and gender exclusion, domination by corporations, market domination, religious conflicts, media domination, mass epidemics, decreasing biodiversity, and lack of education (Almeida and Craveiro, 2011; GI, 2015). In this framework, business schools have a critical role to play in choosing whether to focus on market share, international opportunities, competition and increasing profit, or emphasising social benefits and a caring society to solve urgent global issues (Rayment and Smith, 2013).

Knowledge, skills and attitudes are significant components of management education for fulfilling both paradigms: business ethics and sustainability in operations. The main expected outcomes from these components, are as follows: graduates that comprehend business ethics issues, that have the skills to act in an ethical framework, and that have the right attitude to make a better world, both personally and as business people (Stubbs, 2013).

**Case Study - Methodology**

**Design approach**

This research purpose is exploratory, mainly because the scope of the study focus on the situation under analysis and no concerns for generalization are made explicit at this stage.

The study was conducted using a purposeful sample of 60 business students from first-year masters’ (MMST) students in ISCTE Business School. ISCTE-IUL is a medium-size Public University located in Lisbon, and its Business School has already been recommended for AACSB accreditation. A short case-study regarding corporation’s ethical, sustainability issues and final corporation decision was purposefully introduced in a coursework to seek the extent of the influence of subjective feelings in moral judgments and in EDM of BS, when faced with a corporation ethical dilemma. BS were randomly assigned to two groups before being subjected to case study presentation which presented subliminal stimulus, i.e., either neutral (Group and scenario A) or highly politicized (Group and scenario B) images concerning the topic under discussion. A questionnaire developed for a business case study was designed considering the RQs described above. BS ethical decision taken under competitive pressure in business (the case study), influenced by political feelings triggered by subliminal images, was operationalized as a manipulated variable while the variables were self-reported. This approach allowed us to analyse each of the observed variables in both Groups, with high and low subliminal-induced competitive pressure in decision-making. In the case study presentation, we used a vignette approach with two scenarios representatives to manipulate competitive pressure and examine students’ responses to a typical ethical dilemma in global world: to drill or not to drill oil in an environmental protected area, source of regional wealth through fisheries and ecotourism. Business managers often must balance their responsibility to meet the profit goal of the organization they are working for with the
legitimate interests of other stakeholders (Lund, 2000). The scenarios depict the conflict of interests of local fishermen’s, ecotourism entrepreneurs and residents that are interested in higher standards for the environment and safety versus the vested interest managers and stockholders have in the economic success of their Oil company investment. Subjects had to decide whether to allow the prospection, which could be destructive to the environment and potentially hazardous for marine ecosystems. Two scenarios reflected different degrees of competitive subliminal pressure (CSP) for this decision. The two vignettes contained the following basic information: Whereas the impact of the decision to drill or not to drill for oil is the same in both scenarios for the ecosystem and the local community, the CSP was designed to be higher in scenario B. All subjects were presented with both scenarios allowing us to analyse their responses in both high and low CSP situations. Each questionnaire (A and B), with the same questions and the same case, contained the respective scenario (Group A: low-profile images, with a null political connotation; Group B: powerful images, with a strong extreme political connotation) and a total of 5 questions. It took most respondents between 30 and 45 minutes to complete the answers.

The undertaken evaluation used a framework to analyse the contents of BS considerations. The research follows a grounded approach, emphasizing the understanding of the subjective feelings effect in BS perceptions from qualitative data gathered as shown above.

Sample and Data Gathering
The data were collected in 2019, few months after the social upheaval that resulted from the approval given by Portuguese Environment Agency (PEA) to the ENI/Galp consortium to carry out an oil prospecting survey in 46 km off the coast of Aljezur, in a protected area, without Environmental Impact Assessment. It was not a blind-prospection since a study made by the consortium for the exploration of the Vicentina coast estimates a potential recoverable volume of oil ranging between 1,000 and 1,500 million barrels, equivalent to 17 years of oil imports, with a clear impact on Portuguese trade balance.

In a class of the 1st semester, BS were asked to answer a few questions about a business ethics situation, and to give their opinions about the presented case. The administration of the questionnaire included a cover story of the case suggesting that the purpose of the study was to survey students pertaining to global business issues. Participation was mandatory.

Findings
There are three dimensions’ individuals should bear in mind to make ethical decisions (Betzgen, 2007; Lumina, 2015). (i) Awareness, i.e. the ability to define and describe ethical issues and, to recognize and analyse the impact of the ethical decisions, which concerns the ability to anticipate second and third order effects a very important element of strategic thinking (addressed in RQ1); (ii) Judgement, i.e. the ability to objectively look at alternatives, and reasonably decide what is adequate to the specific situation (RQ2).

Next subsections present the findings obtained within the research scope.

Preliminary Data Analysis
A manipulation check was conducted to evaluate the ability of the vignettes to increase perceived CSP. Data were treated and examined by using the content analysis framework of Brenner and Molander (1977). Our conceptual approach was based on behavioural models. We created a coding scheme with two main categories: 1) The BS identify and interpret conscientiously ethical issues; 2) Presence of cognitive biases due to influence of CSP on BS
The BS analyse and appraise ethically the decisions in the business case study. The sub-categories were derived inductively from the data. Inductive coding was used to ensure that our analyses comprehensively represented the content written by the BS. The categories were ordered within a taxonomy, where each category received a specific definition. The codes were developed successively and were revised or deleted and new codes added as the analyses proceeded. Table 1 contains the comparison of mean scores for the two scenarios. For all four variables, respondents perceived significantly more CSP in scenario B, indicating a successful manipulation.

Ability to define and describe Ethics and Sustainability concepts (RQ1)

Prior to the presentation of the ethic case study, the business students exhibited awareness of Ethics and Sustainability concepts and related frameworks. The answers showed a good ethics notion (90.4 %, considering the answers with minor errors) vis-à-vis the result achieved when BS address the sustainability notion (71.3 %).

Ability to recognize and analyse the ethical decision impacts (RQ1)

One might conclude for a general agreement across the two BS groups, from the perceptions of students concerning ethics issues reported in the presented case study. The majority of students (89.8 %) clearly pinpoint the problems in the presented case studies. In contrast, 10.2 % fails to adequately address the problem. The “Yes” sample of students concerning their ability to analyse the ethical impacts of the decisions rooted in the case study scenario (89.8 %) was further detailed. The results identified the differences amongst students’ responses, as follows: more than half of business students (BS) succeeded in making a correct reasoning and around one third has also achieved good results, but with minor errors.

The Impact of CSP on Ethical Decision-making (RQ2)

Table 2 provides the data addressing RQ2 (Do subliminally presented stimulus influence ethical decision making in BS?). The increase in CSP had a major impact on students’ EDM behaviour and ethical appraisal of the case study resolutions.

In the Group A, with scenario A (low CSP) it was noticeable that there is a slightly advantage to supporting drill decision, with BS presenting reasonable/weighted arguments and evidence to justify their opinion. However, in the Group B (high CSP), the one with extreme political connotation images, only 30% of BS were willing to drill, against an overwhelming consensus among the BS that use strong arguments to reject the oil prospection, defending the environment and populations.
Table 2 – The Impact of subliminal stimulus in BS ethical appraisal of the case study resolutions

The gender variable was not considered at the beginning of our research. However, a brief cross-tabulation analysis was conducted. Comparing male and female BS answers, it was found that in both low and high CSP situations males were more likely to drill than females.

Discussion

Ethical behaviour and intentional behaviour found two different scopes: individuals making both intentional and unintentional, and ethical and unethical choices (Tenbrunsel and Smith-Crowe, 2008). For instance, research in decision-making attitudes reveal that good people occasionally do bad things (Bersoff, 1999), and may not even understand that they are doing wrong decisions. Studies on ethical fading (Tenbrunsel and Messick, 2004) asserts that people do not see the moral components of an ethical decision, not because they are morally uneducated, but because psychological processes fade the ethics from an ethical dilemma.

Based on the findings, we argue that despite BS having revealed reasonable level of ethical maturity and perceptions towards sustainable practices in business (sustainable operations management, corporate and social responsibility, and organizational environmental impact) they do not display consistent answers and BS do exhibit notorious ambiguities concerning the perception of ethics importance in business. The BS answers related to the presented case study reveal a strong love-or-hate feeling and a compulsion to extreme their decisions considering the problem resolution if previously submitted to a specific subliminal stimulus.

We suggest that, when specifically triggered, EDM could rise in BS from depths of nonconsciousness thought. BS behaviour and decisions are guided by targets and targets drive them to pursue. For the most part, research on goals has emphasized the intentional, conscious pursuit of targets toward end states (Dijksterhuis and Aarts, 2010). However, our results comply with other researchers demonstrating that decisions are activated, automatically, either by environmental cues or by subliminal stimulus, and then influence behaviours without any apparent intent or awareness (Bargh, Gollwitzer, Lee-Chai, Barndollar, and Trötschel, 2001). Some authors (Dijksterhuis and Nordgren, 2005; Hassin, 2005; Kastrup, 2017) state that the unconscious has the means to perform every fundamental high-level cognitive function performed by consciousness, such as cognitive control, pursuit of goals, information broadcasting, and reasoning. This large amount of unaware operations that the brain can perform is not disconnected from but has an important impact on the aware operations. Other findings show that subliminal information, such the above referred, can drive executive functions (Lau and Passingham, 2007) and that subliminal priming of stimuli changes how one’s felt about an issue when he is dealing with (Monahan, Murphy and Zajonc, 2000). Other examples confirm the fact that the unconscious plays a significant role in shaping the conscious experiences, like attributions of agency (Aarts, 2007), actual choice (Strahan, Spencer and Zanna, 2002), and even political attitudes (Hassin, Ferguson, Shidlovski and Gross, 2007). Corroborating that premise, our results show answers with a
strongest reaction justified through sound reasoning, either supporting or rejecting the prospection, in the Group B, were non-neutral images stood present. The students use strong party-political claims either to reject the oil prospection, defending the environment and populations (most of the BS) as to defend the consortium and the need to explore Portuguese natural resources which could trigger the hoped-for economic development (30% of BS).

Stepping back to consider what we have previously presented as regards the answers and mental frameworks responsible for business students’ EDM behaviour and ethical appraisal of the case study resolutions, the type of incidental emotion carryover observed appears most consistent with what Wilson and Brekke (1994) refer to as mental contamination and Arkes (1991) calls association based errors – processes wherein swaying, such as the BS cognitive biases resulting from subconscious influence (incidental emotion carryover) arises because of mental processing that is unconscious or uncontrollable. Thus, the best strategy for reducing such biases would be to control one’s exposure to biasing information in the first place. This is a difficult task for the decision maker, mainly if it is a student, a BS, with all the immaturity inherent in his young learner status.

Conclusions
As regards RQ1, business students can use common sense to understand the idea of Ethics in its majority (~90%), while only ~70% showed awareness of the Sustainability concept. On the other hand, from the ~90% of the students that were able to recognize the problems in the presented case studies, more than 80% could make a correct reasoning and show potential toanalyse the impact of ethical decisions. This exhibits a natural ability to apply ethical principles and ideas to business ethics.

As to RQ2, business students Groups exhibit stout ambiguities in the perception of the case issue revealed in different behaviours and shown in their answers. This leads us to conclude that the subliminally presented political stimulus influence students’ EDM, and BS compliance or defiance with the decisions presented in the case study. We also intend to stress the hypothetical BS easiness feeling of take this "guts-feeling" as guarantee of a quick and fair decision without considering all the facts since, unconsciously, BS perceive some of them as not being in line with unconscious thoughts, memories, feelings, and wishes.

We suggest some syllabus developments in business schools, in order to introduce a robust conceptual basis concerning ethics, ethical decision and sustainability, the cornerstones of sustainable business models. The presentation and discussion of cases concerning corporate scandals and unethical behaviour corporations, could overcome this weakness. It will be also useful in order to minimise the problem of subconscious impact in ethical-decision making and the resulting cognitive biases.

A3- vs. 8D-report

- A case study for the investigation of the effectiveness of problem solving methods within assembly

Abstract

The purpose of this paper is to demonstrate the effectiveness and applicability of the most popular problem-solving tools, the A3-methodology and the 8D-methodology. To investigate which method is more effective for internal problem-solving within a company the model factory in Koblenz developed a pre-test of a case study to investigate the following research question: “Which of the selected problem solving tools is more effective”. This investigation serves as a first pre-test of the case study. Data were analyzed statistically by descriptive statistics and hypothesis tests and showed only minor differences due to the application of the two methods.

Keywords: A3-methodology, 8D-methodology, quality management
Introduction
Businesses are confronted with the challenges of globalization and technological progress. These megatrends are accompanied by increasing customer requirements. To meet all these challenges, companies need an effective process management (Dombrowski/Crespo, 2008). For an effective process management, the philosophy of lean management is increasingly implemented in companies. Part of lean management is the continuous improvement of processes. This requires not only a problem detection of the process by the employees, but also root-cause analysis (Šobek/Smalley, 2008). For problem-solving, a structured approach is recommended (Schmitt, 2015). For this purpose, a number of methods have been developed which offer a structured approach. The most common methods are the A3- and 8D-method, the PDCA cycle (Plan-Do-Check-Act), Six Sigma and TRIZ (Theory of Inventive problem solving) (Cloft et al., 2018). Literature review shows that the A3- and 8D-method are the most widely used approaches in practice (Schmitt, 2015). Both, A3- and 8D address the same purpose. They aim to provide a structured approach for a problem-solving process (Gisi, 2018). However, there is no evidence within literature which of the two methods is more efficient and more effective or better applicable. The academic study aims to close the research gap by systematically analysing a problem-solving process and answer the following question.

"Which of the selected problem solving tools is more effective?"

For this, a pre-test of a case study which supports the assessment of the usage of the problem-solving methods was developed. An assembly process was simulated and a fictitious problem-solving process initiated. With the help of quantitative data, first insights about the effectiveness and applicability of the A3- and 8D-method can be obtained. Thus, we receive first indications about the effectiveness of the most common problem-solving methods.

Literature Review
Almost every company faces problems and complaints. For this, companies have often developed their own problem-solving process (Cloft et al., 2018). But not every process ensures an efficient and sustainable problem-solving. That is why companies often rely on the most common problem-solving methods: The A3- and 8D-method (Schmitt, 2015).

A3-Report
The A3-method is a lean management tool for problem-solving and was introduced by the Toyota Motor Corporation (Leyendecker/Poetters, 2018). The result of the problem-solving process using the A3-method is the A3-report. The term A3-report describes the documentation for the methodical guidance of a problem-solving process (Kroeger, 2018). The report is used for the communication within the organization and is based on a single DIN A3 sheet (Liker/Meier, 2008). It was decided to use a DIN A3 sheet as this is the largest format that could be faxed (Liker/Meier, 2013). It not only forces the employees to make assumptions, but also finding the real cause of the problem by analysing the initial situation (Liker/Meier, 2008). The aim is to obtain a representation in which a specific problem as well as all relevant activities and contents for a solution are mapped (Dombrowski/Mielke, 2015). The A3-report can be seen as a template which shows employees what steps are important in order to solve a problem (Gorecki/Pautsch, 2018). The advantage of this template is that all facts and aspects of the problem-solving process are in presented in a short and clear manner (Schewe/Herbig, 2015).
The A3-report has its origins in the logic of the PDCA cycle (Dombrowski/Mielke, 2015). This means that the A3-report is structured into the phases “Plan”, “Do”, “Check” and “Act” (Vetterli/Hollenstein, 2016). “Plan” could be found on the left side of the A3-report. The phases “Do”, “Check” and “Act” are on the right side of the report (Sobek/Smalley, 2008).

During the Plan phase the problem has to be defined. Furthermore, a description of the current situation must be made, preferably with quantitative data and graphs. The use of diagrams reduces the complexity of the problem and is therefore recommended (Liker/Meier, 2013). Subsequently, the target status must be described and substantiated with key figures (Vetterli/Hollenstein, 2016). Within the next steps various tools of the Lean Management are used in order to analyse the root cause of a problem. These tools are the Ishikawa diagram, FMEA (Failure Mode and Effects Analysis) and the 5-Why method (Sobek/Smalley, 2008).

The next steps of analysis are assigned to the Do, Check and Act phases and focus the initiation of countermeasures (Matthews, 2016). The problem-solving section, which is part of the A3-template, is about developing concrete solutions (Gorecki/Pautsch, 2018). It is crucial to solve the causative problem and not to treat symptoms (Vetterli/Hollenstein, 2016). Within this section concrete activities and responsibilities are defined (Sobek/Smalley, 2008). A cost-benefit analysis shows the effectiveness of the troubleshooting (Dahm/Brueckner, 2017). This include for example a comparison of the achieved status and the target key figures. The last step of the A3-report concerns follow-up measures that help to prevent this or a related problem from occurring in the future (Vetterli/Hollenstein, 2016).

The A3-report is a living document, which should be a constant companion during the problem-solving process (Dombrowski/Mielke, 2015). It is not only an instrument for solving individual problems. Employees gain a deeper understanding of the problems (Niermann/Schmutte, 2017). In this way they are given competence to design sustainable solutions that can be implemented into daily business (Womack/Jones, 2005). The A3-report is a simple and efficient instrument for solving problems within processes in a structured way (Forbes/Ahmed, 2011).

**8D-Report**

The 8D-report is a systematic model which should lead quickly and in a structured way to the solution of a problem within a process (Jung et al., 2015). Within companies the 8D-method is often used in context of complaint management (Junker/Griebsch, 2017). It is used to handle complaints of internal and external customers and thus serves to ensure quality (Kuntsche/Boerchers, 2017). The aim of the method is to eliminate the problem permanently (Kaschek/Schumacher, 2015). The term 8D refers to eight disciplines or process steps that are necessary to systematically identify and solve the complaint or the arisen problem (Krausz, 2018). This guide is used for problems that require not only sustainable problem solution but also immediate action in order to prevent further damages to the customer. The most frequent used of the 8D-report are customer complaints, production stops and industrial accidents (Jung et al., 2015). The eight disciplines are as follows (Barsalou, 2015):

- D1: Team
- D2: Problem description
- D3: Immediate containment action
- D4: Root Cause
- D5: Planned corrective action
- D6: Implemented corrective action
- D7: Actions to prevent reoccurrence
- D8: Congratulate the team

The report documents the results of the disciplines and can be exchanged between the supplier and the customer (Daum et al., 2018). The structure of the report supports the systematic problem-solving and helps the customer to understand the measures taken to remove the problem (Bertagnolli, 2018).

In the first discipline a team has to be arranged which is responsible for carrying out the problem-solving process. It is crucial that all team members have the appropriate product and process knowledge and all skills and competencies to apply the methodology (Kaschek/Schumacher, 2015). Within the second discipline the team describes the arisen problem. This description should be as specific as possible, as all other disciplines build up on this (Schmieder et al., 2018). Afterwards immediate action will be taken in order to protect the customer from further damages caused by the problem or error. These are only temporary measures (Mueller, 2014). In the fourth discipline the team use mind maps, brainstorming and an Ishikawa diagram for the first collection of the possible cause of the problem. Afterwards the real cause must be found. For this various tools can be used, such as the 5-Why method (Jung et al., 2015). Discipline five requires the development of appropriate corrective actions. These are of indefinite duration and are intended to replace the immediate measures adopted in discipline three (Nied/Draexler, 2015). The corrective measured introduced in discipline five will be organizationally anchored in discipline six (Brueckner, 2011). Within discipline seven the collected insights, experiences and measures as part of the problem-solving process are transferred to comparable products and processes (Gorecki/Pautsch, 2018). This ensures that the problem does not occur with other products or processes and that the cause has been permanently eliminated (Brueckner, 2011). Finally, the team leader informs the team about the successful completion and recognizes the individual achievements as well as the team performance (Kaschek/Schumacher, 2015).

Case Study and Methodology
This paper investigates and compares the effectiveness and applicability of the A3- and 8D-method. Therefore, a pre-test of a case study was constructed. This pre-test is used to check if the A3- and 8D-method can be used in a case study. Furthermore, the case study process is monitored to ensure the smooth running of a future research with a larger sample size.

A case study is a qualitative approach that can be used for social science research in field of business and education. Furthermore, important aspects of a real-life event can be depicted, and it is used, when the events cannot be controlled by the investigator (Yin, 2009). The aim of a case study is to gain a deep understanding of a problem. Moreover, it is about the exploration of a complex and unique project (Simons, 2009).

3.1 Design of the Case Study
The pre-test of a case study was conducted within the model factory of the University of Applied Sciences Koblenz. The model factory was set up to simulate business processes and makes them tangible. For this purpose, it represents an exemplary value chain in a compact format of the fictitious company “OptiTruck GmbH”. In this case, the following miniature truck is considered to be the product (figure 1).
In addition to this truck, the OptiTruck GmbH also produces a second crane truck. The two trucks are manufactured in two separate production lines. The products require different construction components, which are delivered into a central warehouse. An incoming goods inspection is carried out, so that no defective parts enter the production process. Since the components are delivered to a central warehouse, a picking process must be carried out. This is assumed by a temporary work agency.

At the end of the production the final quality control takes place. Recently there are strong quality issues with the target product of the case study. Wheels drop off from the truck when rotated. Due to incoming goods inspection, a fault on the part of the supplier can be excluded. The OptiTruck GmbH focuses on a high quality standard. Therefore, no components are reused after incorrect assembly. This resulted in a 3% increase in material costs within one week. As complaint have already arrived from numerous worldwide customers, a fast solution for this problem must be provided.

3.2. Procedure of the Case Study

Eighteen students majoring in “Operations Management“ participated at the pre-test of the case study. First the students got a short introduction into the procedure. As part of this introduction the A3- and 8D-method as well as the instruments Ishikawa diagram and 5-why method were presented. This was followed by the division of the students into four groups. Two of the four groups applied the A3-method, the other two groups used the 8D-method. The groups were separated in different rooms in order to avoid manipulations. Subsequently the participants received the case. The groups that used the A3-report received a template with the sections of the A3-method. The 8D groups have been provided with a flip chart. The participants also received the components and a standard work sheet to assemble three trucks. This should allow the participants to experience the problem. This provides the participants the opportunity to go to the place of the event in order to analyze the problem more closely. All in all, the students got a time limit of one hour to solve the case study and thus to find the problem.

At the end, participants completed a questionnaire to measure subjective perceptions. Hereby, the effects of the A3- and 8D-method should be measured by comparing the survey results of the different groups. The first two questions of the questionnaire refer to the level of awareness of the two methods. These questions only could be answered with “yes” or “no”. For the following questions the participants should assess these statements according to their degree of agreement. For this purpose, a 4-point Likert-scale from (1) “completely agree“ to (4) “completely disagree” was used. As part of the interval-scaled measurement, a numerical rating scale was adapted, enabling the classification of the participants based on a multi-stage scale (Scharf et al., 2012). An even number of scale points was chosen, since the middle category is often chosen as the “escape category” for an odd scale (Porst, 2014).
Results
In order to prove possible differences between the effectiveness and applicability of both methods, the collected data were analysed using descriptive statistic and hypothesis tests in Minitab statistics software (version 18.1).

A total of eighteen participants answered the questionnaire. Due to the differentiation of the questionnaires between the methods, a total of nine questionnaires for the A3-method and nine questionnaires for the 8D-method can be evaluated.

The first part of the questionnaire refers to the level of awareness of the A3- and 8D-methodology. Following questions were used for the study of previous knowledge:

- Question 1: The method was known me before this case.
- Question 2: I have already used this method before.

Question 1 and 2 could only be answered with yes or no. The results are shown in table 1.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Question 1 A3</td>
<td>77.77%</td>
<td>22.22%</td>
</tr>
<tr>
<td>Question 1 8D</td>
<td>33.33%</td>
<td>66.66%</td>
</tr>
<tr>
<td>Question 2 A3</td>
<td>11.11%</td>
<td>88.88%</td>
</tr>
<tr>
<td>Question 2 8D</td>
<td>11.11%</td>
<td>88.88%</td>
</tr>
</tbody>
</table>

Regarding the given results, the publicity of the A3-method among the participants is higher than the familiarity with the 8D-method. An examination of the results of the A3-group shows that 77.77% already knew this method before the execution of the case study. In contrast, 66.66% of the participants of the 8D-group did not know the 8D-method before. A Chi² test is used to examine the observed and expected values. On a significance level of 5% there is no statistically significant difference within the level of awareness between the A3-method and the 8D-method, X²(1, N=18)=3.6, p=0.058. However, this p-value is borderline, an increased sample size may well show different levels of familiarity.

The percentages of question 2 shows, that both methods were rarely used by the participants. Particular noticeable is that for this question no differences in the percentages between both methods are recognizable. Regarding the level of awareness and practical use there are no differences between the A3- and 8D-method.

For the following questions the students should assess the statements according to their degree of agreement from 1 (“completely agree”) to 4 (“completely disagree”).

The second part of the questionnaire serves to determine the participants understanding of the respective method. Questions 3 und 4 addresses the comprehension of the methods:

- Question 3: I understood the basics of the method.
- Question 4: I could apply the method using the tools.
Table 2 - Comprehension

<table>
<thead>
<tr>
<th>Variable</th>
<th>N</th>
<th>Mean</th>
<th>StDev</th>
<th>Median</th>
</tr>
</thead>
<tbody>
<tr>
<td>Question 3 A3</td>
<td>9</td>
<td>1,111</td>
<td>0,333</td>
<td>1,000</td>
</tr>
<tr>
<td>Question 3 8D</td>
<td>9</td>
<td>1,222</td>
<td>0,441</td>
<td>1,000</td>
</tr>
<tr>
<td>Question 4 A3</td>
<td>9</td>
<td>1,333</td>
<td>0,500</td>
<td>1,000</td>
</tr>
<tr>
<td>Question 4 8D</td>
<td>9</td>
<td>1,222</td>
<td>0,441</td>
<td>1,000</td>
</tr>
</tbody>
</table>

Table 3 shows the mean values of question 3 which reflect a slightly better comprehension of the A3-method in the sample. However, since there is only a small deviation of the means and the median is the same, the participants seem to have a very good understanding after explaining the basics. In order to solve the case and apply the methods the students got an introduction into the needed tools. Also for tool application, there is only a small difference between the A3- and 8D-method.

Hypothesis testing for question 3 and 4 lead to the following result: The null hypothesis for question 3 states that there is no difference within the understanding of the basics between both groups. The two-sample t-test results in a p-value of 0,556. This value is higher than the given significance level (0,05). Differences in the basic knowledge of the respective methods between the A3- and 8D-group can not be detected. The null hypothesis for question 4 states that there are no differences in the applicability of the tools. The p-value for this test is 0,624. The null hypothesis can be retained as well. There are no significant differences within the applicability of the tools. In summary, no distinctions in the comprehension of the methods can be identified. However, sample size considerations lead to the conclusion, that the power of these tests was low. For example, a potential difference of 0.5 between both groups for question 3 resulted in a power value of only 62%.

The third part of the questionnaire was constructed to check the problem identification. The following questions were considered:

- **Question 5**: The cause of the problem can be detected by the application of the method.
- **Question 6**: I could solve the problem with help of the method.

Table 3 - Problem Identification

<table>
<thead>
<tr>
<th>Variable</th>
<th>N</th>
<th>Mean</th>
<th>StDev</th>
<th>Median</th>
</tr>
</thead>
<tbody>
<tr>
<td>Question 5 A3</td>
<td>9</td>
<td>2,556</td>
<td>0,882</td>
<td>3,000</td>
</tr>
<tr>
<td>Question 5 8D</td>
<td>9</td>
<td>1,778</td>
<td>0,972</td>
<td>1,000</td>
</tr>
<tr>
<td>Question 6 A3</td>
<td>9</td>
<td>1,889</td>
<td>0,928</td>
<td>2,000</td>
</tr>
<tr>
<td>Question 6 8D</td>
<td>9</td>
<td>1,778</td>
<td>0,833</td>
<td>2,000</td>
</tr>
</tbody>
</table>

Referring to table 4, questions 5 shows a differences within the applicability of the A3- and the 8D-method. The mean value for the A3-method is at 2,556 which leads to a median of 3. This median reflects a disagreement of the participants about the problem identification by using the A3-method. They could not easily identify the existing problem within the case study. In contrast to this, the median of question 5 for the 8D-
method amounts 1,778 with a standard deviation 0,972. But the median shows still an agreement of the students about a good problem identification by using the 8D-report. The null hypothesis for question 5 expresses that there are no differences between the A3- and 8D-method regarding the detection of the cause by the application of the methods. For this a p-value of 0,096 is achieved. The null hypothesis will be retained.

In relation to question 6, despite difficult problem identification with the A3-method, the case could be solved well with both methods. For the t-test of question 6, a p-value of 0,793 is generated. Thus, the null hypothesis, which states that there is no difference in problem-solving between the A3- and the 8D-method, can be retained. For problem identification, no method turns out to be more effective. However, as mentioned above, also here sample size needs to be reconsidered.

The last part reviews the applicability of the methods. Question 7 and 8 address this part of the research:

- Question 7: The method is well applicable to the case.
- Question 8: I understood the case and could solve this without problems.

<table>
<thead>
<tr>
<th>Table 4 - Applicability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
</tr>
<tr>
<td>Question 7 A3</td>
</tr>
<tr>
<td>Question 7 8D</td>
</tr>
<tr>
<td>Question 8 A3</td>
</tr>
<tr>
<td>Question 8 8D</td>
</tr>
</tbody>
</table>

The results of table 5 show a mean value of 1,556 (A3-method) and 1,444 (8D-method) for question 7. This indicates that both methods were applicable to the case. The t-test for question 7 leads to a p-value of 0,716. Thus, there is no statistically significant difference between the two methods regarding the applicability of the respective method to the case.

Regarding question 8, differences in the means of the A3-method (1,556) and the 8D-method (1,444) are apparent. These differences do not lead to divergent medians. The participants understood the case and could treat them independent of which method was used. The null hypothesis for question 8 states that there is no difference in the problem-solving of the case with the respective method. Neither method turns out to be more applicable. Again, also for question 7 and 8, sample size needs to be reconsidered.

**Discussion**

The pre-test of the case study developed here proved to be suitable to investigate performance differences of problem solving methods. However, the results of the pre-test do not show any performance differences between the two methods. Overall, among the participants the A3-method was better known. Both methods have not yet been used by the participants in practice. For this reason, learning effects related to the application of the method can be excluded. Referring to the quantitative data of the questionnaire, descriptive statistics and hypothesis testing, there are little differences in problem identification and problem solving. The problem was more easily detected by using the 8D-method. However, the research team noted that the participants of the A3-groups...
were very busy with the template of the A3-report and the aspect of problem solving faded into the background. In total, regarding this case the 8D-report may be more effective in order to identify to identify and solve a problem. However, based on the performed hypothesis tests, no significant differences between the two methods can be identified. This could be related to a small sample size as mentioned above.

**Summary and Future need for Research**

Continuous process improvement also includes troubleshooting. This not only means removing the problem, but also eliminating the causes. Cause elimination is central to avoid the same or similar problem to reoccur. Both in literature and in practice, the problem solving methods A3 and 8D show a high prevalence. But which method is more effective and better applicable, is not described in detail. To take on this problem in this research project the following question was formulated:

"Which of the selected problem solving tools is more effective?"

To test this hypothesis, the A3- and 8D-method were analyzed within a pre-test of a case study. The pre-test was conducted with eighteen participants. The participants completed a questionnaire to quantify the subjective perception of the applicability of the methods. These data were analyzed by descriptive statistics and hypothesis tests. A comparison of the effectiveness of the methods no performance differences can be demonstrated. Nevertheless, the 8D-report may be more appropriate method for problem identification and problem-solving.

As shown by the results of question 2, the participants have not used any of the methods in practice so far. This means that they have no experience in the methodology. They therefore had to familiarize themselves with the procedure and the instruments to be used. The missing experience and understanding of the methodology and instruments can also have an effect on the performance and effectiveness of the results.

The pre-test shows that the A3- and 8D-method can be used within a case study. The results of the pre-test cannot be generalized. Further studies should be performed to increase sample size. Also other types of products can be manufactured. Maybe a product with a higher complexity will have an impact on the results. In order to get more scientific valid results, the case study should be further developed. Participants should receive a deeper introduction to the methodology and tools. Through a better understanding in the application of the methodology, potential performance differences may become visible.

Abstract

This paper presents the initial test of two Virtual Environments (VE) and 3D models as learning tools for workspace design education. A quasi-experiment was designed in which 27 students were assigned to one of four groups (control, physical, digital, physical and digital) and were prompted to read a case and design improvements proposals with the materials available to them. Results showed no significant differences among the groups, which could be partially due to the experiment setting, since participants’ comments highlight, they greatly appreciated the VEs and the activity in general, due to its practical, reality-based and team work nature.

Keywords: Virtual Worlds, 3D Printing, Factory Design.

Introduction

Workspace design has long been a field of interest in operations management, from the macro level aspects of plant location decisions and layout to the micro level of workstation design.

In the past decade, researchers have started to investigate the potential of employing novel technologies such as game engines (GE) to the design and simulation of productive systems (Braatz et al., 2011; Gatto et al., 2013; Carreira et al., 2018; Paravizo and Braatz, 2019). GEs are a class of computer software that enable the development of 2D/3D games and applications using pre-existing modules and tools. There is also an interest in employing these technologies in educational contexts (Braghirolli et al., 2016; Paravizo and Braatz, 2017).

In order to assess how educators and practitioners can employ these technologies, we developed a virtual environment (VE) in a GE that aimed to enable students to redesign the layout and furniture/equipment present in a workplace, considering a series of
problems and issues present in a case report. Besides the VE, the same scenario, layout and furniture/equipment were represented in a set of 3D scale models and a game board as well as a simple 2D sketch for handmade drawings.

This paper reports an initial test with 27 industrial engineering students aiming to validate a proposed experiment design that could enable researchers to better understand the potential and limitations of the VE and 3D scale models as tools for workspace design.

**Materials and method**

The basic material created was a case briefing, which explained to participants the case analyzed, the main issues and problems currently existing in the workspace and what was the work performed there. Participants also had a spreadsheet with a list of the available furniture/equipment that they could choose from. Besides this base material, a digital tool (VE) and physical tools (3D scale models & game board and simple hand drawing) were made available to participants. The virtual environment was created by the authors specifically for this study considering game design (Schell, 2014) and gamification strategies (Werbach and Hunter, 2012) and followed the four major axes delineated in (Paravizo and Braatz, 2019). The VE designed was an evolution of a VE designed for the analysis of the workspace reported in (Paravizo and Braatz, 2019). An overview of the materials is presented on Table 1.

**Experiment Design**

The experiment design that was intended to be validated in this study is presented in Figure 3. Considering that participants were students from the engineering courses who volunteered, and thus a multitude of external factors was impossible to control, this study design is closer to a quasi-experimental design.

The idea was to have participants to use the different available materials to understand a case and assess how well these materials supported participants’ design activities. The facilitators were responsible to give a brief overview of the research project, and hand to the participants the materials they would use, prompting them to read the case description, discuss it among themselves and then propose a solution.

After the workshop session, participants were asked to fill out a feedback questionnaire on their perception of the activity and the tools. The feedback questionnaire had 5 main sections: section 1 focused on participants’ background, section 2 inquired about their understanding of the issues presented in the case, section 3 inquired their perception of the suitability of the materials they used for the task and if they saw the need of other resources, section 4 asked for comments on the materials and overall activity and section 5 was only for those who used the digital tools, inquiring about usability aspects of the VEs.

![Figure 3 – Experiment design](image)

**Results and discussion**

In total 27 students in Industrial Engineering courses of two federal Brazilian universities participated in the 2 hours-long workshops occurred in 8 different moments during July and August 2018. All participants voluntarily agreed to take part in the study, having signed consent forms prior to the activity. The 27 filled out the feedback questionnaires were retrieved via Google Forms, and subsequently analyzed.

One of the main focus of this study was to assess if there were significant differences among the groups in terms of their understanding of the case and the perception of the suitability of the tools employed (sections 2 and 3 of the questionnaire). However,
analysis of the results from the questionnaire showed that there were no significant differences among the groups.

Considering these results, emphasis will be given on the analysis of participants’ comments in order to try to better understand their perception of the activity and the tools they employed. The general inductive approach for qualitative data analysis (Thomas, 2006) was followed for the coding of the participants comments. In total, 65 segments were coded to one of 18 codes. A summary of the coding analysis is presented on Table 2, focusing on the 9 most recurrent codes, which amount to 80.2% of the total codes.

Participants comments show an overall good impression of the activity in general and also the materials employed. The impact of the workshop was such that participants commented they became more interested in the topics approached. One participant from the control group (G1) commented: “Excellent activity. It gave me a better understanding of ergonomics, factory design and simulation. A comprehension level much larger than any theoretical lecture”.

The practical nature of the activity was in itself a highlight of the workshop. Participants commented they liked that the activity was based on a real case and that they actually had to put their knowledge on the topics in practice, in a team work setting. Another participant in a control group commented: “Great activity to improve our team working skills, to broaden our knowledge by facing ‘real’ work situations, to put in practice the knowledge we acquire in the classroom and to get to know novel platforms for simulation/ergonomics”.

In terms of the VE employed by participants assigned to groups 3 and 4, comments focused mainly on the high-fidelity visuals that led to a high degree of immersion on the situation and different interactions possible inside the VE (with non-playable characters - NPCs, equipment, environment, etc.) that enabled them to simulate work aspects and different layout proposals. One participant assigned to the digital group commented: “The utilization of the virtual scenario allowed a different immersion in the problem at hand. This environment allows the interaction with the structural aspects of the physical space, as well as presenting the personal issues from workers, which are fundamental in any improvement project, since they are actors directly involved in the process.”

Overall, the main improvement points participants indicated were related to the short duration of the workshop and the usability aspect of the VE. One of the participants in a digital and physical group commented: “The virtual environment was not used a lot because there was little time, but it is very detailed. The environment has a nice visual presentation but need to be more intuitive and easier to use.”
Furthermore, going back to the initial assumption that there would be significant differences among the groups in terms of their understanding of the case and perception of the materials available to them (which was not verified through the data collected), two comments can bring more context to this. The first one, from a participant in a control group: “My team only used the handmade drawings of the place and it was enough for us to have an idea of the space and allow us to create and present an improvement proposal. I think a virtual environment would enrich the experience and give more precision, however this basic resource was enough.”. The second comment, from a participant on a physical only group: “The activity showed that we can’t only imagine that the simulation is something digital, but rather we can see it with models and objects. And thus, we can show how the layout of an organization would be”.

These two quotes in particular highlight participants perception that the tools they have are enough, however these participants did not use the VEs so they do not have a basis of comparison against which to compare the available materials. Furthermore, the mere setting of the workshop – as a practical activity – is, in itself, something that students tend to like, regardless of the different types of materials used as highlighted in the comment’s analysis. These aspects must be taken into account when designing future similar experiments.

As expected, usability aspects of the VE impacted participants perception of its utility. Although the VE was easy enough so that they were able to use it to propose improvements and scenarios (as seen in Figure 1B, for instance), it still could be greatly improved.

**Conclusion**

This paper reported the development and pilot test of a study aiming to achieve a better understanding of the impact of using VEs and 3D models for workspace design. Despite the lack of significant evidence to substantiate the claim that one tool would be better than other, we find that participants greatly appreciated the virtual environment and the activity in general, due to its practical, reality-based and team work nature.

Future experiments could be designed taking into account the issues raised here, particularly, assuring that all participants have a more symmetric standpoint to compare the tools assessed and also the overwhelmingly good impression of a practical activity that could end up flattening out the effect of differences between the groups analyzed.

Further refinements on experiment design could be useful to realize the full potential of employing VEs and 3D models in engineering design practice and education. The VE developed can be customized and employed in a wide range of industries and contexts for fostering design communication, participation and stakeholder involvement as well as bringing practical activities to the design disciplines.
