The purpose of this paper/research is to study supply chain mapping as a managerial activity and to question the impact of SC maps on SCM. In the literature review, we combine perspectives from SCM and from the ‘network pictures’ literature in industrial marketing (e.g. Henneberg et al., 2006) to ask the following: Do companies produce and use SC maps? Do managers’ individual SC maps reveal different “viewpoints” of the supply chain that could reveal different mental representations of what a SC is? When managers map a SC, what are the differences between what they draw, how they explain their mapping, and how they define the SC? The research design section details our qualitative case study focusing on the outbound supply chain of an industrial company. After presenting the empirical results of the research, we discuss their managerial and academic contribution before concluding.

**Literature review**

Supply chain management and the “images/pictures” of supply chains
Since the early 1980s, the study of SCM has involved the drawing of pictures of supply chains. Some famous figures are commonly cited. They show different aspects of what supply chains are. Stevens (1989) focuses on internal functions that have to be integrated with a linear representation of what an integrated chain is. Harland’s figure (1996) highlights the structure of the “chain” (from a line to a network) and the number of echelons. Mentzer et al. (2001) adds the types of actors participating in the chain. Some figures (e.g. Lambert et al., 1998) are clearly “centred” around a pivot with an upstream SC (up to initial suppliers) and a downstream SC (to end customers). In their framework, Cooper et al. (1997, p.10) identify actors, flows (information and product), business processes and SCM components. With the influence of the network approach (Haakansson and Snehota, 1995), supply chains are also seen as networks (webs) evolving through interactions of activity links, actor bonds, and resource ties (e.g. in Skott-Larsen et al., 2007). Consultants (e.g. Cohen and Roussel, 2005), who focus on the supply chain architecture, frame SCs around entities (actors), processes, data, applications, and infrastructure (IT and physical assets) referring to resources. The SCM literature review shows a variety of ‘pictures’ including different aspects depending on what message authors want to deliver about SCM. A cumulative list of categories of elements that figure on academic SC pictures can thus be established.

Supply chain mapping in SCM
SCM scholars have noted a “profusion of map styles”, with a variety of categories of elements figuring in academic SC maps, and suggesting the need for a supply chain mapping convention (Gardner and Cooper (2003, p.37). Hines and Rich (1997), who studied 7 mapping tools, point out they are contingent and address different objectives, which suggest taking care of the context when choosing one. Probably the best-known source on mapping for SCM is Lambert et al. (2008), which groups maps in two categories. The relationship-based maps often take the perspective of a focal firm, thus they “will look different depending on a company’s position in the supply chain” (ib., p.200). It points out the importance of the “viewpoint” and related “views”. Activity-based maps include: time-based process mapping (TBPM), pipeline inventory process mapping focusing on physical flows and steps in the logistics-production-distribution process, and extended value stream maps. For these maps, “the determination of the unit of analysis is critical to any mapping effort” (ib., p.212). The chapter concludes with: “Many managers believe that supply chain maps, whether they are relationship-based or activity-based are not worth the effort to prepare. However, once management has these maps in hand, they often report that they cannot think of a better way to understand the
nature of their supply chain” (ib., p.216). Maps are useful tools to better understand the “SC territory” and could also be considered as decision tools. Since there is no convention or set of conventions by which to represent SCs, SC maps are influenced by personal mental representations, the SC being a social construct (New, 2004). It is thus worth studying the individuals’ SC maps and the one(s) organizations provide to support SCM activities. It is also worth deconstructing SC mappings to unveil the implicit assumptions “behind” SC maps and the use of maps as tools of “power” in SCs.

Lessons from the network picture literature
Most contemporary SCs are named “networks” and SCM scholars refer to the IMP literature to better understand inter-organisational networks. Thus, the “network pictures” literature (in particular Henneberg et al., 2006 and 2010; Geiger and Finch, 2010 or Leek and Mason, 2010) is relevant to deepen the study of SC maps. In line with this literature, individual SC maps are the managers’ “theories-in-use about what the relevant business network looks like, and how it ‘works’ ” (Henneberg et al., 2010, p.356). Considering the variety of actors in a SC, these views could potentially be different, even between persons belonging to different functions in a company, and the mismatches could reveal important SCM issues.

To our knowledge, no empirical study has been done to question the making, use, usefulness of SC maps in companies and in SCs, as well as to question how mapping (as an activity) could reveal mismatch between mental representations of SCs and be useful for SCM. The research presented is an attempt to fill this gap.

Research design and methodology
We conducted a case study (Voss et al., 2002) in the downstream (outbound) car supply chain of Renault Group (RG), collecting data from December 2018 until March 2019. We gathered existing maps of the distribution chain – from the manufacturing plants to the end dealers – and analyzed their purpose (why do they exist?) and use (how are they used?). We conducted facilitated mapping exercises, combined with semi-structured interviews, with 18 RG managers involved in the management of RG outbound SC. To gather as many different “visions” as possible of the RG outbound SC, we interviewed key informants from different RG functions (manufacturing, logistics/operations, Supply Chain, quality, informatics, commerce), at different hierarchical levels (among the 18 persons, 8 are managers). Table 1 summarises the 18 informants, in 4 main categories. We also gathered many relevant internal documents from RG.

</table>

The interview guide was structured around 4 themes, always asked in the same order:
1. Interviewee’s profile (background, current position in RG, role in outbound SC);
2. Interviewee’s definition of the outbound SC of RG (how he[he] represents him[her]self the “territory” of the outbound SC);
3. Does the interviewee have ready-made maps of the outbound SC? If yes, does he/she use them in his/her work? If no, would a map be a useful device in his/her job?

4. Can the interviewee draw a map of the outbound SC? The facilitated mapping exercise was done on a paper sheet A4 format that was scanned at the end of the interview (Figure 1 shows an example map).

![Figure 1 – Respondent’s n° [1] map](image)

After recording and transcription, two of the authors coded separately the data collected and discussed and resolved any difference of their coding. This was done in four steps using a cumulative open coding: i.e. adding new items at each step. First, the collected maps were coded (what is drawn by respondents). Every piece of the drawings were named (items) and characterised referring to the categories found in the literature review. Second, the discourse of the respondents during the mapping (what is said during drawing) was coded in the same way, including new items if any was found. Third, the outbound SC definition (territory) was coded. Finally, the answers concerning the existence/usefulness of maps were analysed.

We used presence-absence matrices to produce results. At each step, we identified core items in SC maps (sum per line) and difference between respondents (comparisons of the columns). Table 2 shows the coding of the 18 maps (step 1). We then compared the tables produced at each step of the coding process. Appendix 1 shows the items found at each step. We also collected significant verbatim to illustrate some of the results. The internal documents of RG helped us to interpret some results. We split the respondents in 4 groups (cf. table 1) to explore the potential influence of respondent’s role in the management of RG outbound SC on mapping.

**Findings**

**About the company maps.** In fact, there are few maps of the outbound SC available in the company. There are two popular maps used in every presentation to sketch out the outbound SC. They are quite simplistic (linear and including few actors), mainly used for training new staff. They are so old that nobody can remember who drew them! They give a standardized representation of the SC from the moment cars leave the manufacturing plants, helping to develop a common vision and share objectives within
the company. In these maps, the plant, the customer (dealer) at an international level (geography), intermediary warehouses and logistics points, operations done on cars in warehouses, means of transport and the physical flow of cars are all represented. It is worth noting that, during the interviews, five participants (respondent [1], [5], [6], [15] and [16]) mentioned other maps. In the 2 extra maps provided, one is a geographical map of RG distribution; the other links the outbound SC with the overall SC of RG.

About the 18 outbound SC maps. The mapping exercise was not so easy for a lot of people, some respondents being at first reluctant to draw: “I am not good at drawing” (e.g. [E4], [E9], [E12], [E13]); “my picture is not clear” (e.g. [E11]), “have others made better pictures than mine?” ([8]). However, everyone produced a map. Table 2 gives the result of the analysis of the 18 maps. Thanks to the variety of respondents (different view points), we ended with 20 items in total, referring to 8 categories found in the literature.

Total of represented items on respondents’/maps (max = 20 items) 16 10 9 5 8 8 8 7 7 6 6 5 4 4 3 1 6 11 16

Legend: (1) The item is represented on the respondent’s map
(0) The item is not represented on the respondent’s map
(++) The item is implicitly represented on the respondent’s map

Three items are quite systematically represented (plant, warehouses, dealers) and four others are frequently present (means of transport, physical flow, points of tracking and the cars). Note that these items are the ones present in the official company map. The total per column shows a variety of richness of the maps. The individual maps confirm that every manager has his own supply chain vision. If the maps are not focused (centred) on the respondents’ activity, they seem influenced by their experience (e.g. figure 1 has been drawn by a logistics person). Most of the 18 maps are much more complex than the company maps. The richer maps were done by respondents [15], [1] and [12], who have more experience in the company, a transverse role (interacting with many people and functions) and with operational field contacts.

About the 18 discourses during the outbound SC mapping exercise. First, the analysis of what the respondents say while drawing the maps confirms the importance of the 20 items found at step 1. Second, it shows (see Appendix 1) some differences between discourses and pictures: 7 new items mentioned by respondents were not in the maps. The new items did not lead to add any new category of items. Third the comparison of matrices done at step 1 and 2 (see Appendix 2) shows that all items are more cited (step 2) than drawn (step 1). The discourse during mapping is richer than the map for every respondent and every item (except for 2 items) and it confirms that respondent’s experience of SCM influences his/her way of mapping SC (e.g. [2] “since I am in the
export flow…”; [4] “you can have port or not, but since I like ports…”; [E17] “being in charge of quality, necessarily it is the vagaries that give us grain to grind”). Finally, like for maps, there is a difference in richness of the discourses of respondents (range from 17 to 4 items). The mapping exercise led some respondents to ask themselves some key questions regarding: SC perimeter (e.g. [E9] “does the outbound SC begin here or there? […] for me it is a bit unclear”; [12] “the perimeter must go there [the dealer], but it should go further [the end customer]”), or how to represent some items ([E18] “there is also a kinematic part that seems to me to be missing from that representation. But on an A4 sheet I’m sure we can do better than that”).

**About the 18 definitions of what the outbound SC is (territory).** In line with the previous results, the analysis of the definition of outbound SC given by the respondents confirms the importance of the 27 items found at step 1 and 2. 7 new items mentioned by respondents were not in the maps and the discourse during mapping (see Appendix 1). The new items did not lead to add any new category of items. Comparison of maps and definitions (see Appendix 3) shows that all items are more present in definition (step 3) than pictures (step 1). If most definitions clearly mention that the outbound SC begins “when the car comes out of the plant” ([E1]), it is less clear where it ends. In line with the company maps some persons mention the dealer as the end point of the outbound SC, while most (10 out of 18) clearly go up to the end-user. Most definitions (13 out of 18) mention the performance objectives related to the management of the outbound SC that were not much present in maps (5 out of 18). Some respondents go into detail in some aspects of the outbound SC, in line with their experience or their responsibility (e.g. [E3] insists on the SC information system giving visibility to the commerce). Some definitions clearly state that the outbound SC is “complex” and some point out a fuzzy difference between the SC in terms of “physical operations”, “company function” and “company department” (e.g. [E14]).

**About the use and usefulness of outbound SC maps.** Appendix 4 sums up every point gathered in interviews concerning use, usefulness, existence of maps, experience of mapping… The need for having maps is clearly mentioned by a majority of respondents, even if most of them say that they don’t use maps and do not map. Respondents express the need for mapping tools… Could this refer to the need for convention of Gardner and Cooper (2003)? Since SCs are complex (which is a problem for mapping them for a majority of respondents), maps are useful to visualise, represent and better understand the SCs. Respondents spontaneously mentioned 11 types of map usefulness and 7 sources of mapping difficulty. There is a controversy over whether a map should be as complete as possible or not. But some respondents insist on the need for maps to be as faithful as possible. [E13] states “I think for a long time the carmakers didn’t take care of the downstream SC because they didn’t really see the stakes”. Could this explain why there are so few outbound SC maps in RG?

**Difference between the 4 groups of respondents.** The analysis of the differences between the maps, discourses and definitions of the four groups of respondents, even if subject to caution due to the low number of respondent per group, gives support to the importance of the experience of the territory (company, automotive sector, logistics operations and SCM, etc.) on mapping.

**Discussion**

In our case study, the alignment between organisational and individual maps is good. The organisational maps of RG, used for training, are simple and so old that they probably influence employees’ representations. They include such basic and core elements of the outbound SC that it is not surprising they also figure in the individual
maps. The comparison of the individual maps reveals that there are mismatches (e.g. type of map, what is represented, perimeter...). All in all, the sum of what is represented on individual maps is not so different from what is represented in the collection of academic maps. The 18 maps (mailed by RG key informants) tell us about managers' visible horizon (Carter et al., 2015) of RG outbound SC.

The mapping of SC is not an easy task for managers who express the need to develop tool to map. None of the 18 maps refers to or looks like the mapping tools or maps found in the literature. However SC mapping is considered as useful for managers participating to the management of a SC. This encourages researchers to go on working on this aspect of SCM, and to better communicate their results to industry.

The comparison of the results obtained at each steps gives evidence of the varied and more or less complex SC maps, discourses and definitions. This variety confirms the subjective nature of mapping and probably reveals the variety of SC mental representation of managers. It suggests that sharing individual maps could be helpful to improve collaboration between SC actors and eventually to align representations.

The comparison of results from step 1 with step 2 as well as the comparison between the four groups of respondents supports the influence of individual experience and projects (and objectives) in the SC on the individual maps. It suggests, in case of dysfunctions in the management of the SC, that studying the mismatches between individual SC maps could help to better understand where problems come from and to solve them. In line with the network literature perspective, the interviewees’ discourses also suggest that drawing maps made them understand things differently i.e. drawing doesn’t just represent the world, it (re)constructs it.

The comparison of results from step 1+2 with step 3 attests that “the map is not the territory”. The overall list of 33 items and 8 categories obtained at the end of step 3 is a valuable output to discuss and build SC diagnosis tool.

**Conclusion**

Our research questions the “neutrality” of supply chain mapping and helps to better understand the mapping process at the individual level. It also improves our understanding of the role/usage of maps in SCM. Philosophically speaking, it points to the importance of revealing the underlying ontological and epistemological vision of SC managers and researchers, respectively. Maps objectivize but are not objective pictures! Companies need to be fully conscious of the power of SC maps and to take greater care with their mapping activities.

The collected data did not permit us to unveil the implicit assumptions “behind” SC maps and the use of maps as a “powerful” tool in SCM. To go further on this understanding, a focus group with the respondents and other SC actors could be organized to discuss differences between maps and discuss the result of the research. The focus group could also discuss the following two questions. Does a better understanding of the differences between individual SC maps could help explain and solve SCM dysfunctions?

Our data did not permit us to study the potential influence of SC maps and mapping activity on SCM. This could be the aim of the continuing research collaboration with RG, with an action research approach. Can maps be considered (or serve) as intermediary or boundary objects in multi-function SCM teams (Carlile, 2002)?

Since the focus of our case study was the outbound SC of RG, adopting the point of view of the industrial company and studying first the internal actors’ SC maps, further research could replicate the methodology to study the maps of ‘external’ actors such as suppliers (for transport, logistics and operations-on-car activities), dealers, etc.
Finally, the research questions the need for a company to spend time and resources to map its SC. It questions the kind of map to promote and the relevance to adopt a convention (Gardner and Cooper, 2003). Is it a good thing to standardize maps? It also questions the use of maps and mapping in industry as well as in academia. Can maps influence managers’, students’ and researchers’ mental representations of SCs? Do persons’ mental representations of SC influence their mapping of SCs? More generally, how can maps be used in SCM?

Abstract

This research investigates principles to design Circular Supply Networks (CSN). We derive key investigative variables employing Industrial Ecology (IE) theory and Supply Network (SN) research to observe impact of product, production, and location attributes on design and assessment of CSNs. We apply a single case study design guided by a research framework. Findings suggest that certain product, process, and location attributes are required for a reuse based CSN. The research novelty lies in scope and level of analysis of SN. This research contributes to SN design research by incorporating the system balancing concept from IE and principles of Circular Economy.

Keywords: Circular Supply Network, Performance measurement, Reusable packaging

Introduction

The modus operandi of traditional Supply Networks (SNs) is characterised by a unidirectional flow of materials in a take-make-use-dispose mode of operations, resulting in an annual general waste generation of 2.5 billion metric tons in the EU alone, USD 80-120 billion lost material value in plastic packaging, and increased risk of severe health impacts, such as cancer, resulting from these wastages (Tagliabue et al. 2016; EU 2014; EMAF 2016). In addition to these challenges, increasing demand of resources, led by population growth across the world, may lead to a potential gap of natural resource demand and supply of 8 billion tons by 2030, suggesting that the traditional linear model of production and consumption is no longer viable (Esposito et al. 2018).

It is argued, that Circular Economy (CE) might address the challenges of linearity in traditional models of SNs. CE is defined as “an industrial economy that is restorative or regenerative by intention and design”, which seeks to increase resource and process
efficiency while reducing waste (EMAF 2013). The Ellen MacArthur Foundation (EMAF) suggests benefits, such as potential material cost savings of USD 595 – 706 billion globally in the Fast Moving Consumer Goods sector (EMAF 2013).

Even though CE rarely fails to disappoint when it comes to postulating its benefits, its implementation, involving open and closed loop SN practices, is “blurred and uncertain” (de Jesus & Mendonça 2018). We argue that there are mainly three barriers for the limited application: (i) Conceptual development of CE overlooks the importance of its operationalisation, (ii) Circular operations require changes in operational design from the perspective of product, process, and location, and (iii) Understanding of SN relationships between product, process, and location is fragmented and not well understood. Therefore, in this research, we address a key theoretical and industrial challenge of how product, process, and location attributes create circularity in a SN and how these attributes can be evaluated taking environmental and economic feasibility into consideration. We do so by employing a qualitative case study design, informed by literature and guided by the theoretical lens of Industrial Ecology (IE) as key theory for CE. The research novelty lies in scope and level of analysis of SNs. This research contributes to SN design research by incorporating the system balancing concept from IE and principles of CE.

In the following sections of the paper, we present literature on IE and supply networks. Subsequently, we introduce the methodology employed including conceptual framework mainly derived from literature, case study design, data collection and analysis. We then offer the discussion of our results. Finally, we conclude our research with implications to theory, management practice and policy development along with further research opportunities.

**Literature Review**

IE developed various theoretical concepts suggesting that any system operates in a balance, such as the biological ecosystem, where limited disturbances to the balance in a system can be compensated, however if those limitations are surpassed, the system loses its capability to recuperate and may degrade permanently (Graedel & Allenby 1995). The balancing element of IE theory deals with circularity development in a linear system. The system part of IE is a preconceived notion and context-dependent. In this research, we refer SN as the system. This balance and system view, further extended by CE, proposes seven distinct circularity operations: (1) Reuse, (2) Recondition, (3) Repair, (4) Refurbish, (5) Remanufacture, (6) Repurpose, and (7) Recycle (Reike et al. 2018). However, operationalisation of these circularities remains vague. Circular Supply Networks (CSNs) extend SN theory into the sustainability domain. However, theoretical knowledge involving how to operationalise such CSNs is fragmented. It is noted that the implementation of CE is “blurred and uncertain” (de Jesus & Mendonça 2018), and there is an argument that CSN “lack theoretical and paradigmatic clarity” (Blomsma & Brennan 2017), suggesting that contextual and operationalisation requirements are yet to emerge.

SNs can be recognized as systems that are rather evolving than purposefully designed (Choi et al. 2001). However, in the last decades academics have taken the challenge to design such a network (Beamon 1999). SN analysis can be performed from mainly three perspectives: (1) Optimisation modelling approaches of facility-location against a set of objectives (Santoso et al. 2005; Charles et al. 2016). (2) A network theory perspective, based on the notion of multiple nodes in a SN and different types of interdependencies (Kim et al. 2011; Borgatti & Li 2009). These nodes represent a particular operation/factory/organization in certain locations, however, the significance of product
and process attributes is not taken into account. (3) The third perspective takes the focal company point of view, where product and processes are studied with SN mapping approaches but end-to-end supply network attributes are limited (Lambert et al. 1998; Choi & Hong 2002).

In SN design, the most important issue is to understand the dynamics of Product, Process, Location. Product - Process dynamics in SNs suggests that increasing demand for a large product variety results in the requirement of ever more diverse processes. Therefore, companies develop modularity strategies (Huang et al. 2005) to push the customisation of products further downstream to reduce the degree of process diversification. Whereas Process-Location dynamics suggest that geography dependent attributes may result in specific process capabilities: in this context, it is demonstrated that sourcing and production decisions were made on the basis of location attributes (Kumar et al. 2016; Srinivasan et al. 2019). Hence, we argue that understanding the relationship between product, process, and location becomes an integral part of SN design.

Further literature exploration revealed, that general product attributes include functions, architecture shape, etc. (Pahl & Beitz 2013; Ulrich 1995; Otto & Wood 2001). We observed that there are two types of product attributes - Functionality, and Physicality (Table 1). Process attributes include upstream and downstream SN processes, such as production planning, supplier management, stakeholder integration, etc. (Beamon 1998; Reuter et al. 2010; Seuring & Gold 2013), which can be classified into Operational, and Management. Location attributes include key actors, factors of production, demand, regulations, etc. (Brush et al. 1999; Stalk 1988; Kumar et al. 2017; Lorentz et al. 2018), which we classified into Production and Distribution Infrastructure (P&D Infrastructure), and Regulation and Market.

*Sources: various academic contributions, including the ones listed in the text.

On the assessment of CSNs, IE theory interpretation leads to the understanding that the future circular system has to perform better from the environmental and economic perspectives. Here, the SN performance measurement system helps to understand what to measure and how to measure (Neely et al. 2005). In that sense, we refer to indicators and methods. The literature on indicators, which can also be classified from the product, process, and location perspectives, provides a huge library of possible choices (UNEP 2015; World Bank Group 2017; GRI 2011), however, the rationale for indicator selections remains nebulous. Furthermore, there is a wide variety of performance measurement mechanisms, dominated by Life Cycle Analysis (Piezer et al. 2019; Hossain & Thomas Ng 2019), however, lack the SN attributes of product, process, and location. The closest rationale we identified for selecting particular indicators and performance measurement mechanism was that “Organizations should determine what success would look like for them” and choose them accordingly (BSI 2017). However, this appears unsatisfactory considering that any CSN requires justification from the environmental and economic perspective, where a unified approach for comparability appears essential. We further argue that, if CSN design needs to incorporate product, process, and location attributes, a performance measurement system should be based on...
the same dimensions. Therefore, we set out to investigate how product, process, and location attributes create circularity and how these attributes can be evaluated. A set of investigative variables is derived from this literature review that informed a research framework discussed in the next section.

**Methodology**

We argue that the general principles of developing circularity need to be investigated through empirical research within a set boundary of investigative variables mainly derived from literature. This research framework, that guided the data collection and analysis, is illustrated in Figure 1.

![Figure 1 - Research Framework](image)

The research framework has three key elements. The first element suggests the transformation process from single use to multiple use. The second and third elements are supply network attributes and performance measurement, demonstrating requirements for the transformation. We considered 12 product attributes from notable scholar, 16 process attributes, and 26 location attributes to investigate how those attributes create circularity. In order to avoid bias, we confirmed the classification of attributes into those groups with three other independent researchers. On the assessment side, we considered 536 indicators and 161 environmental and economic assessments.

In this research, we investigate the emerging CSN phenomenon with a single-case study design at Nestlé, who is known for their research into CSNs as widely reported in the news, with reusable Häagen-Dazs ice-cream packaging being considered as exemplar and revelatory case for reuse systems, representing a key case selection criterion for this research (Yin 2018). The unit of analysis of this research is CSN design projects and the level of analysis includes attributes of product, process, and location. The single-case study approach promises relevant results, due to the uniqueness and richness of detail required in order to generate key principles based on how multiple attributes of product, process, and location create circularity. We appreciate the limitations that come from single-case study research (Eisenhardt 1989), however follow Dryer & Wilkins (1991) and Flynn (1990)’s view of the benefit of using single-case study in contexts where greater depth and rich details are required (Dryer & Wilkins 1991; Flynn 1990). Other authors, who employed single-case study design on the basis of revelatory, unique and critical cases include (Simons & Russell 2002; Oliva & Watson 2011).

The first point of data gathering effort at Nestlé started with a site visit in December 2017. We conducted expert semi-structured interviews with 10 participants from Nestlé and TerraCycle (multiple use packaging solution provider) ranging from technical specialist to project manager, as well as environmental and economic assessment specialists. Additionally, we collected data from archival records with regards to product
specifications and environmental assessments conducted at the company. The total interview time was around 30 hours and archival records amounted to around 430 pages (product design, environmental assessments conducted by the company). In order to ensure reliability and construct validity, we developed a data collection protocol that guided the research, comprising aims, data collection procedure, and interview questions (Yin 2018). Secondly, we followed data triangulation techniques by using multiple sources of evidence (semi-structured interviews and archival records) and multiple sources per evidence (Yin 2018). Thirdly, we developed a database to maintain a chain of evidence between case study questions, findings, and evidentiary sources (Yin 2018).

A high level excerpt of the data collection protocol, summarising attributes, source of data and participant designation is shown in Table 2.

We analysed the data according to: (1) the three CSN domains product, process, and location, and (2) environmental and economic assessment by the means of a coding framework (Miles et al. 2014), which represented the attributes in each domain, as identified in literature. The second step involved complementing the interview data with data from archival records, such as product design records, environmental assessment reports, etc. We then conducted a product, process, and location analysis, individually and across, in order to identify key patterns and interdependencies.

**Findings and Discussion**

This section presents the key findings and discussion. Five key principles have emerged from our data analysis. The following paragraphs presents and discusses each of the principles. Table 3, on the next page, presents the data analysis, providing evidence for these key principles.

In the product domain, we observed that SN circularity requires changes in product functionality, which translates into changing product physicality. In the case of Häagen-Dazs, additional functional requirements, such as durability (100 use cycles) and cleanability lead to a new physicality of the product by changing its materials. It was stated by the company official, that “The material selection was a decision made through an evaluation of the lifetime, […] quality concerns that could come from the material, [...]”. We observed that changing physicality is a complex process involving not just material but also design of products. In the investigated case, certain designs can lead to higher risks of product safety, for example in the cleaning process, certain designs on the metal, such as embossing, will increase the risk of contamination.

</tbody>
</table>
On the topic of process, our analysis demonstrates that the implementation of circularity requires changes in the operational and management process, that may or may not result in a change of process-ownership. In the case of Häagen-Dazs, additional production processes such as collection of packaging from consumer, cleaning and delivering to Nestlé were contracted to TerraCycle, whereas filling and lidding of the reusable packaging is performed by Nestlé. While this resulted in minimal changes of the production processes for Nestlé, this process-ownership pattern required an alteration of management processes, such as additional supplier management. Nestlé stated that “When we introduce reuse, we want the fewest changes to our existing operations as possible. [This model] required minimal adaptation of the production processes”, suggesting that the type of circularity employed by a particular company may depend on the adaptation requirements of the existing SN. Potentially, such partnership arrangement may shift the power in buyer-supplier relationship. In this case, it means the power shift from main manufacturing firms towards suppliers. Here, Nestlé stated that “our reuse model requires us to be in a partnership with an external company [TerraCycle], knowing that they are potentially in partnership with competitors.”

From the location perspective, we argue that there are multiple unique attributes of location that determine the type of circularity in SNs. We observed, that the Häagen-Dazs reuse SN is dependent on key location attributes of New York linked to consumers’ buying preference, affordability, and transportation distance. In New York, “The success of the project was dependent on ambassadors for sustainability [...] and willingness to pay when it comes to sustainability”. Here, reuse may be particularly feasible for wealthy regions - nationally and globally – whereas other types of circularity may be more suitable for less affluent regions. Additionally, Nestlé stated that: “At the end of the day it really is transportation distance that contributes the most to environmental impact, no matter what material you choose [for the packaging]”. The importance of short transportation distances implies, that a reuse SN may require very localised manufacturing strategies. Therefore, understanding the particular location attributes with regards to the type of circularity is essential. However, this preliminary assumption needs to be tested.

We also observed inter-dependencies between Product, Process, and Location: (1) Product functionality impacts location. In the case of Häagen-Dazs, the ability of the reusable packaging to keep the ice-cream refrigerated contributed to the decision of the location. Nestlé stated that “how long the ice-cream can stay frozen [in the reusable packaging] under ambient delivery conditions drives location”. Especially, the longer the ice-cream can stay frozen the larger the distribution radius from the filling facility. (2) Production processes impact product functionality and physicality. In particular, the shape of the reusable metal container was constrained by the existing filling processes. Nestlé stated, that “We have to figure out what the best way to integrate this packaging in [their] current processes was, [and ...] there was not a lot of freedom to design”.

In terms of evaluation of the attributes of the CSN, indicators and assessment of such CSN projects are dominated by profitability and return on investment. Nestlé stated that “Financials are key. If we make profit after the 1st year and offset the investment in the next [x] years, we go ahead [with the reuse project]”. Environmental considerations are difficult for companies to evaluate because there is an underlying assumption that any circularity is better than the linear system. However, the company stated that “we need to understand under what circumstances reuse is environmentally superior to single use options”. On the environmental assessment, LCA is widely applied, which has inherent limitations and there is a need for a new approach for environmental and economic assessment. In this area, theoretical justification is needed on indicator selection and data
access and capturing of new processes. Here, the company states that: “We selected the indicators based on whether they would create this very impact in our operations”. Additionally, Nestlé mentioned that “The data base we use provides average values of the environmental impact of processing 1kg of a particular material”, neglecting the distinct operational set-up of the CSNs involving geographies and process intensities and efficiencies. This research suggests that specific methodological development requires a more operational perspective on capturing environmental impact directly from the operational set-up.

To conclude the discussion, we propose the following five key principles for CSN design: (1) Changes in usability of product, here: 100 use cycles, leads to changes in its physicality involving materials and design; (2) Changes in production processes may lead to changes in intra- or inter-firm management processes; (3) Certain types of circularity, here: reuse, require localised manufacturing; (4) The interdependencies between product, process, and location determine the type of circularity; (5) Environmental assessment requires access to primary data. We furthermore note, that if the attributes presented in Table 3 are not met, the reuse circularity might not succeed.

**Conclusion**

This research investigated how product, process, and location attributes create circularity in a SN and how these attributes can be evaluated taking environmental and economic feasibility into consideration. The key findings are threefold: (1) Implementation of CSN operations require operational and managerial changes in Product, Process, and Location attributes. These changes have to be made in careful consideration of the dependencies of attributes within and across the three domains including the type of circularity employed, (2) Current environmental assessments of CSNs reflect potential environmental impact within the limitations of the study, suggesting the development of an integrated methodology for CSN evaluation, and (3) We suggest five key principles for CSN design, demonstrating the impact of product, process, and location attributes on design and assessment CSN.

Theoretically, this study introduces the concept of balancing a system from IE theory and integrates it with supply network design. We provide key principles for developing and operationalising CSN. In other words, this research extends IE theory into the SN design research domain. It also extends SN research by incorporating product, process, location, which is not widely inferred in supply chain analysis. It is important to note that supply network research is mainly linked to operational efficiency and capabilities, which has its roots in the notion of manufacturing strategy dating back to Skinner’s seminal work in 1969, challenging the Taylorism view of bottom-up efficiency improvements of manufacturing operations. This research builds on the capability perspective of manufacturing strategy to develop circularity in supply networks. The novelty of this research lies in the scope and level of analysis of supply networks. The scope of analysis included a product, which is not consumed (in this case packaging). The level of analysis incorporated product, process, and location.

From a management practice perspective, this research informs managers with regards to the decisions: How to select a product for the transformation to circularity?, What are considerations for the coordination of product, process, and location decisions in the SN design?, Why should the limitations of environmental assessments of circularity in transformation projects be well understood?

From a policy perspective, we can see that the transition to CE could benefit from developing a standard assessment methodology that integrates environmental and economic assessments to ensure comparability and therefore, helps create visibility
under what circumstances certain circularity projects are successful on a large scale.

We understand the limitations of this research as follows: the case study is limited to one company in fast-moving consumer goods, whereas circularity operations in different industries may result in other conclusions. Generalisability is further limited by the single-case study methodology employed.

Further research into the high-level key principles for CSN includes (1) establishing a hierarchy of attributes in each domain in the context of CE, (2) distributed manufacturing strategies for different types of circularity, and (3) development of an integrated environmental and economic assessment methodology. From an organisational theory perspective, a contingency based approach to investigating product, process, and location attributes can provide valuable insights about the internal and external contingencies that need to be considered in CSN design. This is particularly relevant since one of the interview partners mentioned the increasing number of constraints companies are confronted with. Employing an organisational learning perspective could also yield to relevant insights, in contexts where the scale-up from pilot-projects to projects is planned, in order to create generalisable theoretical insights, how CSNs can be expanded.

Abstract

This paper discusses the effectiveness and importance of adopting a holistic systems approach to complex supply chain issues and illustrates the argument by using the viable system model to investigate offshore wind supply chains in the UK. Systems approaches are often mentioned in the supply chain management literature, particularly regarding supply chain integration, however they remain underutilised by supply chain academics. The discussion’s output will be a proposed research agenda for a follow-up empirical study of the offshore wind industry.

Keywords: Viable system model, Offshore wind industry, Supply chain

Introduction

It has long been acknowledged that supply chains form complex networks of interconnected and interdependent organisations and researchers therefore need to consider them as ‘complex systems’ (Ellram and Cooper, 1990; Choi et al., 2001; Grant, 2012). The term ‘system’ comes from a meta discipline known as systems or holistic thinking and is described as a collection of inter-related parts that work together to create a coherent whole with a purpose (Espinosa and Walker, 2017). One of the key systems thinking ideas is that properties of the parts can be understood only within the context of the larger whole, as opposed to Cartesian science that believes the behaviour of the whole should be analysed in terms of properties of its parts (Capra, 1997). Understanding supply chains as complex systems could help academics and practitioner to understand supply chains holistically by respecting the interconnectedness of businesses that make up the supply chain.

Many logistics and supply chain management (SCM) scholars recognise the relevance of systems thinking, in general, as a valuable perspective needed for holistic understanding and learning of SCM processes, given that the term “supply chain management” itself was born out of the idea of viewing the chain of supply as a single entity (Oliver and Webber, 1995). Systems perspective relevance is especially evident in the concept of supply chain integration (SCI) that is characterised by “joined up thinking, working, and decision making” (Stevens and Johnson, 2016: 22) that lies at the core of
SCM, with a dominant view in the literature that greater SCI leads to better supply chain performance overall (Frohlich and Westbrook, 2001; Pagell, 2004).

Thus, a systems view of the supply chain can help achieve higher levels of SCI by emphasising process optimisation to assist the performance of an entire chain rather than optimisation of individual parts (Sadler, 2007). However, despite the general acceptance of the value of a systemic view for SCI, as well as in the wider logistics and SCM discipline, studies employing systems theories often use them only as a background philosophy rather than as a guiding methodology (Fawcett et al., 2012). Lindskog (2012a, b) found that in general systems theories and associated approaches remain underutilised within the logistics and SCM discipline. Similarly, Nilsson and Gammelgaard (2012) noted that those using systems approaches rarely explain on what grounds, theories and definitions those approaches are derived from.

The purpose of this paper is to address these shortcomings in our knowledge and practice by discussing one of the approaches in the systems thinking discipline, the viable system model (VSM), which focus on analysing organisations and networks as complex systems, and to describe its potential as a methodology to investigate the UK offshore wind (OSW) industry supply chain as a complex system and to aid in the structural analysis of SCI within that sector. The paper first provides a theoretical background of VSM and the UK OSW industry sector to develop a conceptual VSM within the OSW sector. Then, a proposed research agenda for empirical case study in 2019 and its anticipated contributions are provided before the paper is concluded.

**Theoretical Background**

**Viable system model (VSM)**

The viable system model or VSM in short was developed by Stafford Beer in his work on a theory of viable and effective organisations known as organisational cybernetics (Espinosa and Walker, 2017). Organisational cybernetics has developed as a separate strand of the wider science of cybernetics, explained as a science of communication and control (Wiener, 1985). Control, as argued by Beer (1967) does not refer to control in a coercive regulatory sense but to control as a system’s strategy to achieve the organisational purpose. In cybernetic sense, it refers to ‘homeostats’, system’s internal mechanisms able to maintain its state of dynamic stability, and the important principle of self-regulation. Self-regulation means the systems capability to adapt to a changing environment even when it means re-organising its own structure and functions. Organisational Cybernetics and the associated VSM thus draws upon a wider range of cybernetic principles including the theory of viability, the concept of requisite variety, homeostasis, autopoiesis, and the concept of recursive organisation (Ashby, 1958). From an organisational cybernetics perspective, the organisational patterns of higher-level systems can be repeated in the organisation or lower level systems. This can also be observed in supply chains that consist of many different suppliers that can be viewed as separate systems themselves and which are involved in many different interactions, taking the form of a nested system(s), explained as a system that is composed of embedded subsystems (Simon, 1962).

The example of a viable system that served as the basis for the VSM’s birth is the organisation of the brain and the organs in the human body as a neural network, communicated through the neurological system; both the neural network type of organisation and its implicit principles of self-organisation and distributed control appear to be of equal relevance to social organisations of all shapes and sizes as suggested by core principles of organisational cybernetics (Jackson, 2005). Therefore, VSM can be described as a model of the organisational features within any viable system (Jackson,
However, viability in this case does not refer to economic viability. Instead, viability in VSM terms refers to a system’s ability to retain an independent existence within a specified environment (Beer, 1985). It suggests that central to organisational viability is the dynamic structure determining the adaptive connectivity of the system’s components (e.g. some businesses might not survive even addressing all its financial constraints). For example, a company that runs a profitable business may well be regarded as a viable system, but if it depends only on one customer that decides to switch to another company, it puts its viability in question. The VSM, therefore helps to design an organisational structure that can be deemed viable and diagnose a faulty one. Viability, in VSM’s terms, should also not be confused with the concept of ‘sustainability’ associated with the triple bottom line, including economic prosperity, environmental quality and social justice (Elkington, 1997). Espinosa and Walker (2017) argue that adherence to these sustainability principles would require further actions and new responsibilities to be added to the existing business practices and their organisational systems, therefore ‘viability’ can be and should be regarded as a precondition for sustainability.

**VSM building blocks**

The building blocks of the VSM consist of three main elements: a set of operations (O), consisting of system’s basic activities, in which is embedded a meta-system (managerial support) (M); and an environment (E), in which O and M are embedded. The operations and the meta-system are further sub-divided into five interacting systems, called System one, two, three, four and five that can be understood as typologies of functions similar to those performed by the human body, its organs, nervous system and the brain (Espinosa and Walker, 2017).

*System one (S1)* is referred to a collection of operational elements of a system in focus, responsible for the primary activities, which are responsible for implementing the purpose of the system in focus. *System two (S2)* acts as a service for S1 by ensuring that S1 parts act cohesively and do not get in each other’s way, i.e. it provides an anti-oscillatory function. According to Beer (1979), S1 may experience an uncontrolled oscillation unless a sufficient element of ‘damping’ is introduced and thus S2 exists to damp oscillations. In a manufacturing firm an example of an S2 would be a production protocol. Espinosa and Walker (2017) note that a lack of effective S2 mechanisms may lead to ‘oscillatory disease’ resulting in competition rather than collaboration, and conflict rather than harmony.

*System three (S3)* refers to general management of an S1. S3 is concerned with all that is going on inside the firm and ‘now’, as it has direct links with all managerial roles of S1s. S3 works closely with S2 which will be responsible for disseminating policies, guidelines and day to day information to and from the divisions. Therefore, S3 functions are managerial functions at the corporate level that relate to the continuous activity of the firm’s internal operations. S3 primarily functions to govern the stability of the internal environment of the firm or organisation by ensuring synergy of S1 through resource bargain, since S1 may involve more than one operation, each requiring their own resources. In a business environment it would normally fall to the general managers to fulfil the S3 function (Beer, 1986).

*System three star (S3*) is a servant of S3, fulfilling an informal auditing role to ensure that S3 specified targets and S2 rules and regulations are being adhered to (Jackson, 2005). S3* functions can include informal internal as well as external audits but are not there all the time and are rather triggered occasionally by S3. *System four (S4)* is dedicated to the larger environment. Beer (1986) called this function ‘outside and then’ by
explaining that every viable system is involved in an environment that is wider than the sum of S1 environments. While systems 1, 2 and 3 are considered ‘inside and now’ S4 is responsible for the ‘outside and then’. S4 thus performs ‘environmental scanning’ by looking for and capturing information about anything happening in the outside world that may potentially either benefit or threaten the organisation (Espinosa and Walker, 2017). Activities like R&D, market research, corporate planning, economic forecasting, management development, etc., are all S4 type of activities. Organisations need to be responsive to changing environment and remain up to date with information and new innovations in the market. However, just to be up to date with information is insufficient as this information needs to be used. Therefore, whoever performs S4 activities within organisations needs to be able to communicate gathered information with S3 which, depending on a system in focus, can be organised in a more informal or formal way. According to Espinosa and Walker, Beer called this interaction between S3 and S4 the ‘adaptation mechanism’.

*System five (S5)* is responsible for the organisational closure, identity and ethos and organisational policies. In autocratic organisations S5 may well be the corporate directors; but in a more democratic organisation S5 may consist of many people, for example the heads of S3 and S1. It is vital to achieve effective interactions between S4 and S3 on a continuous basis, to ensure system’s viability, and therefore one of the main S5 tasks is to monitor the balance in the interactions between S3 and S4. Further, systems 2-3-4-5 types of roles in a viable system are meta-systemic to operational (missional) roles (S1). Figure 1 shows a graphical representation of the VSM, where S1 including multiple operations and their operational management (1a, 1b, 1c) are represented as (O); the meta-system (M), encompasses all the support roles S2, S3, S4, S5, and the environment (E) which includes all the stakeholders the organisation relates to, which are outside the organisational boundaries (e.g. customers, suppliers, competitors).

The UK Offshore Wind Industry

The offshore wind (OSW) industry, together with onshore wind, form part of the renewable energy source sector and acts as a natural fuel to generate clean electricity by means of wind turbines that are designed to convert kinetic energy derived from wind into electrical energy (EWEA, 2009). What makes OSW different from onshore is that OSW farms are built out at the sea and due to the UK’s favourable OSW market conditions, such as shallow seas and strong winds, the UK has been the largest OSW market in the world since 2008 and continues to maintain its leading position with nearly 40% of the global OSW installed capacity (Danilova et al., 2016). This makes OSW one of the key technologies in meeting the UK government’s 2050 greenhouse gas (GHG) emission reduction targets, aiming to reduce 80% of the GHG emissions by 2050.

Recognising the advantage of its natural wind and sea resources, the UK Government is keen to capitalise on the OSW industry by securing inward investment and by the development of the UK domestic supply chain with an outlook to increase its global competitiveness and reduce costs (LEANWIND, 2017). To achieve its objectives the UK government offers a range of support mechanisms. One such support is a subsidy mechanism known as the Feed-in Tariff with Contracts for Difference (CfD) which became effective in 2017 and replacing the former Renewables Obligation policy. As part of this subsidy mechanism, developers of 300 mega-watt (MW) and above power generation capacity projects are required to submit the, so called, supply chain plan, outlining the ways developers expect to contribute to the domestic supply chain development (Danilova et al., 2016). This requirement is interpreted as a local content requirement (LCR), a policy requiring a foreign investor or other companies involved in the industry to contribute to the national economy by purchasing local goods and/or services (OECD, 2016). While such support mechanism is generally perceived as a positive contribution for the local economy, it might however pose some challenges for the existing supply chains, as the need to comply with LCR policy might put existing buyer-supplier relationships at risk, potentially affecting the viability of the whole supply chain. This, therefore, suggests the need for an in-depth systemic analysis of the OSW supply chain to understand its current integration levels, that according to literature, have direct relation to the performance of the whole supply chain, and to understand the role LCR policy plays in the formation of the OSW supply chain.

Offshore wind supply chain structures

Academic literature recognises that the context of the OSW supply chain is related to the project-based environment that differs from more traditional process-based environments like continuous manufacturing or retail environments (D’Amico et al., 2017). Therefore, the most common perspective currently used to describe the OSW supply chain is by describing its principle phases rather than its structure and processes, which is more accepted in the retail or process-based supply chain environments. Building on this perspective, this study distinguishes five phases that is development and consenting (D&C), manufacturing and supply (M&S), installation and commissioning (I&C), operations and maintenance (O&M) and de-commissioning (De-comm) phase, and views ports as decoupling points in the supply chain that decouple activities that happen onshore from those that happen offshore, as shown in Figure 2 (Danilova et al., 2016).
It is important to note that each phase may be considered as a different supply chain. The same holds true for all the different component manufacturers, who are likely to have their own supply chain networks for parts sourcing. Therefore, it suffices to say that OSW supply chain is complex, constituting different levels of different supply chain networks. Considering this complexity, this study offers another OSW supply chain representation, shown in Figure 3, that encompasses a network perspective and its associated flows (Grant, 2012).

**Development of a Conceptual VSM for the UK OSW Supply Chain**

Espinosa and Walker (2017) suggest their ‘methodology to support self-transformation’ as a guideline to use the VSM for organisational design or diagnosis, as it helps participants to engage in improving their organisational viability (Espinosa et al., 2015). It involves several stages: The first stage is to identify the ‘system-in-focus’ for the VSM analysis by understanding its identity and purpose. This can be achieved using rich pictures, a cartoon like representation of a studied situation that allows to capture the main issues and opportunities people may experience in the studied system; and by doing a TASCOI analysis: TASCOI is a mnemonic that stands for Transformation, Actors, Suppliers, Customers, Owners and Interveners (Espejo and Reyes, 2011), adapted from Checkland’s (1990) CATWOE (customer, actors, transformation, worldview, owners, environment). The second stage involves Recursive Analysis. This concept of ‘recursion’ refers to Beer’s “Recursive System Theorem”, saying that “in a recursive organisational structure, any viable system contains, and is contained in, a viable system” (Beer, 1979: 26th EurOMA Conference Operations Adding Value to Society
The purpose of this analysis is to identify and map the relevant recursion levels of the system. The third stage involves structural diagnosis using VSM as seen in Figure 1. The fourth stage involves aligning strategy and structure, based on identified diagnostic issues. The fifth stage involves securing agreement on the necessary changes needed to achieve desired improvements and implementing them. The last stage then involves monitoring and assessing the changes.

For the purposes of the proposed research, a simplified version of ‘methodology to support self-transformation’ is adopted, involving the first three stages to explore the OSW supply chain based on a single case study of the OSW farm in the UK, namely “Hornsea Project One” that once built will be the largest OSW farm in the world. The stages of analysis include specifying identity of the system, performing recursive analysis to surface the system-in-focus and applying VSM analysis of the system-in-focus to make recommendations on potential improvements of the OSW supply chain integration and its performance. Based on TASCOI analysis, preliminary identity of the system is defined as: “Hornsea Project One offshore wind farm development network is a system comprising businesses that are engaged in the process of building an OSW farm that once completed will produce clean electricity”.

A completed OSW farm is seen as the main output of the transformation process in the identified system; such transformation (T) can be realised through supply inputs as those products and services necessary to build the wind farm. The main actor (A) that carries out this transformation is likely to be the developer and his support organisations, that acts as a focal firm in the supply chain. Suppliers (S) in this case have the direct meaning of all those suppliers of the main components and services needed to build a wind farm. Customers (C) in this case would be those interested in operating the wind farm, once completed, and selling clean electricity, as well as receiving it. These would include offshore transmission owners (OFTOs), who act as owners and operators of electricity transmission assets, national grid electricity transmission (NGET), electricity suppliers and end consumers of electricity. The role of the owner (O) of this system belongs to the developer of the OSW farm. Finally, interveners (I) or external agents that might affect the performance of the transformation process of a given system, are likely to be national and regional governments, environmental agencies and competitors of different types of energy sources.

It is important to note, however, that the above ‘working’ definition of the system is produced initially by taking the researchers’ perspectives aiming to use it to enable further clarifications from the real-world participants in a wind farm build project - as different actors would have different viewpoints about the identity of the system. The following stage involves recursive analysis necessary to identify the levels of recursion of the system, as well as the levels of its complexity. Recursive analysis is based on the primary activities of the system that are aligned with its transformation processes. As explained by Espinosa and Walker (2017), primary activities are directly related to organisation’s purpose that transform certain inputs into products or services. Therefore, this process also helps to distinguish primary activities of the system from support ones.

Considering that this research focuses on the supply network for the Hornsea Project One OSW farm development and construction, its supply chain phases, up to the O&M phase, have thus served as the bases for distinguishing the system’s primary activities or S1s. Figure 4 shows the preliminary recursive analysis of the system in focus, where certain numbers indicate lower recursion levels. For example, development and planning activity contains such activities as consenting, environmental surveys, engineering and consultancy etc, that are considered as the next level of recursion down and are thus numbered as level 1. Engineering and consultancy also contain several more activities
that are considered as the next level of recursion and are thus numbered as level 2. Three dots in brackets indicate that each activity would contain more levels of recursion, however, the importance of this analysis is to identify those activities that are of more concern for the subsequent analysis. Figure 4 only shows lower level of recursions of the system in focus, however, it is important to remember that the system in focus itself is embedded in higher-level systems, therefore upper recursion levels also exist which are not analysed yet in this preliminary research.

The identified system in focus with its levels of recursive organisation, will be used for the subsequent VSM analysis that will involve drawing several VSM diagrams, where each recursion level will be represented in terms of its own primary activities and their interactions with their local environments. Primary activities of each recursion level are considered as the S1s of the VSMs. In the Hornsea Project One OSW farm development, all suppliers of primary activities involving both physical products and services are considered as S1s. Systems 2 to 5 are meta-systemic functions responsible for bringing all operations together into a unified system. Considering that the S2 function is to ensure cohesion among S1s, it is, therefore, of particular interest to this research, which looks to identify the necessary supply chain integration criteria in the OSW farm construction. Part of the research will, therefore, involve identifying any standards in the existing supply chain processes, such as order standards, scheduling, communication etc., including any standards pertaining to supplier selection processes. While studying S3 - a function of which is likely to belong to the wind farm developer or a contractor - emphasis will be placed on the existing and potential synergies among S1s, as S3 needs to ensure that S1s perform their tasks with minimum risks to the performance of the whole system. Resource bargain is one of the mechanisms through which such synergy can be achieved; the accountability channel of S3 then helps to monitor that S1s have delivered on expectations, based on agreed resources. Another responsibility of S3 is to ensure that all operations are performed within legal and corporate norms. Thus, LCR policy compliance will be considered within S3. Within S4, the emphasis is placed on the system’s in focus interaction and adaptation to any changes in the external environment, such as changes in

![Figure 4: Recursion levels of system in focus](image-url)
political and economic environment, technological innovations and so on. Within S5 the interaction between S3 and S4 will be assessed, as it is important for system’s viability to achieve interaction between S3 and 4 on a continuous basis (Beer, 1979).

**Proposed Research Agenda**
The VSM analysis based on Espinosa and Walker’s (2017) suggested ‘methodology to support self-transformation’, as outlined above, will be empirically tested during 2019 based on a single case study research strategy. The case study selected is the Hornsea Project One OSW farm, located off the East coast of the UK. This wind farm, which is currently under construction, will be the largest wind farm in the world, comprising up to 174 turbines with 1.2 gigawatts (GW) power generation capacity. It is selected to provide current ground to systemically explore the OSW supply chain and its integration levels, summarised in the main research question: How can an in-depth systemic analysis of the OSW supply chain support its level of integration and, therefore, increase its potentiality for improved performance? Data will be collected using semi-structured interviews (inspired in VSM theory) with representatives of the main operations of the Hornsea Project One wind farm development network to enable clarifications of system’s identity and VSM concepts.

**Conclusion**
The paper’s objective was to discuss the use of the VSM to investigate the UK OSW industry’s supply chain and create an understanding of the structural organisation of the OSW supply chain and identify necessary SCI aspects pertaining to the construction of an OSW farm. From a theoretical perspective this paper contributes to the logistics and SCM literature by proposing and demonstrating that VSM and related methodologies, provides a useful systemic approach to analyse supply chain structures. This paper also contributes to practice by enabling UK businesses wanting to be part of the OSW farm construction and maintenance sector to understand their supply chain structures and integration factors by using VSM criteria and tools to improve them. As with all papers there are limitations. As a conceptual paper, which develops a conceptual model for the UK OSW industry it will need to be empirically tested later to confirm its efficacy: and this process is already underway and will be the central aspect of this research. Further, this paper only considers modelling and analysing one industrial sector in one geographic location. Future research should investigate application of the model to other sectors and to other wind farms elsewhere in the world.

Abstract

CLSCs in the literature consist of some characteristics that identifying, studying and classifying these features help to formulate new models that do not exist. As there are lots of research on the investigated area, we concentrate on the CLSC models that used the game theory approach. Therefore, gathered works concern a game among the participant parties in the loop in the form of cooperation or competition known as centralized or decentralized frameworks respectively. A systematic literature review is carried as a four-step process containing material collection, descriptive analysis, category selection and evaluation stage. These characteristics are classified into twelve categories.

Keywords: Closed-Loop Supply Chain, Literature Review, Game Theory

Introduction

Closed-loops as a special configuration of the circular economy in the supply chains have received considerable attention due to their applicability in the sustainability process such as remanufacturing, refurbishing and recycling (Masi et al., 2017). They integrate material, financial and information flows connecting downstream to upstream enterprises through a supply chain to construct a unique system and create additional values (cf. Mishra et al. (2018) for real cases). CLSCs consist of many characteristics that identifying and classifying these features help to formulate new models (Souza, 2013; Govindan et al., 2015).

Operations in CLSC have predominantly shifted to exploit the techniques provided by the game theory to analyze the behaviour of the rational player, stakeholder choices and designing voluntary extended producer responsibility policies (Guo et al., 2017). Accordingly, in present research important factors, those which are applied especially quantitatively in the formulation of CLSCs are derived. These factors are categorized in several classes which help not only to build new CLSCs but also to find research gaps. Gathered works concern a game among the participant parties (i.e. manufacturer, retailer, consumer and etc) in the loop in the form of cooperation or competition known as centralized or decentralized frameworks respectively. Fig. 1 shows different parts of a
loops based on three phases as the loop structure (i.e. forward and reverse directions) and the optimization method designed based on the game theory.

Objective and methodology
A systematic literature review is carried out based on the methodology suggested by Mey and Mruck (2010) that introduced a four-step process containing material collection, descriptive analysis, category selection and evaluation stage. It is tried to reply the main question of the research: "which factors are important and effective on the formulation of CLSC models designed based on the game theory?"

**Figure 1 – Closed-loop structure**

**Figure 2 – Different steps of the research methodology**

**Literature search**
Whole of the related literature is searched in four stages including initial search, filter and analyzing step and final search as explained in Fig. 2 in details. More than 1800 papers
are derived based on an initial search in Web of Science™ using the keywords "closed-loop supply chain" and "CLSC", and also a snowball on the references of the related works. Finally, the content of 215 papers published in the area of game-based CLSCs over the span of fifteen years (2004–2018) are carefully inspected and analyzed.

**Descriptive analysis**

Fig. 3 presents the academic peer-reviewed journals as to the number of papers that they are published regarding the investigated topic. Totally 62 journals are searched. However, only the journals with more than 2 published papers (i.e. 21 journals) are shown. *Sustainability* consists the largest number of research articles ($\approx 12\%$). To build a strong integration of CLSC and game theory, *IJPE* has shown its significant contribution by the second largest percentage ($\approx 10\%$) of the total articles.

![Figure 3 – Distribution of the reviewed papers by journal](image)

Fig. 4 illustrates an overall increase of the total amount of articles published after 2011. An intermittent peak is apparent in 2013 when twenty papers are published before dropping to seventeen in 2014. Roughly 76% of the research are published throughout the recent 5 years, highlighting the importance of this field. Although the first paper was published in 2004, it seems this area had not received enough attention initially.

![Figure 4 – Distribution of the reviewed papers across the period of the study](image)
**Category selection**

Considered factors are derived according to studying whole of the selected papers and the objects of the model(s). To do so, after screening each paper carefully, especially studying the notations used in the formulation of CLSC models, the explained factors are derived according to the target of model(s) in each paper. It should be noticed there are 21 papers with the focus only on the structure of the CLSC network and the effect of different relation of the players in the loop in which none of the investigated factors could be found in the model such as the one related to Savaskan et al., (2004). The intention was to assign each factor to a specific class, however, whenever an overlap was seen between two categories, the factor was assigned to the nearest class.

![Diagram of CLSC factors](image)

**Figure 5 – Categorization of the investigated and derived factors in the CLSC models**

Fig. 5 shows the categorization of the derived factors. They are organized into 5 main categories including (1) incentive mechanism, (2) economic, (3) environmental, (4) financial and (5) other factors. The first one refers to the operations in which improve the performance of the loops regarding the sustainability processes such as the subsidy considered for the manufacturer (he) by social planner if he involves in remanufacturing (Mitra and Webster, 2008). The second one is classified in three different categories which mainly can be regarded as economic factors such as the discount for the remanufactured products. The third one is related to the actions to care the environment such as the costs to reduce the hazardous material released to the environment mentioned as green activity. Fourth category deals with the financial factors such as disruption, which is, for example, a fluctuation of the remanufacturing cost due to occurring a natural phenomenon (Huang and Wang, 2018). There are other factors which are studied independently such as trade-in (Genc and De Giovanni, 2017).

**Evaluation stage**

Reliability and validity of the gathered papers are evaluated by the authors where deductive and inductive methods are conducted. In order to derive the structural dimensions which are led to correct classifications, in deductive approach the papers are
chosen and then analyzed, while in the inductive technique these dimensions are
developed from the material by means of generalization (Mey and Mruck, 2010). The
collected papers were again crosschecked with Scopus that it is one of the most
comprehensive academic databases.

**Review results**

Analysis of the main categories shows the concentration of the research, those which
model CLSCs as a game among the loop's players. Based on the Fig. 6, the percentages
of the research approaching to the economic aspects is more than other categories.
Although the difference is not very much, it can show a tendency of tying economic
targets to the CLSC as a growing sustainable concept among the researchers. Meanwhile,
integrating environmental elements to the CLSC still needs more attention with a current
12% frequency among all factors.

![Figure 6 – Frequency of the main characteristics](image)

Fig. 7 compares the application of classified metrics with more details. It is cleared
sharing mechanism which is defined as all types of sharing such as sharing costs or
operations on the collection process of the returned items has received a considerable
attention.

![Figure 7 – Frequency of the derived factors among the investigated literature](image)
Fig. 8 presents the complexity of the designed models regarding the investigated factors. The more the number of discussed factors in the studied CLSC model, the less papers can be found. It shows modelling real cases in this area is rather difficult.

![Figure 8](image_url)

**Figure 8 – Frequency of the derived factors among the investigated literature**

Table 1 which is symmetric provides interesting results for the readers showing the potential gaps for future research. It shows a two-dimensional characteristic of the existent CLSC models addressed in the topic. For example, the blue square shows there is not any research integrating parameter related to the carbon emission with licensing matters considering the scope of present review. A multi-dimensional is also applicable.

**Table 1 – Cross-frequency of the derived factors among the investigated literature**

| Factor | A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V |
| A      | 5 | 2 | 1 | 2 | 3 | 1 | 1 | 2 | 1 | 3 | 1 | 4 |   |   |   |   |   |   |   |   |   |   |   |
| B      | 9 | 2 | 9 | 14 | 7 | 4 | 1 | 3 | 2 | 6 | 4 | 1 | 2 | 5 | 8 | 1 | 7 | 7 |   |   |   |   |
| C      |   | 2 | 1 | 2 | 1 |   |   |   |   |   |   |   |   |   |   | 2 | 4 | 3 |   |   |   |   |   |

Definition of notations in Table 1. An explanation for each one is presented at the end of conclusion section.

A: Advertising, B: Discount, C: Service, D: Carbon emission, E: Green activity,
F: Other environmental factors, G: Subsidy, H: Reward-penalty, I: Two-part tariff,
J: Disruption, K: Franchise, L: Licensing, M: Risk, N: Other financial factors,
O: Deterioration rate, P: Inventory system, Q: Information system, R: Quality consideration,
S: Cannibalization, T: E-tail, U: Trade-in, V: Sharing mechanism.
Figure 9 – Analyzing trend of the investigated factors during the considered period
An analysis is performed regarding each factor separately. Fig. 9 illustrates results of frequency of the derived factors over the period of the study. As it is clear, sharing mechanism and reward-penalty mechanism are two effective factors in which are growing almost consistently during the considered time horizon. Factors such as quality consideration, advertising and two-part tariff have received more attention and are applied incrementally recent years after 2012. Developing CLSCs related to the inventory systems and cannibalization has been slowly decreased recently. Researchers can use the results of other presented bar charts as a guideline in the CLSC area for future research.

**Conclusion**
Circular economy (CE) is a pivotal concept playing an important role in today's modern economic systems in the developed countries. The CE suggests replacing end-of-life products/materials with the reused, recycled and/or recovered ones (Kalmykova et al., 2018). At a micro level (i.e., activities related to the products, markets, consumers and enterprises) closed-loop supply chain (CLSC) operates as an effective approach in the context of economic, environmental and social systems.

This is the first time that a comprehensive research is conducted on the CLSCs existed in the literature in which the models are based on the game theory. Characteristics of these models shown quantitatively in the formulation are derived and categorized. It certainly
can serve companies and practitioners when playing and deciding in operational closed-loops.

A coding-cross-referenced database is designed matched to the discussed factors shown as "Reference: [used factor(s)]". Comparison of these combinations in pairs as provided in Table 1 (e.g. Reference A: [factor a; factor b; factor c] and Reference B: [factor b; factor d]) leads to identify the gaps in the literature while it allows addressing CLSCs with the novel combination(s) for new cases. The mentioned factors and studied papers are classified according to the descriptive statistics such as year of publication, journal, frequency and etc. Contents of the works are analyzed and patterns and research streams are found.

It is shown that updated versions of CLSC models exploit more factors addressing the real situation as compared to the initial models. Results clear that among the categorized factors, sharing mechanism has got the priority by the researchers. However, other areas such as the disruption which is an appropriate approach to control the market fluctuations still need to be investigated more thoroughly.

Explanation of the derived factors:

- **Advertising**: It is cost of the party to increase the selling and demand market.
- **Discount**: It is a discount on the product such as the remanufactured one.
- **Service**: It is after-sales maintenance, warranty repair agreements and so on provided by a player such as the retailer to the customer.
- **Carbon emission**: It is all parameters (e.g. cost or quantity) related to the gas pollutant such as carbon or CO₂.
- **Green activity**: It is the actions to care the environment such as the costs to reduce the hazardous material released to the environment.
- **Subsidy**: It is a support by the social planner, which is usually the government to a party to increase the performance of the CLSC.
- **Reward-penalty (RP)**: If the incentive mechanism has a two-side effect which means includes not only incentive but also a penalty, it is a RP.
- **Two-part tariff**: It is generally a contract in which usually the manufacturer pays a fixed amount to the retailer to motivate him for the recycling.
- **Disruption**: It is related to analyzing the fluctuations of the cost, amount such as order quantity or price.
- **Franchise**: Franchise fee is a common phenomenon in practice, such as franchised store or represents the fee paid by the retailer to the manufacturer for the sale of the product.
- **Licensing**: It is a payment to the manufacturer, or the one who provides the technology licensing in the form of patent licensing fee.
- **Risk**: It is considered to deal with risk matters such as risk aversion cases or the effect of risk reduction of demand and etc.
- **Deterioration rate**: It is related to the depreciation or deterioration of items during their life.
- **Inventory system**: It is related to consideration of the inventory parameters in the CLSC model such as holding cost.
- **Information system**: It includes the subjects related to the information systems such as symmetric and asymmetric cases on information.
- **Quality consideration**: It is investigation of quality matters such as the quality of the returned items or recycled products.
- **Cannibalization**: It is analyzing the effects of selling remanufactured products on selling the new ones.
- **E-tail**: It is online operations which usually defined as online retailing via internet.
Trade-in

It is operations in which a situation is provided for consumers to return back the used items and exchange it with a new item.

Sharing mechanism

It is all types of sharing such as sharing costs on the collection process of the returned items or sharing the return rate and etc.

Other financial factors

It mainly considers different types of cost such as a fixed cost imposed to the players in different process.

Other environmental factors

It is all other types of impacts which is related to the environment.

Acknowledgments

The research was partially supported by Iran's National Elites Foundation during the postdoctoral period of first author at the Kharazmi University. The first author would like to thanks Faculty of Management and Business, Tampere University for providing the opportunity to visit Tampere university as a Research Fellow.

Abstract
This paper seeks to analyse how some structural characteristics of the company’s industry (the competitive intensity of the industry, the complexity of the supply chain, SC), and the company’s competitive strategy influence the implementation of the SC’s Triple-A dimensions (adaptability, agility and alignment). The hypotheses are tested using data from 277 Spanish manufacturing companies (10.5% response rate) analysed with PLS-SEM. The results show that competitive intensity is the most important factor, followed by SC complexity. Additionally, cost strategy is found to negatively affect adaptability and that the differentiation strategy does not exert a significant influence on any ‘A’.

Keywords: Competitive dynamics, business strategy, Triple-A Supply Chain

Introduction
Contingency Theory (Lawrence & Lorsch, 1967) states that contextual variables can affect the level of achievement or implementation of tools and business practices. Therefore, since rivalry is increasingly being contested at the supply chain (SC) level (Ketchen & Hult, 2007), knowledge of the SC’s context is important for the SC to be adequately managed, an indispensable requirement for the success and survival of companies. In this regard, the Triple-A SC emphasises the importance of orchestrating agility, adaptability and alignment for SC effectiveness (Feizabadi et al., 2019). Many authors agree with Lee (2004) that SC agility is important because it allows a SC to
address short-term changes and interruptions in supply or demand. The adaptability of SC that supports adjustments to long-term market changes is also considered necessary. Finally, the alignment of objectives and incentives among the members of the SC has been recognised as an indispensable requirement for success, since it focuses the entire supply chain on serving the final customer.

This study seeks to contribute to SCM by analysing three important drivers of the Triple-A SC that few studies have theoretically and empirically assessed. It also attempts to identify the individual influence of these drivers on each of the Triple-A SC dimensions following an approach that, while not greatly explored, has been used in recent previous research (Dubey et al., 2015; Dubey & Gunasekaran, 2016; Attia, 2016; Feyissa & Sharma, 2016; Gunasekaran et al., 2017; Dubey et al., 2018; Alfalla-Luque et al., 2018; Feizabadi et al., 2019). Considering these three dimensions separately allows any differences between them in temporal terms to be incorporated into the analysis — according to Tang & Tomlin (2008), alignment, adaptability, and agility connote long-, medium-, and short-term perspectives— as well as any differences in their specific effects on several performance measures (Alfalla-Luque et al., 2018). Therefore, this study addresses two relevant research questions: 1) Does a company’s competitive dynamics (i.e., the level of competitive intensity in the industry and the level of SC complexity) influence the implementation of the Triple-A SC? 2) Does the type of competitive strategy (i.e., cost leadership or differentiation) imply any differences in the implementation of the Triple-A SC?

Following this introduction, next section presents a review of prior studies on Triple-A SC and on the three antecedents that are focused on here. The methodology used is subsequently described. The findings are then discussed and, finally, the conclusions are set out.

**Theoretical background and hypotheses**

**Triple-A SC**

According to Lee (2004), achieving a sustainable competitive advantage requires SCs to be agile, adaptable and aligned (Triple-A SC). However, although agility, adaptability and alignment have been defined in different domains (manufacturing, organisational, strategic, etc.), little research has been developed in the SC domain -especially regarding SC adaptability and alignment (Marin-Garcia et al., 2018).

SC agility has been defined as the ability to rapidly detect and respond to short-term changes in real demand and supply in order to generate or maintain a competitive advantage (Alfalla-Luque et al., 2018). An agile SC can adapt to market variations efficiently, respond to final demand quickly, produce and deliver innovative products with cost efficiency and on time, and generate an inventory reduction and external integration (Mason et al., 2002; Swafford et al., 2006; Gligor & Holcomb, 2014). Dynamic and volatile markets need agile SCs that can interpret and respond to customer needs (Scholten et al., 2010).

SC adaptability can be defined as the ability to adapt strategies, products and/or technologies to structural market changes (Alfalla-Luque et al., 2018). The complex and uncertain market environment (economic, political and social changes, demographic trends, changing consumer needs, global context and technological advances) requires an adaptable SC to improve the chance of survival (Tuominen et al., 2004).

Finally, SC alignment is the ability to share information, responsibilities and incentives with SC members in order to coordinate activities and processes (Alfalla-Luque et al., 2018). This holistic focus considers the SC as a single entity (Lee, 2004) and implies strategic collaboration between the different members, with consistent
objectives, strategies and processes (Skipworth et al., 2015; Flynn et al., 2010). The aligned SC should be managed to meet the demands of product speed and complexity by coordinating operations (Kehoe et al., 2007).

The present study follows the approach of considering the three Triple-A dimensions individually, since previous research has still not produced any conclusive results. In this line, Feizabadi et al. (2019) stress that a research focus is required on the antecedents of the Triple-A SC dimensions as a framework. In this regard, the present study analyses the role of three contextual variables as drivers of Triple-A SC, specifically, the competitive intensity of the industry, SC complexity and the company’s competitive strategy.

**Competitive intensity and the Triple-A SC**

At the SC level, the characteristic turbulence of the business environment leads to an agile SC being a managerial imperative not only for the individual chain constituents, but for the entire SC. So, agile SCs outperform less agile competitors (Yusuf et al., 2014) and provide value for mitigating risks from the competitive landscape and for rapid response measures (Braunscheidel & Suresh, 2009).

Adaptability seeks to facilitate close coordination between trading partners and accurate product and service customisation. The objective is to maximise responsiveness, as strategic or extended alliances along the SC (Kim, 2006) are affected by market turbulence (Arora, et al., 2016). Innovativeness is a crucial dimension of SC adaptability since innovation is a means of changing an organisation in response to changes in its environment (Hult et al., 2004). Fundamental shifts in the SC and market environment require firms to increase innovation to remain competitive (Lee, 2004). So, the innovation literature stresses that the more salient competitive benefits that firms facing greater competition can derive are creating additional values for their consumers (He & Nie, 2008). SC adaptability emphasises the need for sensing changes in the SC and market environment and for flexibility in coping with them (Eckstein et al., 2014). Competitive intensity is an external driver that can be used to act on strategic positioning (Hallgren & Olhager, 2009) as it is able to influence SC adaptability.

Lastly, SC alignment involves incentive alignment to prevent any conflicts; information alignment to share equitable risk, costs and benefits; and process alignment to share and exchange knowledge and important and correct information for planning, controlling and decision-making in the SC (Simatupang & Sridharan, 2005). Competitive intensity shapes inter-firm knowledge acquisition (Zhou et al., 2014) and has made organisations rethink the need for cooperative, mutually beneficial SC partnerships and improving business performance (Wisner & Tan, 2000; Flynn et al., 2010). The goal is to achieve effective and efficient flows of information, products and services and money decisions in order to provide maximum value to the customer at a low cost and high speed (Frohlich & Westbrook, 2001; Moyano-Fuentes & Martínez-Jurado, 2016). Proactively sharing information with strategic chain partners is an attribute that is required for gaining a sustained competitive advantage (Roh et al., 2014). In fact, information flow integration provides the basis for financial flow integration and physical flow integration (Sacristán-Díaz et al., 2018). A context of high competitive intensity is what makes the benefits of collaboration with SC partners become more positive (Heirati et al., 2016), as it positively influences SC alignment.

Based on the aforementioned arguments, the following hypothesis is formulated:

**H1:** Higher levels of competitive intensity positively influence the implementation of the Triple-A SC dimensions (**H1a:** agility, **H1b:** adaptability, **H1c:** alignment).
SC complexity and the Triple-A SC

Complexity is inherent in the management of SCs. Blecker et al. (2005) state that in most cases, SCs operate in dynamic environments with multiple connections between companies, so they are exposed to a large number of sources of complexity. Hence, complexity is an important theme in the SC literature and there is a general consensus that SCs have become more complex over recent years (Bode & Wagner, 2015).

SC complexity generally has negative consequences. Despite prior research on supply complexity being relatively scarce, Blome et al. (2014) indicate that on the SC’s upstream side the predominant, overall conclusion derived from the few studies that exist is that greater supply complexity negatively influences performance. Manuj & Sahin (2011) warn that a lack of understanding of the drivers of complexity, and poorly designed and executed strategies to address complexity in SCs, often lead to undesirable outcomes.

Serdarasan (2013) makes an inventory and classification of good practices for managing complexity in the SC. Some of those mentioned may be related to the Triple-A SC: reducing the number of outsourcing partners and distribution centres (to address static complexity), SC integration, collaboration with suppliers, customers and service providers and information sharing (to manage dynamic complexity), among others. We argue that the SC capabilities of agility, adaptability and alignment can also be strategies to respond to SC complexity. For example, Manuj & Sahin (2011) state that SC complexity can lead organisations to develop adaptability capabilities and also (citing Christopher, 2000) that complexity is argued to be a barrier to achieving SC agility. Fawcett & Magnan (2001) consider network complexity to be a barrier to SC integration, and alignment mechanisms to be one of the most important bridges to effectively achieve it. We think that in the case of SC agility and alignment, complexity can also be an incentive for the company to strengthen these capabilities. For all these reasons, we propose the following hypothesis:

H2: Higher levels of SC complexity positively influence the implementation of the Triple-A SC dimensions (H2a: agility, H2b: adaptability, H2c: alignment).

Business competitive strategy and the Triple-A SC

In most cases the literature has traditionally assumed that the generic business-level strategies of cost-leadership and differentiation are generally inconsistent. However, Hill (1988) stated that differentiation can be a means for firms to establish an overall low-cost position, and that a combination of differentiation and low cost may be necessary for firms to generate a sustainable competitive advantage.

With regard to SC strategy, three different strategies are usually distinguished: lean, agile and leagile SCs, depending on whether the chain focuses on efficiency, differentiation or combining lean and agile (Christopher et al., 2006). Qi et al. (2011) find that firms focusing on a differentiation strategy emphasise the agile SC strategy. Thus, when a company follows a differentiation strategy, an agile SC strategy should also be required and, consequently, a higher implementation of the three Triple-A dimensions should be expected. On the other hand, Gligor et al. (2015) state that SC researchers (i.e., Christopher et al., 2006; Sebastiao & Golicic, 2008) connect efficiency and waste minimisation strategies with lean management and suggest that agility is the ability to react quickly to changes and has less of a link with efficiencies. Indeed, Hallgren & Olhager (2009) investigate internal and external factors that drive the choice of lean (focused on efficiency) and agile (focused on flexibility) operations capabilities. The competitive strategy is modelled as a potential internal driver, and findings point to the fact that agile manufacturing is directly affected by a differentiation strategy and
negatively associated with a cost-leadership strategy. However, SC research provides no definitive empirical evidence to indicate that agile SCs cannot also be efficient, and arguments exist that suggest that the main difference between lean and agility appears to be related to the flexibility performance dimension, not cost (Purvis et al., 2014; Gligor et al., 2015). Indeed, Qi et al. (2011) conclude that cost leaders tend to implement both lean and agile SC strategies, although their emphasis on an agile strategy is significantly greater in a volatile than in a stable environment. In addition, Handfield et al. (2015) analyse alignment in supply management and find that internal stakeholder alignment (the extent to which the purchasing function focuses on the firm’s competitive strategy) is an antecedent. Since business strategy planning is, by nature, long term, it could be expected that business strategy also has a clear impact on longer-term oriented Triple-A SC dimensions such as SC adaptability and SC alignment, although the fact that it also has an effect on short-term oriented SC agility cannot be disregarded.

So, the literature leads us to state that a differentiation strategy should be positively related to the Triple-A SC, whereas a cost strategy should be negatively related. On the basis of this evidence, the following tentative hypothesis is proposed:

\[ H3: \text{The business competitive strategy will influence (negatively for cost, } H3C, \text{ and positively for differentiation, } H3D) \text{ the implementation of the Triple-A SC dimensions (} H3Ca \text{ and } H3Da: \text{ agility, } H3Cb \text{ and } H3Db: \text{ adaptability, } H3Cc \text{ and } H3Dc: \text{ alignment).} \]

**Methodology**

A literature review-based questionnaire was designed to gather the required information from a sample of 277 Spanish industrial companies with a minimum of 50 employees (10.5% response rate). Industrial sectors not in an intermediate position in their SC were excluded. To ensure its quality and validity, the questionnaire was divided into different areas depending on who the key informant should be to minimise key-informant bias and guarantee content validity. A pilot study was conducted with five experienced SCM researchers. CATI was used as the data gathering method. In general, there does not seem to be any non-response bias in the sample, including late response bias. In summary, the data and analysis confirm that the sample used in the study was randomly obtained and that it statistically represented the population.

The research model includes seven variables: four exogenous (competitive intensity, SC complexity, and the two types of competitive strategies) and three endogenous (the three dimensions of Triple-A SC). The measures used in this study are all based on previous studies of similar topics to ensure their content validity. Specifically, the scales used to measure these variables were taken, and adapted in some cases, from those proposed by Hallgren & Olhager (2009) for industry competitive intensity and competitive strategies, and Roth et al. (2014) for SC complexity. The Triple-A SC dimension scales have been developed ad-hoc from items in previous studies that specifically focused on each of these. Five-points Likert scales were used.

The model was tested using PLS-SEM with SmartPLS 3 (Ringle et al., 2015). PLS-SEM is a non-parametric, multivariate approach based on iterative OLS regression that seeks to maximise the explained variance of endogenous latent constructs. The choice of PLS-SEM or CB-SEM (covariance-based) is usually based on data characteristics, sample size, complexity of the model, and the degree of maturity of the underlying theory, *inter alia*. We opted for PLS-SEM as, although our sample is not small and our model is not very complex, our data are not normally distributed and the underlying theory is not advanced but, rather, exploratory. PLS-SEM models are comprised of two components: the measurement or outer model, and the structural or inner model. The
measurement or outer model must be validated before the structural or inner model (research hypotheses) can be assessed.

Results and discussion
Measurement model
The evaluation of the goodness of the measurement model usually includes three criteria (Hair et al., 2017): internal consistency or reliability, convergent validity, and discriminant validity. Internal consistency has been evaluated by composite reliability, which, as can be seen in Table 1, ranges between .73 and .93, and always exceeds the minimum of .70. Values higher than .95 are not desirable, since they may indicate that some indicators are redundant. Convergent validity can be measured at the indicator level and at the construct level. At the indicator level, convergent validity is demonstrated when the indicator loadings on the construct are statistically significant. In addition, they must have a value above .70, which indicates that the construct explains 50% of its variance. In our model, all the loadings are significant at p < .001, except for three of the four strategy indicators, which are significant at p < .05. Only one item of the Differentiation strategy is not significant (A12c, p=.155). As regards the value of these loadings, all are above .70, except for 2 values in SC agility, which are nonetheless close to the cut-off value, and a value of .57 in Differentiation strategy. Convergent validity at construct level is measured by Average Variance Extracted (AVE), which must be greater than .50. As can be seen in Table 1, this value has been exceeded in all the constructs. Some items in the original questionnaire have been eliminated from this validation process following the Hair et al. (2017: pp. 112-5) criteria. Discriminant validity has been verified by the Fornell-Larcker criterion, according to which the square root of each construct’s AVE must be higher than its correlation with the other constructs. This criterion has been met. Additionally, the indicator loadings have been verified to be higher on their own constructs than their cross-loadings on the other latent variables.

Structural model
For this phase, PLS-PM as a non-parametric technique relies on resampling. The method used was bootstrapping with 5,000 subsamples. Following Hair et al. (2017), several aspects of the results of the model were analysed: multicollinearity, the sign and significance of the coefficients, the R² levels and the effect sizes of the relationships. VIFs were analysed to rule out any multicollinearity problems that might affect model estimates. Values greater than 5 would indicate that more than 80% of the variance of a construct is explained by the other constructs. In our case, the VIFs of the structural model vary between 1.046 and 1.416, so no collinearity problems seem to exist. As for the relationships of the structural model (the hypotheses), competitive intensity has a positive and significant impact (p<.001) on all the Triple-A dimensions. SC complexity, however, positively affects SC adaptability (p<.05) and SC alignment (p<.01), but not SC agility. Regarding the two types of strategy, all the effects of both

</table>
strategies on the Triple-A SC dimensions are negative, but only one relationship is significant, that of cost strategy on SC adaptability (p<.05). There are two other relationships that would be significant at the p<.10 level: cost strategy on SC agility and differentiation strategy on SC adaptability. The 95% confidence intervals with corrected bias show a similar scenario, except for two exceptions: the SC complexity-SC adaptability relationship, the interval of which contains zero by a small margin and, therefore, would not be statistically significant according to this criterion; and the differentiation strategy-SC adaptability relationship, which would be significant.

Next, we evaluated the coefficients of determination of the endogenous constructs, which in our case were the Triple-A SC dimensions. The dimension that is best explained by our model is SC adaptability, with $R^2=.153$ and adjusted $R^2=.140$. This is closely followed by SC alignment with $R^2=.145$ and adjusted $R^2=.132$. The dimension that is least explained or predicted by our model is SC agility, with $R^2=.077$ and adjusted $R^2=.063$, practically half the values of the other two dimensions. These values are given in Figure 1, which also includes the coefficients and p-values (in brackets) of the different relationships associated with each of the hypotheses. In addition, the type of line used indicates the relationships that are supported (solid line) and not supported (dashed line). We have considered the two aforementioned relationships in which there was a contradiction between the p-value and the confidence interval to be supported.

The next aspect to analyse is the size of the effects, which is related to the practical significance of the coefficients, rather than the statistical significance. This aspect is analysed using $f^2$, which measures the change in the $R^2$ of the endogenous constructs when an exogenous construct is omitted from the model. According to Cohen (1988), the values of this statistic are usually interpreted as small, medium and large for values...
higher than .02, .15 and .35, respectively. In our case, competitive intensity has a small, slightly less than medium size effect on SC adaptability and SC alignment, and an even smaller effect on SC agility. The effect of cost strategy on SC adaptability is quite small (very close to the lower limit of .02). Also close to the minimum level are the effects of cost strategy on SC agility and of differentiation strategy on SC adaptability. All the remaining effects are very small and some practically null. It can be highlighted here that although the two SC complexity effects are statistically significant, they are practically negligible.

Conclusions
The results show that the determinant contextual variable that best explains Triple-A SC implementation is competitive intensity. This variable significantly affects the three dimensions and, in the cases of SC adaptability and SC alignment, with greater force and almost medium size effects. The other analysed competitive dynamics variable, SC complexity, is observed to have a significant effect on SC alignment and SC adaptability, but the coefficients are much lower than those of competitive intensity. Comparatively, the effect on SC alignment is almost a third of that of competitive intensity and the effect on SC adaptability almost a fifth. Thus, companies respond to the greater competitive intensity to which they are subjected with higher levels of SC agility, adaptability and alignment. SC complexity also has an effect, but to a lesser extent. We have seen that the higher the numbers of suppliers and customers that are part of the SC, the more companies seek to increase their SC alignment and SC adaptability levels, but SC agility does not appear to be necessary in this context.

As far as business strategy is concerned, cost and differentiation strategies only have an effect on SC adaptability, but the size of these effects is close to the minimum threshold. In addition, in both cases this effect is negative, which was expected for cost strategy, but not for differentiation strategy. These results are interesting in two aspects, at least. Firstly, the effect is greater on SC adaptability, which is a dimension of long-term flexibility, than on SC agility, which represents the short-term flexibility capability. This could be due to the fact that the nature of business strategy involves long-term planning, although its effects should also be seen in the ability to adapt in the short term, which is agility. On the other hand, it is interesting to note that differentiation strategy has a negative effect on SC adaptability, which is a longer term capability, although from a practical point-of-view, the effect size does not reach the threshold for it to be considered small.

Abstract

Although there are strategies -such as lean, resilient and green- that have been proven as beneficial for companies and their supply chain (SC), the real implementation of such strategies is not uniform in certain sectors. The purpose of this paper is to investigate the perception of the importance and degree of implementation of such strategies in the aerospace manufacturing sector. Results show that different SC levels have a different perception of the importance and degree of implementation and therefore, this difference may lead to discrepancies in the propagation of strategies along the SC as different interests may arise.

Keywords: multilayer analysis, supply chain strategy, aerospace sector

Introduction

Supply chain management (SCM) may help companies to increase their organizational performance and profitability if the right strategies are put in place. Additionally, SCM also facilitates the integration between companies and their suppliers through the development of partnerships and alliances. Therefore, special attention should be payed to the set of practices selected to manage those relationships with suppliers and to the specific strategies that should be implemented in order to achieve optimal results.

Lean, resilient and green strategies applied to the SC have been previously studied in the automotive sector demonstrating the positive impact of such strategies on both, sustainability and SC performance (Govindan et al. 2014, 2015).

Even though lean SC practices have proven to improve company’s performance, companies along the SC still show a high resistance level to lean implementation in certain sectors such as the aerospace sector (Bortolotti et al., 2016).

The aerospace manufacturing supply chain (AMSC) has previously been studied and defined in terms of its structure and complexity (Bales et al., 2004; Ehret and Cooke, 2010; Hickie, 2006). The OEM is structured in Final Assembly Lines (FAL) that carry out the final assembly of aircrafts and Prime Contractors that manufacture and assembly the large aero structures and systems. Tier 1 is composed by large companies specialized
in design and manufacturing of large systems and components with engineering capabilities. Tier 2 and Tier 3 include SMEs that manufacture less complex components and provide basic services to Tier 1 companies and even to OEM, with no design or engineering capabilities. The number of companies in each tier increases exponentially as we move down in the SC towards Tier 3. Additionally, companies become smaller, with fewer resources and manufacture/provide less complex products and services.

In the AMSC, OEM and even Tier 1 companies have successfully implemented lean strategies. However, when trying to extend lean strategies to Tier 2 and Tier 3 companies, Bortolotti et al. (2016) have observed that the needed collaboration for strategy implementation has been scarce and have found a high resistance level on these companies to lean adoption mainly because the final results did not match the initial expectation.

In this type of SCs, being resilient becomes critical due to the very complex final product and production process and the tight production lead time. Any disturbance can considerably affect the production process even stopping it and the final delivery time can substantially increase (Sinha et al., 2004). Additionally, lean strategies make companies and their SC less resilient as previous studies showed (Sezen et al., 2012) and therefore, AMSCs should work on increasing resilience. Finally, the aerospace sector has showed an increasing commitment to environmental and sustainability principles, not only in their final product but also in their manufacturing process (International Civil Aviation Organization, ICAO). Therefore, the AMSC becomes a key sector for the study of lean, resilient and green strategies.

This together with the fact that some of the strategies hardly propagate along the SC and companies’ resistance to implementation becomes higher as moving down the SC leads to the objective of this paper, which is to investigate the perception of the importance and implementation degrees of the three strategies under study for different SC levels in the AMSC.

Supply Chain Strategies
The main strategies considered for this study and that are present in the ASCM are, as explained in the introduction, the lean, resilient and green strategies. For each strategy specific practices need to be identified and for that purpose, we borrow the list of practices for the three strategies -lean, resilient and green- identified in Ruiz-Benitez et al. (2017) (Tables 1, 2 and 3). A total of 34 practices that are relevant for the ASCM are finally considered for this study.

Methodology and data gathering
The main goal of this research is to explore managers’ perceptions about the importance and degree of implementation of lean, resilient and green strategies. Their corresponding practices have been strongly widespread in diverse sectors [i.e., Govindan et al. (2015)], and particularly in AMSC. The implementation and performance of lean practices significantly differ across its supply chain tiers of aerospace manufacturing sector (Bortolotti et al. 2016). In the same vein, it has been highlighted that contextual variables such as the company’s size, collaboration level between entities, and the time length of these practices should be considered when adopting them (Bortolotti et al. 2016; Marodin et al. 2016; Tortorella et al. 2017). Accordingly, we carried out a multilevel analysis of the aerospace manufacturing supply chain. Level 1 brought together the OEM and Tier 1 suppliers. Indeed, these large firms maintain a higher collaboration and integration level. Level 2 included Tier 2 suppliers and Tier 3 suppliers. These small and medium size enterprises (SMEs) present a lower collaboration and integration level.

With the goal of evaluating marketing strategies, the Importance-Performance Analysis (IPA) method was proposed (Martilla & James 1977). Then, it allowed evaluating specific attributes of customers’ satisfaction considering both importance and performance dimensions. The ratings achieved were plotted in a two-dimensional
importance-performance matrix, and thus four strategies could be defined from each of the four areas. Together with the valuable information that this visual representation of results can provide, the IPA method is considered a simple and effective way to evaluate strategies basing on multiple attributes (Hansen & Bush 1999; Abalo et al. 2007). Hence, it had been successfully applied in evaluating technological innovations (López et al., 2019), tourism (Frauman & Banks 2011), project risk management (López and Salmeron, 2012), e-government services (Wong et al., 2011), among other many issues.

Accordingly, the IPA method was chosen to measure managers’ perceptions on both the importance and performance dimensions of each lean, resilient and green practices identified in the literature (See Tables 1, 2 and 3). Those dimensions were conveniently adapted. On the one hand, performance dimension (x-axis) measures in which degree each practice has been implemented in the AMSC (DI). On the other hand, importance dimension (y-axis) shows the importance of each practice for the AMSC (I).

In order to estimate the corresponding pair of ratings \((x_i, y_i)\) for each practice \((p_i)\), two panels of aerospace manufacturing managers were created (one for each identified supply chain level). In this way, we firstly built a database which contains information on active aerospace manufacturing firms operating in Spain. After two rounds contacting these companies by phone, 39 managers agreed to participate in the research. The first panels was formed by 11 managers pertaining to enterprises in the first level of the aerospace manufacturing supply chain, whereas the second panel was made up of 28 managers of the second level. Subsequently, we designed an online questionnaire and sent it to participants via email. Both importance and degree of implementation dimensions were measured on a 5-point Likert scale, where 1 means “not important” or “not implemented” and 5 means “very important” or “completely implemented”. Basing on the replies received, we built the IPA grids, one for each strategy (lean, resilient and green) and supply chain level (Figures 1 to 6). Finally, six grids were generated plotting each corresponding practice according to its importance rating and degree of implementation rating. These ratings were calculated using mean values of managers’ perceptions. Both y-axis line and x-axis line were computed using the global of importance and degree of implementation values for the total of practices in lean, resilient and green strategies, respectively.

Each quadrant in the IPA grid depicts a specific cluster of practices. Hence, different strategies must be followed for individually managing them in a more effective way:

Quadrant A (Concentrate here). Practices present a high level of importance and a low level of degree of implementation. This is known as the preferential improvement area and the recommendation would be to prioritize the practices in this quadrant.

Quadrant B (Keep up the good work). Practices show a high level of importance and a high level of degree of implementation. The managers ought to maintain current efforts and resources allocated to them.

Quadrant C (low priority). Practices achieve a low level of importance and a low level of degree of implementation. Therefore, practices do not provide enough improvements to justify additional efforts.

Quadrant D (possible overkill). Practices reach a low level of importance and a high level of degree of implementation. Managers ought to cut down excessive efforts and resources addressed to developing these practices.
Figure 1 – IPA grid of the lean SC strategy (Level 1)

Figure 2 – IPA grid of the lean SC strategy (Level 2)

Figure 3 – IPA grid of the resilient SC strategy (Level 1)

Figure 4 – IPA grid of the resilient SC strategy (Level 2)
Results

In this section, results on the managers’ perception of each strategy in different levels of the SC are presented. The degree of implementation (DI) and importance (I) of each practice are evaluated and the quadrant containing each practice is determined.

Results reveal strong differences in the perception of the lean SC strategy importance/implementation between managers in different levels of the SC as tables 4, 5 and 6 show.

For the lean SC strategy, there is discrepancy on the managers’ perception in 6 out of 8 practices between different levels of the SC. In terms of the strategy’s importance for the sector, Level 1 companies perceive a higher importance level of lean practices than Level 2 companies. However, there is a perception of higher implementation of lean practices for Level 2 companies, although those companies are the ones that hardly implement such practices into their operations. Additionally, the practices perceived as more important for Level 1 companies do not coincide with the practices that have more importance for Level 2 companies. Therefore, it should be expected some resistance by Level 2 companies to implement the practices that Level 1 companies are pushing down the SC as the perceived importance substantially differ. Furthermore, only Level 1 managers identify lean SC practices in the preferential improvement area (quadrant A), concentrating though into the development of such practices meanwhile Level 2 managers do not identify any of the lean practices as preferent to improve.

In the case of resilient SC strategy, the discrepancy level is lower than in the previous case. Only 5 out of 12 practices present different managers’ perception on the degree of implementation and importance and being therefore in different quadrants. However, for most of the practices both levels perceive a similar degree of importance and implementation level. The perception of the degree of implementation of resilient practices is high for both levels (7 out of 12 present a high implementation grade). Regarding the importance, again, managers at both levels perceive that resilient practices are important for the SC. Nonetheless, when deciding on the particular practices that are really important for the sector, there are still some discrepancies (R1, R5 and R11). In comparison with lean SC strategy, there is more consensus in managers’ perception of the importance and degree of implementation in the case of the resilient SC strategy.

Finally, for the green SC strategy, companies in both levels coincide on the perception of degree of implementation and importance. Only 2 out of the 14 practices considered within the strategy show a different perception and therefore different quadrants in the IPA analysis. Therefore, there seems to be unanimity of managers’ perception in terms of the importance and the degree of implementation of the green SC strategy in the AMSC.

Conclusion

Even though there are some strategies that have proven to be beneficial for companies, their implementation is still scarce and not uniform along the SC in certain sectors. That is the case of the lean strategy in the aerospace sector. The implementation of lean practices is not uniform along the supply chain, being the OEM and tier 1 companies, the ones heavily implementing lean strategies meanwhile tier 2 and tier 3 companies rarely implement such strategies (Bortolotti et al., 2016).

The results in the present study are aligned and reinforce the ones in Bortolotti et al. (2016). Companies in lower levels (tier 2 and 3) of the SC perceive a lower importance of the lean strategy and therefore their incentive for lean implementation is low. Additionally, the lean strategies perceived as highly important for the OEM and tier 1 companies are not the same as the ones perceived as important for tier 2 and 3 companies. Therefore, this calls for a different approach in the efforts of OEM and tier 1 companies to propagate lean practices along the SC as previous studies hinted (Marodin et al. 2016, Tortorella et al. 2017).

Additionally, in the case of resilient and green SC strategies the perception of the importance and degree of implementation is very similar for companies in different levels of the SC. These strategies are perceived as important for companies along the SC and therefore, all levels of the SC make efforts to correctly incorporate both strategies into their operations.

This is an exploratory study with the aim of analysing the perception of managers belonging to companies in different levels of the SC on the different SC strategies. Further investigation needs to be done in order to understand the reasons behind the difficulty of strategy propagation along the SC found in some sectors.

Abstract
This study attempts to answer the question why certain buying firms tend to leverage suppliers’ input better than the others in creating innovations. Using theory of planned behaviour and embeddedness, this paper seeks to shed a light on this by investigating the moderating role of buying firms’ employee’s intent to learn in facilitating efforts in mobilising input from the buying firm’s supply network. The results suggested that the strong moderation of employee’s intent to learn, meaningful work and work-life balance with the two dimensions of embeddedness such as between degree centrality and betweenness centrality on the buying firm’s innovation creation.

Keywords: planned behaviour theory, innovation, supplier network, structural embeddedness, text mining.

Introduction
It is obvious that the supply network is an importance source of innovations for buying firms. There have been a number of studies investigating the link between the buying firm’s reliance on suppliers for innovation creation (Narasimhan and Narayanan, 2013) and there have been a constant stream of research investigating the place of suppliers in buyers’ innovation creation (Wagner 2012; Henke and Zhang, 2010; Wagner and Bode, 2014). However, there is lack of research investigating this from the perspective of a supplier network, which is characterised by interactions and different actors, resources and processes (Bellamy et al., 2014), influence on buying firms innovation performance. A innovation research from the supply network view, however, is still relatively rare. The main reason for this is the difficulty in obtaining a real-life supply network data, therefore, the majority of such studies analysed firm level ego networks (e.g., Kim et al., 2011). In addition, a study by Lawson and Potter (2012) explains how closeness with supplier can uncover protectiveness in knowledge transfer across firms. However, learning intent scale used in the study reflects only the knowledge capture but didn’t say anything about employee’s learning intent. Buying firms extraction of knowledge depends on employees’ intention to invent. There are also studies that support the well-being of
employees and firm’s innovation (Bryson et al., 2009). However, it is still not clear how employees’ intention to learn within a firm helps to derive innovation from supplier.

The literature review revealed three major gaps. Firstly, there is a scarcity of studies integrating planned behaviour theory with embeddedness theory for explaining how a buying firm leverages contributions from external organizations in its supply network towards its own innovation. Secondly, “intent to learn” construct was mostly done through a survey instrument, which may not be sufficient in reflecting “collective intent to learn”. It is obvious that using anonymous platforms, such as a social media review, to measure a construct of this nature would alleviate this issue, however, not widely used in academic literature. It is well established that higher levels of engagement will lead to higher profitability. Thirdly, there is a contradictory argument that innovative culture will lead to lack of attention in work-life balance and causes time-based stress, depletion of resources, including psychological and physical energy (Sok et al., 2014).

Given the above background, we seek to answer the question why a certain buying firms tend to leverage suppliers’ input better than the others in creating innovations by considering the firm’s employees’ collective intent to learn as a moderator.

Literature Review

This paper uses multiple theoretical lens (i) social network theory and (ii) planned behaviour theory the answer the above research question.

**Embeddedness of a Buying Firm in its Supply Network and its Innovation Creation**

The social network theory is based on the idea of embeddedness (Kim et al., 2011). Embeddedness refers to non-economic factors, motivating various economic exchanges (Moran, 2005; Barden and Mitchell, 2007; Cowan et al., 2007; Kim, 2014). One notable example of embeddedness is “a social tie” (Koufteros et al., 2007; Dong et al., 2015), since economic activities are often embedded in them (Uzzi and Lancaster, 2003). The link between a firm’s performance and its embeddedness has been scrutinised by the scholars to find out how the embeddedness would explain how different levels of embeddedness are related to the variations in the firm’s performance (Adler and Kwon, 2002; Kim, 2014).

Firm’s embeddedness has been investigated from two distinctive perspectives, which are (i) configurations of social ties and (ii) quality of social ties, (Gulati, 1998; Uzzi and Lancaster, 2003; Moran; 2005; Autry and Griffis, 2008; Dong et al., 2015; Kim and Henderson, 2015). As such, even though there are some variations of conceptualisation of the embeddedness (Tsai and Ghoshal, 1998; Min et al., 2008; Kim, 2014), two salient forms of embeddedness are (1) relational and (2) structural (Granovetter, 1985, 1992; Uzzi, 1996, 1997; Gulati, 1998; Rowley et al., 2000). Relational embeddedness refers to the strength of dyadic ties (Granovetter, 1992; Moran, 2005; Kim, 2014) that is an extent to which a firm develops close and personal relationships with other members in its network (Barden and Mitchell; 2007; Autry and Griffis, 2008; Landoli et al., 2012; Dong et al., 2015). On the other hand, structural embeddedness, which is the main focus of the investigation of this paper, refers to configuration of linkages/relationships among actors (Nahapiet and Ghoshal, 1998; Gulati and Gargiulo, 1999; Moran, 2005; Barden and Mitchell, 2007; Dong et al., 2015).

Accumulation of knowledge assets for a firm’s innovation creation has two main sources, those are (1) internal knowledge generation and (2) knowledge with an external origin (Cooper and
For a buying firm, its supply network is an important external source for its knowledge assets (Autry and Griffis, 2008; Bellamy et al., 2014) such as knowledge and resources held by its supplier. Such resources can provide a firm with external information necessary for idea generations as well as improving its process (Tsai, 2001) as well as an opportunity to combine their knowledge for innovation creation (Ahuja, 2000). Therefore, a buying firm’s structural embeddedness in its supply network indicates its ability to access the knowledge and information held by its imminent suppliers and beyond (Uzzi, 1996; Tsai, 2001; Cowan et al., 2007; Greve, 2009; Bellamy et al., 2014). The implications of different aspects of a buying firm’s structural embeddedness on its innovation creation has been investigated mainly from the perspective of the buying firm’s centrality in its network. The centrality of a buying firm reflects its relative importance in its supply network (Kim, 2011; Dong et al., 2015).

A company occupies in a central location, it will get access to information and knowledge more easily helping them to create knowledge assets for its innovation creation (Tsai 2001; Bell, 2005; Greve, 2009; Autry and Griffis, 2008; Bellamy et al., 2014). Moreover, the level of centrality of a buying firm would signal its reputation to its suppliers (Borgatti and Foster 2003), alleviating their fear of failing to protect their knowledge as a result of a buyer opportunism (Mayer, 2006) and would result in more information sharing activities.

**Buying Firms’ Employees’ Intent to Learn**

A theoretical aspect to exploit employee’s learning intent in leveraging supplier input for its own innovation creation is the Planned Behaviour Theory, which is used to understand individual behaviour and it is a function of attitude, subjective norms and control (Ryan, 2010). Using the above analogy, in our case, employees’ intent to learn depends of three dimensions such as meaningful work, subjective wellbeing and work life balance.

Meaningful work capture individual’s attitude towards work using four dimensions such as developing the inner self, unity with others, expressing full potential and service to others (Lips-Wiersma et al., 2012). A study by Pradhan and Jena (2019) unfolded the lack of studies that explored the role of meaningful work on the relationship between transformational leadership and innovative work behaviour. Since meaningful work construct is relatively a new term and its usage is limited in the literature. However, subjective wellbeing is a psychological factor that is defined as individual’s cognitive and affective evaluation of the experience in terms of pleasant emotions, negative mood and life satisfaction (Wang et al., 2017). An individual’s subjective wellbeing depends on complex array of contextual factors including individual determinants, socio-demographic, economic, situational and institutional factors (Binder, 2013). Self-esteem or other personality traits are examples of individual determinants, likewise gender, age, education or marital status are examples of socio demographics. Similarly, income or unemployment corresponds to economic status, health and social relationship corresponds to situational factors (Binder, 2013). In addition, it is rare to find the integration of planned behavior theories within and external organization’s contribution to innovation. A study by Binder (2013) states the individual’s preferences are dynamic and the measurement of affective experience is very difficult in practice to capture that reflect the preference changes of individuals over time. To overcome this global corporations are relying on anonymous platforms to measure the satisfaction of employees and fixing them on a swift basis to improve engagement. The companies are keen to do this because it is well know that higher levels of engagement will lead to higher profitability and improved employee’s commitment (Bonnici, 2018).
Employees are juggling with multiple commitments at work and home where the successful people are good at balancing the two. Conceptually, offering work life balance through flexible working hours will enable employees to perform better and stay in a single company for a longer duration. However, in practices employers are not ready to do so until they see a bottom line economic advantage (James, 2014). However, there are a few evidences that illustrates flexible working hours benefits all staff irrespective of caring staff. Besides this generalist view of benefits, there are several dis-benefits such as increased workloads, understaffing, heightened fear of job loss, dramatic change in labour and demands. In addition, from the organisation’s perspective continuous innovation to meet consumer demand and pressure to increase work-life balance of employees to retain them and satisfy customers are the tricky challenges posing those (Malhotra et al., 2016).

**Conceptual Model and Hypotheses**

In this paper, we seek to investigate the impact of a buying firm’s structural embeddedness in its supply network in its innovation creation and how an endogenous organisational factor “employee’s intent to learn” of the employee of a buying firm would moderate this relationship.

First, we investigate the link three centrality dimensions of a buying firm’s structural embeddedness and its innovation output measured in the number of patents it holds.

The first dimension, degree centrality refers to the number of direct links an organisation maintains with others in its network (Provan et al., 2007). Degree centrality can be interpreted as the amount of knowledge, resource and information coming into the buying firm (Provan et al., 2007; Borgatti and Li, 2009). The following is, therefore, hypothesised:

$$H_1:$$ Buying firm’s degree centrality in its supply network is positively related to the number of patents it has

The second dimension, betweenness centrality refers to how often the node lies on the shortest path between all combinations of pairs of other nodes (Borgatti and Li, 2009; Kim, et al., 2011). An organisation with high level of betweenness can act as a gatekeeper to other members in its network (Borgatti and Everett, 2006, Provan et al., 2007; Borgatti and Li, 2009; Kim, et al., 2011). In supply network, this means a firm with high-level of betweenness centrality would act as a hub for material (Kim, et al., 2011) and information flows (Bellamy et al., 2014) enables it performance benefits such as access to novel information. The following is, therefore, hypothesised:

$$H_2:$$ Buying firm’s betweenness centrality in its supply network is positively related to the number of patents it has. The following is, therefore, hypothesised:

The third dimension, closeness centrality refers to how close an organisation is to all other members in its network including those without direct connections (Provan et al., 2007; Kim, et al., 2011). A buying firm can acquire knowledge indirectly through spill-over from its tier 1 suppliers, with its origin back to its interactions with the supplier’s own tier 1 suppliers (Gulati and Garguilo, 1990). Considering this, a buying firm with higher closeness centrality can access information, knowledge and resources from indirect suppliers beyond tier 1 more easily, therefore, it is related to the network effectiveness of knowledge access (Bellamy et al., 2014).
H3: Buying firm’s closeness centrality in its supply network is positively related to the number of patents it has. The following is, therefore, hypothesised:

As per planned behaviour theory, the influence of three dimensions of employees’ intent to learn from suppliers is discussed in the following section. Typically, our intention is to explore to what extent the three dimensions enables employees to better exploit supplier inputs for its own innovation creation. A study by Pantea (2018), it is obvious that the relationship between supplier input and the buying firm’s innovation creation would be stronger if employees’ collectively perceive their works more meaningful. This is because, Meaningful work refers to a place with autonomy, less-tension, spirituality and reduced level of absenteeism.

H1a: As perception of meaningful work among employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H2a: As perception of meaningful work among employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger
H3a: As perception of meaningful work among employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger

Studies explored the rationale for the positive relationship between subjective wellbeing and better work performance, knowledge sharing and achievements (Russell, 2008; Wang et al., 2017). Previous studies have found that satisfaction degree and positive emotions helps individual to remember and boost creative problem solving (Koveshnikov et al., 2014; Hashim and Tan, 2015). Other than performance, positive emotions, such as feeling of joy and pleasure, one among the subjective wellbeing factors will enhance individuals to share tacit and explicit knowledge (Henttonen et al., 2016). The following is, therefore, hypothesised:

H1b: As perceived well-being of employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H2b: As perceived well-being of employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger
H3b: As perceived well-being of employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger

Very few studies attempted to understand the relationship between work life balance and organization culture represented as innovative and supportive culture (Sok et al., 2014). There is a contradictory arguments that innovative culture values behaviours teamwork including solution-oriented, communicative and quick in terms of decision making. The overall understanding is innovative culture will lead to lack of attention in work-life balance and causes time-based stress, depletion of resources, including psychological and physical energy (Sok et al., 2014). However, this is not applicable to all contexts and needs to be investigated further. Based on the above arguments we propose the following sub hypothesis to test the moderation of three dimensions of employees learning intent. The following is, therefore, hypothesised:

H1c: As perceived work life balance of employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H$_{2c}$: As perceived work life balance of employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger.

H$_{3c}$: As perceived work life balance of employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger.

Methodology

This paper investigates if of a buying firm’s employees’ intent to learn would moderate the relationship between the structural embeddedness of a buying firm in its supply network and its innovation output. For this, we used the data of 182 companies from the S&P 500 list by discarding non-manufacturing sectors such as financials and real estate as well as those companies with excessive amount of missing data.

Data

The data set for this study was built using following databases. For the embeddedness of a buying firm, the list of its suppliers was collected from Bloomberg SPLC database and Factset. As for a firm’s innovation performance, the number of patents held by a buying firm was collected using Orbis database. For the intent to learn, employee reviews of their current and previous companies for 182 S&P 500 companies posted in Glassdoor between 2015 and 2017 were collected (475,910 sets of a positive and a negative review). Glassdoor is a social media website, where current and past employees can rate various aspects of their companies such as leadership, work environments and pays (Associate Press, 2013). Glassdoor is the oldest (founded in 2017) and the largest online resources in terms of the number of firms covered and the reviews (Ji et al., 2017).

Measures

In this study, we use social network analysis (SNA) to measure different dimensions of structural embeddedness of a buying firm. Considering a matrix $A_{ij}$, with a set of nodes and a set of edges, degree centrality is defined as the number of edges tied to a node. It is usually interpreted as the size of a node’s direct network. Closeness centrality, in contrast, considers the node’s wider network by measuring the distance of a node to all others in within the network. Moreover, betweenness centrality captures the importance of a node for the network by measuring the number of shortest path that rely on that node (for a more detailed overview on network measures, please be referred to Borgatti et al., 2018).

Table 1: Description of network measures.

Intents to learn

In order to measure employees’ intent to learn of a buying firm, content analysis was used to code the textual reviews from the social media site, Glassdoor. Content analysis is "a research technique for making replicable and valid inferences from texts (or other meaningful matter) to the contexts of their use," (Krippendorff, 2013; p.24). As mentioned earlier, a user can leave
two separate textual review about a company, one for the positive and another one for the negative and these unistructural parts of the reviews were coded using content analysis. Due to the sheer volume of the textual data (475,910 sets of a positive and a negative review and around 17 million words), a computer-aided content analysis (CATA) was selected over manual coding. For this, WordStat 8 from Provalis Research was used. Due to the lack of a pre-made dictionary, a set of new dictionaries for the positive and negative were created from scratch using the dictionary building method suggested by Sodhi and Son (2010). Using these dictionaries, the percentages of positive and negative reviews containing specific words or phrases from the total reviews of a specific company were calculated and then, standardised. The difference between the positive and the negative was used to measure each dimension of employees’ intent to learn. The assumption is that the greater the difference is the more positive employees’ intent to learn.

Innovation Output

In order to measure the innovation performance of a buying firm, the number of patents the firm was used. Use of the number of patents to measure a firm’s innovation output has been wildly used by the previous studies (for an example, see: Tsu, 2009; Bellamy et al., 2014; Isaksson et al., 2016).

Analysis and Results

We conducted hierarchical regression analyses using SPSS version 25 to test our hypotheses. Our main models examined if the level of 3 centrality dimensions of a buying firm is related to its innovation output (the number of patents). The results of the analyses provided support for H1 (degree centrality => patents, β = 0.31, p < 0.01) and H2 (betweenness centrality => patents, β = 0.27, p < 0.01). H3, where the relationship between closeness and the innovation output was postulated, was not supported. In the interaction models, the results supported that wellbeing and work life balance positively moderate the relationship between two centrality dimensions (degree centrality and betweenness) and the buying firm’s innovation, the number of patents.

Conclusion and Discussion

To the best of the authors’ knowledge, this paper is one of the first to combine social network theory and planned behaviour theory to uncover the role of an organisational factor, employee’s intent to learn, in leveraging input from its supply network for its own innovation creation.

Our results for the first set of hypotheses are in line with the findings of Bellamy et al., (2014) that the structural embeddedness a buying firm is related to its innovation creation since it determines (1) the amount of knowledge held by its direct suppliers and (2) how easily it can access it. Also, our results suggested that if a buying firm has high level of betweenness, this means the firm acts as hub (Borgatti and Everett, 2006, Provan et al., 2007; Borgatti and Li, 2009; Kim, et al., 2011) and would enable them to acquire novel information by playing a gate keeper role. On the other hand, H2 for close centrality was not supported suggesting that the value of the indirect ties in a supply network for innovation creation may not be that significant as previously thought. Or findings on the second set of hypotheses on the moderating roles of employee’s intent to learn suggested that their subjective wellbeing as well as work life balance do matter in fully utilising suppliers’ contribution in its own innovation creation. However, our findings suggested that ‘meaningful work’ does not increase the efficacy of supplier inputs and uncovering the reasons behind this require further research.

The role of international NGO in sustainable supply chain management: a conceptual framework

Abstract

By reviewing 47 peer-reviewed papers between in international NGO (INGO) and sustainable supply chain management (SSCM), this paper developed a conceptual framework to offer a new perspective on understanding the SSCM. More specifically, after reviewing the related theoretical frameworks in existing study, we identified four types of drivers building on social movement theory in the process for INGOs to improve SSCM, which are relative deprivation, political opportunities, resource mobilization and collective action. Relative deprivation and political opportunities provide motives and possibilities for INGOs to mobilize resources, in which process, collective identification can be achieved and collective actions can be implemented.

Keywords: International NGO, Sustainable Supply Chain Management, Social Movement Theory
Introduction
Different from corporate organizations, NGOs have more localized knowledge on society, which makes NGOs more efficient at micro level (Frantz, 1987). In prior studies, e.g., Hyatt and Johnson (2016) and Rodriguez et al. (2016), NGOs are considered as a supply chain members to deal with sustainability issues. NGOs are self-governing, private, not-for-profit organizations that aim to improve social and natural systems (Vakil, 1997). It was acknowledged that NGOs are better at addressing many social sustainable issues and managing supply chains to do so (Rodriguez et al., 2016). To better capture the dynamics of this phenomena, social movement theory (SM theory) was adopted by scholars in sociology, political study and other disciplines in order to analyze why and how SMOs initiate social changes. Indeed, SM theory is a rich perspective to explain how organizations successfully mobilize resources to conduct reform and reach their political goals (Stallings, 1973; McAdam et al., 2003). Since we have focused on international NGOs, institutional perspective is adopted in this study.

In this study, we seek to systematically analyze the related works in the existing study and provide a conceptual framework in the context of sustainable supply chain management (SSCM). By doing so, we reviewed 47 papers from 1970 to 2018. After reviewing the existing literature, we proposed a conceptual framework for our study. Thereby, this paper aims to answer the following questions:

RQ1: What is role of NGOs in changing sustainable practices across supply chains?
RQ2: How do relative deprivation, political opportunities, resource mobilization and collective action affect NGOs’ role in sustainable supply chains?
RQ3: How do institutional pressures influence NGOs’ works in sustainable supply chains?

The Review Process
In this section, the overview of research approach has been provided in the following section.

Generally, there’s little overlap between supply chain management, NGO and sustainability literature. Following SLR method, first, to identify the research scope (Figure 1), we divided these fields into four groups: supply chain, NGO and sustainability; supply chain and NGO; supply chain and sustainability, and NGO and sustainability. To identify the scope, we search the relevant literature in the groups above respectively on Scopus. Second, we use the “advance search” on Scopus database to search following keywords for each group. More specifically, we “translate” SCM as (“supply chain management” OR “value chain” OR “commodity chain” OR “global production network”), NGO as (“international NGO” OR “social responsible stakeholder” OR “social auditor” or “activist stakeholder”) and sustainability as (“corporate social responsibility” OR “CSR” OR “triple bottom line”), and adopt these keywords on the database to search the literature for each group respectively to identify the articles. During this process, we choose English articles, peer-reviewed journals as the primary criteria to search articles. In terms of subject, articles are selected in “Business, Management and Accounting”, “Economics, Econometrics and Finance” or “Multidisciplinary”. Finally, the initial search result showed 44,742 related articles on the database. Then, we conducted an evaluation by scanning the title and abstract and adopting the inclusion and excluding criteria in Figure 2, which identified 393 potential articles. Finally, we read and analyze the full text and identified 47 papers to be discussed in this review. Broadly, this process is displayed in figures below:
Construct of Theoretical Frameworks

Relative deprivation

The concept of relative deprivation (RD) was first introduced by Stouffer (1962) in psychology. He claims that satisfaction is relative to available comparison around individuals (Stouffer et al., 1949). Later, scholars such as Pettigrew (1967), Smith et al. (2012) and Walker and Smith (2001) further developed this concept and argue that social judgments are shaped by both absolute standards and standards set by social comparisons. More recently, Pettigrew (2015: p. 12) defined RD as “a judgement that one’s in-group is disadvantaged compared to a relevant referent and that this judgment invokes feelings of anger, resentment, and entitlement”. In sum, RD refers to the absolute level of deprivation of individuals, or partly, the feeling of dissatisfaction and injustice (Pettigrew, 2015). In a similar vein, such comparison occurs not merely at personal level, but also at organizational level. In sociology, RD illustrates the process of intra-group inequity in order to explain the motivations and implications of social behaviors (Flippen, 2013). In social movement, RD experience has been considered as an essential element. It was acknowledged by resource mobilization theory that RD plays a role as background or motivation in social movements (Oberschall, 1973; McCarthy and Zald, 1973). That said, the outcome of interpersonal or inter-organizational comparisons is the reflection that may finally leads to the strong motivation of changing current situation. Given the fact that individuals or organizations are motivated to rearrange the current settings when emotional reflections arises, successful movements can not be ensured if little opportunities exist prior to the actions being conducted. Thereby, after obtaining motivations, opportunity-seeking behaviours are following after RD experiences.

Political Opportunities

Orwell (1990) argues that social movements cannot emerge when people are not able to associate with others for political purposes. In other words, the foundation of social movement relies on “the chance for people to act together” (Goodwin and Jasper, 1999). Tarrow (1983) indicates that political opportunity is a multidimensional concept which includes “the openness of the political system to potential challengers”, “the stability of political alignments” and “the availability of potential alliances”. Further, Rucht (1996) addressed “policy implementation capacity of the state” as another dimension of the political opportunities. In other works, political opportunities were considered as the
non-political factors or processes that affect “the chance to act together”, such as availability of elite allies and access to political authorities (Goodwin and Jasper, 1999). In sum, opportunities for organizing movement might exist when openness is existing in the current institutional settings when stability is relatively weak. In these regards, “political opportunities” is suitable to be used to explicitly explain INGO-organized “movements” in business operations (e.g., supply chain management). And we therefore argue that political opportunities is the second construct to be adopted in our study.

**Resource Mobilization**

Resource mobilization contains societal support and constraint of social movement, which examines the variety of resources that must be mobilized, the linkages between social movements and other groups, the dependence of movements on external support and the strategies used by authorities to control movements (Jenkins, 1983). Different from political opportunity approach, the resource mobilization theory focus on the role of internal resources and mobilization efforts (Tarrow, 2011; Tilly, 1979). As discussed earlier, the basis to survive in the society is legitimacy, which allows organizations to collect resources in the society (Meyer and Rowan, 1977). To further pursuit successful works, however, they must not only achieve legitimacy but also try to obtain more resources from the public (McCarthy and Zald, 1977). In this regard, Tilly (1978) proposed resource mobilization theory (RMT) and suggested that resource mobilization plays a key role for the emerging of social movement and sustaining collective action. As a SMO, the success of INGOs’ work also requires sufficient resources. To mobilize sufficient resource for collective actions, scholars have proposed the process of Resource Mobilization (RM). In these senses, after access was secured, INGOs’ capacity of collecting resources plays a fundamental role in organizing movements. Therefore, resource mobilization perspective is adopted in this study.

**Collective Action**

In prior studies, scholars in sociology mainly concerns mobilization and collective action are based upon the interactions of like-mind networks (McAdam, 2010) and further analyzed the collective action during movement gatherings and campaigns (Benford and Snow, 2000). Alone this line, three components were proposed including identity, injustice and agency (Wojcieszak, 2011). More specifically, identity component emerges when individual identifies his or her group and recognizes that other groups have different interest and values (Wojcieszak, 2011). In other words, this component defines the concept of “we”, which is in opposition to the concept of “they”. In addition, injustice component arises when a situation was considered as “unfair” under a certain social setting (McAdam, 2010). Finally, the agency component concerns individual or group recognition that collective action is the solution of unjust situations (Van Stekelenburg and Klandermans, 2013). In this context, INGOs are seen as the social actors that bring about social transformation by utilizing their resources and networks to provide motivations and mobilize people to raise their voices against dominant social settings (Pattnaik and Panda, 2005). Hence, alone this line, INGOs can be considered as social movers or SMOs. This linkage is discussed in the following section.

**Institutional Theory**

Once again, INGOs’ roles as SMOs extend across national boundaries. Davis et al. (2008) argue that in an increasingly global economy, social movements are growing more transnational. It was also mentioned in the previous section that INGOs are expanding their operations in the global business environment, which are challenged by several institutional
pressures. Hence, institutional perspective is employed in this study to better analyze the impacts of INGOs in supply chains.

According to Keim (2003), institutional forces are formal (e.g., government’s regulations) and informal (e.g., national culture and values). In prior works, the theory of institution contains three drivers that change organizational strategies, structures and decision-making processes including coercive, normative, and mimetic isomorphic driver (DiMaggio and Powell, 1983). Normative isomorphic driver emphasize the operating mechanism of mind, which includes national or regional culture, shared values, logics of action and mental model. Moreover, coercive isomorphic driver refers to the formal rules that regulate behaviors, which include laws and constitutions. In addition, mimetic isomorphic driver includes informal rules and norms that influence organizational behaviors between competitors. In this study, INGOs are not the ones operating in their home countries. In this sense, institutional environment is seen as the external pressures influencing INGOs’ participation in movements. In INGO literature, the most-frequent discussed institutional issue was legitimacy. In other words, external institutional environment making impacts on “movement” carried out by INGOs. Such “movements” can be the ones improving sustainability in firms’ supply chains. Thereby, in our study, institutional theory is adopted to analyze how INGOs operate to improve sustainability in supply chains.

**Discussion and Development of Conceptual Framework**

Based on the constructs above, in this section, we develop 5 propositions and conceptual framework.

As mentioned earlier, relative deprivation theory describes the occurrence of social movement. Pettigrew (2015: p. 12) defined RD as “a judgement that one’s in-group is disadvantaged compared to a relevant referent and that this judgment invokes feelings of anger, resentment, and entitlement”. In addition, the resource mobilization theory emphasizes both societal supports and constrains of social movements, which argues that the resources related to social movements must be mobilized to ensure the success of movements (McCarthy and Zald 1977). Thereby, in social movement study, these theories have linkages. In prior works, RD experience has been considered as an essential element. In McCarthy and Zald (1973)s’ work, RD is the trigger of resource mobilization in social movements. In other words, individuals and groups begin mobilizing resources to prepare for the possible movement when they are motivated by the feeling of unfairness or injustice (i.e., relative deprivation). Hence, based on the discussion, the first proposition is hypothesized as follow.

**P1: INGOs’ possibility to mobilize resources is positively influenced by relative deprivation in supply chains;**

According to Watanabe (2007), the greater gap between people’s level of expectation and level of actual fulfillment, the greater is their dissatisfaction. In response to this, people would be more likely to participate social movements.

Theoretical bases of the RD perspective. The link between RD and SM’s is grounded in longstanding principles of social psychology. Generally, RD was considered as an essential cause of collective action in prior studies. Justino (2009), for example, argues that individuals are driven to join collective actions in order to improve extremely low living standards, rather than making profit. In other words, individuals are motivated by deprivation in collective protests. However, RD is positively related to the engagement in protests when it occurs in the environment with an open political opportunity structures. That is to say, despite RD is able to encourage individuals to participate collective protest,
it is not a sufficient cause of SM activities (Davies, 1962; Geschwender et al., 1969; Gurr, 1969).

Beaton and Deaveu (2005) found that RD based on inter-group comparison may be associated with certain type of collective actions. The impact of economic variables of RD, for instance, depends on the structure of current political opportunities. In this sense, different degrees of efforts required by collective actions have to be identified. In this study, INGOs’ motivation to conduct further works is considered as relative deprivation. Furthermore, as INGOs have local knowledge in different regions, we argue that INGOs’ RD is based on inter-group comparison. Therefore, we suggest that RD is associated with collective actions.

According to the discussions above, we propose the second proposition as follow.

**P2: INGOs are more likely to conduct collective actions in supply chains when they have more relative deprivation.**

Tarrow (1983) indicates that political opportunity is a multidimensional concept which includes “the openness of the political system to potential challengers”, “the stability of political alignments” and “the availability of potential alliances”. Support from authority or openness of institution, for instance, would provide important resources and reduce the autonomy of the SMO as well as threaten its stability, which can impact on the development of SMO. Similarly, the working relationship or political alignment would enhance public recognition in order to access to decision-making procedures and public subsidies with more resources (Goodwin and Jasper 1999). The third proposition is formulated by considering the discussion above, which is presented as below.

**P3: political opportunities of an INGO is positively related to INGOs’ ability to mobilize resources;**

It was acknowledged that organizations have to gain political opportunities and control sufficient resources prior to conducting collective actions (McCarty and Zald, 1977). Khawaja (1994) suggest that the possibility of collective protest depends on the availability of resources. In other words, the more resource people have, the more risk they can take and conduct or participate collective actions. In contrast, individuals with less resources would had a lower possibility to participate in protests. Similarly, Klandermans (1997) found that grievance alone cannot formulate collective action without preparing resources at the individual, social and political level. In sum, in this study, we argue that INGOs have better ability to take risk in protests, which motive them to conduct collective actions in supply chains. Based on the discussion above, we propose the following proposition.

**P4: INGOs’ are more likely to enable supply chains to conduct collective actions when more resources were mobilized;**

As mentioned earlier, political opportunity assumes that the political structures, such as the degree of openness and closeness of institution, influence the occurrence of social movements. Although political opportunity is not significantly necessary for the occurrence of collective action or social movement, social movement would not be able to occur “if the political opportunity structure is closed” (Watanabe, 2007: p. 811). This situation also occurs when relative deprivation is high or resources are sufficient. For INGOs, more political opportunities provide more access to resources. Hence, we argue that INGOs tend to be more active in collective actions when more political opportunities were available. Therefore, according to the discussion above, we develop the last proposition as follow.

**P5: More political opportunities provide more possibilities for conducting collective action.**
In sociology, scholars mainly concern resource mobilization and collective action are based upon the interactions of like-minded networks (McAdam, 2010) and further analyzed the collective action during movement gatherings and campaigns (Benford and Snow, 2000). In supply chains, collective action is required to pursue higher goals. Ring and Van de Ven (1994: p. 96) suggested that the collaboration of supply chain numbers can be understood as “a form of cooperative inter-organizational relationships, which are 'socially contrived mechanisms for collective action’. In other studies, participants in supply chains are together to accept specific roles to perform functions and pursue common goals when each participant’s role is believed to be effective to build better supply chains (Ketchen and Giunipero, 2004). Therefore, we develop the last proposition as follow.

P6: Collective actions improve sustainability in supply chains.

By employing both institutional theory and social movement theory to develop a conceptual framework and model for proposed propositions as illustrated below:

![Proposed Conceptual Framework](image)

**Figure 2 Proposed Conceptual Framework**

![The Motives for NGOs Engaging Social Movement](image)

**Figure 3 The Motives for NGOs Engaging Social Movement**

**Conclusion**

Overall, the contributions of this study can be threefold. Firstly, this may be the first study which provide a systematic review of INGOs’ role on improving social sustainability in supply chains. Secondly, by introducing and adopting social movement perspective from sociology, we opened a possibility to build a new theoretical framework in SSCM study in
the future. More specifically, we argue that relative deprivation, political opportunities, resource mobilization and collective action perspective in social movement theory and institutional pressures should be taken into account in order to understand INGOs’ work across supply chains. Third, as this study is not free of limitations, we also provided a number of directions for further studies.

In this paper, we discussed INGOs’ role on improving social sustainability in supply chain. Meanwhile, after reviewing the existing literature, we proposed a conceptual framework for our study. Our study, however, is not free of limitations. In response to this, we provide the gaps in the current study and open avenues for the research in the future.

First, NGO can be classified as operational NGO (i.e., the NGO that directly involve in service delivery or participation in self- or development-oriented projects) and advocacy NGO (i.e., the NGO that defend or promote a cause by lobbying and activist events) (Nonprofit Expert, 2017). Therefore, NGOs are complex and adopting different methods to achieve their goals. Our study, however, didn’t discuss a particular type of NGO, which is a limitation of this paper. Therefore, the first suggestion is that future research can specifically discuss each type of NGO and provide different types of insights base on the classifications in NGO literature.

Second, as mentioned earlier, social movement theory is a rich perspective to understand how organizations successfully mobilize resources to conduct reform and reach their political goals (Stallings, 1973; McAdam et al., 2003). Indeed, we identified a certain number of constructs under this perspective and selected the related ones for the conceptual framework. Yet, as we reviewed a limited number of relevant literature, the knowledge regarding the social movement perspective is still limited. Thus, the investigation of other constructs of social movement perspective, such as rational choice, may be the second direction for study in the future.

Abstract
This research asks whether protecting the safety of operational workers offers organizations survival advantage or disadvantage. We address this question because there are conflicting predictions on the relationship between worker safety and organizational performance, making it difficult to create effective safety and policy recommendations. The results, based on a unique longitudinal database covering 386,179 organizations across 25 years are unequivocal: organizations significantly decrease their odds of survival by protecting the workforce, especially for older and larger organizations. The result suggests that the market is unlikely to enforce workplace safety, and that current regulations are not sufficiently protecting operational workers.

Keywords: Supply Chain Sustainability, Operational Health and Safety, Quantitative Research

Introduction
The pursuit of profit can lead to job creation, innovation, and enhanced prosperity. But when organizations cannot or will not provide a safe workplace, there are costs to the workers, the communities they live in and society at large. This research exploits unique longitudinal data to address a fundamental question: Does providing a safe workplace improve or hinder organizational survival? Otherwise stated, are organizational goals compatible with societal goals?

We address this question because there are conflicting predictions on the relationship between operational worker safety and organizational performance, making it difficult to make coherent policy recommendations or create safe operations. The policy implications if it is profitable to protect the workforce are very different than if it is more profitable not to protect the workforce.

Managerial research posits that improving worker safety will improve profits (e.g. Pagell et al., 2015). Providing a safe workplace is proposed to increase profits as follows. First, the processes recommended for effective safety management systems such as OHSAS 18001 are highly similar if not identical to the processes recommended for effective operations management systems, such as ISO9000 (e.g. Lo et al., 2014; Pagell et al., 2015). Second, these highly similar systems are both primarily aimed at and performed by operational workers. Organizations can create parallel management systems for operations and safety, but this will
likely lead to confusion on the shop floor as operational workers are given duplicate and often conflicting messages about safety and operational management. Hence, organizations can become safe and productive by creating a single integrated management system for safety and operations, which provides workers a coherent message on how to perform their work.

Further, safe workers do not have to dedicate their resources to self-protection and can be motivated to engage in improving the organization’s operations; safety provides a necessary condition to leverage human capital into the development of unique capabilities and long-term competitive advantage (Das et al., 2008). Organizations that harm their human capital cannot build these capabilities and will be less likely to survive. This suggests that market mechanisms alone should eliminate poor safety.

However, classical economics suggest that that safety regulation exists because organizations would not provide a safe workplace on their own volition. The supposition that regulation that provides a communal good (in this case a safe workforce) is burdensome or costly for employers is often referred to as the ‘costly regulation hypothesis’ (Palmer, Oates and Portney, 1995; Levine, Toffel and Johnson, 2012). From this perspective, organizations that do not protect the workforce gain an economic advantage by avoiding these burdensome costs and being able to push the workforce further, which may explain why even proponents of “it pays to be safe” provide evidence that numerous organizations are not safe (Pagell et al., 2015).

Similarly, many studies in the managerial literature linking workplace safety to improved organizational performance have been hamstrung by cross-sectional analyses, small and biased samples, and poor proxies. For instance, the sample in Pagell et al., (2015) was limited to manufacturing facilities with at least 100 employees. While there is compelling evidence to support the perspective of either the costly regulation hypothesis or the managerial literature concluding it pays to be safe, neither is conclusive.

We further this discussion by directly exploring organizational survival and safety outcomes across 25 years of quarterly data on all organizations in a U.S. state. Directly exploring safety is important because many organizations have accidents and harm their workers without facing regulatory sanctions (Bureau of Labour Statistics, 2018a); safety is the desired outcome of regulation; and worker safety, not regulatory compliance is what leads to the development of human capital or unique capabilities (Pagell et al., 2015). Our data include the cost of all safety-related claims for each organization, as well as its entry date and how long it survived. Additionally, the data allow us to explore the role of factors such as industry, organization size, organization age, and organization growth. Our research explores these competing predictions:

1. Providing a safe workplace reduces organizational survival, in line with the costly regulation hypothesis.
2. Providing a safe workplace increases organizational survival, in line with the managerial literature on safety.

The results are unequivocal and consistent with the costly regulation hypothesis. Organizations significantly decrease their odds and length of survival by protecting the workforce. This effect is most pronounced for older and larger organizations and for organizations in industries where accidents are relatively more common. From a policy standpoint this suggests that relying on the market to make workplaces safe does not work. Beyond that, it implies that current regulations are not sufficiently protecting workers. Given our results, we assert that there is a need for greater and more targeted inspections as well as larger non-compliance penalties.

Data and Methods
The Oregon Department of Consumer and Business Services (DCBS), which administers laws and rules governing workplace safety and health in Oregon, provided data on the cost of all disabling claims made in the state from 1989-2014. Disabling claims are those where a worker
suffers temporary disability, defined as requiring three or more days off work, or the expectation of permanent disability.

DCBS also provided employment data for all organizations operating in Oregon, which originally came from the U.S. Bureau of Labor Statistics’ Quarterly Census of Employment and Wages (QCEW). The QCEW complies quarterly employment and wage data for 8.9 million U.S. organizations, representing 98% of non-farm, payroll organizations. While this data is publicly available in aggregate form, individual organizational records are not publicly available due to privacy concerns (Bureau of Labour Statistics, 2018b). DCBS provided unique IDs allowing us to anonymously link the QCEW and claims data.

The population included 386,179 organizations with establishments in the state between 1989 and 2014. Two samples of organizations with over 5 employees and sufficient data were constructed. To examine the relationship between short-term claims costs and the risk of failure, a sample of 103,906 organizations was constructed.

We focus on claims costs, not a count of claims, because cost is a better indicator of severity (Lebeau, Duguay and Boucher, 2014). Our primary measures, described below, are short-term claims costs (STCC), organizational survival, and failure. The supplement provides additional detail on measurement, and information on the control variables included in the analyses.

STCC were captured in each quarter as a time varying covariate. Defined as the mean cost of claims per 100 workers per quarter per organization in the past two years, STCC was log transformed due to extreme positive skew. To avoid losing 0 values in the transformation, a 1 was added prior to transformation. STCC was top-coded at the 99th percentile to reduce the influence of very large claims. Mean STCC after top-coding was $4,264 (SD= $16,014), or $1.95 (SD=3.71) log STCC. The average claim costs $13,910, meaning on average an organization of 100 employees has .304 average sized claims per quarter.

Organizations are considered to have been founded either on their first appearance in the QCEW data (Knaup and Piazza, 2007) or, for organizations present in the first quarter of the dataset (1989 quarter 1), on the date of initial liability provided by the DCBS. The latter organizations are left truncated. Organizations “exit” the dataset at their last record (Phillips and Kirchhoff, 1989) with those making their exit in the last quarter of the dataset (2014 quarter 4), considered right censored. Organizations were considered to have “failed” at a given time point if they left the data set and did not return. To examine effects of STCC on risk of failure, organizations were dummy coded as “failed” or “ongoing” in each quarter. To examine effects of LTCC on length of survival in quarters (survival), organizations were dummy coded as “failed” or “ongoing” at the last time point of the QCEW dataset (2014 quarter 4), with survival calculated as exit time minus entry time in quarters.

We examined the relationship between log STCC and risk of failure in the current quarter employing sample A (103,906 organizations) using a conditional cox proportional hazards model that deals with left truncation (Guo, 1993; Yang and Aldritch, 2012). Results are presented in table 1 and figure 1. The relationship is non-linear; log STCC squared is significant (table 1 Main effect). Increases in STCC (log STCC + log STCC^2) are associated with a reduction in quarterly risk of failure by up to 30.46% (21.10%, 38.67%) relative to an organization with zero STCC. Only at very high levels of STCC is there a predicted increased
risk of failure; for an organization with 100 employees, this occurs when they average more than 6.68 average sized claims per quarter. 6.68*13,910 = 92,966. The largest reduced risk of failure occurs above the 75th percentile of log STCC, and claims do not relate to an increased risk of failure until they reach the 90th percentile of log STCC. The reduced risk of failure associated with increased STCC is amplified with age while holding employment and other covariates constant (Table 1 Age; Fig. 1B). Similarly, the reduced risk of failure associated with increased STCC is amplified with organizational size (Table 1 Size; Figure 1C).

To summarize the results: Increased STCC predicts a reduction in the risk of failure in the current quarter and this effect is curvilinear. The largest reduced risk of failure occurs above the 75th percentile of log STCC, and claims do not relate to an increased risk of failure until they reach the 90th percentile of log STCC. This pattern is consistent, but strongest for older and larger organizations.

Table 1: Conditional cox proportional hazards models show that increasing STCC reduces hazard but the effect is non-linear. The dependent variable for all models was risk of failure at time t (hazard). Model 1 tests the effects of control variables on hazard (risk of failure at time t). Model 2 tests the effect of STCC. Model 3 tests for polynomial effects of STCC. Model 4 examines the polynomial effects of STCC grouped by organization age. Model 5 examines the polynomial effects of STCC grouped by organization size. Coefficients are rounded to 4 digits, and p<.001 unless otherwise specified.

**Summary Findings**

- **Controls predict hazard.**
- A one unit increase in log STCC results in a (2.01%) reduction in risk of failure.
- The relationship between log STCC and risk of failure is curvilinear.
- The protective effect of recent claims costs is present only for organizations with >10 workers, and is greater.
- The protective effect of log recent claims costs is present only for organizations with >10 workers, and is greater.

Figure 1- Graph depicting predicted values of Hazard Ratio (risk of failure relative to employers with $0 \text{STCC}$, with all covariates held constant) vs. log \text{STCC}, for all organizations (A; Table 1 Main effect), grouped by organizational age in years (B; Table 1 Age) and grouped by organizational size (C; Table 1 Size). There is a substantial non-linear effect (A), which is greater for older (B), and larger organizations (C).
Discussion
The research asked if providing a safe workplace for operational workers improved or hindered organizational survival. The results are unambiguous and indicate that providing a safe workplace hindered survival; organizational goals are in conflict with societal goals. Organizations with claims are more likely to survive than their peers without claims. These results and other recent research (e.g., Kirchhof, Omar and Fugate, 2016) suggest that, for the many organizations who prioritize organizational goals over operational safety, enhanced survival will conflict with societal goals.

The data set is both the key strength and key limitation of the research. The dataset captures almost all organizations that engaged in economic activity in Oregon over 25 years, but the dataset provides no information on actual managerial practices. Hence, the analysis is predictive not explanatory. Still the analysis does provide some direction both to start to explain the results and to guide future research.

One area to explore is alternative measures of harm to the workers. Disabling claims require at least three days off work, and as such are quite severe. Time away from work is linked to negative outcomes for the worker; illness days, medication use, and job and life dissatisfaction (Wright, Beard and Edington, 2002). The assumption that near misses and minor accidents can predict future severe accidents is prevalent in the safety literature (Manuele, 2011). However, the links are tenuous (Bellamy, 2015; Manuele, 2011; Marshall, Hirnas and Singer, 2018). By focusing on only severe disabling claims, we hopefully eliminated noise from minor incidents, which allows us to target only serious harm to workers. In addition, while under-reporting is a possibility (Pransky et al., 1999), it is less likely with disabling claims, relative to non-disabling claims due to their severity. Someone (typically an insurance company for the organizations in this data) needs to cover the wide range of medical and non-medical costs associated with these claims, and that can only happen if they are reported. Hence, worker compensation databases are viewed as providing a robust measure of work injuries (Oleinick and Zaidman, 2004). Future research needs to test this supposition by exploring the same questions with alternative measures of harm, which could include all accidents (disabling and non-disabling), near misses, and regulatory sanctions.

A related area for future research involves the perceptions of accidents of operational workers and how these perceptions feed into developing human capital and organizational survival. High claims costs eventually harm organizational survival (above $92,966 per 100 workers per quarter), although at levels which are well above the average injury rates reported by the BLS. The result may occur because after a certain point, accidents are demoralizing to workers or other stakeholders. However, the current research does not decompose the impact of accident frequency vs. severity, as high costs could be attributed to either. Future research should explore how operational workers react to accident frequency and severity as well as how industry norms influence these reactions. Exploring these issues may help to explain when / if organizations build human capital on the foundation of a safe workforce.

These results do not necessarily mean that research concluding it “pays to be safe” (e.g. Pagell et al., 2015) is wrong. We instead suggest that previous research mainly focused on limited samples of primarily large manufacturing organizations that invested in integrated safety management systems; for these organizations it likely does pay to be safe. Future research needs to explore how smaller organizations not engaged in manufacturing can create the same outcomes. In raising this question we are really highlighting the much wider issue that most managerial research does not capture small and medium enterprises and is often biased to manufacturing; making many of the literature’s conclusions suspect (Kull et all, 2018). Our results suggest that one way to
make research more relevant and useful will be to target a much wider range of economic actors.

Similarly, this research does not invalidate previous work linking inspections to improved safety with no harm to the organization (e.g. Levine, Toffel and Johnson, 2012) - quite the opposite. Many organizations are presently benefiting from externalizing their costs of poor safety on society, driving a need for increased enforcement. The likelihood of an organization getting inspected in developed countries such as the USA or UK is very low (Porter and Van der Linde, 1995) and resultant fines tend to be minimal. Organizations seeking to maximize survival are unlikely to actively put workers in harm’s way. But they are also correct in concluding that the costs of protecting operational workers or complying with regulation are higher than the costs of not doing so. This must change, which will require much higher levels of enforcement and higher penalties for organizations that violate regulations. This increased enforcement need not harm competitiveness, but it likely will rebalance the odds of survival in favor of the organizations that seek to prevent all harm to operational workers.

Crowd delivery: what types of supply chain entry strategies?

Université Clermont-Auvergne & CRET-LOG

Abstract

In recent years, many crowd delivery initiatives have developed, using a connected crowd of private individuals to carry out delivery. The aim of this research is to understand the supply chain entry strategies used by such firms. Based on secondary data from thirty crowd delivery websites, the article introduces a typology of entry strategies followed by these firms: service, intermediation and integration strategies. These results show that such firms use different business models to enter supply chains. Finally, the article discusses the impact these firms have on distribution, and makes recommendations for crowd delivery firms and players in the channels.

Key words: retailing, last-mile, delivery, crowdsourcing

Introduction

In recent years, a new type of delivery to end users has sprung up: crowd delivery. As a crowd practice (Howe, 2006), crowd delivery consists in using a crowd of private individuals to take charge of the final delivery to the consumer. These initiatives have been developed in urban centres for the distribution of meals (e.g., Foodora, Deliveroo), to deliver supermarket food products (e.g., Instacart, Amazon Fresh), or consumer goods in general (e.g., Postmates). Such schemes rely on the universal connection of people through Internet and Smartphones. This new connectivity enables to benefit from the crowd’s physical and logistics resources (Carbone et al., 2017): motive power, the use of private vehicles, the use of public transport, etc.

Supply chain management academics have so far paid little attention to such initiatives. Yet, crowd delivery may upset the competitive balance in supply chains, superimposing a delivery approach to the complex omnichannel (Verhoef et al., 2015) network. Some crowd delivery actors have reached impressive proportions. Instacart was valued at $3.4 billion in 2017 [The Wall Street Journal, 7 March 2017]. Postmates, with an estimated value of $460 million, raised an additional $140 million in October 2016 [Techcrunch, October 31, 2016] and uses 25,000 private individuals who make 1.3 million deliveries per month in 40 cities in the United States [Time, July 11, 2016]. In several activities (accommodation with AirBnB) those digital, collaborative player are decidedly disruptive.

This paper investigates the booming field of crowd delivery. We propose to answer the following research question: what supply chain entry strategy do crowd delivery firms follow? Given the lack of previous work, the methodology is inductive and exploratory, as suggested by Ketoviki and Choi (2014). The analysis is based on thirty case studies of crowd delivery firms, examined via their websites and secondary information sources.

First, we review the crowd delivery boom, and define it as crowd practice. Then we present the results of our research, developing a typology of supply chain entry: services, intermediation, and integration. In the third section, we highlight the theoretical contribution of our research, and in the fourth section, we assess the potential impact of delivery on these
supply chains and make managerial recommendations for crowd delivery players and existing members of those chains. In conclusion, we underline the limits of our work and suggest avenues for future research.

**Crowd delivery, using the crowd to make deliveries to consumers**
The term crowdsourcing, based on the words “crowd” and “outsourcing,” was popularised by Howe (2006). He refers to firms outsourcing activities to the crowd of private individuals. The boom in crowd practices relies on the idea, widespread in marketing (Vargo & Lusch, 2008), that individuals possess resources (financial, intellectual, material, etc.) that can be activated thanks to the development of digital technologies. As a result, individuals undertake a range of activities that had previously been the responsibility of the company.

**Crowd delivery, a form of crowd logistics**
Research on the use of crowd resources has stressed two main types of individual resources: financial and intellectual. The crowd funding practices (Ordanini et al., 2011) exist in the field of creation, and many platforms have developed to fund cultural projects (e.g., Kickstarter, KissKissBankBank). Intellectual resources enable the development of crowd innovation services (Collm & Schedler, 2012) used for example to create advertising slogans.

In recent years, several scholars have insisted on the idea that it is possible to activate the crowd’s physical resources. Chen et al. (2014) mention the development of a paradigm of urban logistics based on the crowd. Mladenow et al. (2015) note that it is possible to deliver logistics services by mobilising the crowd and Mehmann et al. (2015) propose that the principles of crowd sourcing apply to logistics. Carbone et al. (2017) distinguish in more detail between four types of crowd logistics practices: crowd storage (for warehousing), crowd freight shipping (outsourcing continental transport operations), crowd freight forwarding (international transport based on air travel by individuals), and crowd delivery (the use of the crowd for local deliveries). Ultimately, the latter can be considered as a form of crowd logistics that consists in using the crowd of private individuals to carry out a necessary logistics operation within any supply chain: final delivery of the product to the consumer.

**Crowd delivery, a boom in initiatives but little academic research**
Crowd delivery initiatives appear very recently (Ghajargar et al., 2016), and develop rapidly in many urban centres. Punel and Stathopoulos (2017) note that in the United States, on average one crowd delivery start-up is currently launched every week! Some authors (Rougès & Montreuil, 2014) present this phenomenon as a response to increasing consumer expectations with regard to delivery (deadlines, cost, and service). The crowd delivery boom is also based on the development of digital and mobile technologies, which provide new opportunities for organising last-mile delivery (Arslan et al., 2016), considered to be the most expensive link in the supply chain (Frehe et al., 2017). Thus, it is now possible to connect with private individuals and transform ordinary citizens into couriers (McKinnon, 2016), and to recruit urban ‘crowd workers’ (Chen et al., 2014) to carry out parcel deliveries – in exchange for a small payment. Finally, the crowd delivery boom is also a response to the needs of retailers, particularly small operators (Schreieck et al., 2016). It enables them to offer their customers rapid delivery of purchases made at a sales outlet (Ghajargar et al., 2016).

However, the management literature on crowd delivery is for the moment underdeveloped. Most publications on the topic are technical (Frehe et al., 2017), dealing with algorithms or geolocation systems (Mehman et al., 2015). While the managerial literature describing crowd practice strategies is now substantial (Carbone et al., 2017), research in the field of crowd delivery is in its early stages (Frehe et al., 2017).

**Methodology: multiple case studies of 30 crowd delivery firms**
Ketoviki and Choi (2014, p. 134) recommend that when “the research context is new and unfamiliar,” as in this case, a theoretical framework should not be chosen. Our exploratory methodological approach is thus based on multiple case studies that make possible “to explore a contemporary phenomenon in depth and in its actual context” (Yin, 2014, p. 16), and fit with theory development. Multiple case studies allow for “a broader examination of the research questions” (Eisenhardt & Graebner, 2007, p. 27).

Identification of crowd delivery initiatives
To constitute our series of cases, we used lists drawn up by professionals (Rachel Botsman, Ouishare collective), and extended them with Internet searches. The boundaries of this activity are still blurred, and listing firms is not easy. Like others (Schor, 2014), we identified crowd delivery initiatives pragmatically, using the fact that the various players know each other. In late April 2017, we established a sample of 30 firms (list available upon request).

The crowd delivery initiatives we studied operate in many sectors, although catering and food take the largest share. Such initiatives develop in a variety of countries, including the USA (Deliv, Doordash...), Germany (Foodora,Volo), and Australia (Suppertime)... France is also well represented (P opc h ef, Colisweb...), which is certainly due to “nationality” bias (some French language sites we consulted mostly belong to French start-ups). However, it is only to be expected that a great number of crowd delivery start-ups should be launched in Paris: the density of the population, the number of restaurants, and the French love of good food clearly favour the development of these initiatives. Finally, the crowd delivery initiatives we studied are led by start-ups, established distributors (Amazon Flex), logistics services providers (DHL MyW ays), and new economy companies that have diversified by extending collaborative practices to other sectors (Uber e at s).

We first examined the firms’ websites. These secondary data “exists prior to formulation of research objectives” (Rabinovich & Cheon, 2011, p. 303), and limits artefact bias (Herbert, 2007). In addition, using websites data is particularly appropriate, since initiatives are by definition based on a website (Schenk & Guittard, 2011). Analysing these websites requires several tasks: carefully reading all the material available (pages, general conditions, documents downloadable documents, etc.), watching any videos, and exploring links to the initiative’s blogs, forums, Facebook page, and Twitter account. In addition to this data, we collected secondary data from the professional press.

Analysis of the data collected
We used content analysis; its is applicable in a qualitative context, and on a many different types of data, including internet data (Seuring & Gold, 2011), and appropriate for exploratory research. Content analysis is also preferable when the data is unstructured and irregular, and may contain ambiguities (Aureli, 2017). Overall, this method appears particularly appropriate for website content, which undeniably include “propaganda” and extremely varied content. Content analysis enables the classification of raw data by identifying categories and dimensions by a combination of interpretation, subjectivity, and objectivity (Manuj & Pohlen, 2012). Here, we coded the data manually, which is particularly recommended for immersion in emerging phenomena (Thomas, 2006).

During the first “descriptive coding” stage (Miles et al., 2013), we carefully read the content of a dozen websites, alone and then together in order to develop a descriptive coding table (Maas et al., 2014). The objective of the following analytical coding phase was to go beyond description and to develop a conceptual approach. This led us to develop a typology of the supply chain entry strategies followed by crowd delivery firms. Typologies have been a common form of theorisation in the human and social sciences since Weber. In accordance with Doty and Glick’s (1994) recommendations, we described each type with regard to the same set of variables. We identified nine key variables to describe each of the three types.
Three types of supply chain entry
Our analysis of 30 crowd delivery initiatives reveals three major supply chain entry strategies. The first one, followed by “Urban logistics service providers” offers existing distributors a crowd delivery service to the final consumer thus enhancing brand’s delivery offers. The second one followed by “Online urban retailers” develops an e-commerce platform including a crowd delivery service thus operating direct intermediation between producers/distributors and consumers. The third entry strategy is followed by “crowd delivery based companies”. The dominant features of these ideal-types (in Weber’s sense) are summarised in Table 1.

</table>

Table 1: types of supply chain entry strategy followed by crowd delivery firms

The crowd delivery firm as a logistics services provider
The first strategy identified is that of urban delivery services provider. These firms’ clients are retailers rather than the consumers who benefit from the delivery service. These crowd delivery firms provide a home delivery service for retailers (independent or subsidiaries, with physical sales outlets and/or e-commerce websites, incorporated in a commercial centre, etc.), from their warehouses or points of sale at a reasonable cost. The role of the crowd is to transport goods on behalf of a third party. The principal risk for the retailer is that the quality of the service may not be high enough. On the other hand, if the services work well, the retailer can become dependent on the provider, and see the price charged for the delivery rise. The delivery service proposed, based on the crowd, is extremely flexible (single-unit delivery, flexible delivery times, etc.). This crowd delivery service does not generally target a particular sector, it can be used by independent sales outlets, large distribution networks, (for example, Leroy Merlin has tested the You2you model), large stores (BHV with Deliver, for example), or even manufacturers (Addresses of distinction, a mailbox manufacturer, uses Kanga). The crowd delivery service can be part of a wider range of logistics solutions, including collection from the store or pickup points, exchanges between sales outlets, e-commerce returns, etc. Usually, such firms invoice by distance; the retailer decides whether to pass the delivery cost on to the consumer. These systems are based on dedicated software designed by the crowd delivery firm, interfacing with the retailer’s information system. The software can use the internet or sales point interface. A mobile application is also provided for the couriers, but is not usually available for consumers. The key point here is the IT interface with the distributors. Typical examples of such firms include Deliv, Stuart, UberRush, and Zipments.
The crowd delivery firm as an online urban retailer

The service offered by these firms is only available on line and in urban areas. Players target both consumers, who pay the crowd delivery firm for the service provided, and retailers, whose products are listed online. These crowd delivery firms use the retailers in an urban area as suppliers, and position themselves as a visible intermediate, an online marketplace, between the consumers and the retailers. They offer consumers quick delivery and low-cost access to a wide variety of products. The main risk faced by consumers is that the products they buy on line may not be available on the shelves due to stock shortages. As for the retailer, their advantage is based on commercial visibility. The risk they face is that they create a new intermediary between themselves and the consumer. In such a strategy, the crowd is responsible for the transport and for the picking at the point of sale. The crowd constitutes a key actor that can also take on a marketing role, promoting the crowd delivery firm to consumers. Firms often offer a food-oriented product range: catering (e.g., UberEats), cakes and pastries (e.g., citycake), or food retailing (e.g., Instacart, see Box 2). The giant Postmates adds alternative products (gifts, stationery etc.). The pricing system depends on the features of the order, and can vary with the overall cost of the shopping, its volume, and/or the delivery distance. The service is based on a mobile app that consumers download, and from which they may select the suppliers and/or products they wish. These crowd delivery firms can also offer to set up special partnerships with retailers, both in IT (e.g., integration of the solution within the information system, reception of digital orders in real time by a restaurant) and physically (e.g., dedicated checkouts at Costco stores for Instacart). This ability to set up overall IT and logistics interfaces appears to be crucial for these crowd delivery firms. Typical examples of such firms include Deliveroo, Instacart, and Ubereats.

The crowd delivery based company

These firms target customers exclusively, that can be individuals or companies. Outsourcing delivery to the crowd is used to deliver products designed by the firm itself. From its central kitchen in the suburbs of Paris, the catering firm Nestor delivers a single menu on weekdays to addresses in the west of Paris using a fleet of independent couriers. Similarly, Amazon, is developing crowd delivery, under the name Amazon Flex, to guarantee express deliveries of products sold as part of its offer Prime Now. In this strategy, the crowd undertakes delivery, but also plays a key marketing role as ambassador for the firm. Here, the crowd delivery service is a key feature of the company’s offer to its customers, rapid availability and low cost being considered as key success factors. The principal risk for customers is that the offer may not correspond to their need, due to the difficult for the firm to offer its clients sufficient variety. Pricing is either fixed (as in the case of Amazon Prime), or integrated in the price charged to the customer (as in the case of Nestor). Such a strategy is based on a dedicated IT solution interfaced with a mobile application via which customers place orders. The key competences required for success appears to be developing a marketing offer well-adapted to the target. This type of crowd delivery is much less common than the two other strategies, and is used particularly in catering, with typical examples like Nestor and Popchef. It also reflects the desire of certain retailers (such as Amazon) to create their own distribution channel.

Crowd delivery, several business models to enter supply chain

Our results suggest that crowd delivery firms pursue three major types of strategy to enter supply chains, each of which is based on a different strategic logic: outsourcing, intermediation, or integration.

The diversity of crowd delivery business models

Our findings reveal that crowd delivery firms implement different business models (Zott et al., 2011) to enter supply chains. A firm’s business model designates the means it uses to create...
and distribute value. Any business model is materialised by different choices (Lecoq et al., 2006): 1) its resources and competences; 2) its internal and external organisation; 3) its value proposition. Figure 1 describes the different choices around which crowd delivery firms build up their business model (Figure 1).

The resources and competences on which the start-up are based can be divided into three areas: the role of the crowd, whose latent logistics competences are mobilised (Carbone et al., 2017), the physical activities insourced by the crowd delivery platform, and the IT resources it mobilises. Our results underline the contrast between the three strategies identified with regard to these parameters. This is true of the crowd, which in each case plays a more or less comprehensive role: this role might simply involve delivering, or include other operational roles such as picking, or even commercial roles. This is also true of the physical activities controlled by the crowd delivery firm, that can be restricted to transport or include other operational activities such as order preparation. Finally, this is true of IT resources, which may include a mobile application, a planning interface, or dedicated ERP software.

The firm’s internal and external organisation are based on choices made with regard to the offer, clients, and positioning in the supply chain. The offer may target a single or multiple sectors. The clients can be retailers, the final consumer or both. The firm’s position in the chain varies, as the start-up positions itself as a service provider, marketplace, or competitor.

Finally, the value proposition includes the pricing policy, the customer benefits highlighted, and the associated risks. Here again, the choices made by the start-ups are clearly different. Delivery charges can be based on distance or on the service provided, be fixed, or included in the product price. The customer benefits can relate to the features of home delivery (speed, flexibility, etc.), to the breadth or accessibility of the product range, or the uniqueness of the offer. The risks also differ, and include image, dependency, stock shortages, disintermediation, and signing up to a limited offer.

Ultimately, crowd delivery start-ups must find a logical compromise between the three components any business model comprises. Their challenge is to design a model that uses and links the resources and competences developed, the internal and external organisation selected, and the value proposition made to the client. Our finding suggest that the key to success for these “digital” companies is to integrate these technologies within a much larger structure of organisational, marketing, and logistics components. The key issues are those of strategically aligning their IT resources with the other non-digital components (Henderson & Venkatraman, 1993), and beyond this, of successfully interfacing them with both traditional market players and other ‘mobility web’ start-ups (Rougès & Montreuil, 2014).
**Crowd delivery to gain power in the supply chain**

Our findings show that the crow delivery firms try differently to disturb the political and strategic balance that governs any supply chain (Cox, 1999). A services strategy leads crowd delivery firms to take the place of existing logistics service providers (LSP) and position themselves as third-party for retailers (Punel & Stathopoulos, 2017). Crowd delivery can offer cost saving and more flexible services, adapted to consumer behaviour (McKinnon, 2016). They may threaten LSPs (express couriers, local transporters, courier firms, etc.) but their long-term profitability is dependent on a critical mass of distributors and individuals.

The intermediation strategy can also alter the balance. Crowd delivery firm endeavour to manage both delivery and consumer transactions. As brokers (Miles et Snow, 1986), they replace existing retailers by reorganising the channel. As Véтроis and Rimbault (2017) stress, this model both renews and disrupts traditional players. Crowd marketplaces act as integrators (Moati, 2016) by mediating between the producers or retailers and the end consumer, to whom they propose a ‘package’. This positioning confirms the observable convergence (Moati, 2016) “between players of very different origins towards the position of integrator” (p. 116), which lead distributors to adapt.

Finally, crowd delivery firms following the integration strategy design and control the production and transactions of their own offer, and ensure its distribution via the crowd. This model does not appear particularly disruptive when it takes the form of catering. However, it may change the rules when implemented by Amazon, the world’s largest source of parcels and last-mile delivery player (McKinnon, 2016)!

**Potential impact of crowd delivery on supply chains**

Many crowd practices have impacted a wide range of sectors (AirBnB in the hotel sector, Uber in taxi services, etc.). So far, the turnover of crowd delivery start-up firms, whilst difficult to estimate, has often been insignificant. But what does the future hold?

*Urban online retailers: the possibility of disruption remains to be confirmed*

In our opinion, the strategy with the greatest potential for disruption is that of urban online retailer. The marketplaces listing retailer’s products, offer the latter substantial visibility, but they do not restrict themselves to picking up some of their margin. Their arrival is liable to result in the retailer losing direct contact with consumers. If thousands of American consumers keep on using Instacart, nothing will prevent the player from putting traditional distributors in competition by negotiating discounts for its users. This danger is all the greater given that crowd delivery start-ups are no longer the anonymous service providers they initially were, but implement aggressive marketing strategies. Their aim is to target individuals who are a dual target for them, as potential employees and as potential clients.

For the start-ups, the challenge is to reorganise the chain and to substitute retailers “by stealth.” For the moment they have by no means succeeded, because of the weight of retailers, and the fragility of their own employment model raising serious questions about their long-term viability. The challenge for the retailers is to avoid losing their crucial direct contact with consumers and to prevent their shops from becoming warehouses where crowd shoppers go to pick up what their clients require. They can consider developing their own crowd delivery services, buying up a crowd delivery player, or emphasizing experiential marketing!

*Service providers, between crowd and industrial delivery*

These start-ups threaten traditional LSPs operating in supply chains (express parcel deliverers, local transporters, courier firms). The threat is a real one for these firms, particularly as end consumers are demanding with regard to delivery times (less than an hour in urban areas) and expect to benefit from the latest innovations (secure systems, etc.). With their intelligent use of digital technologies and their agility in mobilising simple resources available to everyone, crowd delivery players may establish themselves in this field.
To succeed, such start-ups must be able to provide the customer with a flawless service, which is far from easy when using a crowd of individuals whose logistics skills cannot be guaranteed! Many crowd delivery firms begin by using individuals, but later employ a large proportion of professional couriers…Thus, they are no longer crowd delivery firms, but more like traditional transport firms! It seems to be very likely that LSP’s will see some opportunities in these new initiatives. This is the above all the case for 4PL providers, who are used to taking on the role of orchestrator (Zacharia et al., 2011) and are seeking to benefit from crowd delivery by including it in their own range of integrated services.

**Firms with integrated crowd services and niche strategies**

In the long term, it seems that the impact of firms that deliver their products using their own crowd delivery on supply chains will be limited. Such a strategy requires firms to rethink their products and services, adapting them to the conditions of crowd delivery in line with the principles of *design for logistics* (Mather, 1992). These firms are thus usually forced to limit the assortment they offer. In addition, this restricted offer is only available via a single distribution channel, that of internet orders and delivery (by the crowd or professionals), at a time when the multiple demands of their clients are pushing many players towards omnichannel distribution.

Thus, such a strategic model is likely to follow a niche strategy, in Porter’s sense, insofar as it is only possible to target a restricted group of customers. The potential of these strategies seems particularly limited given that in general, these start-ups only offer their services in clearly restricted areas, major city centres such as Paris, New York, London, etc.

**Conclusion**

In this research we have described the supply chain entry strategies followed by crowd delivery firms. Based on a study of the websites of thirty of these firms and other documentary sources, we have highlighted that these actors use three typical strategies. The first consists in positioning themselves as logistics service providers, aiming to enhance the services of existing retailers by offering them a delivery service. The second consists in considering the firm as an urban online retailer, offering consumers the possibility of buying products from various existing retailers and having them delivered by the crowd. The third consists in producers or retailers developing their own system of collaborative delivery, which they outsource to the crowd.

This research is not free from limitations. These lie in the methodology selected and in our data collections strategy based on analysing crowd delivery initiatives via their websites. These are of course commercial sites, designed to attract users, and this can mean that our data is not objective. In addition, we were unable to measure the commercial and financial results of these initiatives. An examination of the financial statements together with face-to-face interviews, or perhaps targeted in-depth case studies (for example studies of representative firms of each of the three types), would help establish definitively the validity of the typology we introduce here.

But beyond these limitations, our research opens up several interesting research perspectives. A first avenue would be for future research to approach this subject from the standpoint of crowd delivery targets services (retailers and consumers). What are their motivation leverage or brake? Is it possible to identify typical profiles of user companies or consumers?

Another future research avenue would consist in studying human resource management practices in crowd delivery firms. This model offers flexible working, available to all without the need for qualifications or investment apart from the need for a bicycle, and often takes advantage of the limits of the current legal framework. Such human resources management raises multiple, highly-debatable political and societal issues, currently very much in the
public eye. It also raises questions with regard to performance. How can it be possible to guarantee the quality and reliability of the delivery services on offer? How should this new type of work be regulated, to avoid unfair competition between some courier firms subject to strict legislation and others working in the legislative vacuum of the collaborative economy? How can we avoid these new practices leading ultimately to a new kind of exploitation of the crowd?

Hopefully, future research will be able to answer these questions. The development of crowd delivery initiatives raises complex problems that require to consider technical, social, and economic factors, and shape an exciting research field in both logistics and marketing.

Abstract

Operational risks are associated with unexpected events which can affect the regular performance of activities. Colombia has a food supply for human consumption of 28 million tons per year; however, it is not fully exploited, as losses and wastes are generated all along the food chain. This risk may occur in the transportation of fruits and vegetables, in which their damage and loss may take place. Therefore, it is important to manage risks, in order to take necessary actions. A proposal is presented to identify and prioritize operational risks in transportation of fruits and vegetables by road in Colombia.

Keywords: Operational risk, Transportation, Fruit and vegetable products

Introduction

Colombia has a food supply for human consumption of 28 million tons per year (FAO, 2014); however, it is not fully exploited, as losses and wastes are generated all along the food chain.

Operational risks are associated with unexpected events which can affect the regular performance of activities, and it has its origins in machines, workforce, processes or external events. This risk may occur in transportation of fruits and vegetables in which their damage and loss can take place. Therefore, it is important to manage risks by identifying and prioritizing them, in order to take necessary actions towards their mitigation or elimination.

The supply chain of fruits and vegetables is complex compared to other supply chains, due to the seasonal nature of its manufacturing processes, the limitations on raw materials’ lifespan (Lang and Ding, 2013), the perishable time of products, and their transportation and storage requirements, as the products need to be provided with excellent quality, correct quantity, and at the right place in the delivery time established at a competitive cost (Siegel et al., 2010). Given the pervasiveness of risks and massive structural changes in global and national agri-food systems, farmers, agribusiness firms,
and governments face new challenges in the design of risk management strategies (Siegel et al., 2010).

Figure 1 shows a supply chain configuration for fruits and vegetables, which was built based on the papers presented by (Dani, 2009; Siegel et al., 2010; Lang and Ding, 2013; Yeboah et al., 2014; Rebolledo, 2015)

Figure 1. Supply chain structure for horticultural products

A ground transportation activity dominates most of the food supply chain systems, especially towards their final consumer (Ackerley et al, 2010). In Colombia, road transport is one of the most outsourced logistical activities; in 2018, according to (Departamento Nacional de Planeación, 2018) the coverage of this logistical service was near to 45%.

A high participation of road transport in a supply chain, and the inherent tendency of horticultural products to deteriorate due to physiological reasons, as invasion of pests, infections and diseases (FAO, 2014), leads to adopting strict measures to control temperatures and adapt standards for vehicles to be used. In order to preserve their safety and quality of products that will reach final consumers (Procoombia, 2014).

To achieve this, it is important to identify and prioritize operational risks present in the transport of horticultural products which directly may affect food safety.

**Methodological approach**

The methodological approach proposed has two stages as shown in Figure 2:

- Stage 1: Identification of risks present in outsourced transport of fruits and vegetables.
- Stage 2: Prioritization of risks in accordance with strategic objectives of the supply chain

For risk identification, questionnaires and experts are required. A digital questionnaire was designed in which each operational risk identified in the literature had three questions:

- Does it apply as an operational risk?
- What is its probability of occurrence?
- What is its magnitude of impact?

The scale to answer questions 2 and 3 was set out as follows: Very low (1), Low (2), Medium (3), High (4) and Very high (5). With the results, the probability – impact matrix will be built, and risks within the red and orange zones will be prioritized according to stage 2.

For risk prioritization, Fuzzy Quality Function Deployment (FQFD) is applied (Osorio-Gomez et al., 2018). In this case, the linguistic scale showed in table 1 was used to apply FQFD. The complete methodology to FQFD application in risk prioritization might be consulted in (Osorio-Gomez et al., 2018).
Results
The previous methodology was implemented to identify and prioritize operational risks related to outsourced transportation of fruits and vegetables products, and their impact on some performance indicators. This proposal focus on mitigating and reducing these impacts.

First of all, following this methodological approach, operational risks were identified according to the literature review as shown in table 2. Then, using questionnaires the experts chose operational risks that applied to the study case, and defined an impact and
likelihood of each of them. With this information, the probability-impact matrix was built as showed in figure 3. The selection of experts was made based on contacting people closely related to the horticulture sector and their knowledge in logistics; for example, industrial engineers, food engineers, and workers in horticultural entities.

Considering the probability-impact matrix, risks located within the red and orange zones are to be prioritized by using FQFD approach. In this particular case, the most important risks are R2 (Bad road conditions), R3 (Strikes, public demonstrations), R5 (Inappropriate practices, conditions or equipment for loading and unloading), R4 (Disruptions in the cold supply chain), R9 (Vehicles breakdowns), R10 (Improper fleet), R11 (Deficient packing of products), R12 (Inadequate hygienic conditions of personnel and vehicles) and R14 (Cross contamination).

Once the FQFD was applied, a final prioritization was obtained taking into account the final risk priority index (FRPI), which is the highest mean value of the most critical risk. The results are presented in table 3.

Finally, the results show that the most critical risk is R11 (Deficient packing of products) followed by R2 (Bad road conditions). They are the most important risks; therefore, the actions taken are to be oriented to mitigate or eliminate these risks.

Once R11 and R2 are mitigated or eliminated, the next risks to consider are (in strict order) R10, R9, R5, R14, R4, R3 and R12.

According to this prioritization, action plans should be defined to help reduce or mitigate their impact on performance indicators.

After prioritization risks, some interviews were conducted with experts responsible for the logistic operation, such as logistic coordinators and people in charge of receiving fruits and vegetables products in main market places and supermarkets located in Cali - Colombia. In order to know the main causes of these risks and thus to establish actions oriented to mitigate or eliminate each one of them.

Conclusion

Identifying and prioritizing operational risks in the transport of fruits and vegetables is essential to detect risks which may have greatest impacts on supply chain indicators. In this way, companies could make decisions aimed to reduce damage and prevent early disposal of their products. The latter, generate not only economic losses but also affect the quality of life in many societies.

Damage and early disposal of fruits and vegetables increase significantly throughout the entire food supply chain. For this reason, it is highly important that all SC participants ensure an effective interaction with each other, and look forward to maintaining the highest quality of their products.

Among the main weaknesses found in this study for the outsourced transport of fruits and vegetables products are: bad practices in manipulation horticultural products, poor standards of transport and lack of standards in internal policies.

Abstract

To design and implement effective food loss and waste (FLW) prevention strategies, a good understanding of its causes is necessary. In this paper, the interrelationship between 14 causes of FLW in fresh food supply chains (FSC) were analysed using an integrated ISM-MICMAC methodology. The causes were divided in different levels and categorized into four clusters, regarding their driving and dependence powers. The most influential causes are the logistics related causes of food loss and waste, since most of these comprise the top levels of the ISM-based model and the independent cluster, containing the root causes of FLW in fresh FSCs.

Keywords: Food Loss and Waste, Food Supply Chain; Interpretive Structural Modelling

Introduction

Although the prevention of FLW has gained greater attention in recent years, the pattern and range of FLW along FSCs is not yet well understood (Bagherzadeh et al., 2014). There is a clear need to improve the knowledge on the drivers of FLW and on their environmental, social and economic impacts, since this knowledge is crucial for the “design and implementation of effective prevention policies at EU, at national and local level” (Fusions, 2016; Priefer et al., 2016). Hence, the identification of the different sources of FLW should be taken as the first step to study the phenomenon of FLW in FSCs and to establish where and how the efforts should be applied towards FLW prevention or mitigation (Priefer et al., 2016). This first step is crucial for the study of FLW, because food is lost or wasted from its production to its consumption (Martínez et al., 2014; Bräutigam et al., 2014) and the causes of FLW differ significantly, for example, with the type of food and the geographical region.

The study of FLW is even more complex because the majority of the results reported by researchers is not comparable due to different definitions of what is being regarded as
FLW. No consensus has been reached as to what should be the definition of the terms food loss or food waste, but, in several studies, food waste is defined as “any food, and inedible parts of food, removed from the FSC to be recovered or disposed, but not including food, or inedible parts of food, sent to animal feed or used for the production of bio-based material/biochemical processing” (Fusions, 2016). Food loss is used if the discarding of food occurs at the upstream stages of the food chain; if, on the other hand, the food is discarded at the retail or consumption stages, then it is usually referred to as food waste. For the purposes of this paper no distinction between food loss and food waste will be used, therefore, FLW will be used to address all food products being discarded from the fresh FSC.

The main contribution of this paper lies in addressing these shortcomings by focussing on the interactions between the causes of FLW within fresh FSCs. Therefore, the research question guiding this paper is:

How are the causes of FLW along FSCs interrelated from a holistic point of view?

To address this question, the research analyses the main causes of FLW along fresh FSCs and then assesses the interrelationships between them. Interpretive structural modelling (ISM) is used to help develop a more effective understanding of the causes of FLW. Since one cause might lead to other causes of FLW to be noticeable, resulting in a domino effect, then it is very important for the practitioners to understand the relationship between causes of FLW. A group of stakeholders was carefully chosen to aid in the selection of the main causes of FLW in FSCs and to develop the ISM model to draw the relationships between them. The results from the ISM methodology was complemented with a MICMAC analysis to identify the driving and dependence power of each of the causes under study.

The paper consists of other four sections. The next section outlines the theoretical background to the study. The section after that describes, step by step, how to implement the ISM-MICMAC analysis and reports the different outcomes. The following section provides a detailed discussion of the results and the final section summarizes the main conclusions of this paper, highlighting the theoretical and managerial implications of the research and suggesting future research opportunities.

**Literature Review**

Food products have to be transported, cooled, processed, traded, treated and packaged before reaching the final consumer. Because of the variety of activities food products have to endure, it is easy to understand why the products get deteriorated and ultimately discarded from the FSC. So, to fully understand why food products are discarded from FSCs, an analyses at the level of the different stages of the food chain is necessary (Martínez et al., 2014).

Several authors attempted to classify and establish relationships and priorities between the different causes of FLW, instead of only assessing the sources of FLW and where these occurred in FSCs. For example, Willersinn et al. (2015) tried to classify the causes of FLW into four categories: technological, institutional (business and economy), institutional (legislation and policy) or social drivers. Mena et al. (2011), while analysing the causes of FLW in the supplier–retailer interface, started to realise that several causes had interdependencies, but that they were part of a complex web. So, the author used causal maps to study the web, creating a tree where the top nodes, representing the symptoms, were linked to the bottom nodes, representing the root causes of FLW. The root causes of FLW were then classified into: mega-trends, natural constraints and management root causes, the latter being the ones practitioners should tackle.
Even though some efforts are being made to better understand why FLW is generated, Diaz-Ruiz et al. (2018) emphasises that little attention has been devoted to understanding the core of the FLW problem by applying multidimensional approaches with a holistic perspective of the FSC. In this direction, some authors have recently started to use multi-criteria decision-making (MCDM) tools to evaluate different variables in FSCs. The majority of the studies on the causes of FLW in FSCs focuses on the study of the fruit and vegetable supply chain in India (Balaji and Arshinder, 2016; Gardas et al., 2017; Gardas et al., 2018; Raut and Gardas, 2018; Raut et al., 2018). Only one of those studies target other country, namely UK and Spain (Mena et al., 2011). Also, the majority of the articles do not describe the boundaries of the FSC in study and for the ones that do, the focus is clearly on the downstream stages of the food chain (Mena et al., 2011; Raut et al., 2018).

While previous findings provide valuable information for this research, they have limited value in identifying and evaluating the relationships between the causes of FLW across the fresh FSC, because they tend to examine the dyadic relationships between buyers and suppliers rather than the more complex interactions amongst all the participants in the FSC (e.g., Mena et al., 2011). In conclusion, most of the literature that assesses the causes of FLW focus on the downstream stages of the FSC and often use data taken from the literature itself, without resorting to practical or industrial data (Priefer et al., 2016). The focus is mainly on the identification of material flows and the origin of FLW, without trying to prioritize or to analyse the relationship between the different causes. Even though we have seen that some researchers took a step in this direction, they did so mainly in the context of the Indian fruit and vegetable supply chain and no emphasis is given to what are the boundaries of the FSC under study. Hence, it is the key objective of this paper to model the causes of FLW for the fresh FSC and to establish the interrelationship among these using an integrated ISM and MICMAC analysis, from the agricultural production up until retail, since the causes of FLW in household consumption are more of a behavioural nature and harder to relate to the rest of the stages of the food chain.

**Methodology and Results**
Interpretive Structural Modelling (ISM) can be used to identify the structure of the relationships among elements related to a particular complex research problem (Kwak et al., 2018). It is a process that transforms unclear and poorly articulated mental models of systems into visible and well-defined models (Venkatesh et al., 2015). It helps in understanding a complex system by considering the hierarchy and relationships among the variables of the system (Kwak et al., 2018). ISM was used in this research to identify and evaluate interactions among the causes of FLW along FSCs. The findings present a graphical structural map of the causes, highlighting the connections between them and the most critical types of causes requiring mitigation. The hierarchical model developed by the ISM methodology will feed the MICMAC analysis to further determine the driving and dependence powers of each variable, in order to assess which are the most influential causes of FLW along fresh FSCs (Gardas et al., 2017).

To apply the ISM methodology efficiently, one must possess in-depth knowledge of the method and be sufficiently trained to interpret the obtained data. Albeit these limitations, ISM is capable of capturing dynamic complexities, while other methodologies from MCDM, like AHP or Analytic Network Process (ANP), have trouble dealing with complex real life problems and have lower ability to capture dynamic behaviours (Shahabadkar et al., 2012).
Steps to implement the ISM methodology
ISM comprises a set of well-defined steps for its successful implementation and in this research, the works of Venkatesh et al. (2015), Mishra et al. (2017) and Kwak et al. (2018) were used to guide the implementation of the ISM methodology. Therefore, to implement ISM, firstly, the key variables of the system are identified and listed. Secondly, the contextual relationships are identified among each pair of variables identified before. These contextual relationships are registered in the form of a matrix called structural self-interaction matrix (SSIM) and can be of four different types: V, A, X or O (see sub-section Structural Self-Interaction Matrix (SSIM) for more info). Next, the SSIM is converted into a binary matrix, called initial reachability matrix, by substituting V, A, X and O with 1’s and 0’s, following the rules described in sub-section Reachability Matrix. After the development of the initial reachability matrix, the matrix is checked for transitivity. After computing the final reachability matrix, this is then converted into the canonical matrix format by arranging the elements according to their levels, performing the so-called level partitioning. After that, the ISM-based model is drawn by connecting the variables in each level, based on their relationships as defined in the structural self-interaction matrix.

Identification of variables
Magalhães et al. (2019) assessed the major causes of food loss and waste for the different stages of the FSC. That work was used as a basis to build a list that summarized where the different causes of FLW occur in the FSC, from agricultural production up until retail. That list was then presented to relevant stakeholders from the FSC (namely, producers, distributors and retailers), and to prominent academics with expertise in FSC management, and it was reduced to incorporate the FLW causes most relevant to the problem. Fourteen causes of FLW were chosen to be the starting point of the ISM methodology: (1) inadequate demand forecasting; (2) overproduction and excessive stock; (3) poor handling and operational performance; (4) storage at wrong temperature; (5) inadequate or defective packaging; (6) non-conformance to retail specifications; (7) product quality; (8) short shelf-life or expired products; (9) climate change and weather variability; (10) lack of storage facilities; (11) pricing strategies and promotions management; (12) lack of coordination and information sharing; (13) inadequate transportation systems; and (14) inefficient in-store management.

Structural Self-Interaction Matrix (SSIM)
The contextual relationships were summarised into one SSIM, where the relationship between each (i, j) pair of variables was classified into four different types:
- V: variable i leads to achieve or influences variable j;
- A: variable j leads to achieve or influences variable i;
- X: variable i leads to achieve or influences variable j and vice versa;
- O: there is no relationship between the variables i and j.

The panel of experts was asked to assess the contextual relationships between causes and, after reaching a consensus, the interrelationships were converted into the SSIM matrix, as shown in Table 1.

Reachability Matrix
Given the SSIM, an initial reachability matrix was developed by substituting V, A, X, O with 1’s and 0’s, according to the following rules:
• If the (i, j) entry in the SSIM is V, the (i, j) entry in the initial reachability matrix becomes 1 and the (j, i) entry becomes 0.
• If the (i, j) entry in the SSIM is A, the (i, j) entry in the initial reachability matrix becomes 0 and the (j, i) entry becomes 1.
• If the (i, j) entry in the SSIM is X, the (i, j) and (j, i) entries in the initial reachability matrix become 1.
• If the (i, j) entry in the SSIM is O, the (i, j) and (j, i) entries in the initial reachability matrix become 0.

After the development of the initial reachability matrix, seen in Table 2, the matrix is checked for transitivity. In summary, the transitivity means that if variable i is related to variable j and if variable j is, in turn, related to variable k, then the variable i is indirectly related to variable j, and if the entry (i, k) of the initial reachability matrix was 0, then it should be replaced by a 1. Transitivity was checked resorting to Matlab, to avoid human error, and was incorporated into the final reachability matrix, shown in Table 3, by assigning 1* to the identified indirect relationships. Driving and dependence power were also calculated in this step to assist the MICMAC analysis.

Level Partitioning
After the development of the final reachability matrix, level partitioning is conducted. For each variable, the reachability set, the antecedent set and the intersection set are found, to assess the levels of the variables. The reachability set is the sum of the entries equal to 1’s for each line (indicating that variable i influences variable j), the antecedent set is the sum of the entries equal to 1’s (indicating that variable i is influenced by variable j) and the intersection set is the intersection between the variables present in the reachability set and the ones from the antecedent set. When the intersection set is equal to the reachability set, then the variable is attributed to the level of that iteration. The variables assigned to one level are then removed from the remaining reachability and intersection sets for the next iteration and the same process is applied until all the variables are partitioned into levels. Four causes are considered the top-level of the ISM-based model: inadequate demand forecasting; overproduction and excessive stock; short shelf-life or expired products; and pricing strategies/promotions management. After removing these causes from the remaining reachability and intersection sets, then the next level causes are causes
6 and 7, non-conformance to retail specifications and product quality, respectively. After seven iterations, the bottom level of the ISM-based model was found and the results of the level partitioning can be consulted in Table 4.

Note: C[i/j] represents the cause in line i or in column j.

Development of the ISM-based model

A direct graph, or digraph, is built by arranging the variables vertically and horizontally according to the level partitioning and, if variable i influences variable j in the initial reachability matrix, than an arrow is used, pointing from i to j, to show the direct influence between these two nodes.

The ISM-based model, shown in Figure 1, demonstrates the hierarchical structure of the causes of FLW and highlights their interrelationships. The digraph was generated by arranging the 14 causes according to the level partitioning (Table 4) and by connecting the causes according to the initial reachability matrix (Table 2).
The levels of the different causes of FLW in the ISM-based model (Figure 1) provide an understanding of their impact in the reduction of FLW in fresh FSCs. The figure shows that inadequate demand forecasting, overproduction and excessive stock, pricing strategies and promotions management and the short shelf-life or expired products are the causes of FLW at the top level (level I) of the ISM-based model. The following level (level II) comprises the non-conformance to retail specifications and the product quality. Given the ISM methodology, if practitioners implement actions to eliminate the causes from level II, these actions will also aid in the elimination of the causes from level I. At the bottom of the ISM hierarchy is the inadequate transportation systems (level VII), which is the cause that has most influence over the other causes of FLW considered. This is the most influential cause under study, and since the hierarchy has seven different degrees of influence, than management actions taken towards level I or II, for example, will have little or no repercussion at all at higher levels.

</table>

After building and assessing the hierarchy of the ISM-based model, we realised that the causes were organized in the model by their origin, i.e. it was clear that the causes were grouped in logistics related causes, quality related causes and retail related causes (Figure 1). The logistics related causes of FLW incorporate inadequate transportation systems, inadequate or defective packaging, lack of storage facilities, poor handling and operational performance, lack of coordination and information sharing, inefficient in-store management and storage at the wrong temperatures. Quality related causes of FLW comprise the climate change and weather variability, the product quality and the short shelf-life or expired products. The retail related causes of FLW include the non-conformance to retail specifications, the pricing strategies and promotions management, the overproduction and excessive stock and the inadequate demand forecasting.

It became noticeable that the logistics causes are the most influential ones and that if some actions were taken to mitigate these causes, then it would have a major influence under the quality and retail related causes. Therefore, practitioners should focus their efforts to fight the logistics related causes of FLW first. After appropriate actions are implemented and the logistics related causes are eliminated or mitigated, then other strategies to fight the quality driven causes should be sought and implemented. Retail related causes should be tackled last.
A MICMAC analysis was used to further assess which causes of FLW are most prominent to be tackled in the fresh FSC.

![Diagram showing ISM-based model of the causes of FLW in FSCs]

**Figure 1 – ISM-based model of the causes of FLW in FSCs**

**MICMAC analysis**

The MICMAC analysis examines the driver and the dependence power of the variables (Charan et al. 2008). The driving and the dependence powers of each cause under analysis is shown in Table 3. In the final reachability matrix, every 1 in the rows of the table indicates that the cause i influences cause j. Therefore, the sum of the row from cause i determines the driving power of that cause. The same logic reasoning is applied to calculate the dependence power. Every 1 in the columns of Table 3 indicates that cause j is influenced by cause i. Therefore, the sum of the column from cause j determines the
dependence power of that cause. Subsequently, the driving-dependence power diagram is constructed and the causes are classified into four clusters, as shown in Figure 2.

The first cluster consists of the autonomous variables, which have weak driving and weak dependence powers. The causes in this cluster are relatively disconnected from the system, with which they have only few links. The second cluster consists of the dependent variables, which have weak driving, but strong dependence, and comprises the causes that only influence some of the others, but that are influenced by the majority of the causes from the system. Third cluster has the linkage variables, which have strong driving and strong dependence powers. The causes in this cluster are quite unstable given the fact that any action on these causes will have an effect on the others and also a feedback on themselves. Fourth cluster includes the independent causes having strong driving, but weak dependence power. Since these are the causes that have a strong influence on the majority of the other causes, but are almost not influenced by any other, then these are considered the key or root causes of FLW in FSCs.

From Figure 2, we can conclude that the root causes of FLW in fresh FSCs are the independent causes, namely: poor handling and operational performance (cause 3); inadequate or defective packaging (cause 5); lack of storage facilities (cause 10); lack of coordination and information sharing (cause 12); and inadequate transportation systems (cause 13).

![Figure 2](image)

**Figure 2** – Cross-impact matrix multiplication applied to classification (MICMAC) analysis of the causes of FLW

**Conclusion**

In this paper, fourteen causes of FLW in the fresh FSC were selected and their interrelationships was modelled using an integrated ISM and MICMAC analysis approach. This integrated approach established that the most influential causes of FLW in fresh FSC are: inadequate transportation systems, inadequate or defective packaging, lack of storage facilities, poor handling and operational performance and lack of coordination and information sharing, which are exclusively logistics related causes of FLW.

Although this research provides critical insight about the issues regarding the supply of fresh foods, from the moment they are produced until they reach the shelves of the supermarkets, the present results should be interpreted with caution, since the ISM and
MICMAC analysis rely on the subjective judgment of a set of experts. FLW prevention is the most sustainable option to feed the growing world population and, therefore, the proposed model should be used in the future to assess which mitigations strategies the various supply chain members and decision makers should implement for reducing FLW.

Abstract
Even when a food-safety problem occurs at only one point in a food supply chain, the probability that it will disrupt the entire chain is high. Nonetheless, despite the potential of unstructured big data to help resolve such issues, few attempts have been made to use such data in this context. Accordingly, this study aims to explore food risk management issues and to assess the food supply-chain vulnerability. The proposed unstructured data analytics approach reveals that the essential vulnerable phases of food supply chains are caterers, food processors, and food producers.

Keywords: Food supply chain, Vulnerability, Risk management

Introduction
Effective supply-chain management is pivotal to meeting growing consumer demand for food in appropriate ways (La Scalia et al., 2017). However, the operation and management of supply chains involving multiple countries are increasingly complicated, and especially so in the case of food (Ahumada and Villalobos, 2009; Singh et al., 2018), as fresh food’s key characteristic of perishability necessitates technological approaches to traceability and management (Ala-Harja and Helo, 2014). Unfortunately, food-safety crises have gradually increased in frequency due to the globalization of trade in food, and the food industry has struggled to cope with challenges including bovine spongiform encephalopathy, dioxin during chicken feed, foot-and-mouth disease, as well as various outbreaks of foodborne illness (Aung and Chang, 2014).

In every industry, managers seek valuable insights about their rivals from within their own databases. Although one study (Barton and Court, 2012) has suggested that enterprises could enhance their productivity and profitability by using data-driven analytics, decision-makers – notably, in the food industry – still often make questionable decisions according to merely small data samples through market surveys (Singh et al., 2018). Despite a surge in interest in big data and analytics in the sphere of business
strategy more generally, few firms have actually been using them to strengthen their supply chains, arguably due to a lack of knowledge about how to manage and analyze big data (Ross et al., 2013; Yu et al., 2018). Approximately 80% of the world’s vast amount of business-relevant textual information is in an unstructured form that cannot be readily understood by traditional databases (Abrahams et al., 2015; Lavalle et al., 2011; Ur-Rahman and Harding, 2012). Hence, research that facilitates understanding of the content of this unstructured data is of potentially huge value to industry.

A food-safety problem can cause serious supply chain problems. Specifically, even when a food-safety problem occurs at only one point in a food supply chain, the probability that it will disrupt the entire chain is high. Nevertheless, huge unstructured textual data has seldom been included in such investigations. To fill this gap, therefore, this study aims to explore food-safety issues associated and to diagnose the vulnerability of food supply chains through the proposed unstructured data analytics approach.

An unstructured data analytics approach
The researchers’ comprehensive survey of potentially relevant websites identified 12 as repositories of extensive knowledge about the crucial food-safety issues that are most frequently discussed in the context of food supply chains. These included Food Safety Magazine; Food Safety News; IFIC Foundation – Your Nutrition and Food Safety Resource; USDA Blog – Food Safety; Keep Food Safe Blog; US Food Safety; The CAMBRO Blog; Food Safety – National Sustainable Agriculture Coalition; Mérieux NutriSciences – Food Safety & Quality Blog; FoodLogiQ Blog; Unsafe Foods; and Food Logistics.

During the essential text pre-processing stage of the text-mining process, the present study followed Wu and Huang’s (2018) recommendation, based on extensive experience, that data cleaning and data integration be conducted repeatedly via a process of trial and error so as to add value to the output and ensure exceptional results. It is also worth noting in this context that the results acquired from each method often gets back to this stage. In the present study, the principal pre-processing steps were 1) removal of stop words, 2) stemming, and 3) term frequency/inverse document frequency (TF/IDF). The purpose of the first is the removal of uninteresting words as well as deletion of terms that emerge commonly, but are not of value to the intended approach. This study relied, in the first instance, on the default stop word list for data standardization, i.e., the removal of most pronouns, prepositions, and conjunctions, along with numbers, website urls, punctuation, and times. Moreover, the most commonly used word in a given language will happen roughly k times as frequently as the kth most recurrent word (Gerlach and Altmann, 2013).

Stemming is an important step of the unstructured data analytics approach, as it identifies the numerous morphologies that infer disparate forms onto some occurring word-form, especially via suffix changes. Following stop-word removal and stemming, the data were systematically processed using TF/IDF. The overall weight of a term is calculated as the recurrence of that term in a single textual file, as well as the inverse recurrence of the term in the corpus (Zamani et al., 2014).

The present study used text clustering with an expectation-maximization (EM) algorithm (Li and Zhang, 2008; Rigouste et al., 2007) to explore food risk management issues.

Empirical results of unstructured data analytics
Text-mining analytics was conducted using SAS Enterprise Miner 14.1. Based on the analytical results of text clustering, the researchers divided the corpus’ main food-safety
issues into six categories. These categories were named according to both the weights of their keywords and the associations between the documents and keywords. The paramount issues of food supply chains include food-safety inspection, food cleaning, food traceability, food recall, food biotechnology and the environment, and foodborne illness as shown in Figure 1.

![Figure 1 Food-safety issues](image1.png)

To comprehend the circumstances that engender the vulnerability of food supply chains, this study inspected the original unstructured data to extract documents which indicate food incidents and their level of severity regarding food safety problems. Figure 2 exhibited the vulnerability of food supply chains. Consequently, the top three vulnerable phases of food supply chains mentioned according to the most vulnerable were caterers, food processors, and food producers.

![Figure 2 The vulnerability of food supply chains](image2.png)
Conclusion
This study proposes an unstructured data analytics approach to effectively tackle the crucial issues of food supply chain risk from a great number of unstructured data. Food supply-chain vulnerabilities can be identified through the proposed analytics.

The proposed unstructured data analytics approach identifies essential food chain themes involving food-safety inspection, food cleaning, food traceability, food recall, food biotechnology and the environment, foodborne illness. Furthermore, caterers, food processors, and food producers are the critical vulnerable phases of food supply chains.

Abstract

The purpose of this study is to explore the antecedents and consequences of incentive alignment in performing collaborative carbon reduction in supply chains (CCR-SC). To fulfill the research objective, an empirical study was carried out in China, an emerging economy that has in recent years started to undergo a transition towards a low-carbon economy. The statistical technique of structural equation modelling (SEM) was used to analyze the questionnaire data collected from 120 Chinese companies. The research results reveal that incentive alignment has a positive impact on CCR-SC, which is instrumental in the improvement of both financial and environmental performance.

Keywords: Incentive alignment, Collaborative carbon reduction, Supply chain.

Introduction

Incentive alignment refers to the extent to which an organization is able to achieve its goals whilst meeting the requirements of the partner at the same time (Theißen et al., 2014). In the context of supply chain management (SCM), it is recognized as an important factor that motivates the chain members to create value that benefits all members in the supply chain (Simatupang and Sridharan, 2008), ensuring that collaboration outcomes are quantifiably beneficial to all, and securing sufficient levels of cooperation and minimize opportunistic behaviour (Harland, 2004). Given its significance in managing and operating supply chains, particularly its essential role in supply chain collaboration, incentive alignment has received considerable attention from academia. For example, Simatupang and Sridharan (2002, 2005, 2008) recognized incentive alignment as one of the five main elements of the architecture of supply chain collaboration. Chao and Zhang (2011) defined incentive alignment as one of the seven interconnecting components of SCC in a study of the nature of supply chain collaboration and its impact on firm performance. Hinkka et al. (2013) were aware of the role of incentive alignment between buyers and suppliers in supply chains and
explored this issue with reference to inter-organizational system implementation projects.

As awareness of carbon reduction management in supply chains has increased, concern has been raised about the role of incentive alignment in supply chain members performing collaborative carbon reduction. For example, based on a multiple case study, Theißen et al. (2014) ascertained that incentive alignment is one of the five determinants influencing an organization’ readiness to engage in collaborative carbon reduction management. Nevertheless, a close examination of the existing literature finds that the issue remains conceptualized and empirical investigation remains scarce. To fill this gap, this study intends to examine the antecedents and consequences in the setting of collaborative carbon reduction in supply chains (CCR-SC).

The paper proceeds as follows. Section 2 provides a review of the literature on incentive alignment and CCR-SC. The conceptual model and hypotheses of antecedents and consequences of CCR-SC are then presented in Section 3. Section 4 describes the research design for the investigation. Finally, the results and the conclusions of the study are presented. The paper concludes by discussion the limitations of this study and the future research agenda.

Literature review

Incentive alignment

Incentive alignment is described as the motivation to fairly share the benefits of collaboration among members, and to enable members within the supply chain to self-enforce, aligning their individual decisions with the common goal of increasing total profits (Simatupang and Sridharan, 2002, 2005). According to Simatupang and Sridharan (2005), incentive alignment works as a scheme that motivates chain members to act in a way that is consistent with mutual benefit, including making optimal decisions, revealing accurate private information and calculating costs, risks and benefits. It is necessary to be aware of the effect of incentive alignment in reducing anxiety and uncertainty and increasing the prevalence of trust. Sahay (2003) pointed out that it can be seen as a way of initiating increased trust in supply chain relationships. Sierra (2013) ascertained that in the process of greening suppliers, providing suppliers with incentives is an important approach to the improvement of firm performance. Some studies report the results of misaligned incentives. For example, Narayanan and Raman (2004) reveal that misaligned incentives are the main cause of excess inventory, incorrect forecasts, and poor customer service. Voigt (2014) claimed that credible information-sharing cannot be established if misaligned incentives exist. In addition, Lee and Whang (2004) argued that a well-designed mechanism is needed to align incentives across the supply chain; this should enable chain members to commensurately share gains in terms of their investment and risk. Simatupang and Sridharan (2005) suggested that pay-for-effort and pay-for-performance are two major reward mechanisms.

In initiating CCR-SC, firms often estimate whether they can achieve incentive alignment by assessing the congruence of goals. Incentive alignment can only be built on the basis of identical goals among members in order to achieve shared objectives. Goal congruence is referred to “the extent to which firms perceive the possibility of common goal accomplishment” (Lejeune and Yakova, 2005, p.18). Goal congruence can enable firms to interact synchronously (Angeles and Nath, 2001) and reduce the incentives for opportunism. It is identified as an estimator when calculating the degree of alignment throughout the supply chain. Goal congruence is in conjunction with trust
and information sharing, a low rate of exchange of information will result in behaviour invisibility and thus lead to an absence of goal congruence.

Lejeune and Yakova (2005) considered that the degree of goal congruence varied and assumed it to have three levels, namely absence of congruence, moderate goal congruence, and true goal congruence. In the first two levels, goal congruence is weak or even non-existent in the supply chain. The deficiency of goal congruence can be attributed to an inadequate formulation of supply chain incentives (Narayanan and Raman, 2004). In the context of collaborative supply chains, Lejeune and Yakova (2005) also noted that goal congruence is weak to moderate, mainly because the trust in the collaborative supply chain is limited to its openness component. In the third level, i.e. true goal congruence, firms believe that they can achieve their goals by working simultaneously towards the objectives of the whole supply chain.

Collaborative carbon reduction in supply chains (CCR-SC)

CCE-SC has been recognized as an effective way for supply chain members to reduce carbon reduction. For example, Theißen et al. (2014) identified collaborative carbon reduction management as offering firms the ability to establish unique value-added processes through organizational boundaries that better match customer needs. Based on observation and investigation, many researchers support the view that collaboration is a more advanced approach in environmental management. Seuring and Müller (2008) emphasized that cooperation between buyers and suppliers is the only way to achieve an environment-oriented supply chain. Sustainable practices such as carbon reduction require the participation of all members in the supply chain. Chiou et al. (2011) suggested firms solve environmental problems by building a close relationship with their supply chain partners and creating competitive advantages through innovative environmental products. Through joint efforts in the supply chain, firms can simultaneously minimize carbon emissions and climate impacts, reduce waste and energy costs, meet the standards set by policy-makers and improve corporate reputations. To be specific, this includes the process of sharing data, knowledge, assets and other resources related to carbon reduction.

In addition, prior studies also ascertained that CCR-SC is more effective than enforcement under legal compliance, and more likely to produce benefits such as improved public reputation (Sundarakani et al., 2010). Carballo-Penela et al. (2017) demonstrated the effectiveness of CCR-SC through the measurement of carbon footprints. The results of their study show that the lack of mandatory legislation for measuring carbon footprints leads to an unsuccessful CCR-SC. Giurco and Petrie (2007) found that many opportunities for carbon reduction at the supply chain level have been ignored, since most of them focus on the organizational level. To better understand the environmental impacts of products and increase environmental performance, Sharfman et al. (2009) suggested that it is crucial for firms to conduct CCR-SC across supply chains.

Conceptual development and hypothesis development

Incentive alignment and CCR-SC

Many studies have classified incentive alignment as an important dimension of supply chain collaboration (Simatupang and Sridharan, 2005; Cao et al., 2010; Cao and Zhang, 2011). In order to be effective, an incentive alignment mechanism needs to be designed to correlate overall and partial performance, enabling members to consciously make individual decisions under the overall profit target, thus ensuring the successful implementation of the project (Hinkka et al., 2013; Chen and Lee, 2017).
Chen and Lee (2017) found that a well-defined incentive contract design can effectively avoid incentive misalignment by constructing a two-level supply chain game model. Drawing on the viewpoint on trust, Harland (2004) argued that incentive alignment is a sufficient guarantee for supply chain collaboration and commitment while minimizing the opportunism of members. Simatupang and Sridharan (2008) demonstrated that the effective implementation of incentive alignment can increase the enthusiasm and productivity of supply chain members and create value and benefit for the entire chain. Gunasekaran et al. (2015) highlighted the importance of incentives for green supply chain collaboration.

As such, this study argues that incentive alignment ensures the equitable sharing of costs, risks, and benefits, increases trust in the supply chain, and effectively avoids misalignment and opportunism. This should make companies willing to trust their partners and participate in initiating CCR-SC. Therefore, the first hypothesis in this study is as follows:

**H1**: Incentive alignment is positively related to CCR-SC.

**Goal congruence and incentive alignment**

Goal congruence encourages companies to implement incentive alignment to ensure that their members continue to move in the same direction and avoid misalignment. It requires a degree of mutual understanding and consistency in terms of a firm’s attributes, values, beliefs, and practices, which is strongly linked to the scheme of incentive alignment. According to Theißen et al. (2014), the first step when building an effective partnership in supply chains is setting a consistent goal. Lambert et al. (1999) argued that supply chain members should reach an agreement on the management of goals and the key processes to be employed in supporting them. Inconsistent goals can lead to an unreasonable division of work among members, thus reducing efficiency and leading to incentive misalignment. Rossetti and Choi (2008) maintained that incentives work as an intermediation of goal congruence and buyers should consider aligning goals through incentives with their partners. Samaddar et al. (2006) stated that, in the absence of common goals, firms have no incentive to participate in activities such as information-sharing or supply chain collaborations. To a large extent, incentive alignment requires a high degree of information sharing. Governance mechanisms such as goal congruence can mitigate opportunism in incentive alignment. The greater the goal congruence between firms, the greater the strategic nature of their work, and the closer their incentive alignment.

Congruence can lead members to coordinate with each other under the guidance of an overall goal that contributes to the efficiency of incentive alignment. This study therefore argues that goal congruence is an important enabler of incentive alignment if firms are to initiate CCR-SC, hence the following hypothesis:

**H2**: Goal congruence is positively related to incentive alignment.

**CCR-SC and firm performance**

Bowersox (1990) pointed out that collaboration can bring economies of scale to firms whilst simultaneously reducing costs and increasing profits. Vargo and Lusch (2004) emphasized the importance of collaboration for a firm’s business strategy and considered collaboration to be a source of competitive advantage. Cao and Zhang (2011) noted that partnerships can increase profits and reduce risk. Effective supply chain collaboration can reduce conflicts and uncertainties, resulting in collaborative advantages and better financial performance. Kalwani and Narayandas (1995) agreed that a long-term collaborative relationship is a unique resource that enables companies...
to achieve a higher profit. From a relational perspective, Priem and Swink (2012) elaborated that supply chain relationships between suppliers and buyers can be viewed as intangible resources for value creation. In general, the higher the level of supply chain collaboration, the better the firm’s financial performance. In addition, supply chain collaboration can increase the efficiency of operations management, allowing companies to better respond to market opportunities.

In the context of environment-oriented supply chains, collaboration is also recognized as an effective approach for improving firm performance. For example, some studies have clarified that strategic collaboration among supply chain members allows firms to move beyond organizational boundaries and find new ways to reduce environmental management costs, thereby improving environmental performance (for example Giurco and Petrie, 2007; Theißen et al., 2014). The results of their study confirmed the positive effect of CCR-SC on firms’ performance.

In addition, there is a correlation between environmental performance and financial performance. Carbon reduction has been observed to improve a firm’s environmental performance, which in turn strengthens the firm’s financial performance. For example, a reduction of transportation costs in the firm’s logistics will also enhance its financial performance. Previous studies have shown that sustainable management practices, especially supply chain collaboration, contribute to the financial performance of firms (Hollos et al., 2012). On one hand, improving environmental performance can reduce costs and waste, improve resource utilization and operational efficiency, and further improve financial performance. On the other hand, improving environmental performance helps to increase corporate social responsibility and reputation, leading to a growth in market share.

CCR-SC allows firms to obtain economies of scale through resources and knowledge-sharing, both internally and externally. Firms can gain competitive advantages and reduce costs whilst simultaneously improving their environmental performance and financial performance. Thus, three hypotheses were formulated:

- H3: CCR-SC is positively related to a firm’s financial performance.
- H4: CCR-SC is positively related to a firm’s environmental performance.
- H5: A firm’s environmental performance is positively related to its financial performance.

![Figure 1- Research framework of incentive alignment in CCR-SC](image)

**Instrument development**

**Item generation**
To achieve the content validity of constructs when generating items, a critical review of the relevant literature, such as research streams regarding CCR-SC (Theißen et al., 2014) and green SCM (Doran and Ryan, 2014) was carried out. After consulting with both academic and industrial experts, 32 measurement items were created for five constructs, namely, CCR-SC, incentive alignment, goal congruence, financial performance and environmental performance. A 5-point Likert scale was used to indicate the extent to which managers agree or disagree with each statement (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree).

**Sampling design and data collection**

A data sample was collected from 900 Chinese companies engaged in SCM and operations. An online survey was used to administer the delivery of the questionnaire. After eliminating invalid questionnaires with blanks and deletions, 120 valid samples were obtained with a response rate of 13.3%.

The target respondents of this study were middle and senior managers in the company, particularly those involved in SCM practices. The sample respondents were expected to have a comprehensive acknowledge of collaborative and carbon reduction management in supply chains.

The non-response bias of samples was examined using the method recommended by Armstrong and Overton (1977). After comparing those responses returned early (80) with those returned late (40), the result of t-test shows there was no significant difference between early samples and late samples when randomly selecting samples, which means that non-response bias is not a problem with a 95% confident interval.

**Data analysis and research results**

**Reliability and validity analysis**

In terms of the creation of measurement items, Exploratory Factor Analysis (EFA) and Confirmatory Factor Analysis (CFA) were employed to assess the reliability and validity of the scales developed. The indicators used for assessment include Cronbach’s $\alpha$, normalized factor loading, composite reliability (CR) and average variance extracted (AVE). All indicators were significant at $p<0.01$, and all five constructs identified exhibited acceptable fit. The results demonstrated that the model fit indices meet the recommended criteria. Cronbach’s $\alpha$ has a minimum number of 0.821 and a maximum of 0.952; all have alphas greater than 0.70 and are therefore considered reliable. Discriminant validity was tested using the approach recommended by Fornell and Larcker (1981); that is, the AVE of each construct is higher than the shared variances between each of the constructs, as shown in Table 2. Overall, the results show that the scales used had good reliability and validity.

Results of hypothesis tests
To test the hypotheses proposed in this research framework, structural equation modelling (SEM) was used to assess the model fit with the data. The path coefficients
for the SEM model were shown in Table 3. The fit indices for the model were $\chi^2 = 495.035$, df = 293, normed = 1.690, CFI = 0.926, IFI = 0.927, RMSEA = 0.076, indicating that the model was of good fit.

The results of the hypothesis tests were shown in Table 3. The path coefficient was 0.34 and was statistically significant at the level of 0.001, which supports Hypothesis 1. This result showed that incentive alignment was significant and positively related with CCR-SC. Hypothesis 2 was also supported with a path coefficient of 0.64, which was statistically significant at the level of 0.001. The finding indicated that goal congruence was positively related to incentive alignment. Hypotheses 3, 4 and 5 were also supported.

**Conclusion and limitation**

The present study provides an empirical analysis of the antecedents and consequences of incentive alignment in the setting of CCR-SC, a topic that has been under-researched in previous studies. It verifies the enabling role of incentive alignment to CCR-SC and its antecedent, namely, goal congruence. The resulting CCR-SC can however affect environmental and financial performance. From a research perspective, this study advances empirical investigation in the research areas of low-carbon SCM and supply chain collaboration. From a practical perspective, this study is of interest to managers involved in initiating CCR-SC. As shown by the empirical analysis, managers should collaborate with their supply chain partners, developing common goals and designing aligned incentives, in order to ensure that CCR-SC has a positive effect.

While the research has made significant contributions to the existing literature, there are still limitations that need to be avoided in future study. First, because of the difficulty of data collection, the sample size used in this paper was relatively small. Future research could increase the sample size in order to improve the effectiveness of reliability and validity. Furthermore, this research is based on questionnaire data, which means that the conclusion might reflect the current status of firms, although environmental management practices are dynamic under sustainable development. Future research should consider using a longitudinal study in order to incorporate the changing dynamics of CCR-SC.

Abstract

This paper describes how firms can develop Firm Supply Chain Agility (FSCA) and its benefits for operational performance (OP). The purpose of this research is twofold. First, to analyze the role of transactive memory system (TMS) and supply network flexibility (SNF) as potential antecedents of FSCA, also evaluating the moderating role of TMS; and, second, to evaluate the relationship between FSCA and OP, also examining the possible mediating effect of FSCA. The relationships are tested with survey data from 190 Spanish high-tech firms using structural equation and linear regression models.

Keywords: Firm’s supply chain agility, transactive memory system, supply network flexibility.

Main subject text

Theoretical background

Today’s hypercompetitive environment – characterized by demanding customers, short product life-cycles, volatile supply and demand, global supply chains, and rapid advances in technology – has pushed firms towards finding new ways of competing (Swafford et al., 2006; Chiang et al., 2012). Indeed, research suggests that developing a firm’s supply chain agility (FSCA) can be key to improving competitiveness in the current environment (Christopher, 2000; Gligor et al., 2015; Kim and Chai, 2017). FSCA has been conceptualized variously as a comprehensive strategy, a paradigm, a management system or practice, and even as a capability (Shin et al., 2015). In this study, we adopt
Braunscheidel and Suresh’s (2009, p. 126) definition of FSCA as “the capability of the firm, internally, and in conjunction with its key suppliers and customers, to adapt or respond in a speedy manner to a changing marketplace, contributing to the agility of the extended supply chain”.

Given the importance of FSCA, an investigation of how such a capability can be built and the performance outcomes is of utmost importance (Blome et al., 2013; Gligor et al., 2015). The literature has identified some antecedents of FSCA by recognizing, for example, that FSCA depends on: the flexibility of the procurement/sourcing, manufacturing, and distribution/logistics processes (Swafford et al., 2006); internal and external integration of the firm (Braunscheidel and Suresh, 2009); coordinating, cooperative, and communicative mechanisms in the supply chain (Gligor and Holcomb, 2012); and the development of supply- and demand-side competences (Blome et al., 2013). Research has also identified outcomes associated with FSCA. For example, FSCA enables a firm to be more market-sensitive, have greater capacity to synchronize supply with demand, better manage disruption risks, achieve shorter cycle times, ensure uninterrupted service to customers, and accelerate the introduction of new products (Braunscheidel and Suresh, 2009; Blome et al., 2013; Gligor et al., 2015). However, due to limited research in this field, there have been a number of recent calls to explore new antecedents of FSCA and to further scrutinize the effect of FSCA on performance (Chiang et al., 2012; Blome et al., 2013; Gligor et al., 2015; Chan et al., 2017; Fayezi et al., 2017).

Swafford et al. (2006) indicated that agility requires competitive strategies based on both the development of knowledge and the generation of flexible processes so firms can respond to changing circumstances in the environment. Building on this, our study evaluates a variable related to knowledge – transactive memory system (TMS) – and a variable related to flexibility – a firm’s supply network flexibility (SNF) – as potential antecedents of FSCA.

Our first variable, TMS, “is the shared division of cognitive labor with respect to the encoding, storage, retrieval, and communication of information from different domains that often develops in close relationships” (Lewis and Herdnon, 2011; p. 1254). This variable, related to the creation, maintenance, transfer, and coordination of knowledge in work teams (Argote and Guo, 2016; Heavey and Simsek, 2017; Huang and Cheng, 2018), has been applied to various types of dyadic relationships (Hammendi et al., 2013; Argote and Guo, 2016), work groups (Liang et al., 1995; Argote and Guo, 2016), organizations (Heavey and Simsek, 2015; Huang and Cheng, 2018), and even contexts that transcend organizational boundaries, such as the development of TMSs between supply chain partners (Obayi et al., 2017). Although TMSs have received little attention in the operations management field, this variable could contribute greatly to the development of FSCA. For example, it has been recognized that uncertain environments require the rapid generation and coordination of new knowledge (Gligor et al., 2015; Argote and Guo, 2016). Further, firms like Honda, Apple, Zara, and Amazon have all succeeded in developing supply chain agility because they have teams that are motivated to develop creative solutions to unexpected problems (Gravier, 2016).

Our second variable, SNF, is related to an organization’s ability to effectively and efficiently reconfigure its supply base (Liao et al., 2010), enabling the firm to maintain a sufficient set of alternatives and responses to possible changes in the environment (Liao and Marsilliac, 2015). Although the extant literature has recognized the importance of different types of flexibility in achieving FSCA (Chan et al., 2017), SNF is a relatively new concept that remains underexplored in the FSCA literature (Liao et al., 2010; Purvis et al., 2014; Liao and Marsilliac, 2015). As Lummus et al. (2003) argued, supply chain design must take change into account. When the market changes, competitive priorities
also change, making it necessary to find new supply chain partners with the required capabilities. Finding such partners is necessary for high levels of flexibility in supply networks (Purvis et al., 2014). Cisco, for example, uses three different supply networks to manufacture its products (depending on the type, volume, and customization required). When the need arises, it can switch manufacturing from one network to another, achieving rapid response to changes in the environment (Lee, 2004). It is thus reasonable to expect that having different strategic options for product supply would facilitate higher levels of FSCA.

Given the need to further evaluate the effect of FSCA on performance (Gligor et al., 2015), we also examine the relationship between FSCA and a firm’s operational performance (OP). Supply chain managers must know what results to expect from the implementation of FSCA-focused strategies, yet prior studies have evaluated only some measures of operational performance (e.g., Gligor and Holcomb, 2012; Blome et al., 2013; Eckstein et al., 2015; Gligor et al., 2015). Our study expands these measures by exploring the relationship between FSCA and OP in four specific areas – delivery, production cost, product quality, and production flexibility – that reflect the four key capabilities of a focal firm in responding to competition (Wong et al., 2011).

Based on the above, our study has two main goals. First, to analyze the role of TMS and SNF as potential antecedents of FSCA, evaluating the moderating role of TMS in the SNF-FSCA relationship; and, second, to evaluate the relationship between FSCA and OP, examining the possible mediating effect of FSCA on the relationship between SNF-OP. These goals are summarized in the following two research questions:

RQ1. What is the relationship between TMS, SNF, and FSCA?

RQ2. How does FSCA affect OP, either directly or by mediating the relationship between SNF and OP?

The relationships to be empirically investigated are illustrated in the theoretical model in Figure 1.

**Figure 1. Theoretical Framework of the Study**

*Design/methodology*

In order to provide empirical evidence for the proposed research hypotheses, Spanish companies belonging to the high technology sector were selected from the Iberian Balance Sheet Analysis System (SABI) database. Once the total population was defined, a survey was conducted to obtain specific information for our research, following Dillman’s (2000) prescriptions. The unit of analysis was the firm, and the preferred respondents were senior managers with knowledge of the processes and activities of the firm’s operations department and who had the capacity to make decisions in that department. The procedure for data collection was through the computer-assisted telephone interview (CATI) system. Finally, we obtained a final sample of 190 usable surveys and a final response rate of 12.45 percent.

The main constructs used in our model were: TMS, SNF, FSCA, and OP. The measurement scales for these variables were adapted from prior studies: TMS (Lewis,
A seven-point Likert scale survey was designed to capture managers’ perceived levels of these variables (1 = maximum disagreement; 7 = maximum agreement). Moreover, we considered other contextual factors that might have an influence on operational performance such as firm age and firm size.

We examined the reliability and validity of the measurement scales following the procedure developed by Kaynak and Hartley (2006). We also studied all indicators of the measurement scales’ goodness of fit by analyzing the absolute and incremental goodness of fit and the model’s parsimony. In all cases, the indicators are within the levels recommended as acceptable in the literature (Hair et al., 2010).

The theoretical model was tested using the methodology of structural equations and regression analysis. In order to test H1, H2, H4 and H5, we employed structural equation modeling (SEM) to estimate the proposed research model. Results indicate a good fit for the measurement model with a Chi-square of 862 and 549 degrees of freedom, CFI of 0.90, IFI of 0.90, BBNNFI = 0.90 and RMSEA of 0.05. The standardized coefficient weights for each causal path are provided in Figure 2 for the main effects, being all factor loadings significant. The analytical approach outlined by Hayes (2013) was used to test the hypothesis related to moderation (H3). A summary of the moderation analysis results is available in Table I. In addition, Figure 3 presents the moderating effect of TMS in the SNF-FSCA relationship, for low, moderate and high TMS values. The empirical evidence suggests FSCA achieves its optimum when companies have high values of TMS and SNF. However, higher values of TMS weaken the relationship between SNF and OP. In other words, the existence of a highly developed TMS leads to SNF becoming less important in the consecution of FSCA.

![Figure 2. Main Effect Results](image-url)
Findings
The study makes three important contributions to Operations Management research, Supply Management Orientation and the Resource-Based View (RBV). First, in response to suggestions by Swafford et al. (2006), it contributes to the literature on Operations and Supply Chain Management by evaluating the role of TMS and SNF as possible antecedents of FSCA. These antecedents have not been considered before in the literature on agility. On the one hand, finding evidence of a positive relationship between TMS and FSCA (H1) supports the conclusion that the presence of high levels of TMS in the operations department encourages FSCA. This is a novel contribution to the literature in the field. Although the benefits of TMS and the use of knowledge in other areas of the organization are recognized (Zheng and Mai, 2013; Peltokorpi, 2014; Argote and Guo, 2016; Heavey and Simsek, 2017), there has been almost no exploration of these benefits in operations management. Therefore, our study adds to pioneering studies like that of Obayi et al. (2017), which have begun to explore the role of TMS in the field of operations, supply chains and their role in OP. Obayi et al. (2017) considered the TMS generated among the partners in the supply chain. Our study extends the knowledge of the area, by considering the TMS in the firm’s operations department and exploring the benefits that this can have on the FSCA. On the other hand, evidence of a positive relationship between SNF and FSCA (H2) reinforces the need to reconfigure the supply...
base in the face of changes in the environment. This finding is not only consistent with the operations management literature that recognizes the importance of different types of flexibility to achieve FSCA (Swafford et al., 2006, Swafford et al., 2008, Braunscheidel and Suresh, 2009, Chan et al. al., 2017), but also improves our knowledge on the flexibility-agility relationship, by exploring a particular type of flexibility, practically unexplored in this field: SNF. Firms that have different strategic options for product supply and can properly reconfigure their supply base will have a better position to develop the FSCA.

Both antecedents, in turn, highlight the need to develop intra- and inter-organizational competencies to achieve FSCA. FSCA depends on issues related not only to internal management of the firm (such as the presence of high levels of TMS in the operations department) but also to external management of the firm, such as relationships with suppliers (SNF). This need has been suggested by prior studies such as those performed by Braunscheidel and Suresh (2009), Gligor et al. (2015), and Fayezi et al. (2017). This study empirically confirms these assumptions.

Evidence of the moderating role of TMS in the relationship between SNF and FSCA (H3) is also important. In contrast to previous proposals, we find a negative moderating effect of TMS. That is, when the firm has high levels of TMS in the operations department, the relationship between SNF and FSCA weakens. One possible explanation for this finding may lie in the firm’s capability for internal management. A high level of TMS grants the firm greater internal management capability, which facilitates its adaptation or response to market changes using its own mechanisms. Thus, based on survey data collected from 137 start-ups in China, Zheng and Mai (2013) found that forming teams of start-ups that were operating in highly uncertain environments and that had high levels of TMSs did not have to resort to external sources when responding to surprises in their environments. Rather, they responded to surprises by improvising using their own knowledge. Improvisation requires integrating and applying new and preexisting knowledge in real time, and the existence of a high level of TMS in the team facilitated this task.

As a firm’s operations department develops its TMS, the probability of resorting to its supply base to improve FSCA decreases. In other words, the solutions for managing rapid changes can be forged internally. The ability to create, maintain, transfer and coordinate knowledge in operations departments with high levels of TMS enables the firm to draw on its own abilities instead of consulting external players to solve problems (Carney et al., 2008). Further, improving FSCA through the firm’s internal processes encourages quick response and eliminates the costs associated with seeking new suppliers and generating commercial transactions (Williamson, 1975). SNF involves finding the best strategic combination for product supply. Such searches require not only the presence of suppliers available on the market but also the time, cost and knowledge necessary to perform a search and to select suppliers effectively and efficiently. Firms with a high level of TMS in the operations department will thus be more inclined to invest in themselves to respond to uncertainty instead of delegating this responsibility to external agents.

Second, the study makes a key contribution to the agility literature by examining the association between FSCA and OP. The evidence of a positive relationship between FSCA and OP (H4) confirms the importance of developing FSCA to improve the firm’s operating measures. Consistent with prior research (Gligor and Holcomb, 2012; Eckstein et al., 2015; Gligor et al., 2015; Chan et al., 2017), this finding also enables us to extend knowledge in the field by considering four key dimensions of OP: delivery, production cost, product quality and production flexibility. To the extent of our knowledge, prior studies that explore the relationship between FSCA and OP have considered only some
of these dimensions (Blome et al., 2013; Eckstein et al., 2015; Gligor et al., 2015; Chan et al., 2017). Our study provides a more complete view of the operating measures improved by FSCA.

Finally, the study contributes to developing the literature supporting the relationship between flexibility and agility as a competency-capability relationship (Swafford et al., 2006; Braunscheidel and Suresh, 2009; Swafford et al., 2008; Chiang et al., 2012; Blome et al., 2013). However, this study extends past research considering an aspect of external flexibility, related to supply management. Normally, the studies have evaluated the flexibility relative to the internal processes of the firm. There is few research that extend the flexibility beyond the limits of the focal firm. Our findings suggest that the variable FSCA mediates the relationship between SNF and OP (H5). That is, while SNF is a competency, FSCA is a capability. According to the RBV, competencies in themselves do not lead to sustainable competitive advantage. Rather, they must be combined and managed to develop capabilities. Thus, SNF in itself does not generate greater OP per se, but requires FSCA to obtain operational benefits.

This study also has important implications for managers. The empirical evidence obtained highlights the value of investing in FSCA as a tool to build a sustainable competitive advantage. FSCA enables the firm to compete in an increasingly dynamic and changing environment by improving some of the firm’s operational aspects, such as increasing product quality, decreasing production costs, improving issues related to product delivery and/or encouraging production flexibility.

At the same time, the study allows managers to understand how FSCA can be strengthened. We stress that FSCA depends not only and exclusively on internal aspects of the firm but also on parties external to it, which involve different agents in the supply chain. Managers should thus develop both intra- and inter-organizational resources to encourage FSCA. First, managers could focus on the intra-organizational possibility of developing a solid TMS in the operations department. That is, they could build work teams that prioritize collaboration and trust among the group’s members, with members who specialize in a specific area and are willing to share and coordinate individual knowledge. Such teams not only enjoy greater response capability but can develop creative solutions to unexpected problems (Akgün et al., 2006) in the area of operations, increasing FSCA. Second, managers could develop the inter-organizational possibility of SNF by building a network of suppliers flexible enough to adapt to changes in the environment and thus able to respond quickly to new demands from the firm’s customers. For example, in environments with highly competitive and dynamic markets, short product lifecycles and rapid new product introductions, maintaining these flexible networks reduces the firm’s dependence on its suppliers and increases its capability to adjust supply and demand.

However, it should be noted, in the face of the need to prioritize one option over the other, investment in internal resources in the firm seems to be the more effective response when developing FSCA. Specifically, developing TMS in the operations department could be especially valuable when uncertainty is high as with the high-tech industry, because TMS provides a knowledge base that can be coordinated to better address uncertain conditions in the environment (Argote and Guo, 2016) without facing the costs associated with the search for new suppliers and the generation of new commercial transactions.

It is also important to note that while managers can develop SNF to strengthen FSCA, SNF does not improve the firm’s operational aspects directly. A firm that has different strategic options for product supply, has a greater capability to adapt to changing market
requirements which increases its FSCA. This FSCA will lead to improvements in operational measures.

Abstract
This paper aims to facilitate the understanding of the causes leading to the bullwhip effect. Therefore, causes that have been scattered across many publications so far are brought together and structured in a systematic way. To do so, a systematic literature review of the bullwhip effect causes is conducted and identified causes are assigned to inductively derived categories. A comprehensive overview of the causes leading to the bullwhip effect is generated by this procedure and can be used as a starting point for further research as well as by professionals.

Keywords: bullwhip effect, demand variance amplification, systematic literature review

Introduction
Working together in a supply chain rather than exclusively focusing on local interests can benefit everyone (Barratt, 2004). However, to be competitive as a supply chain, it is inevitable to address inefficiencies within the supply chain and familiarize with their causes. By doing so, researchers as well as practitioners repeatedly observed a phenomenon which is nowadays known by the term “bullwhip effect”. The bullwhip effect is characterized by an increase in order variance as one moves upstream the supply chain. This implies that orders issued to a supplier have a larger variance than sales to a customer (Lee et al., 1997). Among other things, this phenomenon causes excessive inventories, low capacity utilization and poor customer service along a supply chain (Disney & Lambrecht, 2008). Since the first academic study conducted by Forrester (1958) who drew attention to underlying mechanisms of this effect and addressed the problematic implications attached to demand variance amplification, one stream of literature has focused on researching the causes of demand variance amplification. A vast number of publications resulted from these research efforts: however, there have been few efforts so far to compile a comprehensive overview of causes for demand variance amplification in a systematic way. This has led to a situation, where quantity and nature of listed causes for the bullwhip effect vary from study to study. This spread makes it difficult to perceive a comprehensive picture and develop a deep understanding of the
causes. Without this understanding, however, it is difficult to design and implement appropriate remedies. This view is supported by McCullen & Towill (2002) stating that the bullwhip effect is often either misunderstood or ignored.

This paper aims to simplify the understanding of the causes behind the bullwhip effect for scholars and professionals. This is done by pursuing the research objective of bringing together and structuring all the causes of the bullwhip effect which are discussed in literature.

**Methodology**

To surface all known causes of the bullwhip effect in the literature, we conduct a systematic literature review, following the steps proposed by Thomé et al. (2016). Thereby, this literature review is not exclusively focusing on primary sources. It is also built upon secondary literature, utilizing existent knowledge that can be drawn from literature review sections that papers usually contain. Thus, our systematic review can be understood partly as a review based on primary sources and partly as a review of reviews.

Keywords were defined according to the research objective and combined in the following search string: ("bullwhip" AND "cause*") OR ("bullwhip" AND "review*"). The search string was used to identify relevant articles in four different databases: Web of Science, Science Direct, Business Source Premiere and Academic Search Premiere. A first set of articles was retrieved by searching titles, abstracts and keywords of all papers within these databases with the search string. In a subsequent step, duplicates were removed. Abstracts of the remaining articles were analyzed. Based on predefined inclusion and exclusion criteria (Table 1), articles were either discarded or qualified for the full text analysis.

**Table 1: Exclusion and inclusion criteria**

<td>Only papers not focusing on specific single causes are of interest for this study</td>
</tr>
</tbody>
</table>

The same inclusion and exclusion criteria were applied to the remaining full texts. Overall, 31 papers relevant for the literature review were identified through this procedure. Figure 1 illustrates the article selection process.

As for the quality assessment of the retrieved papers, the exclusive consideration of peer-reviewed articles minimizes the risk of including low-quality or unreliable studies in the analysis. However, the exclusion of publications outside peer-reviewed papers, e.g. the grey literature, makes this systematic literature review susceptible for publication bias. Furthermore, the search term “bullwhip” limits the time period covered, since this designation for order variance amplification had not been used until Procter&Gamble coined this term in the early 1990s (Wang & Disney, 2016).
A qualitative content analysis approach was applied to analyze the selected articles. To assess all text passages in which causes of the bullwhip effect were discussed, the articles were reviewed line-by-line. Listed causes were coded in-vitro and then consolidated inductively into categories. The inductive categories were derived by following the approach outlined by Mayring (2008). First, codes were paraphrased and in a second step, related paraphrases were consolidated to form categories.

Descriptive findings
The 31 selected articles are published in 22 different journals. Most strongly represented are papers from the “European Journal of Operational Research” and the “International Journal of Production Economics” with 3 publications each. The distribution of the publication over years ranges from 2004 to 2018 and is relatively uniform which indicates a constant interest in reviewing the causes of the bullwhip effect over time.

Thematic findings
Through the qualitative content analysis of the selected articles, four categories were inductively derived in which the causes can be classified: underlying structural factors, uncertainty due to insufficient information availability, misaligned incentives as well as human and process errors.

Underlying structural factors
The review of causes for the bullwhip effect by Miragliotta (2006) identifies complexity, feedbacks and non-linearities in supply chains as important factors influencing demand variance. Complexity of a supply chain stems, for example, from the involvement of a high number of individuals and diverse practices as well as policies, which in turn lead to a high degree of uncertainty (Paik & Bagchi, 2007). Furthermore, complexity is increased by feedback loops. This is illustrated by an example, Miragliotta (2006) gives by referencing Forrester (1980) who wrote that “symptoms, action and solution are not isolated in a linear cause-to-effect relationship, but all change takes place within the control of feedback loops. Growth, goal-seeking and oscillation are consequences of feedback loops dynamics” and, thus, also introduces non-linearities as a factor of concern. The systemic point of view also builds the basis for the recognition that lead times, which describe the time span between initiation and execution of an order, play an integral role for the bullwhip effect. This claim can be found in many of the reviewed papers (e.g. Csik...
& Földesi, 2012; Devika et al., 2016; Gilbert, 2005). The following example illustrates the influence of lead time on the bullwhip effect: Assumed, a company faces a 5% increase in demand rate. To meet the 5% increase in demand, the company must not only increase its ongoing weekly order rate by 5% but also places additional orders to increase the inventory level by 5%. In case of a 2 weeks lead time, the order placed to bring the inventory to the new desired level is equal to 10% of the weekly demand rate. Hence, demand variance is amplified. Another factor causing demand variance amplification, which is similar but driven by equipment lifetime instead of inventory lead-time, is called "investment accelerator effect". Multiple studies in the review sample mention this factor and point out the peculiarity that this effect occurs usually between product manufacturers and their capital equipment suppliers (e.g. Bhattacharya & Bandyopadhyay, 2010; Geary et al., 2006; Kouvelis et al., 2006). Kouvelis et al. (2006) explains the investment accelerator effect by referring to Anderson et al. (2000) as follows: "a plant may use 100 machine tools and replace 5% of them in a typical year. If this firm anticipates a 5% increase in sales, it may plan to buy 10 machine tools this period; 5 new and 5 replacements. Thus, a 5% surge in expected sales at one level becomes a 50% surge for the supplier" (Kouvelis et al., 2006, p. 450).

Complexity, presence of feedback loops, non-linearities and time dependencies are presented as underlying factors in several reviewed papers. For example, according to Paik and Bagchi (2007) complex feedback loops combined with time delays render it very likely that decisions result in demand variance amplification, even if not intended. A similar view is represented by Miragliotta (2006). By pointing out to Sterman (1989a), Miragliotta blames feedbacks created by the interactions between companies for the fact that decisions that were locally rational bring unwanted and dysfunctional results on the global level. Based on these examples and the above explanations, we propose that complexity, feedbacks, non-linearities and time dependencies give rise to a system prone to uncertainty due to insufficient information availability, misaligned incentives and human and process errors. As shown in the following, order decisions made in presence of insufficient information, misaligned incentives as well as human and process errors in turn are causing demand variance amplification.

Uncertainty due to insufficient information availability
Not all the necessary information is always available to everyone in a supply chain. Furthermore, information is often not only missing, but can also be incorrect. Scukanec et al. (2007) even considers the “insufficient flow of real information” as the main cause of the bullwhip effect. Information can be withheld on purpose, for example, the likelihood of sharing point of sales data is greatly reduced, if there are any concerns that a supply chain partner is going to utilize the shared information for opportunistic behavior (Svensson, 2001). However, lack of information sharing can also result from an underestimation of the value information potentially could have for other supply chain partners (Nienhaus et al., 2006). Missing or wrong information leads to a state of uncertainty where no definite answers to pressing questions like “What will be the demand next week?” or “Is the supplier capable of fulfilling my orders?” exist.

To cope with uncertainty in demand and supply, companies usually forecast demand and maintain a safety stock to absorb unforeseen events to a certain extent. In case of new information, parameters of the applied inventory replenishment rule are adjusted accordingly. For example, new demand information may result in an update of the demand forecast, target stock level and/or safety stock level. This behavior is mentioned by all reviewed papers as possibly causing demand variance amplification and most often called demand signal processing. This designation goes back to Lee et al. (1997). Thereby, order variance becomes, for example, amplified by adjusting safety stocks due
to a changed customer demand pattern (Braz et al., 2018). In such a situation, the change in orders is not equal to the change in customer demand but exceeded by the quantity ordered to adjust safety stock. If, in return, other upstream supply chain members decide to change their safety stock level as well, the original demand signal becomes further distorted at each decision point. Furthermore, the forecasting technique can have an influence on demand variance amplification. Multiple authors (e.g. Devika et al., 2016; Hassanzadeh et al., 2014) draw attention to a study by Dejonckheere et al. (2003) who proved that forecasting demand by using exponential smoothing and moving average within an Order-Up-To-policy always results in an order variance amplification, regardless of the demand process (unless the demand is always constant). Hence, the uncertainty about future demand and the necessity to order based on forecasts, can contribute to the bullwhip effect.

The state of uncertainty because of insufficient information about the future also provokes interventions by managers in order quantity decisions (Ancarani et al., 2013). This gives room to behavioral biases distorting the demand signal. Exemplary for this, Disney & Lambrecht (2008) cite overoptimistic attitude and overaction to demand changes or customer complaints. Such exaggerated adjustments of quantitative demand forecasts generally result in higher forecast errors, hence, higher demand variance amplification. The extent to which an order is adjusted also depends on the risk attitude of a decision maker. A risk averse decision maker might overorder out of the fear of facing stock-out situations (Bhattacharya & Bandyopadhyay, 2010). The inflation in orders resulting from overordering itself increases order variance. However, order variance becomes even more amplified due to the necessity of upstream supply chain partners to adjust their orders as well to avoid stock-out situations (Nienhaus et al., 2006). However, a risk seeking individual which is willing to deplete its safety stock can also cause a bullwhip effect. This was demonstrated by Nienhaus et al. (2006) who observed a reoccurring behavior of individuals in supply chains they called “panic strategy”. This strategy refers to the reaction of individuals who emptied their inventories during constant demand and then start panicking because of stock-out situations as soon as the demand rises. Decision makers following this strategy have no safety stock left and do not only face high stock-out costs and the necessity to order more than in a situation with safety stock left, but also force upstream stages to order more and cause possible stock-out situations in upstream stages as well.

Uncertainty, however, does not only exist in respect to future demand and supply quantities, but also regarding supply chain members’ behavior. Even though all supply chain members superficially work towards a collective outcome, there may be reservations regarding supply chain partners’ trustworthiness, motives or cognitive abilities (Croson et al., 2014). Croson et al. (2014) call the risk resulting from this uncertainty “coordination risk”. In the existence of coordination risk, individuals create a so-called coordination stock to be prepared in case of decisions of other supply chain members which are disadvantageous for the own company. Coordination stock can be seen as a type of safety stock which “buffers against strategic uncertainty in orders or delivery due to coordination risk”. A similar observation was made by Nienhaus et al. (2006) who analyzed the decision makers’ behavior in a four-tier supply chain and found a strategy they named “safe harbor”. Individuals following a safe harbor strategy order more than actually necessary resulting in an excessively high safety stock level. Croson et al. (2014) hypothesize that the tendency of accumulating excessive safety stock could be in response to stress resulting from orders or unexpectedly long delivery times. Also, Shee & Kaswi (2016) observed managers’ intent to order higher quantities than actually necessary which they call “extra days of order” and define it as “additional stock amount
being added up on top of the incoming orders received from downstream partner while ordering up to upstream partner”. Shee & Kaswi (2016) see the extra days of stock not only as a buffer against business uncertainties but also because of the pursuit of achieving higher service levels, reducing stock-out situations and the objective to boost customer demand.

**Misaligned incentives**

Incentives, i.e. the rewards and punishments associated with different actions, can have a great influence on decisions. However, the creation of incentives can only be unintentionally, but can also have unintended consequences (Carter et al., 2007). An example of an incentive that unintentionally leads to demand variance amplification is the exploitation of price fluctuations. This cause of the bullwhip effect can be found in all reviewed papers with reference to Lee et al. (1997). In theory, customers ramp up their inventories in periods of low prices to avoid the necessity to place orders during periods of high prices. This kind of forward buying does not realistically reflect the immediate needs in the supply chain. As a result, variability of orders exceeds the variability of the consumption rate (Klug, 2013). Price fluctuations can be attributed, among other things, to promotional campaigns or dynamic pricing (Kouvelis et al., 2006). Furthermore, Kouvelis et al. (2006) draw attention to the so-called called hockey stick phenomenon, where the effect of price fluctuations becomes particularly vivid. The phenomenon is characterized by a steep increase in orders e.g. at the end of a financial year or quarter. Among other things, this can be traced back to sales targets that have been set. In order to boost demand and to meet sales targets, many suppliers offer price discounts at the end of the financial year or quarter. Companies, anticipating this behavior from their suppliers, aggregate customer demand over time and wait for the special offers to buy at a lower price. Thus, demand variance is amplified. The action of aggregating customer demand over time, which is then forwarded in an aggregated form to the suppliers is in literature mostly called order batching or lot sizing. By referring to Lee et al. (1997), this behavior is also listed in all the reviewed papers as a cause of demand variance amplification. The literature review brings various possible reasons for companies’ motivation to batch orders besides the already mentioned advantage taking of price fluctuations to light. Kouvelis et al. (2006) cite the impact of fixed costs and further considerations of economies of scale as examples. Fixed costs can be associated to the costs of ordering, e.g. because an employee must fill out an order form, but also with costs of transportation. For example, the fix costs per unit are less in case of a full truck load compared to an only half-filled truck (Paik & Bagchi, 2006). As stated by Kouvelis et al. (2006), order batching can also stem from the applied inventory policy. A company following a periodic review ordering practice serves as an example. If the company faces a daily demand but places orders to their suppliers every fourth week, i.e. batches the demand, the order variance is increased. As pointed out by Miragliotta (2006) financial deadlines can also trigger order batching. For example, the common payment term of 30 days from the end of an invoicing month incentivizes companies to buy at the beginning of a month and thereby delay the payment by a month. Holland & Sodhi (2004) cite orders issued according to the economic order quantity as an additional cause of order batching.

All articles bring attention to another business which potentially causes demand variance amplification, most often called “rationing and shortage gaming”, following in the footsteps of Lee et al. (1997). In case of a shortage of supply, suppliers ration their products according to specific rules. Very common is the division of available goods in such a way that each customer receives a certain percentage of the ordered quantity. Customers are aware of the supplier’s course of action and consequently artificially inflate their order if they expect a situation of shortage in order to receive a quantity which
is closer to their actual demand (Scukanec et al., 2007). It can be concluded that the supplier’s policy has unintentionally created an incentive for the customers to exaggerate their orders. As soon as the shortage of supply is eliminated, customers cancel their artificially inflated orders (Nienhaus et al., 2006). What remains is a completely distorted picture of end customer demand for the supplier.

**Human and process errors**

Complexity of a system and its components, combined with feedbacks, non-linearities and time dependencies create an environment susceptible to human and process errors which in turn amplify demand variance (Paik & Bagchi, 2007). In such a system, for example, faulty assumptions regarding actual stock or actual supply line level can arise (Goodarzi et al., 2017). Misperceptions about the actual stock level can occur, for instance, in presence of inventory inaccuracies. Bruccoleri et al. (2014) points to the problem that even large retailers experience inventory inaccuracy, meaning that the inventory records differ from the number of products which are actually available for customers to buy. During physical stock counts, which are periodically performed, discrepancies between actual inventory for sale to customers and book inventory are detected. Subsequent orders take these discrepancies into account and the order quantity is adjusted accordingly. This adjustment of order quantity is not reflected in customer demand. Thus, order variance is amplified. Inventory inaccuracies can not only be traced back to inventory misplacement by customers or inventory shrinkage due to theft or damage but also to the reaction of individuals to work pressure. Bruccoleri et al. (2014) demonstrate that the more the level of workload pressure deviates from the ideal value for the specific employee, the more inventory data entry errors arise, contributing to inventory accuracies.

Decision makers’ tendency of faulty assumptions about the supply line was observed by Sterman (1989). Based on experiments he demonstrated the tendency of individuals to underweight the supply line. This means that individuals playing a supply chain simulation game base their order decisions to a higher extent on the discrepancy between desired and actual stock than on the discrepancy between desired and actual supply line. In many cases, this amplifies the demand variance. Different theories exist, why decision makers underweight the supply line. Paik & Bagchi (2007) say it occurs because the supply line is ignored, whereas Wang & Disney (2016) justify it with the argument that decision makers overlook the supply line. On the other hand. Udenio et al. (2017) state that decision makers under-estimate the quantity of the order in the supply line and Disney & Lambrecht (2008) attribute the behavior to the problem that decision makers “do not have a clear idea of what is available in the pipeline”.

Not only human shortcomings give rise to demand variance amplification, but also process errors can evoke responses amplifying order variance. Several reviewed articles (e.g. Klug, 2013; Paik & Bagchi, 2007) point out to Taylor (1999) who demonstrated the impact of variability in machine reliability and in process capability on demand variance amplification. Taylor (1999) illustrates this with an example of a press shop which relies on input from blanking. Assume the press shop has an average demand for blanks of 1000 units per week. However, due to reliability problems, the blanking machine only produced 800 units instead of 1000 units in week 1. In the subsequent week, this shortfall must be compensated, hence, a production of 1200 units in week 2 is required from the blanking machine. This shows that although press shop’s demand was constant at 1000 units, members upstream the blanking machine faced a demand of 800 units in week 1 and of 1200 units in week 2.
Variability in process capability results in fluctuations of service quality. Hence, the inability to produce constantly perfect products leads to varying quantities of units which can further processed downstream in the supply chain. Suppose the demand of the press shop is again 1000 units per week. If in week 1 blanking only delivers 800 units which can be further processed, the press shops’ demand in week 2 is 1200 units to cover last weeks missing quantity. After the press shop received an incomplete shipment, i.e. less faultless goods than expected, it may anticipate potential service quality shortfalls for subsequent weeks and exaggerates the order even more to proactively balance them out (Taylor, 1999).

**Discussion and conclusion**

The conducted systematic literature review combined with a qualitative content analysis surfaced a variety of causes of the bullwhip effect from literature. Based on the identified causes in literature, we argue that there are four underlying structural factors, namely complexity, feedback, non-linearities and time dependencies that give rise to a system in which (1) not all necessary information is always available where it is needed, (2) incentives for decision-makers are often misaligned, and (3) human and process errors can occur. Thereby, identified causes can often be combined to form a causal chain. For example, the complexity and lead times in supply chains result in a situation, where most likely not all information is available to everyone. This lack of information results in uncertainty which in turn makes it necessary to forecast demand. However, as explained above, demand forecasting techniques are susceptible to induce amplification in order variance.

The inductively derived categories of factors and causes influencing demand variance amplification differ significantly from existing categorizations. Usually, causes of the bullwhip effect are divided into two categories: operational causes and behavioral causes. Operational causes refer to structural characteristics that lead rational decision makers to amplify the order variance, whereas behavioral causes refer to the existence of bounded rationality of individuals and the resulting problems thereof (Croson et al., 2014). Typically, the four causes identified by Lee et al. (1997), i.e. price fluctuations, demand signal processing, order batching as well as rationing and shortage gaming, constitute the category of operational causes. Causes like supply line underweighting or coordination risk are, on the other hand, usually attributed to the category of behavioral causes. Our proposed new categorization allows a more targeted classification of causes. Furthermore, our categorization does not put such a strong emphasis on the question if a demand variance amplification results from rational decision or from a decision under bounded rationality. This opens up new perspectives that may for example be helpful in researching mitigation strategies.

Abstract

Artificial intelligence (AI) is a technology which focuses on enabling machines to communicate with and imitate the capabilities of humans. The recent hard- and software advances opened plenty of new application fields for this technology, among them the field of supply chain management (SCM). While different industrial and engineering potentials of AI has been discovered and used, the contribution of AI to SCM, both theoretically and practically, has yet to be explored. The aim of this study is to reduce this gap and provide a systematic and comprehensive review uncovering research gaps and the contribution of AI to SCM.

Keywords: Supply chain management, Artificial intelligence, Marketing, Logistics, Production, Systematic literature review

Introduction

Among the currently upraising technologies that are shaping our lives, AI is going to change business and economics more than others (Dirican, 2015). Due to its ability to recognize business patterns, learn business phenomena, seek information, and analyze data intelligently (Min, 2010a), AI has become a game changer for organizations by creating new business opportunities, accelerating processes and improving the human decision-making processes (Martínez-López and Casillas, 2013; Jarrahi, 2018). In addition, AI has created a wide field for scholars to research and explore the nature and potentials of AI from a scientific point of view.

The concept of AI, defined as the computational study of intelligence (Korf, 1991) has been around for more than two decades (Huin et al., 2003) and many studies have been conducted revolving around this concept due to its broad range of applications in engineering, business, manufacturing, SCM and many other fields (Saidi Mehrabad and Fathian Brojeny, 2007).
In spite of the large number of studies around AI, literature reviews on this topic are scarce; especially in the field of SCM. Attempting to curtail the aforementioned gap, this work provides a Systematic Literature Review (SLR) answering the following research questions:

How can AI contribute to SCM?

To be more focused and explore this topic in detail, we took four main steps: (1) identifying the most influential and commonly used AI techniques in SCM studies, (2) identifying the potential techniques of AI that can be employed in SCM, (3) identifying the subfields in SCM that were already improved using AI, and (4) implications of this study for academics and practitioners.

Methodology

This study follows the five SLR steps suggested by Denyer and Tranfield (2009) plus an additional pilot search. These steps are:

In the first step, between May and July 2018, we conducted a pilot search that enabled us to identify a research gap and establish the inclusion and exclusion criteria as follows: studies need to be published: (1) within the time span between 2008 to 2018 since the majority of the papers and a large number of new ideas, trends and applications, contributing to AI have emerged in the last ten years. (2) in peer-reviewed journals or conferences in order to achieve the highest level of relevance and quality. (3) in the SCM and AI fields.

We also defined a bespoke article inclusion protocol to mitigate the performed opinions that could have biased our assessments of relevance of articles (Orwin et al., 1994). To this end, we, firstly, used our predefined pilot search string. Secondly, articles with relevant keywords but irrelevant topics were excluded. Thirdly, we excluded pure engineering articles that did not have a strong connection or attachment to SCM studies. Due to broad nature of SCM discipline and our aim to conduct an inclusive yet practical literature review, we furthermore focused our search on SCM subfields with the strongest literature background including: supply chain, logistics, production and marketing; based on the SCM definition of Stock and Boyer (2009).

In the second step, we formulated the research questions. In the third step, the selection of suitable identified studies took place. Bearing in mind that we required databases that cover a great variety of journals; we selected ScienceDirect, Emerald Insight, JSTOR, Wiley Online Library and Taylor & Francis.

Containing millions of peer-reviewed articles, these databases are credible and scientifically renowned. The search protocols used to explore these databases are mostly similar with minor modifications due to the search system of each database. The general structure of this protocol was: “artificial intelligence” AND “keyword1” NOT “keyword2” NOT “keyword3”. Keywords are: marketing, supply chain, production,
logistics. Table 1 shows the results of the third step in relation to the number of the articles extracted and in brackets the number of articles selected for the review. The fourth and fifth step were dedicated to the analysis, synthesis and reporting of findings.

**Analysis and synthesis**

In the subsequent sections, we present a categorial analysis of the 64 papers reviewed. Afterwards, we summarize the identified AI techniques and assign them to the individual SCM fields. Finally, we present the outcomes of our study.

**Categorical analysis of the literature according to SCM fields**

In total 14 articles are related to the marketing field. Lee et al. (2012) propose an Artificial Neural Network (ANN)-based system for sales forecasting in convenience store industry. Ketter et al. (2012) present an agent-based model for sales management and O’Donnell et al. (2009) use Genetic Algorithm (GA) to present an online system that helps sales promotion. In segmentation, Casabayó et al. (2015) combine cluster analyses and fuzzy models for a novel market segmentation approach, while Sarvari et al. (2016) use ANN and K-means clustering for customer segmentation. The papers of Bae and Kim (2010) and Martínez-López and Casillas (2009) are focused on consumer behavior. While the former uses association rule and tree-based, the latter uses a genetic fuzzy system. Shakya et al. (2010) use various AI techniques and suggest a pricing system for diverse products and services, while Peterson and Flanagan (2009) use ANN for a pricing model with lower errors and greater precision. Stalidis et al. (2015) also apply ANN to develop a marketing decision support framework. Rekha et al. (2016), in turn, explore the use of support vector data description to facilitate the selection of contacts. Using GA and fuzzy models, Kwong et al. (2016) propose a methodology to integrate affective design, engineering, and marketing for defining the design specifications of new products. Taratukhin and Yadgarova (2018) use multi-agent systems and thereby suggest an approach for product life cycle management, whereas Martínez-López and Casillas (2013) present a historical literature review of AI-based systems applied to marketing.

Seven articles revolve around logistics, from which Salido et al. (2012) and Cardoso et al. (2013) employed heuristics and automated planning. Whereas Salido et al. (2012) offer a Decision Support System (DSS) for calculating the number of resuffles needed to allocate the containers in the appropriate place, Cardoso et al. (2013) present a system for container loading problem. Knoll et al. (2016), developed a predictive inbound logistics planning approach. In order to distinguish between more or less performing human–artificial collaboration systems in logistics, Klumpp (2017) introduce a multi-dimensional conceptual framework. Eslikizi et al. (2015) address an inter-organizational lot-sizing problem which is solved by a set of self-interested and autonomous agents. Lee et al. (2011) examines how AI techniques and RFID can enhance the responsiveness of the logistics workflow and Wang et al. (2012) propose an intelligent system for industrial robotics in the logistic field.

23 studies were on production. Martínez-Barbera and Herrero-Perez (2010) as well as Heger et al. (2016) are concerned with manufacturing systems using Fuzzy Logic (FL) and Gaussian models. Kasie et al. (2016) address manufacturing decision support using Case-Based Reasoning (CBR) and Rule-Based Reasoning (RBR). Camarillo et al. (2018) suggest a production-oriented approach and use CBR for manufacturing problem solving. Kucukkoc and Zhang (2015) offer a GA-based model for the parallel two-sided assembly line balancing problem, while Sanders and Gegov (2013) review some of the applications and examples of AI tools for assembly automation. In quality control and improvement,

In the last field, SCM, 20 articles were identified from which Amirkolaii Nemati et al. (2017), Ahmadi et al. (2017), Efendigil et al. (2008), Bala (2012) and García et al. (2012) worked on forecasting methods using AI techniques. Regarding consumption forecasting, Yu et al. (2017) present an online big data-driven oil consumption forecasting model that uses Google trends, which finely reflects various related factors based on a myriad of search results. Ferreira and Borenstein (2012) suggest a fuzzy-bayesian supplier selection model, while Vahdani et al. (2012) propose a neuro-fuzzy supplier selection model for the cosmetics industry. Pino et al. (2010) worked on a multi-agent supply chain system and Merlino and Sprože (2016) explored the main technological changes and the most advanced cases in sustainable supply chains. Vargas Florez et al. (2015) proposed an AI-based humanitarian facility location Decision Support System that can adequately manage the response to a disaster despite failures or inadequacies of infrastructure and potential resources. By means of agent-based and multi-agent systems, Ferreira and Borenstein (2011) present a simulation framework for supply chain planning, Zgaya et al. (2009) suggest a negotiation model and Dias et al. (2009) forecasts the use of RFID integrated into an ICT framework. The literature review of Min (2010) explores different subfields of AI that are suitable for solving practical problems relevant to SCM. Chong and Bai (2014) examine the predictors of open inter-organizational systems adoption by using Rosetta Net as a case study. Regal and Pereira (2018) present an ontology for conceptual modelling of intelligent maintenance systems. Zhang et al. (2017) proposed an efficient bio-inspired algorithm for design of optimal supply chain networks in a competitive oligopony market. Tsang et al. (2018) propose a risk-monitoring system by means of the IoT (Internet of Things) and AI techniques. And finally, Sinha et al. (2012) suggest an algorithm to solve the problem of inventory replenishment in distributed plant–warehouse–retailer. Table 2 assigns the exemplary articles to the respective SCM fields and subfields.

**AI techniques and their distribution**

From another perspective, we analyzed the literature based on the AI technique that the articles use or revolve around. In doing so, we followed Chen et al. (2008) and Bundy (1997) comprehensive list of AI techniques. In addition, we assigned, counted and ranked the articles that referred to the identified AI technique (Table 3).

We found the highest variety of AI techniques in the field of production. We assume that this is primarily due to the practical nature of this research field which mostly encompasses experimental research, case studies and real-life problem-solving studies. ANN, FL and CBR are the most frequent AI techniques in this field. With 12 AI techniques used, marketing has the second highest variety, in which ANN, GA and FL are the most popular techniques. The third most diverse field is supply chain with ten AI techniques. ANN and FL hold the top ranks in this field. Finally, logistics has the least variety of techniques with only seven AI techniques used.

The most popular AI technique is ANN. It was used 18 times. The second frequent technique is fuzzy logic/models with 11 applications. Intelligent agents are in the third place with nine repetitions. This is presumably due to their wide range of application. GA is the next popular technique with seven repetitions. Both DM and CBR are used four times each in the literature, whereas SI and SVM were identified three times. Simulated annealing and automated planning are used two times each. The rest of the techniques are used once.

**Study outcomes**

Generally, research papers are unique and they usually develop unique results. If papers produce models, systems, frameworks, approaches, algorithms, methods and...
methodologies they have a more experimental or practical nature. Whereas, if they produce literature reviews, examples, concepts, ontologies, comparisons, forecasts and explorations, they can be classified as conceptual or philosophical studies. Based on our review, we found that the majority of papers in all fields have an experimental or practical orientation. The results are predominantly modeling and systems.

**Discussion**

As mentioned, we took four steps in order to answer the research question. In this part, we strive to discuss each of them.

**Most influential and commonly used AI techniques in SCM studies**

There are various AI techniques that can be applied to SCM, however, the results of our study show that ANNs are the most influential techniques in these studies; mainly because they are capable of solving data-intensive problems where the rules or algorithms for solving the problem are unknown or difficult to express (Chen et al., 2008). Moreover, they can be applied to several categories of problems including pattern classification, optimization, clustering, prediction and process control. The second technique is FL which According to (Bundy 1997) are on the border between AI and non-AI with a rapid growth in recent years. The reason for this rapid development is that it addresses qualitative information perfectly as it resembles the way humans make inferences and decisions (Bundy, 1997). Results show that fuzzy logic is widely used as a modeling tool and an element in hybrid intelligent systems. Another group of techniques that are
frequent in SCM studies, are (multi) agent-based systems. An agent is a piece of software containing code and data. A multi-agent system comprises a network of agents interacting to achieve goals. These agents are capable of modelling, designing, and implementing complex systems, and that is the reason behind its wider use in SCM. Results revealed that GA is also one of the most frequently used AI techniques in SCM that mimics natural selection. This algorithm evolves until it solves the problem adequately.

**Potential techniques of AI that can be employed in SCM**

There are many AI techniques that have been employed in SCM studies but there still ones with more potential. While robotics (robotic programming) is not a new topic in SCM, the vast potentials of this area is not fully utilized. Our study indicates a limited use of it in the literature and subfields of SCM. For instance, packaging and container terminal operations are liable for more robotic influence. This could be in the form of more automatic facilities or faster intelligent robots. Another AI technique that has great potential for use in SCM is the Expert Systems. It emulates the decision-making ability of a human and therefore has a great potential in reasoning and decision-making and can be employed in DSSs, especially for lot-sizing and supplier/buyer selection.

**Subfields in SCM that were already improved using AI**

All major SCM fields are currently improved using AI techniques. However, the concentration on subfields is not equally distributed. In particular, marketing, sales and segmentation have received more attention than fields such as pricing, consumer behavior, marketing decision support or direct marketing. In logistics, container terminal operations, logistics systems automation, lot-sizing or logistics workflow already utilized AI techniques, but there are other topics that need to be covered. In production, the subfields of assembly, manufacturing and forecasting are more equipped with AI. Other subfields such as product line optimization, workflow, product-driven control and low-volume production are less improved by AI techniques. At last, in the field of supply chain, demand forecasting is the leading AI-equipped subfield, while other subfields received less concentration.

**Implications of this study for academics and practitioners**

There are potential SCM subfields that can be improved in the future by using AI techniques both in research and practice. Our results reveal that most of marketing articles that employed AI, are revolving around sales and segmentation. Therefore, other members of the marketing mix like promotion, product and place can be candidates for AI applications. Sales promotion, advertising, public relations and direct marketing are consequently the subfields that can be improved dramatically with deeper use of AI. In logistics, distribution and transportation, logistic hub management and logistics risk management can be improved by using AI. Fields such as mega project management and advanced project process management are important fields for consideration in the area of production. In supply chain, buyer selection, automated replenishment, smart warehousing and green supply chain are the fields which need more focus.

**Conclusion**

This paper provides a systematic literature review on articles published from 2008 to 2018 regarding the contribution of AI to SCM. We analyzed and synthesized the data from 64 articles in marketing, logistics, production and supply chain. The results were presented through a tabulation of analyzed data and outcomes. Future practical and experimental
studies are highly encouraged to contribute to the expansion of the knowledge base of AI in the SCM field.

Abstract

The present hostile economic conditions highlight the need for organizations to integrate various supply chain (SC) strategies to compete favourably. Lean and Agile are two critical strategies because the former ensures efficient use of resources while the latter involves matching supply with demand in unpredictable markets. This paper aims at advancing their understanding by conducting a review to unravel the state of art of Lean-Agile SC by examining the procedure of knowledge conceiving, transfer and development via the application of “Systematic Literature Network Analysis”. The investigation enabled unraveling research directions/emerging themes thereby supporting researchers/newcomers to target specific theme to explore.

Keywords: Lean strategy, Agile Strategy, Systematic Literature Network Analysis

1.0. Introduction

Market competition is gradually tilting towards the supply chain (SC) level rather than focal company. This is due to diverse and erratic customer behaviour among others as the world becomes a global village. A conglomerate of companies collaborating together is simply SC. It is “a system whose constituent parts include material suppliers, production/manufacturing facilities, distribution services and customers linked together via a feed forward flow of materials and feedback information flow” (Naylor et al., 1999; Soltan and Mostafa, 2015). For SC to survive, adoption of strategies and business models considering overall organizational objectives need be carefully specified.

Various strategies of SC exist in literature among which are Lean, Agile, Resilient and more recently added due to the need to incorporate sustainability measures into SC operations is the Green SC strategy. Lean and Agile are critical strategies because of their abilities to maximize the efficiency by eliminating non-value adding elements, stock control & centralized management as well as optimizing distribution and production activities (in case of lean strategy). Agile strategy on the other hand proffers
advantage by its capacity of response and flexibility to variable market needs plus risk hedging means.

Lean approach is traced to have originated from the Toyota Production System with main spotlight on “efficient use of resources via level scheduling” (Ohno, 1988). It basically works fine in reasonably stable and foreseeable demand scenario and where variety is low. Conversely, agility, whose principal concern is responsiveness, is suited for situations with volatile demand and high variety requirement. It strives “to match supply with demand in turbulent and unpredictable markets” (Christopher et al., 2006).

The present hostile economic conditions highlight the need for organizations to integrate various SC strategies in order to compete favourably. According to Krishnamurthy and Yau (2007), “there are three general positions with respect to lean and agile: those who believe that they are distinct and cannot co-exist (e.g. Harrison, 1997), those who believe that they are mutually supportive strategies (e.g. Naylor et al., 1999), and those who believe that leanness must be a precursor to agility (e.g. Hormozi, 2001)”. In reality the two approaches can complement each other.

Hence, careful adoption of both strategies no doubt will lead to organizational performance improvement. This work thereby aims to advance the understanding of lean and agile SC strategies by conducting a scientific review through the adoption of the “dynamic literature review” method named “Systematic Literature Network Analysis (SLNA)” introduced by Colicchia and Strozzi (2012). The method combines both the “Systematic Literature Review (SLR)” and “Bibliographic Network Analysis (BNA)”. Adopting the SLNA approach is considered a supreme choice as its application in other settings (e.g. Strozzi et al., 2017) has proven successful at unravelling state of art of dynamic body of knowledge through identification of research trends and evolutionary paths.

2.0. Materials and Methods
The SLNA has two phases, the “Systematic Literature Review (SLR)” and the “Bibliographic Network Analysis (BNA)”. The SLR phase involves scope definition to carve a niche for the study; studies location to retrieve articles from databases using predefined keywords or search strings; study selection and evaluation to filter out the most applicable articles. The second phase, BNA, on the other hand considers the selected articles in the first phase and applies bibliographic network analyses and network visualization tools.

Articles were retrieved from the Scopus database which alongside “Web of Science” (WoS) is the most popularly used scholarly citation database. Both are similar but the former however has advantage of nearly 60% coverage over the latter (Zhao and Strotmann, 2015). Vosviewer software (http://www.vosviewer.com/) was used for building the citation network as well as preparing input file for another software package, Pajek. Pajek software is a Social Network Analysis tool and was deployed in building the main path.

3.0. First phase of SLNA methodology: SLR

3.1. Scope of the analysis
As stated earlier, this work focuses on lean and agile SC strategies. A structured literature review on both strategies could help both practitioners and academia at unravelling the trend and most developed practices of lean and agile which proves a great deal at improving the performance of the organization.
3.2. Locating study

Keywords definition is essential for locating the study. From literature, the following sets of keywords are identified for lean – ‘lean’ and ‘leanness’; for agile – ‘agile’ and ‘agility’ as well as ‘leagile’ that combines the two. The query applied on Scopus database is as follows: ‘lean’ and ‘agile’ OR ‘leagile’ OR ‘leanness’ and ‘agility’. This step is considered crucial as outcomes might change with any change in the applied query. We chose not to incorporate the specific terms connected with supply chain in the chosen keywords at this stage so as not to limit the number of papers to be retrieved. Also, going through literature, we discovered some authors do not relate lean and agile to the whole supply chain, but were specifically related to manufacturing. Hence, the chosen keywords allow us to see lean and agile both directly connected with manufacturing or the entire SC.

3.3. Study selection and evaluation

The identified keywords were used as search query in Scopus database at the end of December 2018 in the ‘Title’ field because we are interested in papers that have lean and agile as the main goal of their analysis. Time restriction was not placed while filtering papers and only papers published in English language are considered. Also, only articles published in journals, conference and review papers were considered in the document type, while the subject areas include engineering; business, management and accounting; decision science as well as computer science. 210 works were retrieved.

3.4. General characteristics of selected studies

As stated in the study selection section, this review work is based on the 210 papers obtained from the SLR phase. In this section, we briefly analyse the features of the selected papers. Firstly, the retrieved articles show that the last decade has witnessed increasing growing trend towards this research area as significant amount of literature revolved around lean and agile strategies. Figure 1 shows how there is a growing trend from 1 article published in 1994 up to 10 in 2009 and 23 in 2018.

Interesting to note is the diverse geographical spread of the papers as they comprise contributions of authors from 42 countries. It is however worthy to note that authors from UK, US, India, Finland and Portugal constituted majority. Distribution of authors by countries is depicted in figure 2.

![Fig.1: Distribution of articles by publication year](image_url)
Fig. 2: Distribution of authors by Country

4.0. Second stage of SLNA methodology: BNA
The 210 articles resulting from the SLR phase constitutes the input for the BNA phase. These were considered as relevant works for the analysis at hand and hence, were included in the citation network analysis.

4.1. Citation Network Analysis (CNA)
In order to perform the CNA, the isolated nodes need be excluded in the network. Isolated nodes are articles which are neither cited nor citing any article in the network. Out of the 210 papers, the only connected component consists of 122 papers while others are isolated; hence, we extract the connected ones for further analysis.

4.2. Analyzing the Connected Component
The connected component is shown in figure 3. To analyse the component, the Main Path (MP) algorithm is deployed. The MP extracts main streams in the evolution of articles by identifying papers that constitute a hub of research realm. Indeed, as Strozzi et al. (2017) pointed out, “the main path underscores the papers that build on prior articles but continue to act as hubs in reference to subsequent works”.

Fig. 3: The connected component of the citation network
The main path of the connected component is depicted in figure 4. The papers range from 1996 to 2018 and their main subjects concern how the lean and agile strategies are associated for better organizational performance as well as the strategic combination of the two paradigms to form leagile. Also covered are frameworks covering their drivers (both internal and external) as well as for measuring their impacts on organizational performance.

![Fig.4: The Main Path of the connected components](image)

The oldest paper of the path, Richards (1996) relay how the term ‘agility’ was initially coined by the US Air Force strategists which to them means ability to change manoeuvre rate of aircrafts before subsequently becoming acceptable strategy to the entire military as the ability of friendly forces to be more proactive and reactive faster than the enemy. He stressed how the notion of agility applies to the business concept where the strategy is for the competitors to fight for customers. He defined agility in manufacturing as “the ability of an enterprise to thrive in a competitive environment of continuous and unanticipated change by responding quickly to rapidly changing markets driven by customers’ valuation of products and services” (Richards, 1996). He further emphasized how the lean production concept is associated with agility. For instance, he argued that inventory elimination which is a concern of Just-in-Time pillar of lean is also required of agility. He further submitted that value creation, which is the centre of lean strategy, can not be determined within the four walls of an organization without considering the ever changing needs of customers who alone can ascertain if any value was added in a production process – This is part of what agility preaches. In the same vein, an agile enterprise also needs to produce products and services that customers want to buy, more than they want to buy those of the competitors in order to avoid stockpiling of inventories – This is one of the preaching of lean philosophy. On overall, the paper stresses the link and association between leanness and agility. Also tolling this line, Christopher and Towill (2000) used the notion of “market qualifiers” (criterion to enter any competitive arena) and “market winners” (particular competencies to win an order) to stress the criticality of the connection between lean and agile strategies. The winning criterion for the former being cost while it is service and customer value enhancement for the latter. In real life, these criteria are essentially corroborative in a competitive environment, hence, buttressing how the association
between the two paradigms could be beneficial to organizational SC. They also added that *leanness* might be an element/portion of *agility* in specific situations; it will not on its own allow the organization meet the exact needs of the customers rapidly. The authors however stress the role of *decoupling points* for the connection between the two strategies. Accordingly, correct positioning of *decoupling points* for information and material flows allow a *hybrid SC* to be engineered. “This encourages *lean* (*efficient*) *supply upstream* and *agile* (*effective*) *supply downstream*, thus bringing together the best of both paradigms” (Naylor et al, 1999; Christopher and Towill, 2000). The paper ultimately proposes a “*cyclic migratory model*” that depicts the PC supply chain qualities while evolving from its *traditional SC* to its current personalized *leagile* operation.

Similarly, McCulen and Towill (2001) while drawing on the result of their SC modelling and dynamic simulation of a case study on a precision engineering factory in the UK indicate a connection between the two approaches. They concluded that viewing manufacturing within SC as a whole makes it possible to perceive how *agile manufacturing* can include the *lean paradigm*. Other authors e.g. Stratton and Warbutton (2003) also investigated the strategic integration of agile and lean paradigms by exploring the *role of inventory and capacity* at accommodating the growing demand and variety uncertainty. Narasimhan et al. (2006) on the other hand discussed *leanness* and *agility* as *manufacturing paradigms* and *performance competencies*. Their empirical research attempted to verify whether *lean* and *agile* strategies occur with any form of uniformity in production plants

Agarwal *et. al* (2006) on their part analyse the relative impact that different *pre-identified enablers* have on *lean*, *agile* and *leagile* SC strategies. Specifically, the paper develops a framework, using “*Analytic Network Process*” (ANP) approach, for modelling performance of lean, agile and leagile SC on the basis of interdependent variables. The ANP methodology allows the authors to assess the impact of various identified performance dimensions on the specified supply chain objectives like prompt response to customers’ demand. It also shows the influence and interdependency of the determinants. For the case study adopted in the study, the framework suggested better performance weighted index for *leagile* supply chain as compared to mere *lean* or *agile* strategy. This favours the policy of combining the 2 strategies as against adopting either uniquely. However, the authors noted that the results can not be generalized yet as the only sector considered is a Fast Moving Consumer Goods (FMCG). Similarly, Hallgren and Olhager (2009) examined factors (both internal and external) driving the selection of lean and agile operations capabilities with corresponding impact on operational performance. The result of their analysis via structural equations modeling shows that *the two strategies are unique in drivers and outcomes*. While the adoption of *cost leadership strategy* drives the *lean approach*, *operational flexibility in terms of product mix and volume* drives the *agile approach* (Hallgren and Olhager, 2009). This again confirms the work of previous researches earlier reported; hence, adopting the two strategies prove a great deal at improving the performance of organization.

Furthermore, Krishnamurthy and Yauch (2007) on their part tried to build on the notion of *leagility* as discussed among scholars with respect to supply chains and focal manufacturing plants. Specifically, they tried to find out whether *leagility* concept can be useful to a multi-unit corporate enterprise by investigating one that displayed both *lean* and *agile* qualities and whether a *decoupling point* would be evident. The results of their simple case study in form of “*theoretical model of leagile organizational infrastructure*” show how *leagility* as a concept can be applied to a multi-unit corporate enterprise. According to them, akin to previous *leagile* models devised for SCs and
manufacturing facilities, calling a manufacturing system leagile is hinged on the boundary location around the system or sub-units within the system – This is decoupling point and affirms its necessity when combining lean and agile characteristics to form leagile strategy.

Soni and Kodali (2009) in an attempt to justify the leagile SC strategy developed a “multi attribute decision model” in form of “performance value analysis” which was demonstrated and validated with an auto component SC case study. The result of the case study showed that leagile strategy outperformed the traditional SC as well as lean and agile considered singly for all the fields of performance measurement considered. Naim and Gosling (2011) conducted a literature review specifically on articles citing Naylor et al. (1999) in order to ascertain the degree at which the leagility concept is receiving assent and adoption among scholars. They highlighted the broadening of the leagility notion to contain not only the decoupling point, which signifies the possibility of having different leagility types. Subsequent upon this, Purvis et al. (2014) extended the leagility concept outside the material flow decoupling point by proposing “leagile with vendor flexibility systems (i.e. one that combine use of agile vendors with lean sourcing)” and “leagile with sourcing flexibility systems (i.e. one that combine use of lean vendors with agile sourcing)”.

Soltan and Mostafa (2015) on their part noticed little researches on performance measurement at the plant level as regards the lean and agile strategies. Thus, they proposed a framework to assess the general performance of a manufacturing organization at the enterprise level based on lean and agile strategies. Stankevice et al. (2018) while realizing the era of innovative capabilities and advancement in manufacturing and the SC as a whole (e.g. era of smart factory; industry 4.0; smart logistics etc.) expressed the need to include innovation into the discussion of leanness and agility. They proposed an integrated theoretical framework that links different innovation practices with low performing, lean and agile enterprises. In more detail, the paper attempts to align innovation practices with enterprises’ capabilities development trajectories towards leanness and agility and conceptualizes an integrated theoretical framework of innovation-based capability development sequence.

As noted in the citation network, some papers among the retrieved set of scientific works constitute outliers because there are no citations linking them; hence, they could not be included in the analyzed connected components in the CNA phase. To compensate this drawback, we performed additional analysis - Global Citation Score (GCS) - on the whole data retrieved from Scopus.

4.3. Global Citation Score Analysis

GCS analysis is useful for detecting seminal works in a particular research field. Papers having high GCS on the concerned database (Scopus in our case) are usually recognized as seminal or prominent papers in a field of knowledge (Knoke and Yang, 2008; Strozzi et al., 2017). However, there is possibility of having seminal papers with significant amount of citations on the Scopus database that will not appear in the citation network. This can be observed by comparing the GCS with the CNA. The top 5 most cited papers as shown in table 1 are ordered in line with their GCS signifying their entire citations in Scopus.

In table 1, we can see that some of the papers belonging to the man path are indeed significant in their topic - not just within the citation network. Also, the two additional papers (# 1 and 4) confirm the increasing considerations for lean and agile SC integration for improved organizational performance.
Table 1: GCS of the 5 most cited Papers

5.0. Conclusions and Research Agenda

This study presents a quantitative bibliometric analysis on the lean and agile SC paradigms, counting on software tools and their algorithms that enable us to perform a dynamic demonstration of knowledge evolution over time. In so doing, we provide a big view of the knowledge on the subject in order to identify some research trajectories and present agenda for future research. From the analysis, some interesting research agenda are identified and a few of them are discussed as follows.

While acknowledging works describing the relationship between SC paradigms and the performance outcomes via frameworks/conceptual model, most of them were anecdotally established from literature review without empirical/statistical validation (e.g. Carvalho et al., 2011; Galankashi and Helmi, 2016 etc.). Even where such models are validated with real-life case studies, bulk of them is on automotive SC (e.g. Cabral et al., 2012; Elmoselhy, 2015 etc.). Hence, more studies where the SC paradigms and relationship with performance outcomes would be empirically/statistically validated on other case studies are recommended.

Ghobakhloo and Azar (2018) obtained that advanced manufacturing technology (AMT) enhances development of lean and agile manufacturing strategies. We submit that these technologies alongside pillars of industry 4.0 technologies capable of acting as enablers to lean-agile strategies should be explored while their impact on SC performance outcomes modelled and subsequently tested and validated. Recall that the era of innovative capabilities and advancement in manufacturing and SC was realized from our main path (Stankevice et al., 2018). Hence, it will be a “hot cake” for future research to move towards identifying innovative capabilities and AMT/industry 4.0 technologies capable of driving various SC paradigms for improved SC performance.
From methodological point of view, it could be interesting to apply and compare different methods of modelling relationship between SC paradigms and performance outcomes. Methods like “Analytical Network Process (ANP)”; “Analytical Hierarchy Process (AHP)”; “Interpretive Structural Modelling (ISM)” and “fuzzy approach” could be combined in a single case to see the result of the relationship from each method. This perhaps could reveal the firmness of one method over another or to solidify researchers’ output if different methods reveal similar results.

As we cannot discountenance the potential demands that lean-agile strategies will place on workforce of organizations who are at the beginning of adopting the strategies, it will be interesting to include human factor consideration, viz-a-viz change management perception from the workers’ perspectives into future researches. Also, contributions that management can make at improving their workforce capability in lean-agile environment should be studied.

Conclusively, this study is not without limitations with the main one being that citation data are retrieved from a single source. Albeit, Scopus has coverage of 60% larger than WoS as stated earlier, it still doesn’t represent all scientific contributions in the studied field. Future studies may select articles from other databases to compare the results on the research trends that will evolve.

Notwithstanding the drawback, this systematic review could give an outlook of the most established study areas in lean and agile SC paradigms thereby assisting newcomers to aim and adopt any of the identified themes as their research focus. Lastly and holistically, a stimulating output of this research is the demonstration of the utility of SLNA as a research means to aid dynamic analyses for unravelling agendas and themes for upcoming research in the realm of lean and agile strategies.

Abstract
This study aims to examine the impact of AGVs on Flexible Manufacturing Systems (FMS) using a systematic literature review of published articles. The initial keyword search in management and business literature produced 1066 articles of which 75 articles were finally included in the analysis representing 59 academic journals and conference publications. Thematic analysis revealed the following key themes: Smart and Flexible Manufacturing Systems; Scheduling and Routing of AGVs; Synchronizing RFID with AGVs; Human-Machine Interface; Sustainability (Economic, Environmental, Social and Employment) Impact of AGVs; Reshoring–Nearshoring phenomenon; Internet of Things (IoT).

Keywords: Autonomous Guided Vehicles, Flexible Manufacturing Systems, Systematic Literature Review

Introduction
Industry 4.0 represents a new industrial paradigm based on the adoption of disruptive technologies such as Autonomous Guided Vehicles (AGVs) and the Internet of Things (IoT) (Wagner and Walton 2016). Industry 4.0 connotes the increasing digitisation and automation of the manufacturing environment: Advanced robotics, autonomous systems, smart and additive manufacturing are expected to revolutionize traditional ways of producing and delivering value (Wieland, Handfield, and Durach 2016; Koenigsberg and McKay 2010). This is the first time in industrial history that such a paradigm shift has occurred at such an unprecedented degree and pace, creating the Fourth Industrial Revolution (Schwab 2016).

However, despite the hype, few empirical studies have synthesized and evaluated the impact of disruptive technologies such as AGVs on warehousing of existing manufacturing systems and, particularly, flexible manufacturing systems. An FMS in general consists of (Buzacott and Yao 1986): (a) a set of machines or work stations, which have some degree of flexibility, such as that they do not require significant set-up or change-over time; (b) a Material Handling System (MHS) that is automated and flexible, so jobs can move between any pair of machines in flexible job routing; (c) a network of supervisory computers to manage job routing, track job status and communicate instructions among relevant parts; (d) monitoring operational performance and alerting
problems; (e) the jobs to be processed by the system; typically there is a constrained number of jobs an FMS can process simultaneously.

This study aims to examine the impact of AGVs on flexible manufacturing systems using a systematic literature review of published articles. The research questions were: in what ways do AGVs influence the performance of FMS? What are the key areas of research in AGVs in relation to flexible manufacturing and what are the practical implications of these findings? What is the role of AGVs in smart, flexible manufacturing? The study uncovered the following thematic areas: (i) Scheduling and routing (ii) human-machine interface, (iii) smart manufacturing, and (iv) sustainability. This study discusses the first two areas.

Methodology
This study conducted a systematic literature review of AGV studies in relation to flexible manufacturing. The primary information source for this study was journal databases. Two databases were used, Business Source Complete (EBSCO) and ABI Inform Complete (ProQuest), with Google Scholar contributing other articles via snowballing in order to enhance the research. The keyword search strings were divided into four main categories that contributed to the efficient search of the articles related to this study. After running a considerable amount of trial-and-error testing, the keyword search strings were completed.

The identified articles were assessed related to the title and abstract screening criteria. Then, the authors conducted a full-text review assessment in two steps: full paper screening and quality assessment. Full paper screening involved analysis and evaluation of the theoretical and empirical papers, not only by screening the title and abstract, but also the full text, based on the following criteria to ensure the most appropriate papers. Theoretical articles had to involve: (i) detailed information on the theory (e.g., impacts and counter-views related to AGV technology); (ii) a theoretical review of AGV-associated trends and implications which can be used to understand better the current position of this technology; and (iii) discussion on future developing scenarios in warehousing and other industries. Empirical papers had to involve: (i) relevant discussion practices, including trends and future developments, impacts, and changes that have come across in AGV applications in warehousing; and (ii) collecting empirical evidence to enhance the knowledge in different AGV implication aspects involved in warehousing and logistics. Full articles were reviewed based on quality evaluation such as the author's contribution, theory, methodology and data analysis. After quality evaluation, 75 articles were included in the review, 41 of which were directly derived from the keyword search (Table 1).

Findings
The 75 articles were derived from 59 academic journals and conference publications. The top journals, ordered by number of articles in brackets, included: International Journal of Production Research (8), International Journal of Production Economics (3) and IEEE Transactions on Industrial Electronics (3). The number of publications depict the diversity of AGV disciplines, however, the most relevant disciplines that appear to relate to AGV implementation in the warehousing industry include: (i) industrial engineering; (ii) supply chain management and logistics; and (iii) computer-data communication/automation.

The number of publications depict the diversity of AGV disciplines, however, the most relevant disciplines that appear to relate to AGV implementation in the warehousing industry include: (i) industrial engineering; (ii) supply chain management and logistics; and (iii) computer-data communication/automation. Most publications appear during the last five years, particularly in 2013 and 2015. The studies in the context of AGVs began in America in 1953, with Europe following a few years later, while the first AGV was successfully installed in 1954. However, the current research focuses on the “third era” of AGVs from 1991 to 2010, which was mostly using AGVs for intralogistics, followed by the “modern era” from 2010 to 2018. Additionally, it is clear from the chart that before the 2000s the journal articles were limited due to the small growth of AGVs to certain years, namely 1991, 1993, 1996, 1999 with only six journal papers in total. During the third era, academics and managers started to change their views because new technological standards were set and new markets established (Ullrich and Kachur 2015). The majority of the journals used in this research come from the UK (23%) and the USA (23%), together comprising almost 50% of the total research articles, while most of the remaining journals come from Switzerland (8%). A number of internationally highly ranked and reputed journals were published in these two countries (UK & USA) and contributed valuable insights into the research.

AGV applications in warehouses have been widely studied in different regions around the globe. Europe and North America comprise a major part of the research...
conducted on this topic. This occurred because both of these parts of the world have flourishing industries, highly developed and expanded economies with balanced business environments and they are considered to be global business leaders. Additionally, despite the fact that some of the articles’ location sources come from Switzerland, the location of the studies took place in the Netherlands. This change of location indicates a potential rise in the country’s economy which led to a boost in the amount of research. However, the AGV industry remains a relatively new topic in this region and the studies of AGV applications remain immature. Finally, India, South Korea, Italy, and Poland contribute to the research with a small number of articles, which indicates that this field is in its infancy in these countries and is about to increase in the near future. Regarding sectors and industries researched in the AGV studies, manufacturing comprises the highest percentage (55%) followed by wholesalers/retailers (21%). Within the manufacturing industry, the sectors with the most interest from the publication point of view are: (a) industrial machinery (b) computer & communication and (c) electronics.

AGVs and Flexible Manufacturing Systems

AGVs impact FMS systems in terms of design, control, communication requirements and technologies. In FMS design, the criteria and method to integrate AGVs into the system has received considerable attention. Farling, Mosier, and Mahmoodi (2001) introduce a tandem configuration to minimize the common congestion and system control issues. By using simulation techniques to correlate the performance of three AGV configurations under diverse experimental settings, the study found that the system size, load/unload time, and machine failure rate factors have critical effects on the operations performance of the system. Um, Cheon, and Lee (2009) combine a multi-objective non-linear programming and evolution strategy to determine the design parameters of the FMS in terms of including the number, velocity, dispatching rules of the AGV, part-types, scheduling, and buffer sizes. Azimi and Alidoost (2011) use a number of the same criteria for planning issues, such as fleet sizes, buffer levels, processing times and control strategies to estimate the appropriate AGV load, resulting in an integrated approach which binds the material handling system to the FMS. Lee, Tangjarukij, and Zhu (1996) examine different heuristics rules in the operation of multiple-load AGVs in a flexible manufacturing system where AGVs can carry two or more loads, and found that the variable-route-part-priority (VP) rule and fixed-route-part-priority (FP) rule generated significantly higher throughput than their counterparts, while the 'pick-all-send-nearest’ (PN) rule outperformed the other rules in part flow-time and work-in-process. Seo and Egbelu (1999) conducted a study concerning the material processing and transportation functions and showed that by simultaneously decomposing the integrated planning model into two sub-problems - machine selection and operation sequencing and flexible guide path design - led to enhanced flexibility in operational processes.

Furthermore, related to the operation dynamics of the production system, another important factor is the estimation of the number of vehicles in the FMS. Vivaldini et al. (2016) extend the work of Mahadevan and Narendran (1993) by developing an analytical method to estimate the minimum number of AGVs required to execute a given transportation order within a specific time-window. Regarding FMS control, the literature proposes two approaches for the routing of AGVs in the FMS: real-time routing and the hybrid model. Buyurgan et al. (2007) modelled real-time routing in a random FMS to use an evolutionary algorithm-based intelligent path planning model and found that this model outperforms the traditional dispatching rules for real-time routing of AGVs in many cases. Similarly, Abdelmaguid et al. (2004) used evolutionary algorithms to address simultaneous scheduling the machines and the AGVs in the FMS while Corréa, Langevin,
and Rousseau (2007) presented an hybrid method to to solve scheduling and conflict free routing of up to six AGVs. Abdelmaguid et al. (2004) used a hybrid GA/heuristic method while Corréa, Langevin, and Rousseau (2007) used a decomposition method. Maughan and Lewis (2000) note that in FMS design, an AGV can be used as both the materials handling unit and the communications line linking each station to the host controller and demonstrated that a control software can allow real-time communication between the AGV and peripheral equipment using a standard infrared data link, eliminating hard-wiring and network protocols.

**Scheduling and Routing of AGVs**

In the past few decades, scheduling and routing of AGVs has drawn considerable attention. Scheduling and routing methods are often mutually connected to achieve the best results within warehouses, such as applications that involve many actions (Qiu et al. 2002). Routing is described as the AGV’s ability to make decisions according to the given guidance paths in order to identify the optimum routes to definite destinations (Martínez-Barberá and Herrero-Pérez 2010). Scheduling involves the allocation of resources to assignments over time and it is a decision-making process that connects the diverse operations, time, costs and goals of the company (Rubrico et al. 2006).

The AGV’s controlling algorithms rely either on centralized or decentralized warehousing design architectures (Martínez-Barberá and Herrero-Pérez 2010). Centralized control is when one central AGV executes various intricate assignments, like mission scheduling, path planning, and movement coordination, while decentralized methods are described as distributed network systems with high levels of AGV autonomy. Based on these two warehousing control architecture systems, the scheduling and routing of AGVs can be programmed. An AGV network can be described as a map including nodes linked with a set of arcs. Each arc is linked with a cost or the related time required by an AGV to cross it. This map acts as the main input to the routing algorithm (Co and Tanchoco 1991). However, these general path topology algorithms consider the routing problem as the shortest path issue, which confuses the trace of nodes and arcs, especially when the time is limited (Qiu et al. 2002). Additionally, the optimal solution may be omitted due to certain imposed limitations. This may lead to failure in identifying a feasible route or induce delays. These algorithms are more appropriate for the small number of AGVs and small size of path networks (Qiu et al. 2002). On the other hand, specific path topologies give acceptable solutions, such as single or multi-loop, segmented path and mesh (collision and bottlenecks, etc.), are easily removed and routing control is simplified. Although these algorithms have been highly implemented in the manufacturing industry, they do not permit many AGVs to be routed simultaneously. Routing can be static or dynamic (Hodgson et al. 1985). Static routing is when the AGVs’ path between any two nodes is determined, while in dynamic routing AGVs can select different paths from one node to another. An essential routing issue is when collisions occur during processes. Rear-end collisions should be prevented and the flow of AGVs into an intersection should be regulated (Egbelu and Tanchoco 1982). Koff (1987) recommends zone control as the most reputed and trustworthy method, preventing AGVs from entering a zone already taken by another AGV.

Additionally, by implementing heuristic rules and diminishing the frequency of AGVs encountering an intersection could decrease AGV waiting time. The optimal situation with zero intersections is the circular or single-loop layout (Co and Tanchoco 1991). In regular systems with few intersection points, AGVs can trace their routes autonomously; however, in complicated layouts, traffic management control is more
effective (Bose 1986). As far as routing interruptions are concerned, Narasimhan (1999) conducted analysis for re-routing AGVs and used route databases to acquire previously created paths in order to quickly re-route the AGVs when interruptions occur.

Martínez-Barberá and Herrero-Pérez (2010) used topological and grid-based maps for routing and showed that the adoption of these tools assists in obstacle avoidance and is recommended for small zones and fast planning. On the other hand, scheduling AGV movements are beneficial for projecting traffic flow, congestion and in making predictions when a busy AGV will be set free from its last assignment. Taghaboni and Tanchoco (1988) point out that two AGVs should not be employed in the same node simultaneously and thus routing should be dynamic to avoid collision. Scheduling of multiple-picking AGVs for warehouse management is also addressed in the literature (Rubrico et al. 2008). For example, Rubrico et al. (2006) suggested a hierarchical decomposition of the multi-AGV-picking problem and found that by decreasing the total time needed to pick a given batch of orders favourably influenced both throughput and due-date satisfaction.

Another area of research is the synchronization of contactless technologies such as RFID with AGVs. RFID is a contactless automatic identification technology (Yamano et al. 2004) extensively used, among other applications, in warehousing to track and trace items and provide supply chain visibility in real-time (Ahmad and Mohan 2014). Within an FMS environment, RFID provides real-time inventory tracking at shelf level (Lu, Xu, and Zhong 2016); however, when AGVs also operate in the same space, there is a need to coordinate and synchronize them to achieve smooth flow inside the warehouse. Zecca et al. (2009) recommend a coordination algorithm to achieve synchronization and collaboration efficiency within a swarm of robots by linking both RFID-tags and robot-to-robot intelligence to harmonize and regulate the swarm and achieve autonomous collaboration without a pivotal framework or global network time.

**Human-Machine Interface**

Human-Machine Interface (HMI) is described as the contrast between safety, harmony, and cooperation among humans and robots (Villani et al. 2018). Even though there is a high degree of automation in FMS, human interference always exists, i.e., in a lean environment where the merits of the automation (high accuracy, velocity, and repeatability) are combined with the flexibility and intellectual skills of the workers. However, HMI, in the case of AGVs in FMS, imposes several challenges in terms of safety, collaboration, and coexistence (Cardarelli et al. 2015). A safe interaction should be assured to avoid the injury of operators when directly contacting the AGVs. It is essential that intuitive user interfaces are correctly outlined so that the programming and physical or cognitive interaction with the AGVs can be easy (Villani et al. 2018). Three safety standards have to be addressed in HMI: Type A that include the fundamental safety prerequisites for common requirements that apply to machinery, type B that are related to generic safety standards, and type C that involve personal safety measures against particular machinery types.

Collaborative operative modes, as stated in *ISO 10218-1/2*, are also important for the co-existence of humans and robots (Dietz et al. 2012). Certain challenges make prerequisite the risk assessment, particularly for those operations that involve dynamic collaborations(Knoop, Pardowitz, and Dillmann 2007) One of the main issues identified in the HMI literature is when the operator is required to have specialized knowledge to interact with the AGV which necessitates intuitive user interfaces and specialized AGV programming (Zoliner et al. 2005). The first method to robot programming is the
conventional lead-through programming, which is based on the usage of a teach pendant for moving the robot via the required motion cycle, by nudging (Villani et al. 2018). However, this method requires programming for each new task, it is only suitable for programming simple tasks and it is time-consuming and expensive (Dietz et al. 2012). To overcome these limitations off-line programming (OLP) is used, by programming the robot from a computer rather than on the robot itself. Modelling and simulation are used to depict graphical representation and the possibility to identify possible collisions (Villani et al. 2018). Nevertheless, according to Pan et al. (2012) employing an OLP system is very expensive and demands great programming effort.

A new approach is a multi-modal interface in which sensing is used to improve the human-machine interface (Roitberg et al. 2015). Sensors enable robots to imitate workers and behave more like humans. Thus, the communication gap between user and machine is diminished and workers do not need previous experience to interact with robots (Cardarelli et al. 2015). Another method is vision-based programming, in which the robot recognizes human gestures and facial expressions and transfers them to the robot for motion imitation (Zhang and Yu 2018). Cardarelli et al. (2015) implemented a 3D visual representation to manage the fleet of AGVs with a centralized data fusion system called Global Live View. This system updates visually both static and dynamic elements in the environment, is very simple to use and does not require the operator to have special knowledge. Similarly, the vocal commanding method appears to be very useful when hands-free intervention is needed. The main advantage of this method is that it does not restrict the operator’s movement. However, misrecognition of the voice instructions and the possible peril of delaying production, efficiency and safety is the reason for the lack of such systems in the industry (Rogowski 2012). Finally, analysis around the augmented and virtual reality programming methods revealed that productivity is increasing and human safety is enhancing (Michalos et al. 2016). The difference between the two methods is that in the former user retains a sense of presence in the real world, while the latter enables a fully engaging environment where the operator’s senses are captivated by the system.

Discussion

This study has conducted a systematic literature review of AGV applications in warehousing and particularly in flexible manufacturing systems, which can be considered as complex systems consisting of people, technology and operational processes (Geels 2004). Industry 4.0 connotes the increasing digitization and automation of the manufacturing environment to higher levels of productivity and competitiveness (Koenigsberg and McKay 2010). The design and integration of Industry 4.0 technologies requires novel business models that integrate these innovative technologies with existing manufacturing practices and engineering processes to increase performance in terms of efficiency, productivity and competitiveness. The literature review has revealed the following key areas: (i) flexible manufacturing including improved scheduling/routing of AGVs and the human-machine interface, (ii) smart manufacturing, and (iii) sustainability. Studies have examined the scheduling and routing of AGVs from many different perspectives and the results indicate that the scheduling and routing should be in-sync on either centralized or decentralized warehousing environments (Draganjac et al. 2016; Martínez-Barberá and Herrero-Pérez 2010). Certain studies highlight the necessity of minimizing the waiting time with zero intersections of AGVs. For simple warehouse layouts, the circular- or single-loop layout is recommended while, in complex layouts, traffic management control is found to be the most suitable (Bose 1986; Co and Tanchoco 1991). However, most of the articles focus on collision, interruptions and bottleneck
avoidance (Koff 1987; Narasimhan 1999; Qiu et al. 2002). The most important solutions to those issues involve reputed methods such as single- or multi-loop, segmented path, mesh, topological and grid-based maps, the zone control method and certain rerouting algorithms that have resulted, also, in better AGV performance (Co and Tanchoco 1991). Lastly, heuristic and metaheuristic methods for the scheduling of multi- picking AGVs in warehousing are introduced to regulate the delay issues, diminishing the make-span and enhancing throughput and due date satisfaction (Rubrico et al. 2008). Related to the RFID-based tracking technologies, its purpose is multi-dimensional when it is linked with the AGV system inside a warehouse. A method is illustrated for controlling and tracking the randomness of inventory located in a warehouse environment (Akerlof 1978). It is also found that RFID improves AGVs and shelf-positioning inside a warehouse (Zhou et al. 2017). The foundation on which human-machine cooperation is relied upon is the combination of the terms safety, coexistence and collaboration (Villani et al. 2018). Additionally, various safety standards and collaborative operative modes were illustrated in the study that highlighted the necessity for the operators to follow the legislation rules (Dietz et al. 2012; Pan et al. 2012). Regarding smart manufacturing, AGVs help manufacturing systems become more agile and flexible by: (a) reducing production bottlenecks and deploying the workers more effectively through the tandem system configuration (Farling, Mosier, and Mahmoodi 2001); (b) combining new sensor and software technologies which are ideal for unpredictable or changing production layouts and dynamic work environments. The proposed solution is by simultaneously decomposing the integrated planning model into two sub-problems, namely machine selection and operation sequencing and flexible guide path design (Seo and Egbelu 1999); (c) operating the AGV controller independently with the Manufacturing Work Order on board. Hence, better manoeuvrability of the system is achieved without causing interruptions (Maughan and Lewis 2000).

**Limitations and Recommendations**

This study conducted a systematic literature review which has several limitations. Firstly, despite the adoption of an extended systematic literature review the data collection process accomplished depended upon three databases, namely ABI, EBSCO and Google Scholar, which restricted the study to articles accessible via these platforms. Secondly, AGV adoption in flexible manufacturing is considered as an emerging practice, thus the academic literature is relatively limited compared to other sectors, such as the shipping industry. Lastly, in the field of the AGVs’ engineering parts, the literature is still evolving, and it was not included in this review. Future studies on the topic of AGV usage should go beyond flexible and smart manufacturing and examine lean manufacturing too. Although this study demonstrates the developments and effects of AGVs in the warehousing industry, studies of the effects of AGVs on sustainability, particularly social and economic, such as and resourcing-nearshoring are scare.

Abstract

Decision models of industrial management articles are often based on an economic criterion to find the proposed solution. They use economic parameters that are generally imported from the firm cost accounting system. When cost information is not adapted to the decision, the obtained solution of the model may be invalid. In this article, we deal with a critical literature review to report the methodological problems encountered in industrial management articles vis-à-vis the used costs. Finally we suggest methodological propositions to be kept in mind by authors when they are using costs in decision models.

Keywords: Industrial management, mathematical model, economic model

Introduction

We are interested in the management of a supply chain (SC) or a sub-system of a SC. It concerns strategic, tactical and operational decisions taken to design, and run production units. To improve their decision making process, managers call in decision models that attempt to reproduce, through a simplified physical model, the functioning of the studied productive sub-system. In these physical models, decisions to take are represented by decision variables that determine, through a number of causal relationships, their impact on some physical characteristics of the studied system (flow, stock, resource use …). Decision variables may be quantitative (capacity of a new plant, reorder points…) or qualitative (opening or closing facilities, production orders assignment…). Across a modelling, we focus more particularly on certain physical quantities calculated by this model and linked to the decision variables, because they condition the performance of the studied system. In modelling, these physical quantities are generally called...
state variables and are used with costs to obtain an economic evaluation of the considered alternative decisions (Giard, 2017).

The physical model is bounded to a studied physical subsystem exchanging flows of goods and/or services with its environment. In a decision model, evaluation of alternative decisions lays on a criterion in relation with the global performance of the studied subsystem. Such criterion may be physical (machines utilization rate, % of unsatisfied demand…) and, in this case, it’s supposed that the variation of the company financial performance (cost or margin) is linked with the one of the considered physical criteria and is assumed to vary always in the same direction (or in the opposite one). The decision criterion may be economic and called on costs information provided by a cost model. In that case, the relevance of the solution provided by the decision model depends on the compatibility of the implicit assumptions of the physical system functioning, used by the cost system with the one used in the decision model. A significant discrepancy invalids the relevance of the proposed solution. Most often, authors focus on the physical model development techniques and resolution methods, without paying attention to the consistency of the implicit functioning assumptions of the used cost model with the one of the physical model used by the decision model. It is assumed that the modelling teams can work independently of those of management accounting. The costs regularly provided by a firm management accounting system, cannot be suitable to any type of use.

This paper present a critical literature review to see to what extent authors check the adequacy of the used cost model with their developed decision model. In each article we dissect the economic function to highlight the considered costs, the way they were defined vis-à-vis the considered time and space horizons and whether the authors studied under which conditions, the proposed solution remains valid, especially when the given solution impacts the system design and the use of its productive capacity.

The rest of this paper is organized as follows, we begin with the theoretical framework, next we present the adopted methodology of the review. Subsequently we report the encountered methodological issues. And finally propositions of contributions and the conclusion are presented.

**Theoretical framework**

We focus here on a description and a literature review of the main theoretical concepts, that are necessary for the discussions dealt in the present paper. Firstly, we deal with highlighting the decision model characteristics, thereafter, we present some cost accounting approaches and briefly some economic concepts and costing theories.

**Decision model underlying characteristics**

Decision models are developed under the assumption that we can explain and capture the behavior of a physical system and/or a decision making process dealt by managers. Causal relationships exist between the considered variables of the model. These causal relationships enable the model to predict the future state of the modeled physical system (Bertrand and Fransoo, 2002).

A decision model has two key characteristics, they are space and time granularities (Giard, 2017). The space granularity concerns the covered perimeter of the studied productive system and the degree of details considered which in turn, determines the granularity of information provided for the user. The time granularity, defines whether the model deals with an operational, tactical or strategic issue. Space and time granularities are not independent; in general, the granularity is fine in operational decisions analysis and more aggregated in other cases. Granularity conditions bill of
materials, production routings, product ranges and the definition of resources used in the physical model. It has an essential impact on the relevance of costs to be mobilized.

Concerning decision models development approaches, we can distinguish two main approaches, mathematical (operation research (OR)) and simulation modelling. The first one refers to i) optimisation that gives the best solution for a particular issue, it’s a very visible and influential topic in the field of operations management and, ii) heuristics which are intelligent rules leading to “good” solution and are used when optimization is impossible or too expensive. The second approach refers to all simulation techniques (discrete event simulation, agent-based simulations, system dynamics).

**Cost accounting**

A cost system refers to means by which organizations calculate costs of products and services to make sales profitable. Moreover, cost system concerns the modeling of costs of organizations resources and operations in order to support internal decision making process. Cost information should be useful to help managers in managing the performance and the profitability of products, customers, productions processes... (Lawson, 2018). Here we distinguish the traditional cost accounting and the Activity Based Costing (ABC) approaches:

The traditional cost accounting system in a company aims to allocate, at the end of each month, costs to products and services. It’s oriented toward a retrospective calculation of historical costs. It’s based on a succession of spills of analysis centers expenses to other cost centers by means of volume key distribution. ABC is a cost accounting approach developed from the eighties. It’s based on the principle that activities consume resources, and products and services consume activities. ABC focuses on the activities that take place within the company, the cost of carrying out each activity and the factors generating these activities. It goes beyond the traditional system by allocating resources, based not only on volume units, but also on the diversity and degrees of complexities of the products (Cooper and Kaplan, 1998). Hence, the ABC approach distinguishes different cost pools (activity drivers): unit-level activities are performed each time a unit is produced, batch-level activities are performed whenever a batch is processed, product-level activities (process engineering, design, etc.) are costs which come into play whenever a particular product (order) is manufactured and facility sustaining activities concern costs related for example to rent, utilities, maintenance, and facility management.

Furthermore, an activity cost may evolve in the long run. Value chain analysis is the way to analyse activities in order to achieve competitive advantages by performing these activities better than competitors. Each activity has its structure and behavior, which determine its cost. Porter calls these determinants “cost drivers”. He distinguishes ten possible causes of an activity cost evolution: i) economies or diseconomies of scale (costs sensitive to volume), ii) learning phenomenon (unit costs depend on time), iii) capacity cost utilization (impacts the fixed unit costs), iv) the linkage between activities that makes an activity cost dependent of other activities costs, v) interrelationships (resources share between different strategic units), vi) the degree of vertical integration (impacts transaction costs), vii) the timing (first-mover reward), viii) discretionary policies that refer to products or services design, ix) localisation and x) change in institutional and regulatory factor that may affect unit costs. (Hergert and Morris, 1989) (Bouquin, 1997).

The absence of the concepts of activity drivers and cost drivers in the traditional cost system is one the reasons that make it inappropriate for the study and analysis of operational and strategic decisions respectively. The traditional system is characterised by a lack of cause and effect traceability (Stratton et al., 2009), that makes it inadequate to understand how activities are performed and makes it weak in cost traceability.
Cost concepts
There is a multitude of cost concepts whose use relevance depends on the studied context:

- **Opportunity cost** is a concept that dates back to the nineteenth century. It is proposed by Friedrich von Wieser, (1851-1926) who was interested in determining the production factors value (Burch and Henry, 1974). He defined the opportunity cost as the net income generated by this factor of production in its best use. (Andreani, 1967) linked it to the existence of a conflict between opportunities that could lead to a shortfall. Opportunity costs are the revenues to be gained from possible actions, but lost because other actions have been taken to achieve a particular goal, (Andreani, 1967), (Vera-Munoz, 1998).

- **Marginal cost** is the cost incurred for the production of an additional unit. The marginal cost differs according to whether it is decided to momentarily increase the volume of production by one unit, or if it is decided to increase it durably by one unit (Boiteux, 1951). In the first case, the additional unit is satisfied by the current capacity, but the second case may require an increase in capacity.

- **Variable costs**: the traditional system accounting defines variable costs as those who change with production volume and fixed costs those who do not change with volume. Cooper and Kaplan propose to use short-term variable cost, they vary with production volume, long-term variable costs which do not vary with production volume but do vary with other activity measures (handling, setup…) and fixed costs that do not vary; in a given period; with any activity driver.

- **Capacity costs** are defined by the set of resources (facilities, staff…) in which the company is committed to achieve a given level of performance. This latter is linked to the estimated maximum demand, the intended degree of flexibility to respond to unforeseen demand and the desire to ensure products diversity. These capacity costs, also called fixed costs, are generated form strategic decisions defining the company's strategy and vision (Bouquin, 1997). “Investments in resource capacity are made based on the expected demand because instantaneous adjustment of capacity is impossible and/or extremely costly” (Balakrishnan et al, 2007). The difference between the maximum capacity and the actual activity level is called unused capacity.

Different economic criterions in decision models
Several economic criterions may be used to assess decisions, their relevance depends on the studied decision nature. Here we retain the three criterions of costs, profit and discounted cash flows (DCF) through Net Present Value (NPV). Investment decisions refer to long-run decisions which focus on studying different alternatives of investment (outflows) in one or several periods to generate returns (inflows) in one or several future periods. They differ from operational decisions in the way that their study requires the consideration of the value of money evolution over time (Shillinglaw, 1963) (Lucey, 2003). Hence, the NPV is the appropriate measure to study investment decisions, it calculates the present values of expected inflows and outflows. Operational and tactical decisions study is based on the anticipated current cash flow only. The profit is the sum of revenues minus costs. When the revues are constant (sales and prices are independent of decision variables), profit maximization can replaced by costs minimization. Accounting profits are not suitable for investment decisions, they are period oriented (quarter, year…) (Lucey, 2003).

Costs and spatial perimeter
Issues dealt by decision models may belong to any SC activity: production, inventory management, transportation, pricing, design, relationship management… We note then
that a decision perimeter may either belong to the internal firm perimeter (production scheduling, investment, transportation…) or extends the firm boundaries (interrelationships management). The former case settles for the firm system accounting (intra costing) whereas the latter one necessitates an inter-organizational costing (inter costing). In fact a cost system is contingent to the studied physical system characteristics. Cost accounting systems of two cooperating companies are seldom similar. The difference between the two approaches creates inaccurate costs and ineffective practices (Kulmala et al 2002). Thus, creating relevant approaches for partnership relations is one of cost accounting challenges. Furthermore cooperation between a supplier and customer is based on trust and their readiness to open their book cost accounting. But this willingness to share information (reliability) is not enough, there should be dedicated approaches to generate relevant cost information (Kulmala et al 2002).

Costs at service of SC professionals
Previous research works has pointed out that often SC managers are not satisfied by the cost information provided by their firm accounting system. (Gurowka and Lawson, 2007) presented a road map to help managers in choosing the appropriate costing approach. When cost information is not correct and accurate, the accounting system has no value for the company, worst it can damage the organization decision making.

According to a survey done on 2003 by the Institute of Management Accountants (IMA)/Ernst and Young, only 23% of the interviewed mangers are satisfied by their accounting information, 92% of them state that this information is distorted. (Gurowka and Lawson, 2007) say that if cost information still irrelevant, decisions are irrelevant and over time, departments managers may stop relying on financial criterion and make decisions based solely on non-financial data (more accurate).

The results of a recent survey (Lawson, 2017) shows that supply chain professionals often view their company’s managerial costing system as being only slightly useful for generating questions and for making managerial decisions. According to (Lawson, 2017), three main causes explain this result: i) many organizations rely on externally oriented financial accounting systems to produce the information supporting internal business decision making; ii) many organizations use outdating cost models; these latter are not appropriate for the current organizations challenges and environment; iii) the third cause is the finance and accounting professionals resistance to change. This is amplified by little pressure from managers; who use costs; to improve data accuracy and relevance (Kilcarr, 2018).

In this paper, we complete this previous works, by a critical literature review of articles dealing with decisions models to highlight methodological problems related to the used costing models. It’s to our knowledge, the first article that fully addresses this literature review.

Methodology
The adopted methodology leads to the selection and the evaluation of selected sources. We followed the same methodology adopted by (Maestrini et al., 2017). We first i) identify articles ii) we select articles, and finally iii) we evaluate and analyze them.

Articles identification
For the sources search we relied on the Business Source Complete base (BSC). Since we are interested in the study of the coherence between the developed decision model and the used economic model, we used the key words “industrial management”, “mathematical model”, “simulation model” and “economic model”. To broaden the search range of articles, we used two key words combinations, in the first one we used
“industrial management”, “mathematical model” and “economic model”, and in the second combination we replaced “mathematical model” by “simulation model”.

The use of two key words combinations gave a total of 1225 articles. We relied on SJR site, we investigate the journal scope and $H$ Index. We considered only IJPE, IJPR, POM, OMEGA and PPC whose $H$ Index varies between 61 and 141. We also limited the period of publication, we focused on the period between 2013 and 2018. We therefore get a sample of 202 articles.

Articles selection
We set boundaries to select the relevant articles to be considered in the present review. We select articles in which a decision model is developed to help users in making decisions related to a sub-system of the considered SC, hence there should be explicit variables that determine characteristics (functioning or design) of this system. The selection criterions are discussed and defined by authors of the present paper, and the task is done by two authors based on the abstract, the conclusion and eventually the introduction. Consequently, we selected a sample of 113 articles.

Articles evaluation and analysis
To evaluate the selected articles we started with an analysis grid. This grid attributes were defined based on previous literature review works (Maestrini et al., 2017), a SC taxonomy developed by (Capar et al., 2004) and additional attributes deduced from the theoretical framework above.

We begin with articles journal of publication. In the second stage we present the modelling approach on which the decision model is based (Bertrand and Fransoo, 2002). Thereafter, we highlight the considered time granularity in each article (Anthony, 1965), (Ansoff, 1980) and the considered perimeter that implicitly determines whether it’s an inter or intra costing. We additionally mention the considered objective function physical or economic and whether it’s costs, profit or NPV and the mobilized cost concepts. A grid summary is presented in table 1 bellow.

Findings
In this section we will present the mains results obtained from the reviewed articles analysis. We begin by reporting the articles journals of publication. In the second stage, we report the decision criteria. And finally, we focus on articles in which an economic model is used, in order to highlight the main encountered methodological issues.

Publication journal
The final number of the reviewed articles is 113. The largest percentage 49% of articles belong to IJPE, succeeded by 40% that bong to IJPR, and succeeded by 7%, 3% and 2%, that belong to OMEGA, PPC and POM respectively.

Decision criteria
13 out of 113 articles deal with problematics in which the developed decision model gives the solution based on the minimization or the maximization of a physical criteria. Most of these articles (11 out of 13) deal with operational and tactical levels issues

12% of articles consider both an economic and physical criteria. In the rest (76 %), the choice of the proposed solution is based solely on an economic criterion. Hereafter, we will exclude articles which are limited to the study of a physical criteria, we retain 100 article.

Encountered methodological issues
In this stage we based on the grid analysis to report the widespread methodological problems encountered in each article.
This figure presents for each decision level the SC activities dealt with. Below, we discuss issues related to cost content explanation (activity drivers), costs traceability, inter or intra costing nature, appropriateness of used economic criteria, capacity costs, cost drivers in the long run and finally the eventual impact of the obtained solution.

In the quasi totality of the reviewed articles, the authors gave no explanation about the used economic model parameters. These latter, are considered as given parameters provided by an external source which is generally the firm accounting system. They do not discuss the relevance of the used cost content according to the spatiotemporal perimeter. This suppose the assumption that modelling and accounting teams can work independently, as if costs could be absolute. No article uses activity drivers to define the relevant content of the used cost parameters. In some articles the authors give details about some used costs, for instance in [90] the unit transportation cost “includes costs of fuel, salaries, wages, operating supplies, insurance, and depreciation”, [62] explain that the unit inventory cost is due to “inventory obsolescence costs and capital costs related to slow-moving parts”, and that the unit manufacturing cost excludes all capacity costs (e.g. machines depreciation).

Generally a firm system accounting has its standards, it regularly calculates costs at the end of a predefined period (month). When a decision model is developed, it may necessitate the introduction of some specific costs that the firm system accounting is regularly not interested in. So here we identify a problem of traceability. In [69] and [105], the salvage value is difficult to be determined a priori, elsewhere there should be a sufficient data to can to estimate it. [37], [66]... models use penalty cost of unsatisfied demand, [103] developed a model for a retailer replenishment under supplier prices discount, and he uses a penalty cost induced whenever the retailer change his order quantity. [12], [33] mobilize the opportunity costs which are future costs that need to be known a priori. In [98] costs of non-conformity and rework cost are considered. Furthermore, some papers deal with batch or order level costs, if the firm system accounting is not based on ABC approach, these costs are not provided. Here then, we mention that there are several costs that are needed by the developed decision models in a company but for which there is no traceability in the system accounting.

The objective in [69] is the comparison between different relationship scenarios between a manufacturer, a distributor centre (DC) and a retailer (i) not using contract, (ii) using buyback contract or (iii) revenue sharing contract. [105] developed a model to coordinate between a supplier and retailer, it determines e-concession as a decision variable (a concession that both retailer and supplier need to make to maximize the whole system profit). Their model mobilizes the following economic parameters the supplier production cost, the retailer wholesale price, retailer salvage value and the retailer shortage penalty. [21] focus on the comparison between centralized and decentralized strategies between a retailer and its supplier. These examples of articles and others that compare different relationship strategies between different SC players imply that the applicability of the presented models is conditioned by the involvement and willingness of the considered firms to collaborate and share their costs information with other firms, which is not evident in practice. Through this inter costing necessity we signal the problem of the model perimeter which presents a new methodological issue.

In several of the reviewed articles, the authors deal with some top strategic issues. [37] developed a decision model for a network design, it determines facilities (production plants, warehouses and DC…) to be opened, the supplier selection. [66] models defines production and inventory capacities in a correctional institution... [92] presents a model
to compare different strategies to meet demand satisfaction, one of which consists on capacity investment. Even if all these issues imply investment with long term impact, the authors used costs rather than the NPV. They mix in one economic function costs related investment decisions and recurrent costs related to operating decisions. Here we identify the problem of discounting that should be considered when we deal with investment decisions whose impact is recorded along several periods. In the strategic level costs aren’t the relevant to solely be considered, but they still the criteria adopted by the majority of authors. Only 3 of all reviewed articles [41], [34] and [104] consider NPV as the choice criteria.

In this paragraph we are interested in reporting the methodological issues related to capacity costs. We separate strategic form operational and tactical levels:

- **Strategic level**: in 85% of the studied articles consider full costs. However, since the activity levels are not necessarily the capacity level, they are decision variables of the model, the use of full costs leads to sunk costs that penalizes the considered cost objects (products, orders…). [37], [79], [78]… determine the production level in each plant and the inventory level in each SC node (e.g. DC, warehouse). [21], [109]… present models that determine economic order quantity (EOQ). Full costs include capacity costs that are not generated by the chosen activity level but rather by the firm strategy. These sunk costs are due to unused capacity. One article [93] considered unused capacity costs concept.

- **Operational and tactical level**: capacity costs are not controlled in the operational and tactical levels. Decisions related for example to week production planning, or orders scheduling during a month don’t affect this category of costs. [106] model determines products scheduling in production machine. [71], [67] developed a model that define the orders distribution planning, they consider as decision variables, each product start and end dates, number of storage days… In [58] the model determines the production orders scheduling in parallel machines. In all these examples, the authors consider full costs, which are not relevant to all kind of uses as the case for operational decisions. Only 6 out of 16 articles consider variable or marginal costs rather than full costs to evaluate operational decisions. This full costs lead to biased economic evaluation.

Concerning cost drivers, none of the reviewed article considers cost drivers implying the eventual evolution of unit costs on the long run.

A new methodological problem is related to the impact of the obtained solution on the productive system. [93], [97], [37], [78], [26]… present developed models that define SC network designs. [1] developed a model for cellular manufacturing design, in each plant the model determines installed capacity in terms of machines number of workers… This kind of models, start from an initial physical system from which we deduce a cost model, and then the model use these information to obtain an optimal solution. The decision variables in these cases may affect the physical system, which calls into question the used cost parameters and then the obtained optimal solution. None of studied articles, studies the impact of the obtained solution on the used cost parameters.

---

8
Contributions
The presented results reveal that indeed authors neglect the costs relevance which leads to the reported methodological issues that affect the relevance of the proposed solution. In this section, we suggest some methodological guides that industrial management researchers need to keep in mind when they define costs in their decisions models.

- **Need of reprocessing the firm accounting system information:** One of the main revealed findings, is that authors consider costs as given parameters without any explanation. A cost calculation makes sense if it is only adapted to the decision-making system that will use it. As a result, a decision model cannot take the output of full cost calculation without analysis and reprocessing. This means that decision models need to be provided by an ad hoc economic evaluation adapted to their spatiotemporal perimeter. If not, these decision models do not really improve the decision making, since the solution search relies on this economic evaluation. Therefore, the costs introduced in the decision models cannot be considered as valid physical parameters regardless of the physical system that they seek to improve. They are contingent to physical and functioning characteristics.

- **Costs specification and appropriate cost approach:** To ensure a relevant economic evaluation, the one need to determine charges that are impacted by the studied decision and exclude from the evaluation all charges that do not stem from this decision. The understanding of costs behaviour; through the use of relevant activity drivers; and the use of appropriate cost concepts help to establish incremental cash flow report that measures the real impact of each scenario on the company income statement. Our findings also explore the use of specific costs (nonconformity costs, product or batch level cost…) or specific contexts (inter costing) which generally are not included in traditional system accounting. The companies need to change or complete their cost accounting by new costing approaches. If not, an inappropriate costing system will produce distorted information leading to a poor decision making (Gurowka and Lawson, 2007).

- **Collaboration between cost accounting and production management:** As a result of the two previous points, cost accounting, modelling and SC managers cannot be independent. They need to collaborate in order to determine and calculate the adequate costs to each studied context. This can help to overcome the resistance of accounting professionals to integrate new costing methodologies.

- **Impact of the obtained solution:** Concerning decisions related to production system design, one starts from a basic scenario from which he deduces cost parameters. He feeds a decision model by these cost information to obtain a new design solution. Since, costs are contingent to the organization physical characteristics, the solution of the decision model can lead to inconsistencies between the initial costs used and hypothesis, and the physical system new characteristics. This may make the obtained solution unworkable.

Conclusion
This article is grounded on the question: to what extent authors of industrial management articles study the adequacy between their decision models and the used cost system.

To answer this question we led a critical literature review whose finding reveal several methodological issues encountered when defining costs in decision models. i) In almost all articles authors give no explanation about the used economic parameters content, they...
assume costs as given parameters provided by an external source; ii) the reviewed decisions models use some costs that are not necessary traceable in the firm system accounting; iii) some articles suggest models that involve different companies, the applicability of this kind of models depends on the willingness of these companies to share their cost information; iv) the majority of search articles which study investment decisions having multi periods impact still base their decision criterion on costs rather than NPV; v) the majority of articles use full costs which generate inconsistencies related to capacity costs.

This work is intended to attract industrial management specialists to pay more attention about the relevance of the costs they use in decision models. The full costs of traditional system accounting cannot be used without reprocessing. To provide relevant and accurate costs, accounting professionals need to be open to integrate new costing methodologies. Modelling and cost accounting teams should be interconnected and work together to provide ad hoc economic evaluation for each decision model and finally we emphasize that decision models are a priori decision making oriented they need to integrate relevant costs concepts and to use activity drivers to can compare the existing alternative decisions and measure the impact on the company income statement.

Abstract

Intelligent Decision Support System (IDSS) is a novelty concept that applies Artificial Intelligence techniques to the decision support systems. The purpose of this research paper is to present a systematic literature review at the intersection of IDSS and supply chain integration (SCI), which main focus is the communication between different parties of the supply chain. This research analysed a total of 31 published articles. Moreover, it provides a visual representation of the main industries, methodologies and software, as well as a cluster representation of the keywords used.

Keywords: intelligent decision support system, AI, systematic literature review

Introduction

In today’s era of digitisation, more and more companies are revising their current strategies and approaches to business, in order to be able to maintain a competitive position on the market. One of the difficult tasks that businesses are facing on a daily basis is filtering, analysing and using in an appropriate manner the huge amount of data that is gathered. By having access to effective data management, the companies can strive to enhance the supply chain integration, which can therefore increase the business value (Zhao et al., 2008; Min, 2010; Alfalla-Luque et al., 2013). Decision Support Systems (DSS) have long been used to aid managers in making the most efficient and effective decisions aimed to resolve various problems encountered, however its application has, since then, shifted towards solving more current issues, while using more advanced technologies. With the application of Artificial Intelligence (AI) within DSS, thus creating Intelligent Decision Support Systems (IDSS), a completely new set of issues can be tackled.
Therefore, this paper will attempt to conduct a systematic literature review (SLR) of DSS that uses AI, within the context of supply chain integration. The SLR will aim to provide more clarification into the current uses of DSS and the respective AI techniques that are currently being applied in the supply chain management.

**Methodology**

Having the aim to identify and analyse the literature of a high scientific value, this paper is applying the systematic literature review approach. By overcoming potential weaknesses of a narrative literature review approach. By overcoming potential weaknesses of a narrative literature review approach, the SLR can offer such advantages as: transparency and replicability (Tranfield et al., 2003; Correria et al., 2017). It provides scientific insight into a given topic, while following strict guidelines (Ali et al., 2017). Moreover, it aims to minimise any potential bias by thoroughly researching published and unpublished studies, and provides a following trail of the reviewing decisions (Tranfield et al., 2003). The systematic review is then followed by a meta-analysis, the aim of which is to synthesise the finding through a statistical procedure. Furthermore, the SLR can help practitioners and academic to save time by reviewing the existing literature through a set of predefined filters, which can assure them the quality of the studies (Rousseau et al., 2008).

The process of the SLR is therefore described below, as adapted from Colicchia and Strozzi (2012):

- Defining the research question. As stated by Denyer and Tranfield (2009), the clearly formulated research question helps define the inclusion and exclusion criteria of the review;
- Identifying relevant studies through the use of appropriate tools, such as databases, by selecting the appropriate criteria (keywords, language, publications, time frame, etc.);
- Selecting and evaluating the studies through meta-analysis.

Therefore, for the purpose of this paper, the following research questions were formulated:

**RQ1.** Does IDSS provide support to supply chain integration?

**RQ2.** What type of IDSS is best to use for data filtration and sharing in supply chain management in order to obtain a better supply chain integration?

By having formulated these research questions, the following keywords were identified: decision support system, artificial intelligence, supply chain integration, supply chain management, intelligent decision support system, information sharing, information filtration. The databases selected for the purpose of this study were: Scopus, EBSCOhost, and Emerald Journals. These databases have been selected due to their extensive libraries of peer-reviewed academic literature, as well as their availability at the author’s academic institution (Ali et al., 2017; Qaiser et al., 2017).

The initial keywords were introduced as corresponding in either keywords, title or abstract section of the articles. The initial search result returned a total of 39 articles (20 from Scopus, 13 from Emerald Journals and 6 from EBSCOhost). It has to be mentioned that among these 39 results, there were 8 conference papers. A following search of the identified keywords, by using different types of combinations, revealed additional 27 articles. The search results were then reduced by excluding any articles that were in any
language other than English, published before 2010, and belonging to the Engineering or Computer Science fields. The latter was decided due to this paper aiming to analyse the managerial implication of IDSS in the supply chain, and the papers with extreme technical focus would not provide much understanding to the target public. After introducing this exclusion criteria, the search returned a final number of 31 academic and conference papers. The reason for taking the conference papers into consideration is the fact that, with IDSS being such a new topic, there are more chances to present a conference paper than to publish an academic paper, which can take longer time.

After the articles were gathered and thoroughly studied, they were evaluated applying a literature mapping process, as well as by using tables, graphs, and charts, that show the frequency of publications, location, and methodologies used.

Data analysis

The data analysis focused mainly on the literature mapping and text network visualization, in order to produce a clear image of the current state of the literature, as well as identify the possible gaps.

Firstly, in order to determine the reoccurrence of the published articles within literature, the statistical data is presented in Figure 1. Therefore, since 2010, there were 31 academic and conference papers related to the area of intelligent decision support system and supply chain integration. It can be observed that there was an interest regarding these topics in the 2010, where 3 of the articles were presented at a research conference. The interest spiked again after 2015, however the number of articles is still low.

![Figure 1. Number of published papers per year](image)

The following set of analysis is literature mapping, created with the help of Creately website, which classifies the existing literature. Therefore, the main topic of the literature is Decision Support System. The next step of classification is the methodologies used in
the identified articles, which were defined as follows: Simulation, Coding/algorithms, Modelling, and Others (literature review). Moreover, the articles were then classified into the associated industry for each study. It can be noticed that there are a number of articles that focus mainly on the food and manufacturing industry, with a total of 5 and 8 articles respectively. Moreover, for each of the articles, the appropriate used software was identified. It can be observed that the methods used differ for every study, suggesting that the research topic can be approached from various angles.

Furthermore, one of the initial conclusions that can be drawn from this study is that there is a scarcity of literature that tackles the area of information value and sharing through IDSS in the supply chain integration. Thus, it is suggested that there is an existing gap in literature that can be further approached.

This type of literature mapping permits the assessment of all the existing methods of analysis available. It can be observed that some of the existing articles have a combination of methods, such as modelling and simulation, or modelling and coding. Moreover, by identifying the used software, the scholars can determine the most appropriate to use for future research in different domains. It can be noted that for simulation the software Anylogic was used twice, while for modelling the loop diagrams are more popular. In the coding area, there are a number of programming languages to choose from, and it can be observed that all the examined articles have adopted different approaches to designing the programs.
Figure 2. Literature mapping

5
For the text network visualization, the software VOSviewer was used. The software extracts keywords from the titles and abstracts of the selected articles, and maps them into a network. The program identified a total of 1,018 terms, and 78 of them were selected for the visualization process, based on the minimum number of occurrences – 3. It can be noticed that some words and circles are more prominent than others, which is dictated by their occurrence in the texts. An additional feature of the text visualization is the observable link between various terms.

Although, there is observable noise in this representation, an initial analysis of the keywords can be made. Most of the papers were concerned with developing a decision support system or framework, with the main focus on efficient supplier selection or sustainability. Furthermore, such topic as performance measurement and feedback systems were prioritized. A number of papers were more theoretical, and offered systematic literature reviews and bibliometric analysis of the existing literature.

By combining these two forms of analysis, it can be observed that there are two types of published papers: the theoretical papers and the practical papers. The first set of papers are primarily concerned with identifying the main theories behind decision support systems and supply chain integration. They also revise the need for DSS implementation and possible applications within SCI. It has to be considered that there are not many articles that combine these two major topics. However, a number of articles mention that DSSs can influence the

Figure 3. Text network visualization

Although, there is observable noise in this representation, an initial analysis of the keywords can be made. Most of the papers were concerned with developing a decision support system or framework, with the main focus on efficient supplier selection or sustainability. Furthermore, such topic as performance measurement and feedback systems were prioritized. A number of papers were more theoretical, and offered systematic literature reviews and bibliometric analysis of the existing literature.

By combining these two forms of analysis, it can be observed that there are two types of published papers: the theoretical papers and the practical papers. The first set of papers are primarily concerned with identifying the main theories behind decision support systems and supply chain integration. They also revise the need for DSS implementation and possible applications within SCI. It has to be considered that there are not many articles that combine these two major topics. However, a number of articles mention that DSSs can influence the
SCI, provide an opportunity for more sustainable logistics, and improving the communication between different parties of the supply chain.

On the other hand, the practical papers offer different models of DSSs which are compiled and tested in different settings. Another statement that can be made is that the developed systems are either tested in case studies, at various companies, or simulated using different software. Nevertheless, all the proposed systems are validated through testing and comparison with previous results from the companies. This in turns demonstrates the functionality and performance of the decision support systems.

Contributions

This research aims to contribute to the young growing IDSS body of knowledge by identifying the gaps and making suggestions for future research. The possible implications of DSS in the supply chain context are massive and understudied. The recommendation for future research can vary from investigating the usefulness of DSS in SC context (Hilletofth & Lattila, 2012) to comparison of different Artificial Intelligence types for suitability in the SC context (Deva et al., 2016) to providing empirical studies of trust, privacy, and security in the information sharing aspects of supply chain integration (Kahki & Gargeya, 2019). While the more practical papers involved the development of the programs themselves, the more theoretical papers were more concerned with issues that are gaining more and more importance such as data trustworthiness and more sustainable processes in the SC.

The graphical representation of the literature offers researchers a better understanding of the industries that are thoroughly studied, at the same time emphasising the gaps. For example, there is limited research in car manufacturing or textile industries, with the majority focused on manufacturing and food services. Moreover, the representation emphasise the possible methodologies that can be used for future research, as well as different combinations of methods.

This research paper can serve both academics and industry practitioners. For academics, it can provide a good starting point for future research, while for industry practitioners it can serve as a good indicator for their resource investment and company development.

Conclusion

This research presented a systematic and bibliometric analysis of the current state of the literature surrounding the topics of Intelligent Decision Support System and Supply Chain Integration. One point of observation is that the combination of these two research topics is still in its infancy, and the area is understudied. While there are many articles that are concerned only with ‘IDSS’ or ‘supply chain integration’, the combination of these two terms does not provide many results. It is an often occurrence that the term ‘supply chain integration’ is only mentioned once or twice in an article about ‘IDSS’ or ‘DSS’. However, the research shows a trend of papers regarding areas of ‘supplier selection’ and ‘sustainable logistics’. The ‘sustainable logistics’ topic is the latest trend across a number of research fields, and it comes as no surprise that an advanced technology such as IDSS to be used in order to obtain more sustainable processes. Moreover, this research has identified potential gaps in the literature, and provided a detailed overview of the areas and industries that were already researched. Consequently, a representation of potential combination of different methodologies is presented in this paper, which can be of help for future research.

Abstract

The purpose of the paper is to identify the issues and challenges to employing blockchain technology for different operations context. The paper analyses five cases to identify drivers and barriers to adopting the technology. Our findings suggest that interoperability and platform dependency can limit the wide-scale deployment of the technology. Additionally, trust in rule-based software automation and consensus among supply chain actors can inhibit effective adoption. In summary, the paper finds that care should be taken when applying blockchain, since there are many situations where its implementation is not feasible or not beneficial.

Keywords: Blockchain, Challenges, Limitations

Introduction

Blockchain has emerged as a technology that can provide visibility, traceability and transparency in business operations, which will lead to better accountability. The potential usefulness of the technology has been reported in many sectors such as: energy (Adoni et al., 2019); health-care (McGhin et al., 2019); digital supply-chain (Min, 2019); retail (Morkunas et al., 2019); financial services (Tapscott and Tapscott, 2017); and transportation (Lei et al., 2019). The key properties of this technology that makes it a valuable proposition to handle heterogenous transactions in different sectors are discussed below and these have been reported in the pilot studies undertaken by technology providers such as IBM (2017), Capgemini (2017) and in academic research.

- **Immutability:** The transactions recorded in a blockchain cannot be tampered, deleted and revised, i.e. the process and information stored in each block is irreversible, thus providing an accurate view of the activities. However, the
authenticity and quality of the information will depend upon the author and source.

- **Distributed:** The blocks and corresponding chain is stored among all the entities in the network participating in the transactions, which increases visibility of the information. However, access restrictions may apply depending on the nature of the information and the rules associated with the creation of blocks.

- **Decentralised:** The transactions occur based on automated rules set in the network (mainly through a process of consensus), which eliminates the need of a central authority, i.e. this potentially will lead to faster transactions, and eliminates the risk of the data being held centrally in a server (as in contemporary information systems). However, as the size of the chain increases the processing time to create or retrieve a block will increase.

- **Automation:** Most processes in the network, i.e. creating a record, processing transactions, are executed automatically by the software codes deployed in the network. The cryptographic verification process ensures authenticity of the transactions and makes the process incorruptible, i.e. devoid of errors (if the software codes do what they are meant to or agreed upon in a suitable manner). It is worth highlighting that the process of rule creation and revisions is a grey area and will depend on the context and purpose of using the technology.

- **Single Unified Ledger:** This helps in aggregating all the records in a single network, i.e. provides the actors with high-level as well as low-level view of all the transactions, linked-information efficiently, thus reducing the information and cognitive overload to some extent. Employing blockchain analytics to provide such a view can be complex and inefficient, due to size of the chain and automated access rights imposed by automated rules.

The existing literature has focussed mainly on the advantages offered by the technology in different business sectors. Though, the merits offered by the technology are demonstrated through pilot projects undertaken by technology providers, it is necessary to understand the challenges to large-scale adoption of the blockchain and readiness of businesses to deploy the technology.

**Issues and challenges identified from the literature.**
The literature gathered from various business disciplines, information systems and computing science was systematically reviewed to identify the potential challenges associated with the adoption of the technology from a business perspective. Though, the emerging technology has been tipped to transform businesses in a 'positive way', the key issues associated with the technology (usage, implementation and deployment) and organisation needs (value of using the technology, skills and expertise) are yet to be understood and discussed comprehensively. Table 1 will present the key challenges that can be potential barriers towards the wide-scale adoption of the technology in business domain (in-particular global supply-chains which are increasingly becoming complex). A quick review of the table highlights: the need to understand that will aid in managing and implementing the technology (skills and expertise); agreement between various businesses adopting the technology on the automated rules (process and author), and operational software platform; assessing the long-term benefits of the technology (i.e. consider its efficiency to process multiple transactions and viable integration with the existing operations and processes).

**Review of industry pilot cases**

Blockchain is considered as a valuable solution in different areas because it can record transactions in a secure, transparent, decentralised, efficient, and low-cost way (Schatsky & Muraskin, 2015). It can simplify the transmission of information to eliminate the commonly conflicting layers found in supply chains, making information more reliable,
timely, highly visible and incorruptible. The purpose of this section is to present different instances in which blockchain has been implemented to investigate the themes identified in the literature review and to understand the requirements to leverage the potential of this technology. The five cases selected are looking at the food industry, energy, disaster relief, housing and banking. The findings stemming from the review of the pilot cases is summarised in Table 2.

- **Food Supply Chain.** The food supply chain is an excellent example of the potential value of blockchain. Freshness of food, especially meat, is a significant health concern. That was the motivation behind Provenance (Provenance, 2019), a company that has implemented blockchain to provide more certainty and transparency in the food supply chain. The purpose is to allow users/companies to know more about the origin, travel and destination of food. Talking about meat that can allow users to trust the “kill” dates in their meat products, thereby ensuring freshness. In fact, the company implemented a similar idea in Indonesia, in which they used blockchain to track tuna from the moment it was caught until it reached the consumer (Safaryan, 2017). That way, it was possible to add traceability to the supply chain and ensure consumers about the journey of their product. The potential of blockchain in this setting is not only to increase traceability though. It can allow to support commodity management to reduce duplication of certificates and paperwork, allow marketplace creation by connecting suppliers and customers, increase data sharing among different members of the supply chain through collection of information from different sensors at different stages, increasing access to capital investments, and enhancing payments (Noel, 2018).

- **Energy.** Introducing a fully decentralised energy system is another potential venue for blockchain. The technology available nowadays allows people to be not only consumers of electricity, but also producers. Blockchain has the potential to support transactions among customers with different roles. Elektrify is a good example of the use of blockchain to allow these interactions (Electrify, 2019). In fact, a project between Busan City, Nuri Telecom, Pusan National University, Busan City Gas, and Korea Industrial Complex Corporation tries to exploit this possibility, to improve power generation and distribution in the region (Marley, 2019). This would also facilitate the creation of a micro-grid in regions of the country, which is a project currently pursued by Korea Electric Power Corporation (KEPCO). Beyond that, also in Korea, Swytch, is partnering with Chuncheon to use smart meter and blockchain technology to incentivise and provide benefits for companies and people looking to reduce carbon emissions (SmartCitiesWorld, 2018). On top of that, blockchain can also be used to allow metering, billing and clearing processes (PwC, 2016), which shows the reason this technology is very promising for other countries as well.

- **Relief and disasters.** Collaboration and cooperation are very complicated in situations in which a disaster has affected a region because of the multiple number of organisations involved. Governmental organisations, non-governmental organisations, charities and civil organisations try to provide support for the affected people, but it is complicated to provide a honed response because of the duplication of efforts and the centralised systems used by these organisations. The U.S. government realised that blockchain could be effectively used to enhance collaboration. Blockchain can be used to create a decentralised system through improved information sharing exploiting its traceability, transparency and immutability (Akilo, 2018). In that way, organisations could have more clarity about
the activities of the other stakeholders, helping guide their activities. Moreover, this would allow to pool resources and introduce a coordinated response. This benefit, however, would not be only for the organisations. Transparency and traceability would allow donors to increase trust in NGOs and charities and ensure a more efficient response to the victims. From that perspective, blockchain can allow to provide support for donations and financial transaction in disaster settings (Phil, 2018).

• **Housing.** The housing industry represents an area with huge potential for the implementation of blockchain. A very interesting example comes from the intersection of housing and public policy. The Kenyan National Housing Fund provides government-funded housing for families in need. However, the scheme has been criticised because of fraudulent activities and corruption (Aki, 2018). The use of blockchain would allow to ensure the transparent distribution of houses because blocks cannot be altered once these have been added to the chain. The notoriously porous land registry database would be recorded using blockchain to ensure that houses go to the people who need them. Additionally, funds would be more difficult to embezzle, and bribes would be reduced considerably (Sharma, 2018).

• **Banking.** The most notorious application of blockchain is related to cryptocurrency. Looking at financial services, blockchain has an incredible potential to improve transactions. The We.Trade platform from HSBC in collaboration with another 9 banks is a clear example (Finextra, 2018). HSBC has been at the spear point of the use of blockchain to improve financial transactions. In 2018, the bank was able to perform the first trade finance transaction using R3’s Corda scalable blockchain platform, in the situation of a Cargill shipment of soybeans going to Malaysia from Argentina (HSBC, 2018). The purpose of this test was to use a shared application instead of applications in multiple systems, which reduced the transaction time from days to less than 24 hours. This outcome showed the feasibility of trade digitisation and emphasised the potential to reduce fraud risks in letters of credit, and introducing more efficient procedures (Ganesh, Olsen, Kroeker, & P, 2018).

**Research Agenda**

An important contribution of this research is to convert the themes identified in the literature and illustrated through analysis of cases, into possible directions for future research. We identify four research questions that demand attention, if blockchain is to be seen as a valuable technology for operations management.

• **Interoperability.** Research on blockchain focuses on the benefits and the characteristics, but often overlooks the technical requirements and implications. For example, each actor in the system must possess the required expertise and equipment to effectively share data. Therefore, research should investigate the minimum technical requirements and how big a challenge it may be to bring organisations to the required standard. Additionally, when discussing cases in which individuals also read or write data, this becomes even more complex.
Table 2: Summary of the business cases

<table>
<thead>
<tr>
<th>Cases</th>
<th>Technical</th>
<th>Social</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interoperability</td>
<td>Different levels of IT expertise and equipment among different links from supply chain (from fisherman to retailer).</td>
<td>Rules development and agreement can have a significant effect on the different links in the SC</td>
</tr>
<tr>
<td>Food SC</td>
<td>Data recording methods and technology might be inconsistent. Different stakeholders can have multiple platforms.</td>
<td>Permissions for data editing/access need to be properly agreed. Acceptance to technological innovation can be challenging.</td>
</tr>
<tr>
<td>Energy</td>
<td>Highly complex system with multiple nodes in which a single platform across all users/producers would be required.</td>
<td>Data protection can be problematic because of GDPR. Data sharing rules would need to be clearly defined.</td>
</tr>
<tr>
<td>Disasters</td>
<td>Multiple platforms should be integrated, and databases consistently prepared.</td>
<td>The different type of participants would need to define who would be making the rules, how/if these can be modified and how are all the stakeholders integrated.</td>
</tr>
<tr>
<td>Housing</td>
<td>Different branches of government need to interact through the integration of different systems.</td>
<td>The level of access to producers/users should be well-established and agreed upon. There is a need to ensure consistency in practice.</td>
</tr>
<tr>
<td>Banking</td>
<td>Multiple platforms should be integrated into a single platform.</td>
<td>The combination of private and public funding could affect the interests of different stakeholders. Decisions on how much information is shared and what information can be taken should be agreed.</td>
</tr>
</tbody>
</table>

GDPR requirements can be complicated. The level of personal data shared, its use and level of access would need to be carefully stated.

It requires involvement of contractors/suppliers and governmental officials to identify the kind of data shared and who would be the main participants.

Banks and authorities would need to agree on what data can be taken from the transaction and what access level is required from the different parties.
• **Platform dependency.** As with information technology, the extent to which blockchain delivers benefits is affected by the data in the system. This means the platforms used, the way in which they are used by actors and the level of expertise of these actors are all important. In particular, the way that data are captured and communicated could be crucial. For example, if objective data are captured using a standardised approach, the data will be more trusted than data input manually, with implications throughout the lifetime of these data. Research should seek to understand data management, platforms and readiness for blockchain implementation.

• **Trust in rule-based automation software.** Rule-based systems, whether electronic, economic or otherwise, are important in enabling business. Trust in such systems, however, is greatly affected by the source of the rules. Whether blockchain rules are set by regulatory bodies or by individual companies and whether they can be modified by individuals or not can affect the trust and hence the adoption or success of blockchain. Research should investigate the behavioural aspects in particular, to understand how and when blockchain can command sufficient trust to be adopted.

• **Consensus among supply chain actors.** The adoption of the technology will require an understanding and agreement between all the actors (for example, supply-chain entities) participating in the blockchain network. This will require have an agreement on the rules set-up within the network, using a platform provided by a technology provider, which will require integration with the existing processes, and participating in the transactions (i.e. willingness and mindset to use the technology). The consensus between the firms will be driven by the potential benefits offered by the technology to the individual firms and the awareness/expertise of the managers about this new and complex technology. The consensus within firm will be driven by the organisation culture to take risks i.e. adoption a technology whose benefits are yet to be validated through long-term usage and technical complexities involved to integrate with existing process in the firm, which will require persuading the management and updating the skill-set of the relevant employees throughout the processes involving technology adoption, deployment and maintenance. Research should understand and investigate various consensus factors within and between firms that will lead to wide-spread adoption of blockchain and eventually make it scalable.

**Managerial Implications**

Operations Managers in a variety of business contexts may find blockchain being offered as the silver bullet that will solve all problems. Examples, including the cases discussed in this research, demonstrate the breadth of applications, from supply chains for consumer products, to government contracts and from energy to banking. Blockchain can be applied in almost every business context. Before leaping into the unknown, however, managers should question whether it should be used in their specific context. This research outlines four key questions that should be considered before deciding that blockchain offers the appropriate solution.

- **What kind of expertise is required?** Implementing a blockchain based solution requires both strategic and technical expertise. The former is to evaluate and
decide on the most appropriate implementation of technological possibilities. The latter must be updated as the technology will evolve, and its complexity increases. This complexity is particularly clear in cases such as the energy one, in which the number of actors contributing energy (and data) is enormous. Ensuring that all of these actors are appropriately connected and that the sources of data are integrated, as well as being certain that the system will remain suitable over time, represents a considerable technical challenge.

• **Who has the right to input data?** Assuming the required technical expertise and strategic decision making are in place, one of the key challenges is platform governance. Consider, for example, the case of the food supply chain, in which traceability depends on the information in the system, how it is input and how it is communicated. If false data are input, these will be stored and transmitted through the whole system. While using blockchain should give confidence that fish have been caught legally or food safety standards have been maintained, this confidence would be unfounded if an actor in the supply chain has deliberately or inadvertently supplied inaccurate data. It is essential, to be sure that the right people have the right access and use it appropriately for blockchain to be useful.

• **Who will decide the rules, and can they be modified?** Access rights are among the aspects that should be defined in the rules of a blockchain system. For example, in a smart contract, it is important that access is restricted to those affected by the contract and that decisions are made when rule-based conditions are met, e.g. once payment is made by one party, the ownership of a property is transferred to that party. Managers should be aware of which actors can decide the rules, for example, in a supply chain, will suppliers have any say and, should the members of the supply chain make changes, will there be ongoing implications? Moreover, should the situation change, the original rules may no longer be relevant, but if they cannot be changed, blockchain may not be appropriate. For example, if a buyer and seller change their agreement, so that a higher amount is payable at an earlier date (or vice-versa) it is possible that blockchain would limit flexibility and prevent changes.

• **What level of transparency is good for business?** Blockchain provides potential benefits in terms of transparency and traceability. An important consideration, however, is whether this is always desirable. In most business contexts, holding back some operational details can be very important. For example, knowing which sources of supply are used or how efficient equipment is can affecting negotiating positions between buyers and suppliers. The transparency offered by blockchain can be of benefit between partners in a supply chain, but managers must consider whether too much transparency may be involved. Consider, for example, a situation where a supplier also supplies competitors, who therefore have access to information. Or an alternative situation in which the agreement with a supplier ends and their access to their own data is restricted. Neither of these situations suggest that the benefits of blockchain should always outweigh the costs.
Conclusion
The limitations of the blockchain technology has received less attention, leading to an inaccurate impression that it can address any challenge pertaining to transparency, reliability, effectiveness, efficiency, accuracy, decentralized information storage and distributed information. The paper contributes to theory by developing the understanding of the key challenges of blockchain implementation and proposing a research agenda (Figure 1) that warrants further investigation to understand potential realistic solutions for addressing these challenges. For operations managers, the paper offers a useful starting point to reflect on several key questions that are likely to impact intra-firm relationship, inter-firm relationship and key decisions pertaining to benefits of adopting blockchain (i.e. both short and long-term). However, the key question for the managers is 'If blockchain is the solution, what is the problem'.

Abstract

This research investigates the relationships between supply chain relationships/integration, innovative capabilities and manufacturing performance. Data was collected from 171 organisations based in three rapidly developing countries – Brazil, India, China. Data was collected as part of the International Manufacturing Strategy Survey (IMSS VI) and analysed using Structural Equation Modelling. The findings indicated that supply chain relationships and integration relate positively to both product and process innovative capabilities. The study also found that there were positive relationships between both product and process innovative capabilities and manufacturing performance. Finally, there was a positive relationship between product innovative capabilities and process innovative capabilities.

Keywords: Innovative capabilities, Supply chain management, Developing countries

Introduction

This study investigates the relationships between supply chain relationships and integration, innovative capabilities and manufacturing performance within the context of three rapidly developing countries - Brazil, India and China. Previous studies including those by Back, Parboteeah, and Nam (2014) and Ren, Eisingerich, and Tsai (2015) have highlighted the necessity for more research on innovative capabilities and product development in developing countries. Developing countries such as Brazil, China and
India are increasingly seeking to improve their global economic presence and influence. To this extent, many organisations in these countries focus extensively on the development and exploitation of innovative capabilities. This study seeks to investigate if the supply chain relationships that manufacturers in these countries develop encourage them to develop their innovative capabilities. In addition, the study investigates if the development of these innovative capabilities result in improved manufacturing performance. Hence, the key questions that motivate this research are as follows:

**Within the context of manufacturers in rapidly developing countries, do supply chain relationships and integration relate with the development of product and process innovative capabilities?**

**Do product and process innovative capabilities drive manufacturing performance in these rapidly developing countries?**

**Literature Review and Hypotheses**

According to Tsai and Hung (2016), supply chain performance can be improved by developing a well-integrated supply chain. In essence, organisations that become more integrated or which develop better relationships with their suppliers and customers improve co-dependency and can develop an innovative advantage (Day, 2000; Souitaris, 2001). However, despite increasing evidence that manufacturers are under increasing pressure by their customers to adopt innovative practices and improve their innovative capabilities (Laosirihongthong, Punnakitikashem, and Adebanjo 2013), the relationship between customer relationship and integration and the development of innovative capabilities of manufacturers remains largely unexplored. The key hypotheses investigated in this research are now presented.

The study by Ren, Eisingerich, and Tsai (2015) suggested that within the context of developing countries like China, organisations tend to lag in technology development and are under the control of their western customers. The impact of the control of western customers is that the manufacturers in developing countries are necessitated to tailor their innovation-related activities to meet the needs of their customers (Bullinger, Auernhammer, and Gomeringer 2004). Increasingly, these customer needs include the ability to develop their innovative capabilities (Mishra, Chandrasekaran, and MacCormack 2015). Such innovative capabilities can be either product-related or process-related. Hence the following are hypothesised:

**H1. Improvement in supply chain relationship and integration will relate positively with improvement in product innovative capabilities in manufacturing organisations in developing countries.**

**H2. Improvement in supply chain relationship and integration will relate positively with improvement in process innovative capabilities in manufacturing organisations in developing countries.**

Product innovation is important to organisations because it has the potential to deliver new streams of income (Kleinschmidt and Cooper 1991; Teece 2010). However, Martínez-Ros and Labeaga (2009) and Ballot et al. (2015) noted that while product
innovation and process innovation are different, they could have a complementary relationship and could lead to each other. Linton (2015) also suggested that product innovation is likely to result in process innovation. Therefore, the following hypotheses are proposed:

\[ H3a. \text{Improvement in product innovative capabilities will relate positively with improvement in process innovative capabilities in manufacturing organisations in developing countries.} \]

\[ H3b. \text{Improvement in product innovative capabilities will partially mediate the relationship between supply chain relationship and integration and Improvement in process innovative capabilities.} \]

The main reason why organisations focus on the development of product innovative capabilities is the need for organisations to maintain a competitive edge in the market place (Leskovar-Spacapan and Bastic 2007). This relationship between product innovative capabilities and organisational performance has been explored in previous studies. The study by Yang et al. (2015) concluded that supply chain performance is influenced by innovation capability. This argument also extends to process innovative capability. The potential impact of developing process innovation on the performance of an organisation was investigated by Oke and Kach (2012) and they found that the benefits included improvements in the production process, efficiency and cost. Hence the following are hypothesised.

\[ H4. \text{Improvement in product innovative capabilities will relate positively with improvement in manufacturing performance in developing countries.} \]

\[ H5. \text{Improvement in process innovative capabilities will relate positively with improvement in manufacturing performance in developing countries.} \]

**Methodology**

The study collected data from Brazil, India and China through the International Manufacturing Strategy Survey (IMSS) version VI between June 2013 and June 2014. For this study, manufacturing performance was measured using a combination of quality and flexibility because these two dimensions of performance should be of major concern for all organisations that are focussed on product and process innovation. The responses for manufacturing performance were assessed using a five-point Likert scale that compared organisational performance to the main competitor. The measures for all other constructs were developed from established scales and were measured on a five-point Likert scale as well. The study collected 171 valid survey responses which were used to test the hypotheses presented above. The dataset comprised of 28 (16.4%) responses from Brazil, 56 (32.7%) from India and 87 (50.9%) from China.

The study performed a principal-component exploratory factor analysis for each survey item to check for the specified constructs. The results showed that all the items of each construct had factor loadings between 0.725 and 0.896, exceeding the recommended coefficient of 0.50 (Hair et al. 2010). The constructs were also examined for internal consistency and the results showed that every construct had Cronbach’s Alpha ranging from 0.840 to 0.900, meeting the desirable value of 0.70 (Hair et al. 2010). In addition, the study also checked the composite reliability of all constructs and the results showed...
that the values of composite reliability for all the constructs ranged between 0.894 and 0.928, which are above the recommended value of 0.60 (Bagozzi and Yi 1988). The values of average variance extracted (AVE) for each construct were above 0.50, indicating convergent validity. To address the problem of multicollinearity, the study evaluated multicollinearity through the variance inflation factors (VIF) and the values of all variables were between 1.287 and 1.942, lower than the recommended thresholds of 3 (Hair et al. 2010), thereby confirming there was no multicollinearity problem in this study.

The study then used structural equation modelling to test the hypothesized relationships. The SEM results showed a good model fit with normed chi square ($\chi^2$) = 1.114, GFI = 0.923, AGFI = 0.893, RMSEA = 0.026, RMR = 0.053, NFI = 0.928, TLI = 0.990, and CFI = 0.992

Findings
The study found that supply chain relationship and integration had a significant and positive relationship with product innovative capabilities ($\beta$=0.682; $p$-value < 0.001). Supply chain relationship and integration was positively related to process innovative capabilities ($\beta$=0.294; $p$-value < 0.01). There was a positive relationship between product innovative capabilities and process innovative capabilities ($\beta$=0.475; $p$-value < 0.001). Product innovative capabilities was positively related to supply chain relationship and integration ($\beta$=0.270; $p$-value < 0.05). Process innovative capabilities ($\beta$=0.305; $p$-value < 0.05) was found to have a significant and positive relationship with manufacturing performance. The results provided evidence to support hypotheses H1, H2, H3a, H4 and H5. These results are shown in table 1.

The significant positive relationship between product innovative capabilities and process innovative capabilities resulted in the testing of a mediating effect for product innovative capabilities. The bootstrap approach (Preacher and Hayes, 2004) was adopted to test the mediation hypotheses. The indirect effect of product innovative capabilities on process innovative capabilities was calculated as the product of the path coefficients between supply chain relationships and integration and product innovative capabilities ($\beta$ = 0.682) and between product innovative capabilities and process innovative capabilities ($\beta$ = 0.475). This indirect effect coefficient was equal to 0.324, which can be validated for significance using a bootstrap approach. The indirect effects were significant given that the lower confidence interval of the bias-corrected bootstrap does not contain zero. As both direct and indirect effects were significant, the partial mediating effect (H3b) was supported for product innovative capabilities.

Conclusion
The study shows that for manufacturers in Brazil, China and India, the ability to develop supply chain relationship and integration will significantly and positively impact on their ability to develop their product innovative and process innovative capabilities. The study also found that, product innovative capabilities have a strong positive relationship with process innovative capabilities. The implication of this finding is that organisations that develop strong product innovative capabilities are also likely to develop process innovative capabilities thereby improving the overall level of innovativeness in the
organisation. Finally, the study found that both product and process innovative capabilities have significant positive relationships with manufacturing performance. From a theoretical perspective, the findings suggest that institutional pressures that affect manufacturers such as pressure from supply chain customers can lead them to develop new capabilities with respect to product and process innovative capabilities. From a competitive perspective, the findings show that that manufacturers in the countries that were studied are increasingly beginning to focus on product and process innovative capabilities. If and when they develop such capabilities to an advanced level, the impact on global manufacturing and trading relationships could become very significant.

When deviating from standard processes leads to higher performance - How companies can improve complexity management by understanding deviations of process standards

Prof. Dr. Julia C. Bendul (bendul@scm.rwth-aachen.de)  
RWTH Aachen University

Abstract

Deviations from predefined process standards often occur in order to reach higher performance levels. Based on a structured literature review and a data analysis of over 1,000,000 data lines, we developed a theoretical framework to understand the characteristics of desired and undesired process complexity. To validate the positive performance impacts of process deviations we present a case study of two production companies and demonstrate the findings of their analyzed end-to-end processes of actual process paths, as opposed to their predefined processes. We conclude with actionable alternatives on how management can use complexity to enhance logistic performance.

Keywords: Process complexity management, business process reengineering, process mining

Introduction

With expanding interlinking activities between business partners and the increasing demand of customers for individual products, complexity management became an integral part of the management agenda. Fulfilling this new market need and simultaneously enhancing logistic and financial performance has become one of the major challenges for top management (Bode, Wagner, 2015).

Complexity can influence performance in both positive and negative ways. For example a larger product variety can help the company to open up new markets and increase revenue (Aitken et al., 2016).

(Marley et al., 2014), (Bode, Wagner, 2015), (Fisher, Ittner, 1999) investigated the negative impacts of complexity on increasing supply chain disruptions, a higher failure rate and increasing need for supervision and control. Aitken et al. (2016) raised the position that there is a difference between necessary and unnecessary complexity: Necessary complexity can be helpful to reach strategic company goals, for instance by accepting a larger product variety to offer customers a wider product range. Unnecessary
complexity can hinder reaching the strategic company goals and thus, must be avoided. However, complexity can also have positive performance impacts when deviating from predefined process standards.

Latest technology developments gave rise to software programs called process mining tools, which help to analyze large data volumes and identify actual taken process paths within a company’s business wherever electronic data is available.

In this research we aim to understand the positive aspects of additional process complexity through deviation from standard processes by using the term “desired” and “undesired” complexity. We aim to investigate the characteristics and emergence of desired and undesired complexity and to develop a heuristic framework to illustrate the cause-and-effect-relationships between impact factors and performance effects of desired and undesired process complexity. Further, we show how latest process mining tools can be used to identify process deviations in order to apply this approach to multiple processes by introducing a case study of two companies.

The remainder of the article is structured as follows: First, we illustrate a review of the current state of literature. Second, we present the theoretical background. Third, we expose our heuristic framework and highlight the research gap. Fourth, we present and discuss the main findings of our case study. The paper concludes with some theoretical and managerial implications and gives advice for further research.

**Structured Literature Review**

In order to investigate the current state of literature and highlight the research gap we did a structured literature review on articles between 1998 and 2017. For the literature review we identified 18 keywords, which were supplemented during the search process, documented in Table 1.

These keywords were combined to research strings resulting in 248 papers. For the subsequently followed forward and backward search relevant criteria were defined. This search resulted in 314 papers. To reduce the number of papers we choose criteria such as focus on process complexity, measurement techniques of complexity and business process improvement methods, resulting in 38 papers. All remaining papers were investigated by using a structured analysis approach. The focus of the article analysis was investigating (1) the used theory, (2) characteristic of complexity, (3) complexity drivers and (4) the impact of complexity on performance to develop a general understanding of complexity and to develop a framework to explain the cause-effect relationship between the different complexity types.

**Theoretical Background**

We give a brief definition of process complexity. In order to show how process complexity can be analyzed we present several graph theoretical measurements and
highlight the influence of process complexity on performance. Then, we present reasons for deviating from process standards and show how business process reengineering can be solved with the help of process mining tools. Based on this analysis we highlight the research gap.

**Process Complexity**
A high task variety, a variety of different inputs and uncertainty are characteristics of complex processes (Mani et al., 2010). (Karimi et al., 2014) added to that definition the uncertainty and interdependence between the individual activities of a business process. (Größler et al., 2006) state process complexity also named internal complexity is an answer to the complexity resulting from the outside business environment. (Schäfermeyer et al., 2012) indicates that business processes even need a certain level of complexity to be able to respond to the environment.

Process complexity therefore can be defined as a process characteristic describing the effort which is needed to fulfill the process goal. Task variety, involved parties and subject areas determine the level of process complexity.

As business processes are the core element of a company’s operations, it is absolutely important to understand the characteristics and influences on process complexity to be able to respond with the correct management action.

**Measurement of complexity**
In order to define the level of complexity and therefore respond with the correct action alternative it is necessary to measure the degree of complexity.

In the field of network research there exist several indicators to measure complexity (Boccaletti et al., 2006). For this paper we used the relevant indicators which are necessary to define the level of process complexity. The shortest path length is one of the basic indicators which defines the shortest connection between two nodes within a network. Another quite commonly used indicator is the so called betweenness centrality. This measurement is based on the shortest path length and characterizes a node as important if it belongs to a high value of shortest path lengths. (Boccaletti et al., 2006).

**Performance vs. Complexity**
The majority of business literature focuses on the negative impacts of complexity.

According to (Bode, Wagner, 2015), (Marley et al., 2014) (Allesina et al., 2009) complexity should be reduced or avoided wherever possible. They argue with the negative impact of complexity on logistical performance, a more complicated decision-making process and increasing supply chain disruptions.

Following the argumentation of the normal accident theory, the likeliness of failures increases with an increasing complexity and tight coupling of processes (Perrow, 1999). This theory was applied in several research field of supply chain management, manufacturing and transportation to explain why failure and process disruptions occur. According to this theory due to the high number of interactions errors will occur in unexpected ways. In combination with the tight coupling, therefore failures can spread easily within the network and it’s “normal” that failures and therefore disruptions will occur (Marley et al., 2014).

(Aitken et al., 2016) questioned whether the only possible impact of complexity is negative and therefore distinguish in their paper between “strategic or necessary” and “dysfunctional or unnecessary” complexity.

According to the authors (Aitken et al., 2016), (Bozarth et al., 2009) strategic
complexity empowers the company to reach their strategic goals like a higher product variety increases the complexity but also enables the company to gain market share. In contrast, dysfunctional complexity in a process impedes its performance. Thus, a healthy level of complexity can have positive performance impacts and even deviations from standard processes can lead to an increase in performance.

*Deviation from Process Standards*

People often take alternatives to reach their goals despite of predefined standard process steps. They do so actively but sometimes also unconscious.

Deviating from standard processes could mean on the one hand, doing process steps in a different sequence than the standard process pretends. On the other hand deviation could also result in a completely new set of process activities which are not intended in the standard process.

Especially the external factors time pressure and multitude of information encourage the phenomenon of cognitive bias and lead people to deviate from predefined standard processes (Arnott, 2006). The employee has to react fast and there is not enough time to comply with all necessary process steps, therefore the employee seeks possibilities for reaching the process goal as fast as possible in spite of known, standard process requirements (Bendul, 2016).

Additionally, missing knowledge and lack of transparency are reasons influencing why people deviate from process standards. They are just not aware of how the process should be exactly executed and therefore decide on their own what they think is the best way to reach the process goal. Lastly, another reason might also be that employees sometimes get the instruction from their supervisors to do a task in an unique way, which is not in line with companywide defined process standards.

While these are more of an unconscious action, some people also actively deviate from standard process. They are convinced that their process path is better than then defined one to reach the process goal. Moreover, after a process change this is a quite common phenomenon. Accordingly, people also tend to do their task the same way they have carried out in the past, even if new process standards have been implemented by the company’s management. (Marjanovic, 2000).

*Business Process Reengineering and Process Mining*

As presented in the previous section on normal accident theory, depending on their complexity level, systems contain an inevitable failure potential and the only way to abandon this is to redesign the system. This is also true for the system of business processes. Beside other business process improvement techniques such as Six Sigma, continual business process improvement and core process redesign, Business Process Reengineering (BPR) is one approach to improve business processes (Grant 2016).

BPR is a method used for achieving higher performance through a radical change of current business processes (Hammer, Champy, 1993). Therefore, BPR entails a total rethinking of how processes are currently carried out and how process goals can be achieved. (Murray, et al., 2000).

When selecting which processes should be reengineered, a company should focus on strategic processes. Strategic processes are defined as core processes which are directly related to the company’s business purpose and contribute to reach the strategic goals (Hanafizadeh, Osouli, 2011).

Other than the need to select the right processes to re-engineer, choosing the right
method for their alteration is a key factor for successful BPR. Cheung (1998) suggest two types of appropriate approaches for BPR projects, one is non-digital and the other is software-supported or software enabled.

Process Mining is a young software technology which could be used as a support tool for BPR. Based on the analysis of event-logs within the system of a company this technology enables analyzing really taken process steps. It supports process analysis, process policy conformance and the understanding of process models and is therefore a useful tool to support business process improvements (Polpinij et al., 2015).

**Theoretical Framework of Process Complexity and Research Gap**

**Process Complexity Framework**

Based on our structured literature review, we developed a heuristic framework for explaining the emergence of process complexity, taking into account its characteristics and interdependency to other complexity types within a production company.

![Fig. 1 Process Complexity Framework](image)

In general, there are three categories of complexity within a production company; which are product, process and organizational complexity (Größler et al., 2006).

Different developments such as technical development, market and customer demands are global trends which have either directly or indirectly influenced product or process complexity (Bode, Wagner, 2015). The different product variations and relevant number of components determine the product complexity.

Process complexity in general is determined by the number of possible process path alternatives and process steps actually taken (Mani et al., 2010). Organizational complexity can be characterized as the structure of hierarchy and delegation levels in an organization. Product complexity as itself also influences process complexity and organizational complexity (Größler et al., 2006). Organizational complexity can be characterized as the structure of hierarchy and delegation levels in an organization (Größler et al., 2006).
Their interdependencies can be exemplified through the following sample; a larger number of product variants and components require a larger number of suppliers which in turn often require different sourcing processes. Thus, an increase in product variants and therefore complexity, often directly leads to correspondingly higher process complexity. Increasing the number of product components also leads to the need for more employees (for example for product design, construction etc.) and therefore, also to an increasing organizational complexity (Bode, Wagner 2015).

These interdependencies go both ways, product complexity impacts organizational complexity, but organizational complexity can also affect products. Organizational complexity is often characterized by many levels of hierarchy and unclear responsibilities, which can lead on the one hand to higher product complexity due to unclear construction standards for example and on the other hand to a higher process complexity (Aitken et al., 2016).

Human factors are also reasons for deviating from predefined standard processes which influence process complexity (Arnott 2006), (Marjanovic, 2000). It is undisputable that process complexity impacts the performance of processes in terms of their lead times, inventory, delivery reliability and working capital (Bode, Wagner, 2015), (Aitken et al., 2016) as well as on network indicators like robustness, shortest path length and betweenness centrality (Boccaletti et al., 2006), (Meyer et al., 2015).

Research Gap
Aitken et al. (2016) argue that the desirability of different complexity levels should be distinguished, such that an acceptable level is identified depending on the strategic relevance. As only negative impact of complexity on corporate performance has been addressed in literature, there is a need for further research of the positive impact of process complexity on specific key performance indicators like process throughput times.

Furthermore, the reasons for deviation from predefined process standards must be further investigated. To further discussion on this gap, this paper aims to contribute to the research goal; how process deviation increase corporate performance in terms of process throughput times and how people behavior affect deviation from process standards.

Case Study
In order to explore above-mentioned question we present a case study of two German production companies (see table 2) and demonstrate the findings of two analyzed end-to-end processes, with a combined total of 1.794.000 data records of process paths truly taken, as inputted by employees in each respective companies SAP system. The characteristics of the two chosen companies are presented in the table below:

Table 2: Key facts of the companies

<table>
<thead>
<tr>
<th></th>
<th>company I</th>
<th>company II</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch</td>
<td>metalworking plant engineering</td>
<td>aviation</td>
</tr>
<tr>
<td>annual turnover</td>
<td>&gt; 900 Mio. €</td>
<td>&gt; 400 Mio. €</td>
</tr>
<tr>
<td>employee</td>
<td>2,000</td>
<td>1,500</td>
</tr>
</tbody>
</table>

The two chosen production companies dispose about all relevant key business processes with a relevant spectrum of attributes and complexity aspects like number of suppliers and customers, invoices in different currencies and delivery routes. The two chosen companies are large corporations. Therefore, also the company size, involved
departments and employees as well as the data and process volume represent the situation of a multitude companies. As both companies are production companies they often deal with all three presented complexity types; of product, process and organizational complexity. Moreover, there are many involved parties which contribute to the complexity, such as various departments, and employee hierarchies within a single process, which allows for an assessment of the underlying human factors on process complexity can be investigated.

For the analysis we used extracted data of one accounting period from the company’s Enterprise Resource Planning (ERP) system of the purchase-to-pay and order-to-cash process. In total 1,794,000 single data records were analyzed by using a process mining tool, named Celonis.

Table 3: Analyzed data records

<table>
<thead>
<tr>
<th>process</th>
<th>data record</th>
</tr>
</thead>
<tbody>
<tr>
<td>purchase to pay</td>
<td>1,593,000</td>
</tr>
<tr>
<td>order to cash</td>
<td>201,000</td>
</tr>
</tbody>
</table>

Based on event logs within the ERP system and the time stamps of the several process step activities the process mining tool is able to mirror the actually taken process paths. Based on the analysis of the time stamps Celonis is also able to determine the used throughput time. It is possible to define a target process and doing a conformity check if the process path and the specific steps are the same as they were defined in the target process or if there occurred some process violations.

The central measured values from the tool are the throughput time based on the analysis of the time stamps and the cases per step, based on the analysis of the IT-documents per process activity. In the following section we show the process deviations taken, as well as their identified influence on performance indicators.

Findings

Comparison of Planned vs. Actual Process Paths

The standard process predefined by management are first shown for purchase-to-pay (Figure 2) and order-to-cash (Figure 3).

![Fig. 2 Standard purchase-to-pay process](image-url)
To validate our framework about desired and undesired complexity we present the following example from our analysis of the invoicing part of the order to cash process. We investigated in the order to cash process a normal throughput time of 23 days. For this sub process part a normal throughput time of 8 days is defined as a standard. The activity “send overdue notice” for sent invoices where there is no cash income yet, is defined by the company as a desired activity. Even the throughput time of the whole process increased by 17 days and also the process complexity increased due to the extra loops, it is a necessary complexity increase and certainly also by management a desired process step, from a company strategic point of view.

Figure 4 shows the comparison to Figure 2 of the network topology between the purchase-to-pay standard process with its accepted path alternatives and the process path actually within the company.

As also the figure illustrates, we investigated a higher static complexity due to the increase of possible path alternatives. Also, a higher dynamic complexity occurred due to the taken process paths and the deviation from the standard process.

We investigated the shortest path length of the taken process path. $D_{ij}$ defines the length between one node $i$ to another node $j$.

$$L = \frac{1}{N(N-1)} \sum_{i,j\in N, i\neq j} d_{ij}$$
The shortest path length increased by 7-9%. This means there is a higher effort necessary to reach the process goal and confirms the increase in complexity.

By using a process mining tool process throughput times can be easily investigated. We analyzed the throughput times of the two end-to-end processes in the several taken process path variants. Apart from the standard process there were 655 alternative actions in the purchase-to-pay process of Company I and 11,421 variants in Company II, taken by the employees involved in the process. In the order-to-cash process 636 variants exist in Company I and 76 variants in Company II.

Regularly the throughput times increased when deviating from predefined standard processes. But we also identified between 10% and 20% process variants where the deviation from the standard process has led to a decrease of throughput time by 10-12%.

Further, we found that even when people deviate from predefined standard process within the process activity sequence, the start point and the process end for each taken variant was always identical. This indicates that the employees which are involved in the respective processes, actively or unconscious, take alternatives but always to reach the identical process purpose. For example in the purchase to pay process we investigated cases where the process starts directly with the order and afterwards the purchase request was placed in and approved in the system. This indicates that the employee was under time pressure to quickly receive the goods and there was no time to wait for the approval of the request.

**Performance increase due to process deviation**

Further, we investigated, deviations from standard processes resulting in a shorter throughput time for example due to different starting activities as predefined in the standard process or due to different process activities within the process or due to a different sequence of process steps. These were undesired process steps, but contributed to a better corporate performance.

Therefore, this is already a first indication for a necessary Business process reengineering. This implies that the really taken process path leads to a better performance result than the defined standard process. Are there undesired process alternatives which lead also to a performance decrease management should choose action alternatives to abolish this situation. In case there is a performance increase and also the process steps are desired management should proceed and maintain the current situation. Whereas a performance decrease in combination with desired process steps also indicates a necessary business process reengineering. This implies also that the predefined standard processes lead to a lower performance than the really taken process paths.

**Conclusion**

This paper investigated the characteristics and emergence of desired and undesired process complexity.

The presented heuristic framework illustrates the cause-and-effect-relationships between impact factors and performance effects of desired and undesired process complexity. It has been shown that an increase of process complexity and the deviation from standard process can increase performance.

First approaches have been developed to explain reasons and influencing factors of process deviations.

From a practical perspective the used data analytics methodology of the process mining tool shows how current data analytics tool can be used in practice and help to analyze big volumes of process data and identify really taken process paths within a
company’s business. Further we gave advice for management to choose the correct action alternative based on the level of desired complexity and the performance impact.

Stakeholders’ involvement in additive manufacturing innovations

Miia Martinsuo
Industrial Engineering and Management, Tampere University

Abstract
Additive manufacturing (AM, 3D printing) is gaining increasing attention in the manufacturing industry as a collection of novel advanced technologies, supply chains and processes. Firms implementing AM are active in innovation, but successful innovation requires support from other firms in the supply chain and secondary stakeholders. This exploratory study seeks new knowledge on secondary stakeholders’ involvement in AM innovation activities. The findings reveal who the secondary stakeholders are and their scope of involvement in the AM firms’ innovation process. The study contributes by characterizing the network complexity in AM innovations and guiding AM firms’ actions toward stakeholders.

Keywords: Additive manufacturing, stakeholder involvement, innovation

Introduction
Additive manufacturing (AM) is a relatively novel manufacturing approach that implies changes in manufacturing technologies, the use of digital product designs, and a new process of joining and adding material, usually layer by layer (ASTM, 2012), to produce goods. The diffusion of AM technologies in the manufacturing industry will require innovations in the business models, supply chains for the firms involved, and products and services (Weller et al., 2015; Martinsuo and Luomaranta, 2018), driving AM firms to be very active in their innovation activities. Innovation, in its classical sense, means the introduction of a new product, process, or business model for a commercial purpose (Schumpeter, 1934). We concentrate on innovations in AM-related products, including both the manufacturing technologies and the new goods being manufactured.

Creating and introducing new offerings in the competitive industry requires a systematic innovation process (Drucker, 1985). This innovation process can then be divided into three sequential phases that are idea generation, idea development, and the diffusion of the developed concepts (Hansen and Birkinshaw, 2007). In idea generation stage, an idea for the innovation is generated inside a firm or through external sources. In the idea development stage, the best ideas are chosen and the development work starts internally or with external sources. In the diffusion stage, firms try to commercialize the outcome of the innovation.

In the innovation process, the innovating organization can use the support of external resources. Besides firms operating in the direct supply chain of AM, various stakeholders with different interests and demands have an influence on AM product innovations. There are multiple definitions of stakeholders (Miles, 2017) and these different definitions serve their dedicated purposes by focusing on the relevant stakeholder attributes in their context.
This study concentrates on secondary stakeholders - those external organizations with an interest in or contribution to AM product innovations, but who are not the key firms, institutions or customers in the direct AM supply chain.

Previous AM-related research has identified that research and training organizations have an important role in giving training regarding AM and transferring knowledge to firms (Rylands et al., 2016). Standardization organizations are important stakeholders when standards are created in the emerging technology (Monzón et al., 2015). Before the specific work of standardization organizations, other stakeholders such as trade organizations and engineering associations specify the need for standards and influence through the standardization process (Koch, 2017). Previous research has identified and mentioned such AM stakeholders only briefly and their input in AM innovations is poorly understood.

The purpose in this study is to explore the involvement of secondary stakeholders in the innovation process of AM products. The goal is to create knowledge on how different secondary stakeholders take part in AM innovation activities with firms in the AM supply chain and, consequently, help firms benefit from their involvement. The primary research question is: How do different secondary stakeholders participate in AM innovation processes with the firms in the AM supply chain? The question is approached from the perspective of the innovating firm in the AM supply chain and at the product level in an emerging industry of AM.

**Literature review**

*Defining stakeholders*

The term ‘stakeholders’ has many alternative definitions (Miles, 2017). In stakeholder theory, stakeholders are assumed to be a part business and are defined as “groups or individuals that have a stake in the success or failure of a business” (Freeman et al., 2010, p. xv). Often the definitions of stakeholders use the context and stakeholders’ attributes to serve the purpose of the study (Freeman et al., 2010), meaning that in a case of a large multinational firm, stakeholders could be the customers, suppliers and employees. In the strategic management literature, the focus is usually on the attempt to define which stakeholders are important from a firm’s perspective and to which stakeholders should the managers pay attention (Mitchell et al., 1997). Usually stakeholders in strategic management are categorized into shareholders, firm employees, customers, suppliers and sometimes competitors, which can be referred to as primary stakeholders, and then to the secondary stakeholders who are external organizations with regards to the supply chain, not directly involved in for example manufacturing and delivery, but may indirectly influence the innovation process (Freeman et al., 2010). These secondary stakeholders can be for example national governmental organizations and labor associations.

Some management frameworks handle business environment changes for the firms as external forces (see for example PESTLE analysis), and for example legislation is part of such forces. These external forces are difficult to influence, but they have an influence on the firm, and the organizations in question could well be categorized as secondary stakeholders. Stakeholder theory suggests that the relationship with secondary stakeholders is more complex and despite secondary stakeholders’ influence, firms can also use these relationships as two-directional (Freeman et al., 2010).

It has been noticed that firms give relatively little attention to systematically identifying and analyzing important stakeholders (Bryson, 2004), but such relationships can cause uncertainties in the innovation process. Therefore, exploring stakeholders and their relationship with innovating firms in the innovation process is relevant for managers and practitioners. Defining the stakeholders in a too narrow manner would most likely lead to ignore some important stakeholders from the perspective of innovation in an emerging technological area. This study purposely looks beyond the manufacturers’ customer-oriented core supply chain and concentrates on those external organizations – secondary stakeholders - with an interest in or contribution to AM.
**Involvement of secondary stakeholders in the innovation processes**

A focal firm’s relationships with the secondary stakeholders have increasingly been considered as an important way of developing innovations (Haeckel, 2004). The secondary stakeholders can participate in the innovation process, for instance, by offering knowledge through a network that they represent (possibly including customers). In some cases these secondary stakeholders are non-profit organizations whose interest is not to make profit by conducting business, but to serve a social cause (e.g. environmental protection, or a university offering education). Developing relationships with these secondary stakeholders can foster innovation by creating suitable conditions for discovering relevant ideas. Gaining access to these dense networks that differ from the focal firm’s direct supply chain can offer a different view of the marketplace and offer early warning signs about shifts in public tastes and values (Yaziji, 2004). An empirical finding from biomedical innovations shows that a firm’s experience of collaborative relationships with partners in a hub provided by secondary stakeholders was a key determinant of innovation (Powell et al., 1996).

In addition to this passive involvement, secondary stakeholders can have a more active role in the innovation process. Findings from strategic management show that organizations are more inclined to protect their existing processes than develop new ones until they are sure that the development is almost risk free. Therefore, a stakeholder (primary or secondary) outside of the firm can try to force the innovation if a firm does not do it voluntarily (Van de Ven 1986). Developing relationships with non-governmental organizations (NGOs) is good for the firm’s social legitimacy. Firms may need these relationships with NGOs to be perceived as socially and environmentally responsible (Berger et al., 2004). Firm-NGO partnerships can address both broad and complex societal issues and they can become a source of competitive advantage (Bonfiglioli et al., 2006).

The earlier studies in the context of AM have mentioned secondary stakeholder involvement in innovation processes briefly. For example, research and training organizations have an important role in giving AM-related training and transferring knowledge to firms (Rylands et al., 2016) so that they can start the AM innovations in the first place. They can be of help also later in the innovation process for example in the testing and development phases. In the case of an emerging technology, standardization organizations are important stakeholders when standards are created (Monzón et al., 2015). Before the specific work of standardization organizations, other secondary stakeholders such as trade organizations and engineering associations specify the need for standards and influence through the standardization process (Koch, 2017). By developing relationships directly with the standardization organizations or more likely through associations, firms can influence in standardization for example so that it enhances their chances to diffuse their innovations.

**Research design and method**

The research design is qualitative and exploratory in nature because of the limited previous knowledge on stakeholder involvement in AM innovation activities. The study was targeted at two major industries where AM has shown great potential: car manufacturing and medical implants. The focus is on secondary stakeholders.

Figure 1 illustrates the research context. The AM supply chain is presented in the middle. Any firm within the supply chain can be considered as a focal firm, and the other firms are its primary stakeholders. Outside of the supply chain are the secondary stakeholders, whose participation in the innovation process of the focal firm is covered in this study.
Figure 1 – Illustration of the AM supply chain (primary stakeholders) and secondary stakeholders

Data collection
Data were collected through two workshops and a survey with thirteen AM firm and stakeholder representatives (labeled as organizations A...M). Background information on firms that participated in the workshops and survey is presented in table 1. Organizations A and F are involved solely in the medical implants industry. Organization B represents car manufacturing industry, whereas the rest of the organizations are involved in AM industry more generally, including both – car and medical implants industries.

During the first workshop, the participants were instructed to map their dedicated supply chain and actors in it, including all the organizations and institutions inside and outside the supply chain with whom they are developing innovations.
After the listing of stakeholders, a survey was sent to the firm representatives concerning the activities that the stakeholders engage in with the AM firms. The question in the survey was: “Based on your experience, what inputs or requirements do the external stakeholders bring to the network of firms in additive manufacturing supply chain?” External stakeholders were divided into: funding and insurance firms; training organizations; regulators and patent authorities; trade associations and customer representing organizations; research organizations; and other. Respondents had a chance to offer an open-ended response systematically to each identified stakeholder, and also add stakeholders they considered as relevant.

Another workshop was organized with the same firms and a group of researchers to recognize the interactions, activity inputs and outputs of stakeholders with the firms in the AM network. In this second workshop, the participants discussed in industry-specific teams (car manufacturing, medical implants) to fill in and organize a process map that included the previously identified stakeholders and their inputs and requirements. The data created during the workshop covered: the stakeholders’ relationships with the firms in the AM supply chain, requirements of the secondary stakeholders, benefits to AM firms from the relationships, and phase in the innovation process of the secondary stakeholders’ involvement. Discussion during the workshop was documented into memos and flipcharts.

Analysis
The analysis concentrates first on identifying and defining the secondary stakeholders (results in table 2) and then mapping the secondary stakeholders’ involvement for three AM innovation process phases (table 3). Based on the answers about secondary stakeholders in workshop 1, table 2 was formed by listing all the relevant stakeholders, removing those expressions that concerned primary stakeholders, and combining the repeating attributes of secondary stakeholders into logical descriptions.

Based on these data, the power/interest matrix analysis was done, according to the three phases of innovation process, i.e., idea generation, idea development and the diffusion of developed concepts (Hansen and Birkinshaw, 2007). One of the most common stakeholder mapping methods is to use a two-by-two matrix with key attributes on both axes. These attributes can be for example power and interest, importance and influence, or support and opposition (Bryson, 2004). For this study, the power and interest matrix was chosen since it offers the most insight for studying the stakeholders’ involvement in innovation. The data from the survey and the second workshop were used, to analyze each phase at the time using the power and interest matrix.

Interest attribute reveals if the secondary stakeholder is very pro-active in its involvement or if is more passive. It is also important to understand the power that each stakeholder possesses, because it creates understanding on whether the secondary stakeholder is empowering or controlling the innovation process. Also the power may lie in the ability to affect innovation in the short term or affect its success and acceptance in the long-term (Mathur et al., 2007) Figure 2 illustrates the power/interest matrix used in this study. During the analysis, the interest of the secondary stakeholder was considered as high if an AM firm respondent described a secondary stakeholder’s participation for example as follows: “they brought the idea” or “they started the discussion” or “they were very active”. Concerning responses by secondary stakeholders themselves, the interest was considered as high if they claimed an active role such as “we had the idea and then we tried to find a firm to collaborate with us”. In the analysis of power, strong power was coded if the respondents expressed that: “we have to comply” or “it is very important to collaborate with them”. Weak power was coded if the expressions were for example the following: “it was not necessary but beneficial to us” or “we collaborated voluntarily”.

Analysis
The analysis concentrates first on identifying and defining the secondary stakeholders (results in table 2) and then mapping the secondary stakeholders’ involvement for three AM innovation process phases (table 3). Based on the answers about secondary stakeholders in workshop 1, table 2 was formed by listing all the relevant stakeholders, removing those expressions that concerned primary stakeholders, and combining the repeating attributes of secondary stakeholders into logical descriptions.

Findings

Identifying and describing secondary stakeholders

This study identified the key secondary stakeholders for AM innovation processes. They are: Regulators, NGOs, funding organizations, training organizations, research institutes, standardization organizations, patent organizations, trade associations, organizations representing customers and end-users and insurance firms. Table 1 shows the identified secondary stakeholders and their description from the perspective of the firms involved in the study, based on their answers to the survey.

<table>
<thead>
<tr>
<th>Secondary Stakeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regulators</td>
<td>Regulators regulate laws such as tax laws. They also try to secure reliable and sound products, by giving regulations for compliance and granting certificates. For these certificates and laws there needs to be collaboration with research institutes, AM machine manufacturers and AM producers. Regulators also set regulations or encourage firms to develop clean, material- and, energy saving technologies, they set safety regulations and try to create new job opportunities.</td>
</tr>
<tr>
<td>NGOs</td>
<td>NGOs in the context of AM most often are protective of the environment and/or the society. Damage to the environment may seem like a small issue at present but as time goes on, repairing such damage becomes increasingly costly. The information that NGOs can provide about the effects of new technology on environment and society can be used to enhance the responsibility of the industry and to protect end-users and the wider society from the social consequences of AM applications.</td>
</tr>
<tr>
<td>Funding organizations</td>
<td>Funding organizations can be national or for example European level organizations. Their input - funding - enables new product development in a quicker pace. They require from firms comprehensive resource allocation and reporting to support the AM innovations in the most efficient way.</td>
</tr>
<tr>
<td>Training organizations</td>
<td>Training organizations provide standardized training, give knowledge as quickly as possible to the organization in AM and offer different formats in training (including degree programs and lifelong learning). The training can deal with general AM knowledge as well as best practices. Training organizations need to accumulate the state of art knowledge, gather funding, and analyze firms’ current situation and the market. Trainings with multiple attendees can enhance the connections within the AM network.</td>
</tr>
<tr>
<td><strong>Secondary Stakeholder</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Research organizations</td>
<td>Research organizations are sometimes the main contributor and starting point for developing innovations in the early phase (idea generation, development), but they need firms to commercialize the innovations (development, diffusion). Research organizations rely on funding organizations and firm partners to fund their research and development activities to develop innovations. Research organizations contribute to new regulation creating processes, and new standard making processes. They also transfer knowledge to training organizations.</td>
</tr>
<tr>
<td>Standardization organizations</td>
<td>Standardization organizations set the standards for characterization of AM produced parts. This includes data formats, reliability, quality requirements and restrictions on software use. Through the standard compliance, this can foster some technologies more than others. To create standards, standardization organizations need to collaborate with industry experts, research organizations and firms in AM value chain. Standards ensure common understanding among stakeholders, which is important for communication and innovation purposes. Standardization organizations also coordinate the expert groups to develop standards.</td>
</tr>
<tr>
<td>Patent organizations</td>
<td>Without patents the innovations would be freely adoptable by any competing firm. Since there is a cost associated with innovation, the patents serve as a securing mechanism to protect the ownership of the innovation and enable the owner to make profits to cover the costs of the innovation. Patent organizations provide help and instructions to the firms seeking to file a patent application. Patents can serve also as source of knowledge after they expire and become public. Especially if the patented technology becomes industry standard, firms have all the knowledge about the technology, after the patent expires or it is licensed by the patent owner.</td>
</tr>
<tr>
<td>Trade associations</td>
<td>Trade associations provide new knowledge to their members, strengthen current networks, create, and explore new networks. Trade organizations seek to gather information about the markets to provide marketing possibilities to different countries. Trade associations need to collaborate with research organizations, regulators both within their country on outside as well as with its members. Professional associations such as engineering associations are included in this category.</td>
</tr>
<tr>
<td>Organizations representing customers and end-users</td>
<td>Organizations representing customers and end users identify possible applications and thematic areas for AM. They collect requirements of the customers and end-user needs to analyze possibilities for further applications of AM. They have the possibility to influence the market (and in this way, the whole value chain) through the feedback of customers and end users. For this, they need to collaborate with communities of interest, informal networks, educators and technology users. Firms in the AM value chain can use the knowledge from organizations representing customers and end users to help to understand the potential needs and concerns from customers and end user.</td>
</tr>
<tr>
<td>Insurance firms</td>
<td>Especially in the medical sector, insurance firms can foster some technologies more than the others through the insurance decisions. This is an economic aspect for the medical sector in terms of risk management (granting insurance for AM implants vs. traditional implants), and has to follow regulations as well. Insurance firms also offer background information about risks that inform AM firms about the possible volumes and needs of certain medical implants.</td>
</tr>
</tbody>
</table>

Analyzing the involvement of the secondary stakeholders in the innovation process
The power/interest matrix analysis was done for each of the innovation process phases respectively and the results are presented in the table 3. For example research organizations had a high involvement in the innovation process phases of idea generation and development, as workshop participants discussed this actively. In the car manufacturing sector, research organizations were mentioned as stakeholders who most often generate and introduce new
AM component ideas or AM methods to car manufacturers’ products or production. Especially in the medical implant innovation process, workshop participants mentioned that the research organizations have high interest of being involved in the innovation process in the development phase when the implants go through clinical testing. Ultimately they do not have enough power to go through the whole innovation process by themselves, but they need the AM firms. On the other hand the focal firm does not necessarily need the research organizations, but they can benefit from the faster development through the involvement of research organizations.

An example of low interest and weak power in the first phase of innovations comes from training organizations. According to the workshop participants, innovating firm needs training organizations to supply the education, and they have weak power to involve in the innovation process. Of course training organizations try to market their services, but their interest was seen as lower than research organizations among the respondents. This was considered to be applicable in both the medical implant and car manufacturing sector.

</tbody>
</table>

In the diffusion phase of the innovation process, organizations representing customers and end-users have a powerful position and they have a high interest in involving in the innovation process. These organizations are advocacy groups that can represent for example customers in a certain medical field, or conduct testing and inform the customers about the new innovations and their reliability in the car sector. According to the workshop participants, such organizations try to provide the best new innovations to the customers they represent. Therefore, their role is important for AM firms trying to diffuse their innovations,
and AM firms try to convince and involve organizations representing customers so that their innovations would be successfully diffused.

Insurance firms are an example of the other extreme of the scale compared to the research organizations. Based on the answers from the survey and data from the workshops, insurance firms do not seek the involvement to the innovation process actively at all and their involvement was only seen in the last phase of the innovation process – innovation diffusion. Especially in the case of medical implants manufactured additively, the innovating firms have to convince the insurance firms that their product, which might be more expensive than traditional implants, is in the long scope better for the patient. Therefore, insurance firms were considered to have a low interest in seeking to involve in the innovation process, but they have a great power whether the innovation – medical implant – can successfully be diffused to the market. This can of course be the case because of the rather emerging sector of AM and AM implants, and in the future their role can be more active. The insurance firms were not considered to be very important for car manufacturing sector.

**Discussion and conclusion**

This research started with the premise that AM innovations require the involvement of stakeholders both within and outside the direct supply chains of AM firms. The research question was: *“How do different secondary stakeholders participate in AM innovation processes with the firms in the AM supply chain?”* With this study, we draw attention to the complex networks where also the secondary stakeholders have an important role with regards to creating and implementing AM innovations. The focus was on stakeholders’ participation in terms of interest and power throughout the innovation process.

This study reveals that secondary stakeholders have different types of involvement over the innovation process, and this involvement varies during the innovation process very differently, depending on the specific stakeholder type. Different secondary stakeholders are involved in the AM innovation process with the firms in AM supply chains in four different ways. 1) Their participation may be reactive only when AM firms seek external support and their power is weak meaning that their advice or involvement is voluntarily from the perspective of the AM firm. 2) Their involvement can be very active but weak in power, potentially reflecting the stakeholders’ unique capabilities that are useful in the innovation process. 3) Some stakeholders’ involvement can be very active and powerful meaning that AM firms need to comply with everything that the secondary stakeholder advises (usually these kinds of stakeholders would greatly endanger the success of the innovations if AM firms do not comply). 4) Some stakeholders’ interest is low but powerful (it would be for example against the laws and regulations for AM firms not to comply).

The findings offer contributions by adding to the limited previous research about secondary stakeholders’ involvement and, particularly, by offering a holistic view to the stakeholder landscape of AM. This study adds the perspective and involvement of secondary stakeholders to the AM innovation process, while previous attention has tended to be on company dyads or direct AM supply chains only. The findings provide AM firms a way to identify the central stakeholders, promote market access, and achieve other benefits during the innovation process. The study creates new knowledge from the perspective of the firms directly involved in the supply chain of AM, acknowledging the complex business network around them.

The study also lends support to some studies that have covered certain stakeholder groups separately. For example, the findings are in line with Rylands et al. (2016) concerning training organizations and research organizations as important stakeholders in the AM innovation process, Monzón et al. (2015) regarding standardization organizations influencing and being influenced during the AM innovation process, and Koch (2017) about engineering associations as important hubs of knowledge and ideas. The findings of this study also support the views of stakeholder theory (Freeman et al., 2010) in proposing that AM innovations do not happen in isolation within one firm alone, but there are other stakeholders - especially secondary stakeholders - that have an influence on the innovation process.
This study used an exploratory research design with workshops and a qualitative survey to collect data. This research design allowed to have a wide understanding about the phenomenon of secondary stakeholder involvement in the innovation processes. As a limitation, however, the design does not allow to analyze single secondary stakeholders or single innovations very deeply. The findings are limited to medical and car manufacturing sectors of the AM industry. Each of the respondents also gave their firm’s point of view to the research task, possibly causing a single-respondent bias. In the future, more respondents from each firm could be involved for a more in-depth study on secondary stakeholders’ involvement.

Abstract

Existing studies on the antecedents of innovation performance have focused on firms’ internal capabilities. However, the importance of supply chain capabilities in improving innovation has not been fully investigated. In supply chain management practice, managers commonly face conflicting decisions between internal and external capability areas. This causes firms to fall in dilemmas around supply chain decisions for innovation. Drawing upon the extant literature, this paper proposes a conceptual framework to investigate how firms develop supply chain capabilities to improve innovation performance. The framework is exemplified by a longitudinal case study highlighting decision-making dilemmas around supply chain resources, coordination and learning.

Keywords: Supply chain capability, Innovation, Longitudinal case study

Introduction

Innovation is essential for firms to achieve superior business performance. Scholars have conducted numerous studies to investigate the antecedents of firms’ innovation performance. In the extant literature, one of the commonly adopted theoretical perspectives is the resource-based perspective, including the resource-based view (RBV), dynamic capability and other branch theories. These studies highlight a focus on firms’ internal capabilities. However, firms’ innovation decisions are embedded in their supply chain (SC) network, where their connections and interactions with supply chain partners place impact on their innovation performance. This calls for an extension of the resource-based perspective in order to link the innovative firm with its supply chain network.

Recently, the importance of supply chain capability in improving innovation performance has attracted increasing attention (Gao et al., 2017). Supply chain capability is a collective ability or learning of supply chain members to achieve strategic objectives through accessing and deploying dispersed resources (Zhang et al., 2016). It involves the firm’s upstream, downstream and spanning processes (Tracey et al., 2005) and is regarded as a kind of network capability. A higher supply chain capability allows more innovative product development and hence more competitive advantages in the market (Morita et al.,
2018). Therefore, supply chain capability serves as a link between the firm and its supply chain network.

In firms’ supply chain management practices, it is common that managers face conflicting decisions between internal and external capability areas. This causes firms to fall in dilemmas around various decisions. In the extant operations management (OM) literature, there is a dearth of studies on how firms make decisions when there are conflicts in resource allocation, supply chain coordination, and supply chain learning, which are key dimensions of supply chain capabilities (Zhang et al., 2016). Drawing upon the extant literature, our paper proposes a conceptual framework to investigate how firms effectively develop and utilize supply chain capabilities to improve their innovation performance. The framework has three dimensions, i.e., supply chain resources, supply chain coordination, and supply chain learning. We aim to scrutinize the potential decision-making dilemmas in each dimension. In doing so, this paper is expected to contribute to the supply chain innovation literature by providing a systematic theoretical model to possibly resolve conflicting arguments for internal and external capabilities.

**Conceptual Development**

This paper proposes a conceptual framework of supply chain capabilities for innovation. It is argued that the supply chain capability development is realized through accessing and deploying supply chain resources (Esper and Crook, 2014), coordinating and integrating activities along the supply chain (Cao and Zhang, 2011; Shou et al., 2018), and adopting effective learning mechanisms with supply chain members (Yang et al., 2018).

The importance of supply chain resources has been widely reported in the OM literature. There are diverse views on their contribution to innovation. In one side of the debate, scholars with the traditional RBV believe that external resources can supplement internal resources and as the result will expand the scope of and speed up the process of innovation. In the other side, scholars with the resource dependent view warn managers about the risk of relying on external resources and subsequently failing to maintain a consistent priority to build up critical resources for innovation. Supply chain managers in practice often find themselves falling in a hopeless situation to avoid the possibilities of being unwillingly constrained by internal resources (path-dependent) and being overly dependent on external resources (hollowed-out) in their innovation initiatives.

Supply chain coordination has two options in general based on collaborative or transactional terms. Collaborative relations can lead to obvious benefits, but the focal firm must possess necessary bargaining power and be prepared to invest in effective coordination mechanisms (including formal and informal processes). Otherwise, the focal firm has to work with suppliers on a transactional basis. In a rapidly changing operations context, managers may consciously maintain a transactional relationship with suppliers in order to explore flexible choices and avoid the risk of being locked in. Dynamic switches between collaboration and transaction are required by the uncertain nature of supply chain innovation, which lead to another set of dilemma decisions.

Supply chain learning, based on shared cognition and practice, has been increasingly recognized as a key strategy for innovation. Such learning practice can focus on the reuse of existing knowledge and the creation of new knowledge. Such explorative and exploitative orientations, albeit being popularly promoted in an ambidextrous strategic setting, require very different toolsets and processes to overcome learning boundaries among individuals, organisations and disciplines. These boundary spanning decisions lead to the third area of innovation dilemma in supply chain management.
Figure 1 brings together the above conceptual development in a structured framework. The framework has been used to guide our case study to exemplify how these dilemmas exist in a consistent research setting and to suggest directions to identify possible means to deal with them for supply chain innovation.

**Methodology**

This paper adopts a case study approach (Yin, 2018). It analyses multiple decision-making frames within a consistent setting of the sampled firm. Our analyses are based on qualitative evidence, as the observations and summaries on firm innovation and supply chain decisions involve qualitatively different types of firm behaviours that are hard to quantify and show variation in kind instead of in degree (King, Keohane, & Verba, 1994). Primary data was collected in three years from 2015 and covered the firm’s development in the past over forty years. Hence this case study has a longitudinal nature to possibly identify evolving decision frames around the three dilemmas. Secondary data were used to triangulate the data sources and increase the validity of the study (Voss et al., 2002).

In order to understand the firm’s decisions in the process of innovation, relevant context (e.g. key actors, the internal processes of the firm and the network interaction in its supply chain) cannot be separated from the research subject. The research method of case study has the advantage of involving relevant contexts of the research subject (Yin, 2018), and serves as a reasonable strategy for describing a phenomenon as well as exploring theories (Eisenhardt, 1989). This method therefore allows us to develop an in-depth examination of firm decision-making.

This study adopts theoretical sampling in firm selection. The sampled firm – Wensli Group – is a textile and clothing manufacturer in China. In the past four decades, Wensli has achieved lasting superior innovation performance through supply chain management and become a leading firm in the industry. It has established its own brands, partnered with world-class companies, and demonstrated constant strategic capability development for innovation, which has been maintained and supported by various internal and external decisions along time. This firm is therefore of great value for this study.

**Data Collection and Analysis**

The analyses in this study are mainly based on data collected through semi-structured interviews. A group of managers were interviewed and each interview lasted 3.5-5 hours. Besides primary data, we also collected secondary data from a variety of sources, with the objective of strengthening the validity of observations and analyses. Our first visit to the case firm was in June 2015. This visit established a bilateral agreement between the company and the researchers on the research project and interview plans. Based on the outcomes of the first visit, interview questions were designed with a clear definition of
the research theme and focused subjects related to the research objective. This aimed at achieving a systematic collection of information (Eisenhardt, 1989).

In-depth interviews were then conducted with a group of senior executives of the company in July 2015. Two interviewers in the research team each occupied a unique role. A senior scholar focused on raising questions and chasing detailed answers, and a junior scholar took both audio and written records of the questions and answers. The audio record was taken for the full length of the interview without interruption or manual editing. It therefore provided complete first-hand data of the case study. A third researcher jointly analysed the audio and written records of the interview together with the two interviewers. Information was captured as both integrated notes and original narratives. These two versions of records were cross-checked among all researchers in order to enhance confidence in accuracy and avoid omission of important information. The separation of the two interviewers and the third researcher offered an opportunity for objective analysis. Considering the fact that the research method of case study has the weakness of involving an overwhelming amount of information, the process of partly separating observation and analysis allowed the third researcher to avoid being distracted by a large amount of details during the interview arrangement (Eisenhardt, 1989). The interviews were transcribed in text format, amounting to 37 pages.

In the process of data analysis, evidence was kept chained with research questions (Yin, 2018), and observations were matched with theoretical concepts (Rasmussen, Mosey, & Wright, 2011). Primary data were triangulated with secondary data from multiple sources. These include existing case studies published by local scholars in Chinese, the official company website, archived news and business magazines, and the official firm account on social media. They were used for triangulation (Eisenhardt, 1989) and to enrich the details included in the discussion. This provides information on multiple aspects of the firm’s strategies, and therefore increases the comprehensiveness of observations and understandings (Baxter & Jack, 2008). In the presentation of case findings, relevant interview quotes were included as examples of evidence (Yin, 2018).

Case findings were established through analyses of interview data. The initial results of data analysis were presented to the company executives in a third visit in January 2016. This visit aimed at verifying the findings of data analysis with feedback from the interviewees, as well as collecting supplementary information for case analysis. The three visits formed a process of systematic data collection with consistent checks and feedbacks on observations and analyses. This helps to reduce bias and enhance the accuracy of the researchers’ understanding and summary on interview data. It therefore improves the reliability of the case finding.

NVivo software was used to facilitate data analysis because it allowed us to identify and develop emerging decision frames with a large amount of qualitative data. Supply chain decision-making dilemmas were identified by coding and comparative analysis across different development stages.

Finding
Wensli Group was founded in 1975 in the city of Hangzhou, where the local manufacturing cluster enjoys traditional craftsmanship in silk making. Wensli focused on the production of silk textiles and women’s wear during its early development. The firm was initially founded as a township factory, collectively owned by the local government and community. Between 2000 and 2003, it went through a privatization process and became a limited liability company. The management has remained in the family of the founder general manager, and the positions of chairperson and CEO were handed over to the general manager’s daughter and son-in-law in early 2000s. According to the official
company website, the company had over 2,000 employees and annual sales of RMB 16 billion in 2016. The rest of this section summarises Wensli’s main innovation performance in the three stages of its historical development since its privatization. Each stage features distinctive strategic challenges and focuses.

Silk products used to enjoy strong advantages in the competition with chemical fabric products, as the texture of the latter was relatively hard and rough. However, technological innovations on porous fibre in 2003 improved the softness of chemical fabrics, making them a cheap but qualified substitute for silk. This caused serious shocks to the market of silk products. As a result, silk-textile producers encountered difficulty in maintaining profitability after 2003, including Wensli. Around the same period, recruitment of factory workers became difficult and wage level rapidly increased. The double challenges in product and labour markets pushed Wensli to adjust its strategic focus. Wensli’s initial strategic adjustment was reducing production capacity of traditional textile and clothing products and switching business focus to sales of silk-material gifts. To achieve this, the firm subcontracted most production activities to small manufacturing firms in nearby areas and started to focus on design of gift packages and promotion of gift sales.

A new firm was set up for the new business. Wensli took orders from customers and purchased finished products from suppliers. These purchased products were mainly silk scarves and pyjamas. Wensli then designed packages and sold them as gifts.

“I decided to close our stores, sell out our production plants and set up a new company without production equipment. I call this an asset-light business model, which focused on the sales of silk gifts.” (CEO, 14 Jan 2016)

For the purpose of cost reduction, Wensli adopted a new organisational structure – asset-light model – and diversified into silk-gift sector. This was realized through the removal of production activity and development of a targeted sales team. The new asset-light model enabled Wensli to remain profitable in a declining market.

Wensli was not able to stand out in the domestic market by selling homogeneous products purchased from subcontractors. After the first diversification into the gift sector, the CEO, Li Jianhua, noticed the potential of cultural concepts in promoting sales – gifts became more meaningful and valuable to consumers when there were cultural stories behind them. Consequently, Wensli began to pay attention to cultural elements that can be linked to silk products.

“It was not easy to sell silk gifts, unless you can tell a story which adds value to the products... Our experience in selling silk gifts led us to the idea of promoting cultural elements related to silk materials.” (CEO, 21 Jul 2015)

Wensli then added training process of the sales team to encourage employees to research on Chinese historic stories related to silk materials. For example, speech contests were organized as a training process for employees to present products with a cultural background. Gradually, cultural elements became the potential basis of Wensli’s product innovation.

“We paid special attention to the training of our salesmen, encouraging them to research on the Chinese cultural elements related to silk...” (CEO, 21 Jul 2015)

This led to the second step of Wensli’s strategic transition – further diversification into cultural and creative industry.

The first strategic transition made Wensli realize the opportunity of differentiating itself
through focusing on cultural elements related to silk. This led to the firm’s focus on innovative concepts and designs with silk-material products. Wensli then set its strategic focus as creating silk-material products to represent the traditional Chinese culture. Its product portfolio initially included mainly scarves, and later expanded to silk books, silk painting decorations and other silk artworks. The CEO described this as a unique and innovative move in the textile industry:

“I don’t think any other firm had the same vision [of the value of cultural elements in silk products] as we did... This distinguished us from the competitors.” (CEO, 21 Jul 2015)

The adoption of the “cultural and creative product” concept was a major turning point of the company’s strategic transition, and it was achieved through a vital event in 2008 – the Beijing Olympic Games. In order to put the new strategic direction on track, managers of Wensli worked on the establishment of a strong brand image closely associated with Chinese silk culture. However, this required substantial investment in advertisement and the company could not afford it. The 2008 Beijing Olympics Games then provided an extraordinary marketing opportunity:

“Sponsoring international events is brilliant marketing opportunities. Through these events, we sell products, promote our brand and build networks with media. Photos on our website with government officials wearing our products drew massive attention to our brand... I believe that this is the most cost-effective marketing approach one could hope to achieve.” (CEO, 21 Jul 2015)

The experience of sponsoring the Beijing Olympic Games gained Wensli opportunities to participate in other events (e.g. 2010 Guangzhou Asian Games, 2010 Shanghai Expo, 2016 G20 Hangzhou Summit etc.). Wensli then quickly built up its new position in the silk market. It became a symbol of the Chinese culture and thus a popular choice for cultural and creative gifts. The brand image of Wensli was then differentiated from those of other silk producers, through a cultural and creative brand image.

Stage 3 (Post-2015): Business Model Innovation

Through sponsoring major international events, the Wensli brand became well-known in the domestic market. This led to the firm’s ambition of gaining a competitive position in the global market. Although Wensli ranked among top Chinese textile firms, compared to global leader firms in the industry, it has significant gaps in terms of product quality and brand awareness. In order to further differentiate itself from other Chinese textile firms, Wensli attempted to create a China-based luxury brand in 2015:

“We’ve done well in building our brand name in China. The new objective is to further improve our products and promote our brand globally. We aim at pushing Wensli to the very top of the sector, and so we decided to develop a China-based luxury brand.” (CEO, 14 Jan 2016)

This new objective led to a higher level of complexity of Wensli’s business portfolio. After a decade of relying on suppliers for production, Wensli acquired a French factory for high-quality scarf production and recruited the former CEO of a French luxury brand for the purpose of learning. The acquisition enabled Wensli to gain some advanced techniques in silk production and learn experiences in luxury brand operation. The new production facility enabled Wensli to provide high-end products labelled “Made-in-France”. This also turned Wensli into a China-based subcontractor of some world-famous luxury brands.

The three development stages of Wensli and its innovation performance in each stage are summarized in Table 1.

### Discussion

The 2003 transition enabled Wensli to change its focus from production activity to sales of silk gifts. The objective was to remove the historical burden of the old organisational structure and establish a new one. However, in 2003 Wensli had a large amount of real estate assets and a number of plants, but limited cash to support the development on sales activity. The management hence wanted to dispose of the lands and buildings for cash.

In order to realize the new organisational structure – the asset-light model, Wensli negotiated with the local government to join the ongoing urban renewal project. As a result, the firm’s lands and buildings were involved and the municipal government acquired them with financial compensation.

“With the government’s support, we adjusted our asset structure and invested in the new business... We recruited college graduates to be salesmen and were able to develop the new firm for gift sales.” (CEO, 14 Jan 2016)

The local government helped liquidate Wensli’s physical assets, which provided the firm with financial resources for the implementation of the new structure. The CEO stated that without Wensli’s connection with the local government, it would have been very hard to realise the change.
“I took over the management of Wensli in 2003. Before that, the founder general manager had built close connections with the local government. These relationships played a critical role in facilitating our changes.” (CEO, 21 Jul 2015)

“The local government helped Wensli… we were not part of the urban renewal project in the beginning.” (HR Dean, 21 Jul 2015)

In this development stage, Wensli made use of its network connection with the local government to adjust its internal pool of resources and realised a change of non-strategic, physical resources into strategic, financial resources. In terms of supply chain activity, the realisation of Wensli’s new organisational structure depended on its partnership with suppliers. After removing production activity, Wensli relied on external suppliers for product manufacturing.

Since 2003, Wensli had switched its business focus from textile production to gift sales. During the process of concentrating on sales activity, Wensli discovered the benefits of cultural elements on gift sales, and the firm developed a specialized focus on the training of its sales team. This self-learning led to its latter positioning of the brand image as a representative of the traditional Chinese culture.

The 2008 Beijing Olympic Games enabled Wensli to firmly establish its brand image. The firm’s connection with the local government again provided important aid in the realisation of this marking approach. There was a fierce competition among firms for the sponsorship license of the Beijing Olympic Games. Wensli became one of the candidates in 2006, and proposed product design catalogues with silk materials. Instead of waiting to be selected, Wensli made use of its network connection to pursue a winning chance. When the founder attended a government conference, she showed Wensli’s catalogue to state government officials, and explained Wensli’s idea of promoting the Chinese culture through silk products. The state government officials then recommended Wensli’s design to the organizing committee of the Olympic Games in Beijing. Soon after, Beijing sent out a consulting team to Wensli for discussion on potential silk products for the games. As a result, Wensli won the opportunity to provide uniforms, medal ribbons and souvenir products with silk materials for the games.

“The Beijing Olympic Games were a major turning point in our development... Our success in winning this chance significantly benefited from the support of the government... The medal ribbons we provided for the event were patented after the games, and this was the start of our product-design activities. The experience of sponsoring this event also won us opportunities to participate in other events... The organizing committee of the 2010 Guangzhou Asian Games offered the sponsorship license to Wensli, because of the reputation of our brand name.” (CEO, 21 Jul 2015)

Wensli’s products significantly featured the Chinese culture with creative design of silk materials. They therefore attracted great attention through wide media exposure, and the company’s concept of cultural silk product was firmly established among consumers.

For the marketing approach of promoting the brand through participating in international events, Wensli’s network connection brought the opportunity for the company to demonstrate its expertise in silk materials and win the sponsorship. It was also during such cooperation with external designers in this international event that Wensli gradually built its own design team and developed the capability in creating cultural and creative products with silk materials.

Since its first transition in 2003, Wensli had been relying on external suppliers for production activities. The firm was once highly dependent on the manufacturing resources and capabilities of its suppliers. But during its development, continuous upgrading of the production process was necessary for Wensli’s new product lines. As a result, Wensli slightly adjusted its asset-light model at a later stage, from completely relying on external suppliers to building a self-owned factory. This is for the purpose of
quality assurance on high-end orders, product R&D, as well as the protection of intellectual property in its unique design and technology. The self-owned production extended further when Wensli acquired the French factory and undertook production for some international luxury brands:

“Our cooperation with the French enterprise improved our knowledge in running a luxury brand. It also enabled Wensli to join the global network of luxury brands, through being the subcontractor of many of them.” (CEO, 14 Jan 2016)

Therefore, Wensli’s organisation of production activity, although featuring a stable cooperation with its supply chain partners, showed a high level of flexibility and demonstrated considerations on various factors. The firm constantly receive and produce knowledge during its interactions with various partners in the supply chain network. But the external learning showed a focus on knowledge-reuse, whereas knowledge creation appears to have happened mostly inside the firm itself, e.g. its discovery on cultural value of gift sales and its design on cultural and creative silk products.

“We have over 3,000 self-designed styles of scarf in our database, and we upgrade our software for continuous innovation in design. In contrast with firms struggling in the industry, we enjoy a 28% growth of sales revenue and a 40% growth of profit this year.” (CEO, 14 Jan 2016)

Figure 2 summarises the case findings in the proposed theoretical framework.

*Figure 2 – Theoretical Framework with Initial Results*
Conclusion
Drawing from the existing literature, our paper proposes a theoretical framework of supply chain capabilities for innovation. Based on this framework, the case study illustrates the complex interactions among critical supply chain decisions for innovation in internal and external areas. It is evidenced that there are three typical dilemmas in supply chain capability development decisions. For resource access and deployment, a key question is to rely on internal resources or external resources for innovation performance. The results showed that external resources facilitate the strategic use of internal resources as well as the re-configuration of the firm’s internal resource base. For the coordination and integration of supply chain activities, there are multiple factors to consider in order to serve different types of innovation performance. For supply chain learning, while external learning leads to knowledge re-use, the firm’s creation of new knowledge appears to rely heavily on its internal processes. High quality decision-making in these three dimensions helps enhance the firm’s innovation. This study contributes to the supply chain and innovation literature by providing implications of building supply chain capabilities, as well as guidance for firms’ dealing with decision making dilemmas in enhancing innovation performance.

Abstract

Although many scholars have investigated the impact of supply chain integration (SCI) on performance, there is no consensus about their relationship. This paper conducts a first tertiary review to synthesize the main methodological approaches adopted in literature reviews (LRs) on the field, as well as to identify mediation and moderating factors that influence the link of SCI and performance. Findings indicate that the field has matured and reveal the main types of variables discussed (moderators and mediators) in the LRs. The present study also reinforces the high variety of dispersed results in the literature.

Keywords: Supply Chain Integration, Tertiary Literature Review.

Introduction

The advent of global markets, technological breakthroughs, and higher customer expectations are some of the factors driving companies to integrate efforts with supply chain members to face increasing competition as well as to better fulfill customer demands (Simatupang et al., 2002; Tarifa-Fernandez and Burgos-Jiménez, 2017). Therefore, firms are integrating intra- and inter-company processes and information, downstream or upstream the supply chain (Flynn et al., 2010), with the ultimate goal of achieving mutual benefits (Prajogo and Olhager, 2012; Huang et al., 2014). On the same vein, recent studies have revealed that such inter-organizational integration efforts, in the literature referred to supply chain integration (SCI), are an essential source to obtain companies’ competitive advantages (Zhao et al., 2013; Vanpoucke et al., 2017).

Although inter-organizational integration along supply chains is of significant theoretical and practical relevance, it is far away from being linear and straightforward. One of the most researched issues in the literature is the complex relationship of SCI and performance. This research topic has been intensively investigated in the last years by
empirical studies; however, their results show divergent conclusions. (Chang et al., 2016; Ataseven and Nair, 2017). While some researchers claim that integration directly impacts companies’ performance (Rosenzweig et al., 2003; Li et al., 2009), others advocate that this relationship is not always direct, or, in specific cases, might not even be positive (Hertz, 2001; Wiengarten et al., 2014). Since empirical studies have not reached a consensus on the integration and performance relation, literature reviews (LRs) have played a significant role in this discussion to comparatively understand their main findings, as well as to structure the main variables (mediators and moderators) that are constituting and influencing the integration and performance interdependency. Despite the high importance of these findings for both academics and practitioners, no study has comparatively analyzed and synthesized the LRs, and their evolution on “SCI and performance”. For this reason, this present paper conducts a first tertiary review with the focus on (i) synthesizing the main methodological approaches of the different LRs and (ii) identifying mediation and moderating factors, which influence the relationship of SCI and performance. Thus, the following research questions (RQ) are investigated:

- RQ1: How have the LRs on “SCI and performance” been conducted?
- RQ2: What are the main variables influencing the relationship of SCI and performance?

By integrating the findings from previous LRs on SCI and performance, this paper, firstly, provides a better understanding of the methodological steps applied in these studies, addressing RQ1. This analysis reveals valuable finding on how SCI research on performance has evolved in recent years. Secondly, concerning the RQ2, this work provides a first comprehensive overview of the variables (mediators and moderators) that can explain how and under what conditions integration can positively affect performance. This is particularly relevant for practitioners to understand and improve integration practices within real-life settings. By identifying trends and possible future research directions on the moderators and mediation variables and their role in the relationship between SCI and performance, the paper paves the way for future research in this area.

The remainder of this paper is organized as follows. First, the methods applied to the tertiary research synthesis are described. Second, the study descriptors and the LRs’ methodology evaluation are presented. Third, the main variables involved in the relationship between SCI and performance are structured and analyzed. The paper ends with the presentation of conclusions and future research directions.

Research Design
This paper adopts a tertiary review approach, which is a systematic literature review (SLR) from existing LRs in a specific domain (Kitchenham et al., 2009). The three steps for SLRs from Tranfield et al. (2003), which offers a methodology for management research, guided the present study: (i) planning the review; (ii) conducting a systematic review; (iii) reporting and disseminating.

In the first stage, planning the review, the authors identified the need for an analysis of the increasing number of LRs on SCI and performance, in order to assess how these works have been methodologically conducted, what variables have been addressed and what still needs more attention in future research. Based on that, the authors specified the research problem/questions and developed a research protocol, which structures the activities and the content for the following steps.

In the second stage, conducting a systematic review, the keywords were defined according to the literature, as well as providing tests in search platforms. The selected keywords were adopted from studies in the literature and can be divided into two main groups: (i) supply chain integration (Alfalla-Luque et al., 2012); (ii) research synthesis,
systematic review, evidence synthesis, research review, literature review, meta-analysis, meta-synthesis, mixed-method synthesis, narrative reviews, realist synthesis, meta-ethnography, state-of-the-art, rapid review, critical review, expert review, conceptual review (Thomé et al., 2016). Scopus and Google Scholar were chosen as the search platforms.

Regarding the articles’ selection process, title, abstract and keywords were first analyzed for identifying LRs on the topic SCI and performance. For that, the authors applied the following exclusion criteria: (i) the article is not a LR approaching the research topic SCI and performance; (ii) the main focus of the study is not the development of a LR; (iii) the article is not a journal publication; (iv) the study is not in English. Moreover, the search process was not limited to a specific timeframe.

As a result, an initial sample of 141 articles was obtained, from which 23 were duplicated. After screening title, abstracts and keywords from 118 unduplicated articles, 32 LRs were selected for a more detailed evaluation of their full texts. Finally, 22 LRs were selected and form the final sample of the present study. To address RQ1 and RQ2, a content analysis of selected articles was conducted (Seuring and Gold, 2012).

First, concerning RQ1, the LR’s evolution and methodological contributions were reviewed based on the number of LRs published per year as well as on the analytical categories from the research process model of Thomé et al. (2016). The analyses were developed based on the three most recurrent LRs’ types in operations management (OM): narrative, meta-synthesis, and meta-analysis (Thomé et al., 2016). Narrative reviews have been linked in literature to studies, in which “scholars read various literature sources, relate them to each other, and try to make sense of them.” (Seuring and Gold, 2012, p. 545). Although these reviews can bring significant findings, they lack explicit, transparent and rigorous processes, what is overcome by meta-synthesis and analysis. Meta-synthesis focus on qualitative SLRs, which, in some cases, can be used together with quantitative methods, for instance, in quantitative content analysis (Krippendorff, 2004; Thomé et al., 2016). Meta-analyses are statistical analyses for SLR, which is normally applied to integrate various quantitative results of individual researches (Glass, 1976).

The review of the content for addressing RQ2 was conducted by taking into consideration the qualitative analyses, research models, statistic evaluations and the variables selected by the studies, including dimensions, moderators and/or mediators. Mediators are variables, which can explain the ways by which integration dimensions affect performance (Magon et al., 2018). Moderators are variables, which explain when integration dimensions show variations in relation to performance outcomes (Magon et al., 2018). For identifying them, coding schemes were developed by the authors to comparatively synthesize this content (Tranfield et al., 2003; Seuring and Gold, 2012).

Regarding the final phase, reporting and dissemination, the findings regarding RQ1 and RQ2 are presented in the following sections.

**Evolution and Methodological Evaluation of SCI-Performance LRs**

This section reveals how LRs have been conducted in the SCI and performance research field over the years with the target of answering RQ1. Many LRs have investigated the relationship of SCI and performance with the main target of synthesizing and analyzing previous empirical research. The selected LRs were published in journals from different disciplines, like OM, information management, economics, and business. This fact shows the multidisciplinary nature of the topic. However, the majority of publications, around 85% of the selected LRs, were published in operations and technology management related journals (according to the British Association of Business Schools (ABS) 2015 classification). This indicates the importance of the OM field for the topic. Almost 50%
of the total number of studies selected were published in four journals: *The International Journal of Logistics Management* (4 studies); *Supply Chain Management: An International Journal* (2 studies); *International Journal of Physical Distribution & Logistics Management* (2 studies); *International Journal of Production Economics* (2 studies).

Figure 1 presents the LRs evolution by year and review type. The number of LRs has significantly increased over the last decade, especially after 2013. Narrative reviews represent the lowest number of LRs on SCI and performance, reaching an amount of 5 studies until 2018. The first meta-synthesis was identified in 2007, while its importance increased along the years and turns into the dominant research approach until 2018 with 12 publications. Meta-analyses are more recent contributions than meta-syntheses with 5 articles in total. The limited number of meta-analyses might be related to the heterogeneity of dimensions, data and measures in management research, what hinders its application for synthesizing empirical studies (Tranfield *et al.*, 2003; Denyer and Tranfield, 2009). The lower number of publications in 2018 can be explained due to delays in updating the selected databases, and by the fact that the literature search covers publications until October 2018 (Tarifa-Fernandez and Burgos-Jiménez, 2017).

![Figure 1 - LRs evolution by type and year (n = 22)](image)

* January to October

Figure 1 also shows that the growing number of LRs comes along with more transparent, reproducible and thorough research approaches such as meta-synthesis and meta-analyses (Tranfield *et al.*, 2003; Seuring and Gold, 2012). This can be seen as an indicator that SCI and performance research is maturing and consequently evolving to become a more consolidated research topic. The same development can be observed in more evolved research areas, such as medical science or OM (Tranfield *et al.*, 2003; Seuring and Gold, 2012; Thomé *et al.*, 2016). To explore the way LRs have been conducted, Table 1 presents a synthesis of formal review steps and types.

Table 1 shows that a majority of meta-syntheses and meta-analyses transparently presents the research descriptors, whereas this is often not the case for narratives. Especially meta-analyses showed to be rigorous and transparent regarding the descriptors. “Research questions (RQs)/hypothesis” were reported by 60% of the narrative reviews, 83% of the meta-syntheses, and 100% of the meta-analyses. “Analytical categories” were defined by the majority of the studies. Regarding the descriptors: “period covered,” “criteria of study selection,” and “description of keywords,” meta-analyses have the most transparent results, while almost no narrative study has applied these steps.

In relation to the “number of databases,” it was difficult to accurately code this information from some meta-syntheses and meta-analyses since many of them limit their research to specific journals, thus, not making clear the utilized search platforms. Even so, the value obtained for meta-synthesis and meta-analysis is around 60%. “Backward/Forward search” is the descriptor presenting the lowest percentage of all categories, 0% for narrative, 8% for meta-synthesis and 60% for meta-analysis. For future studies, more attention should be given towards snowball search, as this is a powerful step against selection bias. The “participation of more than one reviewer/coder” and “the statement about literature type (e.g., peer-reviewed, grey, etc.)” is almost not reported in narratives, inhibiting the reproducibility of these studies. “Quality appraisal of primary research” is more likely seen in meta-analyses (80%) than in meta-syntheses (58%). Finally, the “likelihood of publication bias”, in which authors state possible bias or limitations of their research, was reported in 40% of narratives, 75% of meta-syntheses and 100% of meta-analysis.

SCI Mediators and Moderators

The present section addresses RQ2 and summarizes the main variables (moderators and mediators) which, according to the literature, can influence and explain the relationship between SCI and performance. In a nutshell, more recent SCI publications strengthened the evidence that SCI positively affects a majority of the measured performance relations (e.g., internal and external integration to strategical, relational and operational performance) (Kim, 2013; Mackelprang et al., 2014; Chang et al., 2016; Ataseven and Nair, 2017). However, the same studies also claim that this relationship is not always direct and can vary depending on the environment and/or on specific organizational factors (Kim, 2013; Mackelprang et al., 2014; Chang et al., 2016; Ataseven and Nair, 2017). Chang et al. (2016), for instance, investigate how three types of firm performance (i.e., strategic, relational and operational) mediate the integration-performance link, as well as how time, relationship quality and national culture influence the strength of the measured relations. To structure the dispersed findings in that regard, Table 2 depicts the main categories of mediators and moderators discussed in the selected LRs. Moreover, the identified trends and possible future research directions are also discussed in the following.

Regarding Table 2, it is important to highlight that one variable can be seen both as a mediator and as a moderator, which relates to the author’s interpretation, or also on the theoretical lenses applied in the selected LRs (Magon et al., 2018). The present
investigation identified a high amount of different variables with distinct names and conceptualizations that have been structured into the main categories presented below. A text coding process was developed by the authors to synthesize this content. According to Magon et al. (2018), the variety of variables and approaches is a common phenomenon in maturing research fields with an increasing number of publications, which fits with the literature’s evolution depicted by Figure 1. Table 2 also shows that moderators have the highest rate of occurrence (60) followed by mediators (13). The low number of occurrences regarding mediators was unexpected and indicates the need for more LRs critically reviewing empirical publications with the focus on better understanding the mechanisms through which integration dimensions impact upon performance.

* One study can have more than one occurrence

The most discussed variables (25 occurrences) were related to uncertainty. In the last decade, there have been many calls, based on the contingency theory, for investigations of the question “under what conditions integration can be beneficial to performance” (van der Vaart and van Donk, 2008; Fabbe-Costes and Jahre, 2008; Leuschner et al., 2013; Mackelprang et al., 2014; Ataseven and Nair, 2017). Since uncertainty is one of the main categories often related to the contingency theory (Sagawa and Nagano, 2015), many works might have recognized the importance of these calls, and incorporated them into their analysis. The uncertainty category consists of variables related to two main groups: environment and organizational processes (e.g. production, transportation) (Sagawa and Nagano, 2015). Most of the papers discuss the moderation effect of environmental uncertainty focusing on a broader external context, such as “demand uncertainty/seasonality,” “market characteristics,” “competitive intensity,” “technological uncertainty,” “supply complexity.” In relation to the organizational process uncertainty, “lead-time,” “product quality,” “failures and machine breakdowns” were mentioned as possible moderators. The amount of papers, which approach environmental uncertainty were more frequently discussed than those that reviewed process uncertainty, indicating a necessity for further research related to process uncertainty. In general, the moderation effects of uncertainty present negative or positive variations, depending on the SCI dimensions and performance measures (Tarifa-Fernandez and Burgos-Jiménez, 2017). The most frequently quoted variables were “technological” and “demand uncertainty.” For “technological uncertainty,” most of the
reviewed works present a positive moderation effect when considering customer integration and sharing information to performance. Regarding “demand uncertainty,” which depicts the difficulty to predict customer demand, authors have not reached a consensus about its moderation effect yet.

Another important category with a higher number of occurrences (19) is supply chain, industry or firm characteristics. In this group, variables such as “company size”, “company location”, “organizational structure”, “supply chain (network) configuration”, “supply chain position”, “type of industry”, “production complexity”, “firm age”, “product and processes types” are mentioned as factors, which can increase or decrease the integration-performance relationship results. These are traditional variables in OM for contingency investigations (Magon et al., 2018). From the variables mentioned above, however, only the impact of “company size” on integration-performance was reviewed by the selected LRs; the other variables were suggested for future investigations by the authors of the selected LRs. Concerning “company’s size”, Tarifa-Fernandez et al. (2017) and Kim (2013) state that it is expected that larger companies, which have greater capacity and access to resources, are in a better position to design and implement integrative efforts, and in doing so, have also more chances to increase their performance outcomes. However, the reviewed LR’s findings present mixed results about the “company size” moderation, and, therefore do not permit generalizations. Further studies are still necessary in that regard.

Still concerning the results depicted in Table 2, organizational relationship factors might act as moderators of integration performance outcomes. This means that companies working in a friendlier environment, in which there are commitment and mutual trust among the supply chain partners, are more likely to achieve higher levels of integration and performance (Tsanos et al., 2014). The most discussed variables under organizational relationship were, “relationship quality,” “cultural aspects,” and “trust.” In a meta-analysis, Chang et al. (2016) combined the results from different publications to homogenize the moderation effects of “relationship quality” and “cultural aspects” into one study. Firstly, the authors found that supplier integration can achieve better performance results when focal firms and suppliers have a high relationship quality. Secondly, the research also reveals that internal and supplier integration can be translated into higher levels of performance in Asian than in Western cultures. The authors state that the research’s nonsignificant results, especially in relation to the moderators and customer integration-performance, may be associated to smaller numbers of estimates available in literature (Chang et al., 2016). The moderation from “trust” was not measured by meta-analyses, nor sufficiently reviewed by any of the selected others LRs, which also indicates a gap to be fulfilled in the literature (Ataseven and Nair, 2017).

SCI Dimensions (6 occurrences), more specifically, internal, supplier and customer integration, comprises the most frequently quoted SCI variables in the literature. These variables have been operationalized in two different ways to measure the link between integration and performance: first, as part of a direct relationship (e.g. Mackelprang et al., 2014), and, second, also as moderators with the aim of identifying if one dimension can influence the outcomes of the others (Kim, 2013; Tarifa-Fernandez and Burgos-Jiménez, 2017). In this sense, a consensus in the selected LRs is that internal integration positively affects external integration by the effect of moderation (when customer and supplier integration are jointly considered). Internal integration helps companies to build the necessary foundations to absorb, interpret and apply external integration (Kim, 2013). Furthermore, supplier integration has also been mentioned to have a positive moderation effect on customer integration (Tarifa-Fernandez and Burgos-Jiménez, 2017).
The category with the lowest number of occurrences (2) is concerned with the positive moderating effects of information systems capabilities on integration and performance. Since information systems are a critical resource in the integration of information and processes among supply chain partners (Ataseven and Nair, 2017), it seems that there is a need to increase research on how this variable influences the relationship under investigation.

Moreover, Table 2 also depicts that “performance measures” (7 occurrences) and “organizational relationship” (6 occurrences) act as mediators in the integration-performance relationship. This means that “performance measures” (i.e., operational performance, relational performance, strategic performance) and “organizational relationship factors” (i.e., trust, commitment, mutuality, and power) are drivers of integration practices to foster higher performance levels. As stated before, the low rate of mediators occurrences in the literature was unexpected. Mediation variables were very disparately mentioned (concentrated in only 5 LRs). Besides that, only one meta-analysis measured the mediation effects on integration and performance (Chang et al., 2016). Chang et al.’s (2016) findings indicate that operational, relational and strategic performance significantly mediate the relationship of SCI dimensions and performance. However, the mediation of other frequently investigated variables in the OM field, such as “SCI dimensions”, “supply chain practices” (e.g. information sharing) “relationship factors”, among others (Hsu et al., 2009; Wu et al., 2014), are still an open research avenue for LRs in integration and performance.

Discussion and Conclusions
The present work offers a tertiary review of peer-reviewed LRs on the topic of “integration and performance”. In a nutshell, the integration and performance research field has matured and presents an increasing number of LRs as a response to synthesize a growing amount of empirical studies. In relation to RQ1, the third section offers a discussion of the importance of LRs design and respective guidelines for more transparent, reproducible and thorough research approaches. Narrative reviews represent 5 of the selected articles. The first SCI meta-synthesis was conducted first in 2007, turning to the dominant research approach until 2018 with 12 publications. Meta-analyses counts with only 5 publications and have demonstrated higher methodological rigor than narratives and meta-syntheses. These findings support the evidence that the LRs in this research field have evolved, offering increasingly more systematic and transparent approaches.

Although the field has matured, and more recent SCI publications strengthened the evidence that SCI is positively related to the majority of performance measures, the literature presents a high variety of dispersed results, which hinder generalizations about the conditions and ways by which integration influences performance. The analysis of RQ2 shows that the reviewed studies present a high variety of different variables, making comparisons of the results difficult. On top of that, the results, which can be compared, are, in many cases, not free from contradictions. Most of the LRs focused on the direct relationship of integration and performance, and are, with little exceptions, superficially discussing the influence of moderation and mediation variables in their analyses. The low number of occurrences regarding mediators was unexpected and indicates the need for more LRs, which are critically reviewing empirical publications in that regard. Despite these issues, some consensus could be identified in LRs. “Technological uncertainty,” according to the most reviewed publications, present a positive moderation effect when considering customer integration and sharing information to performance. Supplier integration can achieve better performance results when focal firms and suppliers have a
high “relationship quality.” The same meta-analysis also reveals that internal and supplier integration can be translated into higher levels of performance in “different cultures.” “Internal integration” helps companies to achieve better results with external integration (Kim, 2013). Finally, Chang et al.’s (2016) findings indicate that “operational, relational and strategic performance” significantly mediate the relationship between SCI dimensions and performance.

Considering these findings, the literature results still are too dispersed. Therefore, research needs to be conducted for unequivocally understanding under what conditions, as well as in which ways integration dimensions impact performance measures. This opens opportunities for future research directions. A comprehensive investigation of the main SCI and performance variables, as well as their conceptualizations could contribute to the development of a common understanding about SCI in a consistent and comparable way. Since the empirical publications in the SCI field are growing and only 5 meta-analyses were identified, there is room for the development of more studies applying this approach to align the dispersed findings in the integration-performance literature. The analysis and discussion of mediators should be more explored in future research. Moreover, as internal integration represents an important enabler for external integration, it appears promising to conduct an investigation regarding the moderating and mediation effects within internal integration practices, such as Sales and Operations Planning.

Abstract

Stakeholders strongly oppose negative and unethical incidents immediately after their occurrence. However, as the stakeholders temporally move away from the occurrence of the incident, they have been observed to forget the incident and the negative impact it had on the associated individuals. The objective of our research is to empirically investigate this observation by longitudinally examining the perception of stakeholders on Rana plaza incident. Rana plaza incident in Bangladesh was one of the biggest tragedy witnessed due to lack of health and safety mechanisms. The incident had a detrimental impact on the reputation of various renowned western clothing brands and their associated supply chains. The quick backlash after the incident from different stakeholders such as consumers, non-governmental organizations, social activists and government bodies was immense, and it significantly affected the perception of the brands and their supply chains.

To achieve the objective of this research, we mined the tweets of different brands which were associated with Rana Plaza incidents from 2013 until 2018. Sentiment analysis were conducted on the collected tweets to understand how Rana plaza incident affected the stakeholder perception of different brands and how their perceptions changed year after year. The results show that average yearly sentiment score of majority of the brands consistently increased from 2013 to 2018. We further explain this observation by drawing from willfully ignorant memory effect where consumers/individuals exhibit a systemic bias while trying to remember the ethicality of the brands or products. Our results raise questions for further research such as what should be the immediate and long-term response of ethical supply chain to negative events after their occurrence to differentiate themselves from unethical brands, and how can they transform forgetting stakeholders to forgiving stakeholders for rebuilding a long-term relationship. This research will provide insights on good practices that ethical supply chain can follow in the aftermath of negative incidents to retain or recover the trust of stakeholders.

Keywords: Stakeholder memory, Ethical supply chain, Social Media, Sentiment analysis, Rana plaza incident.
Introduction
Supply chain (SC) management literature has studied different types of negative incidents that have disrupted the supply either via catastrophic disasters or by minor business disruptions. Natural disasters are one of the crucial source of SC disruption. The flooding of Daimler Chrysler suspension parts manufacturing factory by Hurricane Floyd eventually closed their seven other plants across North America (Norrman and Jansson, 2004). Similarly, the outbreak of diseases have a widespread impact on agri and manufacturing SC. For instance, the impact of foot and mouth disease in UK in 2001 has a much wider impact than its occurrence twenty-five years ago (Juttner et al., 2002). In addition, car manufacturers, Jaguar and Volvo, were forced to halt deliveries pertaining to shortage of quality leather supply. Fire in the manufacturing factories is also widely discussed in literature for their potency for SC disruption (Ellis et al, 2011). One of the crucial example is fire in Aisin Seiki in 1997 leading to closure of eighteen plants owned by Toyota accounting for financial loss of $125 million (Norrman and Jansson, 2004). Inaccurate supply planning could also significantly hamper the product/financial flow within SC (Hendricks and Singhal, 2005) as it lead to inventory shortage of sportswear giant, Nike and consequently sales for third quarter in 2001 were lagging $100 million behind the target (Norrman and Jansson, 2004). Similarly, briskly declining demand in conjunction with supply agreements led Cisco to get rid of inventory worth $2.5 billion in second quarter of 2001 (Norrman and Jansson, 2004).

All stakeholders including consumers, non-governmental organizations (NGOs), environmental watchdogs, government agencies, social activists, media and human right entities react punitively to negative incidents that arise due to SC inefficiency or ineffectiveness, especially to those with catastrophic environmental and social consequences. The most severe and immediate reaction usually comes from consumer stakeholders who decide to boycott the product (Hartmann and Moeller, 2014). For instance, the western consumers boycotted some of the clothing brands that were found to be the reason behind Rana Plaza incident. The stock prices of firms and demand of products that are involved in the SC glitches have a significant decline (Hendricks and Singhal, 2005; Jacobs and Singhal, 2017; Endrikat, 2016). For example, the sales of meat products in UK and Ireland started falling after the outbreak of horsemeat scandal (Barnett et al., 2016). Labour union along with NGOs have raised their concern over manufacturing firms for overlooking safety violations in factories. They urge them to improve working conditions for labourers and failure to do so can be proclaimed as criminal negligence (Jacobs and Singhal, 2017). The leading press and social media also echoed similar arguments and held culprit firms accountable for unsafe working conditions deeming it to be their moral obligation (Bhagwati and Narlikar, 2013). The government bodies in developing countries might be paralysed pertaining to lethargic and corrupt legislation framework. However, the government entities in developed nations where buying firms are based have taken stringent action in the event of SC related negative incidents. For instance, US government revoked certain trade privileges for Bangladesh in aftermath of Rana Plaza incident and similarly the European Union signed a sustainability pact with Bangladesh government to enhance factory safety and worker rights (Jacobs and Singhal, 2017).

However, all the aforementioned stakeholder reaction were immediate reaction post SC disasters. The intensity of these reactions usually become milder or totally insignificant over time. For instance, stock market reaction to western retailers was extremely negative at the very day of occurrence of Rana Plaza, however, for the next eleven days, there was no evidence of stock market catastrophe attributable to Rana Plaza.
and for slightly longer time duration, sixty days, the impact of Rana Plaza incident was completely nullified (Jacobs and Singhal, 2017).

To answer the above stated research questions, we use the lens of willfull ignorant memory effect. Willfull ignorant memory effect suggests that consumers allow their want self to dominate over should self to overlook negative information pertinent to a firm involved in a conflict. The want self typically attempts to forget non-pleasant information whilst the should self emphasizes what the consumer considered is righteous. Usually, the solution of this conflict is more aligned in favour of want self by overlooking negative information associated with a firm. Reczek et al. (2017) demonstrated that consumers perceive overlooking negative information associated with a firm as more morally acceptable than remembering it but avoiding it, thereby illustrating that willfull ignorant memory is a more morally conventional way out of addressing conflict amongst want self and should self.

For gathering the data to answer the research question, we first mined the tweets using Twitter streaming application programming interface (API) by employing relevant keywords pertaining to various stakeholders and Rana plaza incident since its outbreak from 2012 up until 2018. After pre-processing the collected tweets, support vector machine was used to perform sentiment analysis of tweets (positive, negative) and thereby gain intelligence into the variation in stakeholder’s reaction over time using the lens of wilfully ignorant memory effect.

The results of sentiment analysis reveal that the stakeholder reaction is strongly negative immediately after the occurrence of Rana plaza incident. However, the intensity of their negative reaction became milder over time in line with wilfully ignorant memory effect. To further validate the result of this study, sentiment analysis prior (2007-2012) to Rana plaza incident was also performed where it was evident that sentiment score was mostly inclined towards neutral or positive. However, the outbreak of Rana Plaza incident had a devastating impact on the sentiment score of the firm just like the prices of their shares in stock markets.

The structure of the paper is as follows. In the next section, we review the literature on stakeholder’s reaction to negative supply chain incidents. In methodology section, support vector machine is introduced to analyse collected tweets and gain contextual intelligence from it. The methodology section is followed by results and discussion, where the rising sentiment score is explained using the wilfully ignorant memory effect underpinning the stakeholder’s reaction. Finally, the paper concludes by providing valuable insights into good practices that firms could mimic to prevent reputational damage through their involvement in negative supply chain incidents.

Literature Review

Impact of negative incident on organizations

The extant literature have demonstrated how firms entangled in social, ethical and product harm scandals (i.e. negative incidents) have witnessed reputational damage (Balmer et al., 2011; Firestein, 2006; Beder, 2002) amalgamated with financial consequences. The scale of reputational damage imposed by a particular scandal varies depending on the nature and magnitude of scandal (Lauffer and Coombs, 2006) along with the extent of accountability of a scandal attributed to the firm (Coombs, 2007). Also, the past of a firm with respect to its association with former scandals and the image of firm prior to scandal plays significant role in the reputational damage (Coombs, 2006). Hartmann and Moeller, (2014) proposed that the impact of SC liability is severe if environmental deteriorating incident is generated by either behaviour of supplier instead of force majeure or decision
of a firm instead of an employee. Chain liability effect pose a significant risk for the focal company as higher responsibility attributions adds up to consumer’s anger and eventually their tendency to boycott. Media is also very potent in this context as the firms with high media visibility are prone to experience higher reputational damage given the familiarity of their brand name amongst the masses (Fombrun and Shanley, 1990).

Collective reputation suggests that reputation of a focal firm is not influenced by merely its own activities, however, it is also affected by the actions of its industrial peers. This phenomenon is widely discerned in oil and gas, and chemical industries (Bertels and Peloza, 2008, Barnett and Hoffman, 2008). These negative incidents could lead to reputational spillover thereby jeopardising the image of firms within similar domains irrespective of their association with negative incident (Yu and Lester, 2008). An example of collective scandal is from year 2013 when beef products across Europe were exposed to be adulterated with horsemeat thereby tarnishing the reputations of multiple beef suppliers, retailers and restaurants (Comyns and Franklin-Johnson, 2018). Barnett et al., (2016) further highlighted the major issues in having an impact on consumer’ trust on meat processing industry post-horsemeat scandal. They employed an online tool VIZZATATM for collecting responses of 61 consumers in UK and Republic of Ireland. It was revealed that consumers trust on processing food consisting of meat has diminished along with their consumption of these products.

Sometimes, firms ignore harsh working conditions under their premises and are therefore more accountable for the consequences. For instance, Foxconn (Apple’s major supplier) labourers committed suicide (Parmigiani et al., 2011) pertaining to miserable living conditions, frequent overtime and appalling behaviour such as restriction on toilet breaks and conversations. Apple being aware of these conditions sent their monitoring unit, however, still they couldn’t breakthrough on how to improve social sustainability across their supply chain. Social issues of this magnitude if overlooked could induce product boycotts, spoil brand equity and thereby lower economic performance (Parmigiani et al., 2011). Keeping in mind the hostile publicity generated from social disputes in sourcing as faced by Levi-Strauss and Nike in 1990, numerous retailers revamped their sourcing policies to address environmental and social inconsistencies (Doorey, 2011). Social and environmental oriented undertakings uplift the reputation of a firm along with raising the goodwill trust of stakeholders (Siltajoa, 2006). The extant literature on social financial performance also validates this notion as environmental and social ventures enhance reputation eventually raising revenue and profit (Surroca et al., 2010).

SCM literature has paucity of work investigating the risk generated from consumer’s perception of non-sustainable activities of supplier. Sen and Bhattacharya, (2001) suggests that negative events have wider influence than positive events. Consumer’s reaction to negative events are emotional and behavioural reflecting their anger towards culprit firms (Struthers et al, 2005). Emotions pave the way for coping behaviours such as boycotting (Rowley and Moldoveanu, 2003). Hence, social and environmental inconsistencies could impact purchase related decision making of consumers (Klein et al., 2004).

**Research Gap**

None of them have investigated the variation in the intensity of stakeholder’s reaction over time. In this study, we bridge this gap by longitudinally analysing the stakeholder reaction over social media (Twitter) to Rana Plaza incident by using wilful ignorant memory effect as the theoretical lens.
Theoretical Background
Willfull ignorant memory effect suggests that consumers allow their want self to dominate over should self to overlook negative information pertinent to a firm involved in a conflict. The want self typically attempts to forget non-pleasant information whilst the should self emphasizes what the consumer consider is righteous. Usually, the solution of this conflict is more aligned in favour of want self by overlooking negative information associated with a firm. Reczek et al., (2017) demonstrated that consumers perceive overlooking negative information associated with a firm as more morally acceptable than remembering it but avoiding it, thereby illustrating that willfull ignorant memory is a more morally conventional way out of addressing conflict amongst want self and should self.

Data & Methods
The number of tweets mined for this paper were 10,068. They belong to the time range of year 2013 to 2018. The tweets mined were confined to those in English language only with no geographical barrier. Thereafter, keywords were chosen to mine the tweets pertinent to this study. In order to select the keywords, around 55 academic journal and newspaper articles published on Supply chain incident on Rana plaza incident were thoroughly investigated. This led to the selection of optimum keywords given the scope of this study. The aggregate tweets were then pre-processed via this keywords list resulting in the focused set of 3340 tweets. It was observed that amongst those, 52% of tweets were made in Europe and 32% originated from North America. Some of the mined tweets are depicted amongst the flowing word clouds:

Figure 1 – Visualisation of mined tweets via word cloud
Results & Discussion
Sentiment analysis was performed on the collected data (3340) sets by using Support vector machine on R platform. They were classified based on year in which they were made and the brands (Primark, Walmart, Mango, Benetton, H&M, Zara, Matalan, Calvin Klein, Kohl’s) they are associated with. Then, variation in yearly sentiment score of individual brand was investigated. For instance, the annual variation in sentiment score of Gap is depicted in following figure:

![Figure 2 – Average Sentiment scores of Gap (2013-2018)](image)

It could be observed that in year 2013 when the Rana plaza incident happened the sentiment score of Gap was really low -0.022. However, it has increased from there on up until 2018. It reflects that the intensity of Rana plaza incident amongst stakeholders primarily consumers have became milder over the time.

Similarly, the yearly sentiment variation of Zara is shown in Figure 3. Unlike Gap, Zara’s sentiment score in 2013 when Rana Plaza collapse happened was relatively positive (0.083). This could be due to the sustainable brand reputation Zara has accumulated over the years and also significant amount of their manufacturing operations are done in Europe (Spain). From year 2013 onwards, the sentiment score of Zara has also risen. Although the slope of increment is not as high as Gap, yet, the sentiment score of Zara in 2018 was 0.132, which is much higher than that of Gap (0.082).

To further investigate the variation in yearly sentiment scores of different brands, a cumulative sentiment score of all the fashion brands accused in Rana Plaza incident was calculated. This annual variation is depicted in Figure 4.
The cumulative score of fashion brands in year 2013 when Rana Plaza incident happened was 0.014, which not as low as that of Gap (-0.022), which reflects the reputational damage Rana Plaza incident has caused to Gap in year 2013. From time period of 2013-2015, the aggregate sentiment score has risen but at a very low pace. This was the time when various Western Brands got united to address this issue and two frameworks were set up: Accord on Fire & Building Safety in Bangladesh led by European fashion retailers and Alliance for Bangladesh worker safety, which was led by American counterparts. From year 2015-2016 which is 2 years after Rana Plaza, the average sentiment score has risen rapidly reflecting that stakeholders had forgotten the accused firms completely during this time period. In the time period 2016-2018, the sentiment score kept on increasing although the slope was not as high as its predecessor time period, yet it was much higher as compared to 2013-2015 where the memories of Rana Plaza incident was fresh amongst the consumers. This observation was in line with the wilful ignorant memory effect discussed earlier. The stakeholders primarily consumers tend to avoid or boycott the accused firms at the occurrence of negative events like Rana Plaza where their should-self dominates over want self. However, with the passage of time, they tend to willfully forget these negative ethical past of accused firms in the influence of want-self dominating over their should-self.
Conclusion
In this article, Twitter data was employed to study consumer sentiments associated with numerous fashion brands accused in Rana Plaza incident. More than 10,000 tweets were mined using multiple thoughtfully chosen keywords. Sentiment mining grounded on the Support vector machine was utilised for investigating sentiments of various stakeholders: consumers, non-governmental organizations (NGOs), environmental watchdogs, government agencies, social activists, media and human right entities towards the accused fashion brand during the five year time duration (2013-2018).

The results obtained via sentiment analysis revealed that the aggregate sentiment score of all the fashion brands combined has increased over the years since the time of Rana Plaza in 2013 until 2018. The rise of sentiment score was slow in 2013-2015 where the atrocities caused by this disasters was fresh amongst stakeholders. However, in the following time period (2016-2018), appreciable rise in sentiment scores has been recorded thereby reflecting the stakeholder’s primarily consumers tendency to wilfully ignore the negative past of accused firms in line with the wilful ignorant memory effect. After elapse of certain years, stakeholders mostly consumers let their want self to dominate their decision making over their should self by knowingly ignoring the negative ethical attributes associated with a corporate firm.
This study would be insightful for corporate firms in designing their mitigation strategy in the occurrence of disasters like Rana Plaza to prevent their reputational damage thereby preventing their revenue from declining. Also, simultaneously emphasizing the significance of having sound sustainable image amongst passive stakeholders as that of Zara in this article, whose sentiment scores in year 2013 was much better as compared to that of Gap’s sentiment score in 2018.

The limitation of this study is the results are generated based on information gathered from Twitter, which may not be the reflection of true opinion of the stakeholders. Future research could be conducted to address this by utilising conventional primary data collection channels: survey, interviews amalgamated with reliable secondary data sources such as company databases, sales figures, etc.

The information exchange pyramid in construction supply chains

Micael Thunberg (micael.thunberg@liu.se) and Anna Fredriksson
Linköping University, Sweden

Linea Kjellsdotter Ivert, Swedish National Road and Transport Research Institute, Sweden

Abstract
The purpose of this paper is to identify the information need in order to facilitate efficiency of the construction industry. Over 20 interviews were conducted with different actors in the construction supply chain. It was found that different actors have similar needs of information type, namely information concerning delivery, plans and projects. Thus, the need of information can be described as hierarchical with delivery information in the bottom, delivery plans, in the middle and project information on the top. The result contributes to the current debate on information exchange in construction.

Keywords: Construction supply chain, Information need, Information exchange,

Introduction
The Swedish national board of housing, building and planning has determined that the need for new housing in Sweden 71000 per to 2025 (Boverket, 2018). Despite this, only about 50 000 homes per year were constructed between 2012 and 2019, i.e. far from the need (Boverket, 2018). The production of houses follows the economic cycles. With an upcoming recession in economics, the need for increasing productivity and lowering construction costs become even more important for reaching. There are many reasons why the construction industry do not reach the productivity needed, of which the most frequent issues are: insufficient information exchange and complex communication channels (Titus and Bröchner, 2005), low degree of digitalization (Bossen and Ingemansson, 2016), and low understanding of the need for logistics planning (Thunberg and Fredriksson, 2018). Information exchange in supply chains can decrease costs and improve productivity as a prerequisite for improved planning and control (Prajogo and Olhager, 2012). One of the consequences of lacking information exchange is decreased efficiency, illustrated in the infamous Bullwhip effect (van Ackere et al., 1993).

However, to reach the efficiency boost of sharing information, the exchanged information need to be relevant and meaningful to the receiver (Kaipia and Hartiala, 2006). Understanding what information to exchange with whom in the supply chain is part of information quality (Gustavsson and Wänström, 2009). Though, what information is relevant is context dependent and the construction industry differs context-wise from other industries.
by being project oriented, fragmented, opportunistic, and with temporary supply chains. Information exchanged in other industries like point-of-sales data and inventory levels, might not necessary be of the same importance in the construction supply chains. It is therefore relevant to explore what information that needs to be exchanges among which actors in construction supply chains. Briscoe and Dainty (2005) showed that attempts to integrate construction supply chains and exchange information has been hampered by the reluctance of clients and contractors to exchange information with all parties in the supply chain.

Cheng et al. (2010); Pala et al. (2016); and Samuelson and Björk (2014) all study how information could be exchanged in construction supply chains through use of IT systems and tools. Samuelson and Björk (2014) argue that a lot of information exchange is done through the use of Electronic Document Management (EDM) systems and portals; thus, rather digitizing information than digitalizing it. This still makes it difficult to exchange information as manual work on uploading, downloading, reading and extracting relevant information has to be done. Cheng et al. (2010); and Pala et al. (2016) suggest the use of IT tools like Enterprise Resource Planning (ERP) systems. However, they also stress that ERP systems many times are not developed for project driven industries and that it is difficulties in “aligning” systems between actors in a construction supply chain. They recognize the importance of understanding what information to digitalize and the importance of using IT systems for future information exchange.

As elaborated on, we need to increase understanding of what information is needed by whom in construction supply chains. Thus, the purpose of this paper is to identify the information need of different actors in order to improve efficiency in the construction industry. Construction, as a fragmented engineer to order industry, requires vast amount of information to be gathered and exchanged with several actors. The focus in this paper is on the information exchange between the actors in the construction process and the actors in the supply chain process. This interface has been identified by many as a critical area for information exchange (Thunberg and Fredriksson, 2018), illustrated in Figure 1 below.

Based on the focus of this paper, as illustrated in Figure 1, an overall classification of information needs can be that the information in question is either concerning the construction process or the supply chain process. Information concerning the construction process is based on how project management is defined by the PMBOK issued by PMI. This means that information regarding the construction process concerns the scope, time, and budget of the project; the quality of the product; procurements, human resources, and
communications necessary for the success of the project; but also information concerning risk and stakeholder management.

Regarding information of the supply chain process, focus here is on the interface between the construction process and the supply process. This means that information is exchanged through customer orders from the contractor/installation company to the supplier. A general customer order consists of agreed price, delivery quantities, delivery due-dates, delivery locations, and other relevant delivery information (Jonsson and Mattsson, 2009). The customer order can therefore be seen as consisting of one-part delivery plan (or delivery schedule) and one-part delivery information/call-off information. The former one consists of a mid-term long plan of quantities of a good to be delivered and when (type of product, amount, delivery due-date and time, delivery place, necessary documents) while the latter one consists of other relevant information of the good such as quality aspects, any hazardous aspects, contact information, help with unloading, specific roads to use etc.

To sum up, three main groups of information relevant to analyze here are project related information, customer order information, and delivery call-off information.

The paper is outlined as follows. The next chapter describes the research design and methods used for collecting and analyzing data. Thereafter the empirical data collected is presented followed by a data analysis chapter. Last, the paper is wrapped up with discussion of conclusions, research implications, managerial contributions, and future studies.

**Research Design and Method**

Semi-structured interviews allows for an understanding of a subject from the perspective of different responders (Flick, 2009), and is therefore a suitable methods to fulfill the purpose of this paper.

The first step in the research process was to identify which actors to interview. The goal was to get a width by covering three perspectives in logistics; the goods owner, the carrier and the transport infrastructure. Therefore, responders representing seven different actors (covering the three perspectives on logistics in the construction supply chain) were interviewed: clients, contractor firms, installation companies, machine rental companies, material suppliers, recycling companies, transport actors and municipal offices. Relevant respondents were identified by an initial workshop consisting of project members of the Vinnova financed research project, DigiPlan, coming from different parts of the construction and the IT industry. A total of 23 respondents were interviewed, presented in Table 1.

</tbody>
</table>
Semi-structured interviews focusing on the following topics were held; the information needs, the consequences of inadequate information exchange, and how the information exchange is currently done.

The analysis was done by first analyzing the data derived from each actor to find common areas of information needs. This was implemented through a coding principle called thematic coding (Flick, 2009). After analyzing data from each group of actors, a cross-analysis of data from the different groups was made to see the communities and differences between actors.

Data Description

In this section the information needs, current information exchange and consequences of not exchanging relevant information is presented for each actor. The information needs for each actor in summarized in Figure 2 whereas the current information exchange and consequences of not exchanging relevant information is described in text.

Client/Municipality

- **Current information exchange**: Much of the information is sent via email in the form of PDF files, exchanged orally or through project portals. E.g. through tender documents, drawings, structural documents, timetables, and weekly meetings with the contractors; via meetings with the municipality or via catalogues regarding product information. Information is also sourced from detailed development plans and traffic request plans submitted to the municipality.

- **Consequences**: Impaired overall coordination of project and its impact on surrounding society and the environment. Cannot provide the authorities and the general public with the right information. Cannot ensure right type of temporary roads to be built, planning routes and dimensioning unloading sites. If the information is not updated, it is likely that decisions are made on incorrect basis.

![Figure 2: The different information needs.](image-url)
Contractor

• **Current information exchange:** The information exchange today takes place mainly through weekly meetings with all actors on-site. Some information is exchanged internally at the contractor when work disposition plans are developed. The information is distributed to subcontractors and suppliers orally or through PDFs via e-mail. Some contractors use digital delivery calendars, updated manually.

• **Consequences:** Do not know what delivery to site is to what recipient among the subcontractors, which increases the risk of time waste. Difficult to plan the time for a delivery, where to put the material, what resources are needed to unload the material. Use of too heavy trucks and that subcontractors store materials in the wrong place. This makes the delivery process taking longer time than necessary and the material must be moved around often. Knowing what material to go via terminal enables planning of the terminal and facilitates deliveries from there. If all activities are not included in the time plan, with associated material needs, there is a risk of missing relationships between activity and material. This can lead to delays or that the subcontractors arrive when there is no possibility for them to perform their job.

Installation Companies

• **Current information exchange:** Building meetings, team meetings, inspection protocols, drawings.

• **Consequences:** Have to move and look for material, start new activities, rush activities (several activities might be done at the same time, cannot work efficiently, wastes, a lot of ad hoc work, and bad mood in the team), chaos, and delays.

Machine Rental Company

• **Current information exchange:** Start-up meetings with contractors where checklists are used to ensure that they get the right information. Much information exchange takes place the day before shipping, by phone. It is desirable to get information via ERP systems/web-systems.

• **Consequences:** deliveries go to wrong address, machines that cannot be used on the project are delivered, and that the transporter cannot reach the construction site with large bulk deliveries. The rental company cannot provide machines and tools as they are not available nearby, leading to unnecessarily long delivery and waiting times. Nor is it possible to efficiently plan their own resources, which increases transport costs. More than necessary time is spent on managing rental lists.

Material Suppliers

• **Current information exchange:** takes place through start-up meetings with project managers and site manager at the contractor. The material suppliers’ sellers have a checklist to capture what the contractor want. Call offs are made by email, telephone, personal meetings or via a web portal. Efforts are made to get more and more contractors to use suppliers’ project portals.

• **Consequences:** wrong type of transport cannot be unloaded as planned or that the wrong goods are delivered, resulting in more transports than necessary. Not reaching the person who will receive the delivery may result in waste and additional work. A problem associated with the short planning of orders from contractors (i.e. that orders
the sent the same day as the need arise and that they change their orders the same day) is unnecessary transport.

Recycling Companies

- **Current information exchange:** Orders are received via an ERP system, current container locations, contact person, delivery information, and time plans are usually exchanged through start-up meeting, where recycling companies and contractors and sometimes transporters participate.
- **Consequences:** difficult for recycling companies to plan and perform their business effectively. This is reflected in deliveries that are not possible to carry through and must return to the recycling company, delays, and ad hoc deliveries.

Transport Actors

- **Current information exchange:** EDI, e-mail, and phone calls. Additional services needed are often order by phone in panic by the contractor. The rough plan for mass handling that the carrier receives in the beginning is perceived to be insufficient and rarely updated. Current delivery information given includes street address and a phone number to a goods receiver on-site.
- **Consequences:** the carrier must return material, the contractor gets the wrong material, that the contractor does not receive material, equipment deliveries and waste collections at the wrong time. In general, transport actors in most cases cannot contact construction sites directly and they have to hunt information many times.

Analysis

Figure 3 below illustrates each type of information need from the different actors categorized as either project, customer/purchase order, or call-off information. It can be seen that project information seems to be of more importance for those actors managing the project such as clients and contractors. But it also tells us that most actors are of interest of customer order and call-off information. The text below describes what each category of information consists from the point of each actor.

The information for the clients concerns necessary information for successfully realize the project in accordance to different authority claims such as impact on environment, applicable detailed development plans and traffic requirement plans, and surrounding society, but also to different customer requirements. Information such as quality of the building materials as well as its environmental impact of vehicles to site becomes important to facilitate maintenance in the future and fulfill requirements from authorities. The clients also need to know building and installation material/systems being built-in (product information) so that those who manage and maintain the installation systems later have access to the right information. Relevant project information for contractors are information regarding the actual construction process such as time plans, materials to use, suppliers to buy from, etc. However, it is also important that requirements from the customers and the authorities put on the client is handed over to the contractor. Therefore, is also information such as temporary roads to use and its bearing important for the contractor. The information need for the installation companies are similar as for the contractors with the addition of knowing when deviations in the time plan exist.
The second category of information is customer order related. Those who are in most need for this kind of information are actors associated with the supply process such as suppliers and transporters. However, the contractors and installation companies act as the customer here and the coupling point between the construction process and the supply process. The contractor acting as the coordination party in the projects is in need of material delivery plans for all subcontractors and installation companies. This also includes number of packages delivered for ensuring space on-site. The contractors also raised the question of how packages should be labeled and if deliveries should go through a construction logistics terminal or not. Installation companies also report on that information about when delivery notifications will be done in order to prepare for unloading their incoming deliveries on-site. From a supplier’s perspective they need to know what to deliver, when, and where. However, supplier-internal IT systems have problems with consolidating deliveries to the same construction site, e.g. if there are several contractors or addresses for the same site. This is a problem as larger construction sites almost always work under these conditions. The machines tie up large amounts of capital for the machine rental company and if information is provided in good time, they can reallocate their machines between their rental centers and thus have the right machines available on time, minimizing tied up capital. The same goes for information about when rental machines will be returned. There are many similarities among the transport actors’ information needs. It concerns knowing delivery-related information such as: what kind of material should be delivered and when.

The final category of information, call-off information, is of importance mainly for those actors working with transporting goods to the site, but also for those receiving it on-site. Even the clients need some information regarding call-off information such as the weight of the transport and delivery site condition. This is important for planning future access roads in upcoming projects. For contractors and installation companies it is important with notification of incoming deliveries for making resources available for unloading deliveries.
The contractor also needs unloading time slots for all their subcontractors, where they will store materials, how much will be stored. They also need to know if the equipment for unloading goods is necessary, turning radius of the trucks, weight etc. For the transporter actors is it necessary with unloading time slots, contact information on-site and site condition for knowing how to enter and exit the construction site. It is also necessary for them to know if extra services such as unloading help, help with transferring goods to mounting location, etc is ordered or not.

**Discussion**

Based on what is presented in previous chapters, it can be seen that different information needs in the interface between the supply chain process and the construction process, as summarized in Figure 4 below. The figure should be read as each layer in the pyramid adds to the lower layers.

As Kaipia (2009) notes, it is of utmost importance to exchange for the receiver relevant information. Exchanging too much information can counteract the positive effects of exchanging information, leaving the receiver to sort out relevant information in a vast amount of information (called *information overload*). This counteracts information quality, i.e. not meeting the receiver's demands of information (Gustavsson and Wänström, 2009). The kind of information needed depends largely on the actor’s role in the supply chain. What we can see is that transport actors foremost need delivery call-off information, such as address, contact persons, slot times, site conditions including access roads and parking spaces, unloading spaces, storage locations, and the need for unloading facilities. Having this information enables them to easily plan and control their deliveries, which avoids consequences such as searching for recipient staff and unloading spaces when arriving at site and increasing efficiency in their deliveries. This in turn reduces the risk of transporters just dropping goods outside the construction or to anyone nearby (a real problem). Enabling all project partners, including all subcontractor and in turn their subcontractors, to have access to the above-mentioned delivery information will increase the delivery reliability.

The next level of information need concerns all those actors responsible for delivering materials, machines, or waste management services. They as the transport actors also need delivery information as they hand them over to the transport actors, but they also need information about delivery plans in order to plan their deliveries and their operations. Delivery plans include time and date for deliveries and what to deliver and in what amount, if packages should be marked, and whether it will be stored on a distribution terminal or not. Providing suppliers with an updated picture of when their materials/machines/services are needed at the construction site is important for them to better plan their work and this information can reduce impacts in the form of extra transport and unnecessary storage, both on site and at the material supplier. Furthermore, this also improve the availability of these goods to the contractors.

The final level of the information need applies to all those actors who are required to perform work on site or are responsible for the product after it is completed, i.e. contractors, installation companies, and clients. They need information about the products and building material and how the project's actors plan to perform their work, for coordination purposes. Project information includes e.g. time plans, involved actors to be coordinated, product information, and detailed development plans from the municipality. In addition, different site conditions are included such as load-bearing on roads and information about surrounding buildings and roads.
The information needs hierarchy in Figure 4 helps in understanding that the closer an actor is to the customer (i.e. developer), the greater the information needs is. However, it is not self-evident that all actors on the top layer (project information) need the underlying information. Those with a transport infrastructure perspective on logistics constitutes an exception, like the municipality. They only have a certain need of project information, the one that relates to how other infrastructure and social functions will be affected by the construction project. They are not primarily dependent on delivery information and delivery plans as suppliers and carriers are and are thus located outside the pyramid of information.

Conclusions
This study has focused on information needs and provided a suggestion on how to look at information needs in the interface between the supply chain and the construction process. This has been achieved by interviewing actors from different parts of a construction project that has different perspectives on the construction process and supply chain process interface: clients, contractors, installation companies, machine rental companies, material suppliers, recycling companies, and transport actors. Similar information needs were identified among most actors, but some of the information needs identified differed. The information need among the actors in a construction project can be divided into three hierarchical layers, see Figure 4, where the bottom layer regards delivery call-off information, found to be relevant for everyone in one way or another. The middle layer regards customer/purchase orders, information relevant to everyone except the transport actors but especially relevant to machine rental companies, material suppliers, and recycling companies. The top layer is project information and is only relevant to clients, contractors, and installation companies.

Some of the challenges associated with increased information exchange in the construction industry are: (1) there are many actors who need information and need to exchange information; (2) not known what information is needed by whom and when; (3) information is stored in many IT systems without the possibility of exchange between systems (4) who should take the coordination responsibility. Questions like who generates what information, where should it be stored, who should have access to it, what are the value for the companies in exchange this information, who should be responsible for collecting, storing and providing access to the information needs to be answered. The effects of information exchange also need to be quantified.

The result of this research contributes to the academy but also provides practical benefits to different organizations associated with the construction industry. From an academic point of view, research continues on both Pala et al. (2016) and Samuelson and Björk (2014) on information management and digitization. An interesting insight was that all information may
not need to be digitized in the way Pala et al. (2016) suggests (such as ground conditions) but may be better suited according to a well-structured and accessible EDM system that Samuelson and Björk (2014) highlight. It also contributes by showing that information needs are context dependent as suggested by Kaipia (2009) and that improved information quality can improve efficiency as suggested by Kaipia and Hartiala (2006).

There are practical benefits for several industry actors. From a municipality perspective, the results of this study can be a part of an investigation, which deals with how collaboration in the construction industry can be improved. The study shows what information needs to be exchanged between municipalities, contractors and clients during a construction project to minimize the impact on third party. For contractors, this research contributes with the knowledge that what seems to be irrelevant information to some is actually information that almost everyone needs, such as delivery plans and delivery information. This can provide better resource utilization for all involved. One last positive impact that the work contributes to is an increased understanding among IT system vendors about what kind of information needs to be included in different systems. Industry standard Beast e.g. provides a clear understanding of what kind of delivery information needs to be exchanged between contractors and suppliers. However, Beast lacks information needs from municipalities and clients, and does not include any information other than the delivery information.

Making sense of cost-driven outsourcing

Carsten Scheibye (cs.om@cbs.dk)
Copenhagen Business School, Department of Operations Management

Kim Sundtoft Hald
Copenhagen Business School, Department of Operations Management

Abstract
This study contributes to operations management and supply chain management literature and in particular that on cost-driven outsourcing. It explores events, actions and altered management situations that followed cost-driven outsourcing and, how senior management enacts and makes sense about organizations’ cost-driven outsourcing. The study widens the understanding of cost-driven outsourcing and complements contemporary research, which increasingly challenges outsourcing decisions based on pure cost efficiency considerations and calls for further understanding of cost-driven outsourcing. It advocates that cost-driven outsourcing based on narrowly confined decision-making schemes can hamper organizations’ strategic development and stresses managements’ concerns regarding competences, revenue and strategic opportunities.

Keywords: Outsourcing; Supply chain management; Case study.

Introduction
Cost reduction is a prominent argument for organizations’ to outsource and relocate production, and during the last four decades jobs have migrated from high-cost to low-cost areas (e.g. Kakabadse and Kakabadse, 2002; Kinkel and Malloca, 2009; Kinkel, 2012; Drauz, 2013). However, research on offshore outsourcing increasingly reports a lack of achieved benefits from cost-driven outsourcing (e.g. Kinkel, 2012, Larsen et al, 2012), and a relative increase in backshoring and insourcing (Tate, 2014).

Following these tendencies, authors now call for a broadening of our understanding of the outsourcing and insourcing decision-making processes (Kinkel, 2012). They urge a depart from a pure cost focus to an enquiry into how managers take into account the broader value chain perspective in their sensemaking and their decisions related to opportunities in outsourcing and insourcing (Young and Macinati, 2012). Specifically there is currently scarce empirical knowledge on, how senior managers make sense of the managerial consequences following cost-driven outsourcing. Therefore, the purpose of this research is to deepen our understanding of the managerial sensemaking process in relation to cost-driven outsourcing. A multiple case study approach is applied to explore the effects, actions and altered management situations, which followed cost-driven outsourcing in six different companies. The following research question is addressed: How does senior management enact and give meaning to the managerial implications that follows cost-driven outsourcing?

Cost-driven outsourcing decisions
During the last two decades, literature on production relocation has been growing. This includes literature on outsourcing, insourcing, offshoring and backshoring. Also, and
more recently the number of studies that explore and problematize decisions to outsource value chain activities has been growing.

Defining outsourcing

Outsourcing and offshoring are sometimes used as synonyms. However, the concepts differ significantly in nature and purpose (Kinkel and Maloca, 2009). Offshoring is a ‘spatial’ concept within literature and denotes relocation of production outside the home country. Outsourcing, on the other hand, does not indicate a geographical relocation (Olsen, 2006), but is defined in terms of ‘ownership’ and the organization’s degree of vertical integration. Thus, outsourcing reduces the share of the company’s in-house production related to the total value creation of the final product (Drauz, 2013) and implies an alteration in the scope of the organization’s operation. In this research, outsourcing denotes such a change in ownership, where a company transfers production to a third party outside the formal boundaries of the organization.

Antecedents to outsourcing

Many factors have been reported as antecedents to outsourcing. Most predominantly however is ‘costs’, or rather ‘cost reduction’ as a motive for outsourcing (e.g. Kakabadse and Kakabadse, 2002; Arlbjørn et al, 2013). The cost-argument often relates to expected reductions in direct operating costs due to regional differences in wage levels. However, literature also irradiates other, though still explicitly cost-related reasons for companies’ outsourcing decisions: Reduction in transaction costs (Kakabadse and Kakabadse, 2002); assumed differences in productivity (Arlbjørn et al, 2013); increased capacity utilization (Kinkel and Maloca, 2009); and reduction in capital layout and capital costs (e.g. McFarlan and Nolan, 1995).

In relation to other antecedents to outsourcing the following have been reported in literature: Access to other competences and skills (Arlbjørn et al, 2013; Drauz, 2013); altered organizational focus on core competences that has made certain activities less strategic important (McFarlan and Nolan, 1995; Kakabadse and Kakabadse, 2002) and vicinity to customers (Kinkel, 2012; Drauz, 2013). Accordingly, these motives for outsourcing fall in a somewhat broader strategic category that embraces the organizations’ core competences and position in the value chain.

Failed cost-driven outsourcing

Research reports increasing concerns regarding, cost-driven outsourcing decisions based on narrowly confined cost efficiency considerations (Kinkel, 2012). These more contemporary ideas stem not only from studies on the effectiveness of outsourcing but also from studies exploring the antecedents to insourcing of previously outsourced production. Some contributions even suggests that a reverse shift in production location is understood better in a sequential empirical setting (Kinkel and Maloca, 2009).

In addition, several studies direct their attention to the discrepancies between expected and realized costs (e.g. Veltri et al, 2008; Kinkel and Maloca; 2009; Arlbjørn et al, 2013; Drauz, 2013). These discrepancies manifest themselves in a variety of ways. That is for instance in: Increased cost of coordination and monitoring (Kinkel, 2012); differences between expected and realized productivity (Arlbjørn et al, 2013); quality breaches (Arlbjørn et al, 2013); and reduced capacity utilization (Kinkel and Maloca, 2009).
Outsourcing decision-making

Most literature on outsourcing decision-making is dominated by contributions applying a transaction cost perspective (Larsen et al, 2012) or a resource-based perspective (Liao et al, 2009) in order to understand and normatively guide outsourcing decisions.

Although these contributions are highly valuable in broadening our understanding of the complexity necessary in making outsourcing decision not only taking into account the labor cost dimension, they also fail to see outsourcing decisions as embedded in a more complex and dynamic practice. Kinkel (2012), for instance, argues that decision-making schemes should embed qualitative environmental factors and advocates that organizations in their practices integrate dynamic concerns and use scenario planning. Along such more complex perspectives, academia also directs attention to loss of knowledge (Drauz, 2013), thus adds a knowledge-based perspective (Liao et al, 2009).

Another problem is that the many reported cases of failed cost-driven outsourcing, challenges the suitability and robustness of the outsourcing decision-making practices actually performed in firms. However, literature is rather sparse on attempts to understand these practices and do only rarely follow outsourcing and insourcing decision-making processes and its embedded managerial reasoning in empirical settings.

Design, methodology and approach

The presented research takes a philosophical stance in pragmatism (Bernstein, 2010) and adopts a sensemaking perspective (Weick, 1995 and 2001). Sensemaking is in this research understood as the process of ‘reciprocal exchanges between actors (Enactment) and their environments (Ecological Change) that are made meaningful (Selection) and preserved (Retention)’ (Weick et al, 2005, p. 414) as shown in Figure 1.

Figure 1 – The connectivity between Ecological change, Enactment, Selection and Retention. Based on a simplification of the model presented in Weick et al, 2005, p. 414

This paper has an onset in senior management’s enactment. Enactment ‘is first and foremost about action’ (Weick, 1995, p. 36), which creates new understandings. If these are selected and retained, they provide a new perspective, which is subject to the ongoing, reciprocal exchange with changes in the environment. Observed discrepancies between expectations and experience become instances for new actions, enactment and the making of sense. Therefore, the events, actions and altered management situations that followed the cost-driven outsourcing come into the forefront, when we study, senior management’s enactment and, in turn, their formation of meaning about the organization’s outsourcing.

In order to track and portray the effects, actions and altered management situations cost driver theory and taxonomy were applied (Shank and Govindarajan, 1993; Anderson and Dekker, 2009). Specifically the structural properties of the organization understood as its scope, scale, competences and complexity, i.e. the breadth and depth of the product portfolio including its supporting service offerings, were used in the analysis. Thus, based on this perspective we assume that structural decisions defines the cost structure and confine the executional maneuverability of the organization. In relation to executional cost drivers, quality, capacity utilization, flexibility and management of relationships were included in the analysis.
The research utilizes a qualitative research methodology and mobilizes a multiple case study approach. With support from the national industrial confederation, six companies were approached and selected as cases. They are non-deviant and non-extreme cases, share fundamental strategic and operational similarities and are larger manufacturing companies with own international affiliates. They produce different tangible products, which are augmented by supportive technologies and services. The organizations operate as suppliers in international business-to-business environments. All have undertaken cost-driven outsourcing, which structurally altered the scope of their in-house upstream operation; i.e. altered their backwards integration. In addition, all case organizations have to some extend insourced previous outsourced activities. For all involved firms their overall corporate strategies had remained unchanged since their outsourcing.

Data was collected based on interviews with senior management and archival material (e.g. accounts, investment appraisals). In total, 31 interviews were conducted in the six different organizations.

During the first analysis of transcribed interviews and archival material, data was coded and presented as emplotted narratives. Emplotted narratives introduce a 'structure that allows making sense of the events reported' (Czarniawska, 2004, p. 122), which includes ‘the chaining of cause and effects or stimulus and response into a pattern, structure or network’ (Boje, 2001, p. 108). This enabled the linking and explication of structural decisions and executional implications into a more coherent whole. We applied both a ‘feedforward’ and a ‘feedback’ strategy (Czarniawska, 2004, p. 119). The former emphasizes the chronological account of the events, actions and altered management situations retrospectively in a historical process perspective to represent the organizing process, the organizational transformation and ecological changes. The purpose of the latter is to achieve an understanding of among others the cues (e.g. Weick, 1995 and 2001) that interweaved in the organizing process; e.g. cost calculations, cost representations and similar insights into cost structures and drivers. In addition, the research applied a ‘zooming in’ approach that enriches the accounts and a ‘zooming out’ approach, which entrenches details to a larger picture of the organization (Czarniawska, 2004, p. 120).

Thus, the narrative approach exhibits plausible explanations for the events, actions and altered management situations and in turn the formation of management’s perspectives and meaning about the cost-driven outsourcing that had taken place. The development of the narratives was an iterative process moving between the field and the literature. Narratives-in-the-making were shared with respondents during the research process and often prior to interviews and the gathering of additional data. Thus, they formed part of the basis for further probing and documentation. The final case narratives were all subject to approval by senior management.

Case study findings
The research found that all case organizations experienced numerous effects following the cost-driven outsourceings, which surprised the organizations beyond that of simple calculative errors. Some of these effects were completely new to the organizations in the sense that they have not formed part of the decision-making schemes. Other unexpected effects had been stipulated beforehand, but wrongly as to their operational impact. The unexpected effects required actions that incurred costs. This section unfolds these unexpected effects and the subsequent managerial actions. These actions, in turn, enacted new environments in the form of new understandings and altered managements’ situations as well as new, unanticipated, selected and retained managerial perspectives.
Immediate and unexpected executional effects and subsequent actions

The involved case organizations’ outsourcing ventures were all cost-driven, and all organizations outsourced primary activities, which altered their vertical scopes. Our analysis found that all case organizations experienced more or less immediately, unanticipated executional effects that required managerial intervention.

The analysis found many examples of breaches in quality of the intermediate products, which were now produced by suppliers. In addition, many issues in terms of lack of flexibility in the operations were identified after the cost-driven outsourcing decision was implemented. Another set of issues related to the fact that all case organizations had to implement extra initiatives related to the management of their inter-organizational relationships and this more than expected. These initiatives were for instance remediates for monitoring and enforcing the relationship, and this incurred costs. Table 1 lists examples of identified unexpected effects. Our analyses also demonstrated, how the executional effects were highly interrelated. One example was an instance of a quality breach, which required management actions and remedies such as a stop/decrease in in-house production. This in turn, affected in-house capacity utilization in organization 6.

The connection between flexibility and that of the management of relationship is another example of interrelations between the executional factors that the involved organizations experienced. Here, organization 5 experienced a larger need for relationship management resources than expected prior to the outsourcing decision; and that was both upstream with the supplier and downstream towards the organizations’ customers. The findings in Table 1 by large confirm existing contributions on effects of outsourcing and various reasons for insourcing, although the immediate effects are more prominent within literature compared to reflections upon the nature and extent of the interrelated effects.

Senior management acted upon all the immediate and interrelated effects. As an example, organization 6 who experienced breaches in quality and subsequent effects that materialized in reduced in-house capacity utilization took obvious management actions in respect to their operational problems. Management put additional quality control in place and increased stocks of the intermediate product now provided by the supplier. In addition, senior management strengthened the enforcement of the relationship and contract. The other organizations also took actions that are manifest and thoroughly explicated in operations management and supply chain management literature.

The structural concerns and enacted understandings

It is likely of no surprise that the executional effects and related actions just reported, both seen in isolation and intertwined, evoked senior managements’ structural considerations. This is demonstrated in this section, where we again use organization 6 as an example.
The cost-driven outsourcing altered all organizations’ scope in their production (i.e. their vertical integration), and some companies experienced immediate quality breaches. Figure 2 illustrates, how senior management in organization 6 acted upon the encountered effects and evoked an altered understanding.

This enacted an understanding that enabled sensing the discrepancies and anomalies compared to the company’s expectations prior to the cost-driven outsourcing. It followed, that senior management increasingly questioned both the comprehensiveness of the outsourcing decision-making scheme and, perhaps more important, the scope of the organization. Simply stated, the alteration of the scope lead to quality breaches that required action, which in turn ignited managerial interest and queries related to the new scope. Thus, senior management enacted a new understanding of the relationship between scope and quality (see the grey-toned ellipses in Figure 2) and raised management issues that questioned the scope (see the ‘spotted’ ellipses in Figure 2).

Senior management also enacted new understandings about other structural properties because of the interrelated executional effects. The aforementioned interconnectivity between breaches in quality and in-house capacity utilization in organization 6 brought forward the relationship between capacity utilization and scale. This is well known within production economics and operations management. Thus, senior management not only commences questioning the scope due to breaches in quality as illustrated in Figure 2. Senior management also took actions in relation to the in-house capacity issues (e.g. increased stocks), which spawned from the quality issues. Thereby senior management also enacted structural queries regarding the scale of the in-house operation. The relationship is portrayed by the ‘spotted’ ellipses in Figure 3.

Thus, senior management enacted new understandings of the relationships between the fundamentally different structural themes of scale and scope. This did not form part of the decision-making scheme prior to the outsourcing.
The issues of quality and in-house capacity utilization were interrelated with the issue of flexibility in upstream production and downstream delivery. Flexibility was part of the concerns prior to the outsourcing decision. However, upstream and downstream flexibility were affected more than assumed, and therefore called for unanticipated management interventions. In addition, our study also found that the issue of flexibility and associated management remedies (e.g. stock and inter-organizational relationship management) induced structural themes in relation to complexity and internal competences in organization 6. The latter structural theme of competences, however, mainly related to an emerging, ongoing exchange with management of linkages and scope. This is illustrated by the white ellipses in Figure 3 above.

**New enacted organizational perspectives**
This could have been portrayed much more complicated, if Figure 3 had included all the effects and actions in our study. However, this is not necessary to convey the idea that new meanings steamed from senior management’s continuous enactment; an ongoing creation triggered by continuously enacted understandings and ecological changes. In addition, competences were not only about capabilities in relation to altered operational tasks associated with the management of new inter-organizational (and intra-organizational) linkages. The concerns about structural property of competences also emerged from within due to among other evolving ideas about the organizations’ abilities to develop new products. The study also found conditions outside the organizations that primed these management queries. Altered external conditions (e.g. change in customers’ requirements and new emerging markets), for instance, fostered the calls for competences in product development. This accounted for all the organizations though differing in nature and magnitude.

All organizations to some extent insourced previous outsourced production, although the insourcing was not fully comparable to the previous outsourcing. One organization for instance only partly insourced previous outsourced production, and the organization later sold off the production to another company. However, the organizations’ insourcing of production addressed, at least partly, the same activities in the value chains, and the overall corporate strategies remained unchanged.

Table 2 summarizes some of the more significant structural themes that senior management enacted after the outsourcing decisions. In addition, the table provides an overview of the major reasons for the subsequent insourcing.

**Discussion of perspectives in cost-driven outsourcing**
The analysis shows, exemplified primarily by organization 6, how the case organizations did prepare the outsourcing ventures with the intention of adopting the most appropriate
structure and approaches. In more detail, all the analysed organizations were well prepared in taking into account the structural change embedded in their cost-driven outsourcing, the organizations’ aim to align with the corporate strategies as well as for a smooth implementation and subsequent operation. However, all organizations experienced numerous unanticipated effects, which affected each other and created new enacted understandings and perspectives.

The ongoing creation and management perspectives

The emplotted narratives introduce a relationship between the events, actions and altered management situations by connecting ‘cause and effect’ and ‘stimulus and response’ into a structure (i.e. Boje, 2001; Charniawska, 2004). They evidently exhibit that senior management enacted new understanding of the relationship between executional issues such as quality and capacity utilization and the structural properties of scope and scale of the operation. These are well known to academia and practitioners, and by large the study confirms contemporary research’s contribution as to numerous and unanticipated effects from the cost-driven outsourcing (e.g. Veltri et al, 2008; Kinkel and Maloca; 2009; Arlbjørn et al, 2013; Drauz, 2013). In addition, our case analysis demonstrates the limited usefulness of narrowly confined decision-making schemes that rest upon pure cost efficiency considerations. Thus, the study confirms contributions that call for a broader and more dynamic perspective on the outsourcing; thus in the management of the companies’ value chain (e.g. Kinkel, 2012; Young and Macinati, 2012).

The research also highlight that the normative and prescriptive decisions-making models may be contested for not attributing sufficient emphasis to the notion of the ongoing creation. Our exploration demonstrates that there is an ongoing creation at the senior management level, which involves alteration of the perceptions about the relationship between executional and structural themes as well as the formation of new, unanticipated relationships between various structural properties in the organization. This includes relationships between the organizations’ structural properties such as the scope in terms of vertical integration and the scale mainly related to the horizontal integration as well as the organizational competences and complexity. In addition, the analysis shows how cost-driven outsourcing and the possible effects, actions and altered management situations are contextual. Although the organizations shared several similarities, the effects of the cost-based outsourcing endeavor evoked a process of very different actions, understandings and management perspectives.

The study suggests that the relationships between scope and quality as well as that of scale and capacity utilization is subject to somewhat generic management issues, even when they interrelate. However, the elevation of the management perspectives regarding the structural properties of competences and complexity seem more unpredictable and subject to an even more complex process in the organization. It is plausible that the enacted environments and the subsequent understanding of complexity is a multi-faceted construct with both an internal and an external customer-oriented dimension. Thus, it is plausible that it is not only a question of breadth and depth in the product portfolio including its service attributes such a flexibility in delivery. This also becomes a question, which relates explicitly to the process of managing the linkages across the organization and inter-organizationally and, in turn, how that connects to the offerings downstream. In terms of the organizational competences, this also has both an internally as well as an externally driven aspect. The latter, of course, associates to the competences needed in product development to meet market and customer requirements, thus it ties to
complexity in the product portfolio, not least in terms of process-related service offerings such as flexibility in delivery, while the former interconnects with the executional issue of managing the inter-organizational relationships.

**A structural property perspective on cost-driven outsourcing decisions**

This indicates that a transaction cost economics approach; a knowledge-based perspective; and a resource-based view on cost-driven outsourcing appraisals is not sufficient. Thus, it is plausible that organizations would benefit from extending decision-making schemes in cost-driven outsourcing with appraisals that problematized the relationship between key structural properties of the organization in various scenarios.

![Figure 4 – Structural properties in cost-driven outsourcing](image)

Building on this, Figure 4 relates the structural properties and the various, possible executional effects and indicates that cost-driven outsourcing, despite its straightforward conception within literature, is a highly complex and contextual decision. This, in turn, fundamentally questions outsourcing based on a perspective, which solely rely on narrowly confined cost considerations related explicit, and solely, to scope-related issues.

**Conclusion**

The presented research complements contemporary research, which calls for a further understanding of the managerial perspectives and implications of cost-driven outsourcing (Kinkel, 2012). The findings suggest that senior management enacts organizational perspectives that embed new understanding of the relationship between the various executional themes and structural properties of the organization. Hence, cost-driven outsourcing should be understood as an ongoing creation with highly complex interconnectivity between events, actions and new management situations.

The study challenges normative and prescriptive decision-making models and approaches. It suggests that while such might be rooted in views based on transactions cost economics, knowledge and resources, or a combination hereof, which indeed offers highly valuable insights, it is plausible that organizations would benefit from adding a structural property perspective, which recognizes the contextualized interconnectivity between the structural properties and the ongoing creation and organizational learning.

The research presented in this paper further supports contributions, which advocate that cost-driven outsourcing based on narrowly confined decision-making schemes can hamper the organizations’ strategic development. Such endeavors are partial per se. They are literally ‘experiments’ due to among other an absence of management concerns regarding competences and the ongoing formation of sense. In that respect, the need for certain competences is also related to product development and meeting markets’ and customers’ needs. Revenue and strategic opportunities becomes apparent foci even in simple cost-driven outsourcing decision-making schemes.
Thus, this research supports contemporary research and adds a structural property perspective that also infers revenue and strategic opportunities. It gives a contemporary view that counterbalance ideas of alignment and adaptation. However, we need more case studies to develop our insights into the complex implications of cost-driven outsourcing and the forces that govern management practices. We suggest in particular that future research further explores the interconnectedness between structural concerns such as scope, scale, complexity and competences in outsourcing. This is important as structural changes embed substantial risk and define executional maneuverability; thus, in turn connects to corporate and competitive strategies. Although, this study does adopt an empirical setting based on known sequential events prior to the commencement of the study, and contributions suggest possible benefits from such an approach (e.g. Kinkel and Maloca, 2009), it would be of value to opt for longitudinal studies, which are commenced at the very beginning of the cost-driven outsourcing.

Abstract
This paper discusses the social risk supply chain management through a case study in a Brazilian company. We map the social risks and the main consequences of these risks tracked by the organization. By comparing the findings of the case study with the literature, the paper contributes to the academic studies with 2 new social risks, the main consequences of these risks, and the description of the company's strategy to manage its risks.

Keywords: Social Risk, Risk Management, Case Study.

Introduction
Academic researches in supply chain risk management (SCRM), in general, address the risks that occur due to interruption at some point in the chain, which later blocks the flow of materials, funds or information among the entities of the supply chain (Bode et al., 2011). Therefore, they approach the traditional view of SCRM, with the focus on avoiding interruptions along the chain to reduce financial losses that this disturbance can cause (Bode et al., 2011; Hofimann et al., 2014).

The risk management literature is diverse, but researches on financial risks have been studied for a longer time and have greater repercussion due to significant economic changes for organizations. However, this classical approach focused on financial performance does not consider the social view to be purely economic (Busse, 2016).

The social risks started to gain academic attention with the introduction of the concept of Triple Bottom Line (Elkington, 1994). Nevertheless, research on the social risks in which the supply chain of a company may be involved is still needed (Tang, 2018). Basta et al. (2018) also argue that when addressed, social risks are mostly
limited to labor rights and working conditions.

Therefore, the present paper aims to study the social risks in supply chains through a case study answering two research questions:

(i) The social risks and consequences found in academic literature are found / relevant also in a business enterprise?

(ii) What strategies does the company use to manage its social risks?

The case study considers a Brazilian company of Cosmetics, involved in the manufacture, industrialization, distribution and sale of cosmetics, fragrances and personal hygiene products. We compare and validate the results of the case with the list of 24 social risks and 13 consequences proposed by Cunha et al. (2019).

The remainder of the paper is organized as follows: Section 2 addresses the case study methodology. Section 3 presents the results and discussion of the case study, followed by a section presenting the concluding remarks and suggestions for future research.

Research Methodology

The present research adopted the case study methodology proposed by Yin (2013), composed of six steps: plan, project, preparation, collection, analysis, and sharing.

The plan aims to identify the relevant situation for the accomplishment of the case study in detriment to other research methods. Thus, the event to be studied within the context of real life is the management of social risks in supply chains.

We present a unique case as an exploratory study of a theme little covered by the literature. The present research considers common case study to capture the circumstances of a daily situation to provide processes related to some theoretical interest.

The project was carried out with a Brazilian company of Cosmetics recognized for its vision of sustainability, the principle of generating positive impacts on society and for being an organization that combines economic growth with the promotion of social and environmental well-being. The research question compares the social risks and the consequences that these risks can generate for a company covered by the academic literature with what is observed in a supply chains of a real company. The criteria for data interpretation to actual data that can reinforce, complement or contrast with the results derived from the academic literature to bring new insights to the strategies to mitigate these risks.

In the preparation stage, we developed the case study protocol, defining candidates, selecting the final case to be studied and synthesizing the initial definitions of the study.

Data was collected through documents made available by the company, interviews, and secondary documents from the internet. First, the professionals of the studied company answered an online questionnaire. This questionnaire was based on Cunha et al. (2019) and made available to respondents through the SurveyMonkey platform. Then, we conducted face-to-face interviews with open questions based on answers previously reported by company professionals. Finally, we compiled documents made available by the interviewees and secondary materials available on the website of the company studied.

The professionals considered in these interviews effectively deal with the risks of the company, and are: (i) the Supply Manager, responsible for Performance
Management and Relationship with Suppliers; (ii) the Audit Coordinator of Supply Management, and (iii) the Compliance Coordinator.

The data analysis considers the pattern matching technique, in which the theoretical reference is used as prognosis and compared with the results of the case study.

Finally, the sharing stage consists of the publication of the present paper.

Results and Discussion

The company's mission is to promote well-being through the mobilization of a network of people capable of integrating scientific knowledge and the sustainable use of the rich Brazilian botanical biodiversity, in order to deliver the cosmetics manufactured from natural elements of the Brazilian flora, processed, distributed and sold.

Through the online questionnaire, it was possible to understand that the company has three areas responsible for its risks, namely: (i) the Supply area, which deals with risks related to suppliers; (ii) the legal and Compliance area, an area concerned with issues related to labor laws, including the risks of corruption and bribery; (iii) the area of Corporate risks, encompassing other risks.

Through the interviews, it was possible to understand that the Brazilian cosmetic company has means of identifying social issues present in its supply chain through an audit carried out periodically by the company, through a complaint from one supplier over another (which has already occurred with a textile supplier), and through the media.

The interviewees stated that the company has a list of risks predefined by a multidisciplinary group (encompassing area of supplies, risk management, legal area and relationship with suppliers), which is reviewed every two years and serves as the basis for the supplier's audit checklist.

Among the 24 social risks found in Cunha et al. (2019) and listed for the interviewees, 11 of them are not on the list of pre-defined risks to be audited for the studied company, these being: unfair or low wages, although the same worries about workers' compensation however, it still cannot reach the level of detail of the amount paid by its suppliers to employees; access to drinking water; access to basic sanitation; unfair compensation; reallocation or rupture of indigenous peoples; exposure of communities near the end of activity; unavailability to public facilities; expropriation; exposure to unemployment; reallocations without explicit grounds and equality before the law.

Some of the social risks present in Cunha et al. (2019) do not fit directly with the area of cosmetics addressed. However, some risks such as low or unfair wages, exposure of communities close to the end activity and unavailability to public facilities are suggested as possible risks to be added to the list of social risks to be audited as they can cause significant damages to the company.

The respondents added two social risks to the list of Cunha et al. (2019): Corruption and Bribery and Compliance with Local Labor Legislation. Corruption and bribery should be added to the list presented in Cunha et al. (2019), as they may create critical social risks. For example, if the money destined to the aid of an Amazon community is diverted, the community will not receive the necessary assistance and may trigger various social risks. However, concerning local labor legislation, this risk applies to the cosmetics company studied because its suppliers
are within the Brazilian territory. If the company has suppliers located outside Brazil, the law to be followed should be the one proposed by the International Labor Organization (ILO, 2017).

Besides the company's identification of the social risks found in the academic literature, the developed questionnaire also addressed the consequences that these risks could bring to the company.

Regarding the consequences presented in Cunha et al. (2019), those that appear most frequently in the questionnaire are the damage of the company's reputation, the risk of operational stops, individual claims or collective action and payment of mandatory compensation by the court. The profit reduction consequence was mentioned only twice which demonstrates that the company has a social concern that goes beyond the financial consequence that these risks can cause.

In addition to the two respondent areas of the online questionnaire, the Audit Coordinator explained the process in more detail during the interviews. As strategy to manage the social risks that may be present in its supply chain, the company performs two types of audits, one related to the new suppliers and another related to the contracted suppliers of the company.

The main objectives of the Audit process for the company are to mitigate risk of shortages of products, to protect the company's image and the integrity of employees, contributing to the maintenance/obtaining of certifications and awards which guarantee brand value, and to integrate company beliefs and values into the supplier relationship network, ensuring the development of the value chain.

The audit process takes place through a checklist questionnaire answered by direct suppliers. According to the criticality of the supplier, audits take place at one-year intervals (most critical suppliers) to five years (less critical suppliers). The company studied has a partnership with eight different companies that perform around 300 audits per year with their suppliers. The companies to be audited are defined by the company studied, and the process of auditing the suppliers happens with a marked date, that is, without surprise for the suppliers.

The checklist is based on six pillars: Quality, Environment, Health and Safety at Work, Legal Requirements, Code of Conduct, and Social Responsibility. In this way, the supplier can be classified into three groups: (i) approved; (ii) approved with restrictions, where the supplier is still able to sell, but must adapt within 3 months with the requirements demand in a corrective action plan; (iii) Disapproved, where the supplier will not be able to supply. The corrective action plans are individual and depend on the responses of each supplier. Some items make suppliers automatically disapproved, such as: forced or compulsory labor, child labor, environmental requirements, legal noncompliance, non-compliance with benefit payment rules, non-compliance with health and safety standards, and corruption.

**Conclusion**

The case study answered two research questions. The first one was answered as several social risks found in the literature coincide with the social risk monitored by the studied company. However, it became clear that social risks vary according to the area in which the company operates. Therefore, risks related to areas of construction, mining or oil and gas may or may not refer to the risks present in the area of cosmetics.

The second research question encompassed the strategy used by the company
to deal with its social risks. Cunha et al. (2019) presented the strategies in a general manner, whereas in the case study the process of supplier auditing was discussed as the strategy used by the company to manage social risk in its supply chain.

In this way, the main contribution of the paper to bring new insights to the academic literature through comparison between a real case and the results from Cunha et al. (2019). The social risks found by the academy may be included in the social supply chain management of the company. On the other hand, we demonstrate that the business environment brings updates back to the academy.

As future research, more case studies should investigate other supply chains, highlight disparities in relation to the private and public sector, and explore different types of organizations as well as different organizational areas, such as oil and gas, mining, construction, cosmetics, and textiles. Additional studies may also focus on the importance of stakeholders and their social risk management actions and other social risk management strategies.

Abstract

As a response to global climate change, decarbonizing supply chains has gained increasing attention from academia and industry. Motivated by the evolving role of third-party logistics providers (3PLs) from a service provider to a resource integrator in supply chains, this paper investigates when 3PLs initiate supply chain integration in order to decarbonize their supply chains. Drawing upon three theoretical lenses, i.e. social network theory, institutional theory and resource-based view of the firm (RBV), this paper develops a theoretical framework and tests it using survey data from 348 Chinese 3PLs. The findings have implications for both researchers and managers.

Keywords: 3PLs, Supply chain integration, Low carbon supply chain

Introduction

With growing pressure on reducing carbon emissions from supply chain management (SCM), decarbonizing supply chains has gained increasing attention from academia and industry. Given the critical role of third-party logistics providers (3PLs) in supply chains, previous research has examined the operational importance of 3PLs in decarbonizing supply chains (Das, 2018). However, the strategic role of 3PLs in decarbonizing supply chains has not received enough attention, although many researchers show that 3PLs have now taken on a more proactive manner for customers by organizing networks, sharing information, managing assets, and reducing inventory (Zacharia et al., 2011).

Further, despite the substantial amount of research on supply chain integration (Flynn et al., 2010; Huo et al., 2017), the majority of these research focuses on manufacturer-initiated SCI, and there is a dearth of research on the antecedents and effectiveness of SCI from the perspective of 3PLs, let alone in LCSC research. To fill the gap of low carbon supply chain integration (LCSCI) from the perspective of 3PLs, this paper focuses on 3PL-initiated LCSCI, namely a customer integration initiated by 3PLs to achieve LCSCs, and investigates the drivers and outcomes of 3PL-initiated LCSCI.

Based on the social network theory (Choi and Kim, 2008), institutional theory
(DiMaggio and Powell, 1983), and the resource-based view of the firm (Barney, 1991), we propose a theoretical framework of the antecedents and consequences of 3PL-initiated LCSCI, including customers’ outsourcing scope, government (environmental) regulation, 3PLs’ decarbonisation capabilities and 3PLs’ financial performance.

The remainder of this article is structured as follows. The subsequent two sections review the literature and develop research propositions. This is followed by a description of research method, in which the sampling method and measures are illustrated. Next, analysis and results are presented and discussed. The conclusion is then put forward.

**Literature review**

*Low carbon supply chain management (LCSCM)*

Low-carbon supply chain management (LCSCM) is considered as the combination of low-carbon operations management and supply chain management in response to climate change, focusing on activities that reduce carbon footprint in supply chains (Damert et al., 2018). Although some researchers argue that the drivers, barriers and performance outcomes of LCSCM should be similar to those of green supply chain management (GSCM), the empirical findings on the determinants and effectiveness of LCSCM have been inconclusive (Rivera, 2004; Zhang and Wang, 2014).

*Low carbon supply chain integration*

Supply chain integration (SCI) refers to “the degree to which a manufacturer strategically collaborates with its supply chain partners and collaboratively manages intra- and inter-organization processes” (Flynn et al., 2010, p. 59), where the inter-organization (or external) SCI includes collaboration that takes place between a focal firm and its suppliers and customers. With the evolving importance of LSPs in supply chains, there is a rapidly growing research on the effectiveness of SCI between a focal firm and its LSPs on firm performance (Huo et al., 2017). The common feature of these research is that they all take the perspective of the focal manufacturing firm; the amount of research on SCI from the perspective of LSPs is limited.

Vachon and Klassen (2006) are among the first who link supply chain integration and the green supply chain practices. Mao et al. (2017) show that manufacturing firms’ low-carbon supply chain integration (LCSCI) have positive effects on their environmental and financial performances. Nevertheless, there has been no research on LCSCI from the perspective of 3PLs, and it remains unclear about the drivers and outcomes of 3PL-initiated LCSCI. To fill the research gap, this research takes the perspective of 3PLs and focuses on their LCSCI. In particular, we define 3PL-initiated LCSCI as a customer integration initiated by the 3PLs to achieve LCSCs.

**Theoretical foundations and hypothesis development**

*Relationship between outsourcing scope and 3PL-initiated LCSCI*

The social network theory (SNT) has conceptualized the supply chain as a functional social network between companies consisting of nodes and links (Carter et al., 2015). Embeddedness is one of the core ideas at the heart of organizational social network theory and is defined as “the extent to which a firm relies on a supply network and perceives the influence of the network” in the context of SCM (Kim, 2014, p.220). Usually, the structural and relational embeddedness are adopted to measure the social capital within supply networks (Choi and Kim, 2008).

The impact of outsourcing scope on the supply network as well as 3PL-initiated
LCSCI can be understood from the perspectives of the relational embeddedness, which refers to the quality or the strength of a relationship (Moran, 2005). Since a wide outsourcing scope is usually associated with increased mutual dependence, commitment and interactions, it gives rise to the strong tie. As the relationship between firms becomes stronger, environmental collaboration in supply chains is more likely to occur (Tate et al., 2013).

Therefore, an increase in the outsourcing scope can lead to an increased level of relational embeddedness of 3PLs, which is positively associated with 3PL-initiated supply chain integration and environmental collaboration. Hence, we propose that the outsourcing scope of 3PL services may have a positive relationship with 3PL-initiated LCSCI.

**H1:** Outsourcing scope has a positive relationship with 3PL-initiated LCSCI.

*Relationship between environmental regulations and LCSCI*

Institutional theory identifies three dimensions of isomorphic drivers as institutional pressures that influence firms to adopt organizational competitive environmental alignment, namely coercive, normative, and mimetic drivers (DiMaggio and Powell, 1983), where coercive pressure refers to pressure exerted by those in power, such as the government environmental regulations (Sarkis et al., 2011). To conform to the environmental regulations by the government, 3PLs are motivated to form environmental collaborations in the supply chain (Vachon and Klassen, 2006), and build the strategic supply chain relationship and dependence with their customers (Huo et al., 2017), and thereby leading to 3PL-initiated LCSCI. Thus, we propose the following hypothesis:

**H2:** Government regulation has a positive relationship with 3PL-initiated LCSCI.

*The role of 3PLs’ decarbonisation capabilities*

Decarbonisation capabilities refers to firm-specific capabilities to decarbonize the supply chain. Previous research has indicated that the lack of firm-specific capabilities is one of the most common obstacles to GSCM practices (Wu et al., 2012). According to the resource-based view (RBV), firm-specific decarbonisation capabilities are rare, valuable, non-substitutable, and difficult-to-imitate resources in LCSCM.

We argue that these organization-specific capabilities and resources contribute to the collaborative relationship between the 3PLs and their customers, since the decarbonisation capabilities enable 3PLs to circulate their professional knowledge and resources efficiently to their customers, which is helpful for building strong ties with dependency and trust, thereby increasing the 3PLs’ relational embeddedness (Choi and Kim, 2008). Therefore, we propose that the effect of outsourcing scope on 3PL-initiated LCSCI can be stronger if the 3PLs have higher decarbonisation capabilities.

**H3:** Decarbonisation capabilities play a positive moderating role in the relationship between outsourcing scope and 3PL-initiated LCSCI.

Although 3PLs with higher decarbonisation capabilities can be more able and willing to initiate LCSCI proactively rather than responsively, they may become more self-motivated and less motivated by coercive pressures, such that the effectiveness of government environmental regulations on motivating 3PL-initiated LCSCI could be stronger for the 3PLs with lower decarbonisation capabilities than on their higher capabilities counterparts. Therefore, we propose that 3PLs’ decarbonisation capabilities may weaken the effect of government environmental regulation on 3PL-initiated LCSCI.

**H4:** Decarbonisation capabilities play a negative moderating role in the relationship...
between government environmental regulation and 3PL-initiated LCSCI.

**Relationship between 3PL-initiated LCSCI and 3PL’s financial performance**

3PL-initiated LCSCI is related to interaction and collaboration in the social networks. As 3PLs build tense and strong ties in their networks through frequent interaction and intense collaboration with their customers, operational efficiency and economic performance will follow, as long as they are not embedded too much (Uzzi, 1997). Also, the relational capabilities gained from increased level of embeddedness will ultimately enable them to combine cross-organizational complementary resources in unique ways and realize sustainable advantage over their competitors (Paulay, 2011). Therefore, we propose a positive relationship between 3PL-initiated LCSCI and 3PL’s financial performance. 

**H5:** 3PL-initiated LCSCI has a positive relationship with 3PLs’ financial performance.

The theoretical framework in this study as well as the proposed hypotheses are shown in Figure 1.

**Research method**

**Data collection and sample profile**

The sample was derived from 3PLs located in Guangdong province, China. As one of the earliest regions to open up in China, Guangdong province enjoys advanced economic development; its logistics industry grows rapidly. To collect the data, we collaborated with logistics and SCM organizations in Guangdong province, inviting them to participate in an online questionnaire survey. A total of 1300 3PLs took part in the survey, which was distributed in two rounds. After screening out invalid responses such as blank and incomplete questionnaires, we identified 191 and 157 valid responses for the first and second rounds, respectively, resulting in 348 in total. Thus, the response rate was 26.7%. Table 1 outlines the profile of the sample in line with four characteristics: business origin, ownership, the number of employees, and firm size.

**Construct measurement**

The constructs measured in this study were derived from the existing literature. Since the empirical investigation was carried out in China, we employed back-translation in order to ensure conceptual equivalence (Cai et al., 2010). The measurement scales were first translated into Chinese and further amended by two research assistants. The initial questionnaire was developed and then examined by using a random selection of 60 samples to conduct validity analysis, exploratory factor analysis (EFA), and correlation analysis using SPSS software. After this, three SCM professors were invited to verify the questionnaire, and the final version of the survey used for delivery was confirmed.
The items in the questionnaire were measured using a five-point Likert scale, with a score of 1 indicating ‘strongly disagree’, 2 indicating ‘disagree’, 3 indicating ‘uncertain’, 4 indicating ‘agree’, and 5 indicating ‘strongly agree’.

**Non-response bias and common method bias**

We used the method recommended by Armstrong and Overton (1977) to compare the two samples. As shown in Table 1, a Chi-Square test for the firm characteristics variables indicated that there was no statistical difference between the two rounds, thus confirming that both rounds of samples were unbiased.

Since the data investigated was derived from a single source, common method bias was likely (Podsakoff *et al.*, 2003). Therefore, we implemented Harman’s single factor test, whereby we conducted an unrotated principal component analysis, yielding 5 eigenvalues greater than 1 after extraction. The first factor explained 38.203% (lower than 40%). In addition, we conducted a confirmatory factor analysis (CFA) for Harman’s single factor model (Sanchez and Brock, 1996). Compared to the measured model, the indicators of the tested model were poor (\( \chi^2/\text{df}=3.297 \), GFI=0.635, AGFI=0.539, IFI=0.595, TLI=0.551, RMR=0.077, and RMSEA=0.081. This showed that overall, common method bias was not a problem in the data.

**Reliability and validity analysis**

The results of the reliability and validity tests are shown in Table 2. Internal consistency was measured using Cronbach’s coefficient. The Cronbach coefficients of all the constructs ranged from 0.808 to 0.898 (above 0.7). This confirmed that the constructs had psychometric properties. An examination of the CFA of all the constructs showed that all the indicators of the measurement model, such as \( \chi^2/\text{df}, \text{GFI}, \text{AGFI}, \text{IFI}, \text{TLI}, \text{RMR}, \text{RMSEA} \),
RMR, RMSEA, were ideal, and therefore that the constructs were unidimensional (Bentler and Bonett, 1980). In addition, as suggested by Fornell and Larcker (1981), we measured convergent validity. The results showed that all the standard factor loadings were above 0.7, and the t-values were above 10 for all but two items (0.67 and 0.692). Thus, convergent validity was confirmed. Composite reliability and AVE can be used to measure the reliability of constructs (Hair et al., 2006). When CR and AVE are above 0.7 and 0.5 respectively, it indicates a high degree of internal consistency, and that the consistency between the constructs/traits is higher than that of the errors (Hair et al., 2006). As shown in Table 2, the composite validity values of the constructs ranged from 0.807 to 0.873 (above the threshold value of 0.7), and the AVE values ranged from 0.527 to 0.635 (above the threshold value of 0.5). Table 3 presents the arithmetic square roots and correlation coefficients of the constructs. The results showed that the arithmetic square roots were larger than the correlation coefficients of the construct and the correlated construct, thus confirming that the measurement scale of the constructs had sufficient discriminant construct validity, as suggested by Fornell and Larcker (1981).

Results

Using SPSS 20.0 software, we set two explanatory variables (‘government regulation’ and ‘outsourcing scope’) and moderating variables, and multiplied them to obtain interaction items. Next, we set ‘3PL-initiated LCSCI’ and ‘economic performance’ as dependent variables and used stepwise regression to perform a hypothesis test. As shown in Table 4, Models 1-3 set ‘3PL-initiated LCSCI’ as the dependent variable, and Models 4-5 set ‘economic performance’ as the dependent variable. The tolerance of all the models was above 0.15, indicating that multicollinearity was not a problem. In Model 2, the regression coefficients of ‘outsourcing range’ and ‘government regulation’ were 0.579 (t=13.503, p<0.001) and 0.233 (t=5.550, p<0.001). This result indicated that these two factors had a positive impact on ‘3PL-initiated LCSCI’, and therefore H1 and H2 were verified. In Model 5, the regression coefficient of ‘3PL-initiated LCSCI’ was 0.323 (t=0.323, p<0.001), indicating that ‘3PL-initiated LCSCI’ had a positive impact; hence, H5 was verified. Model 3 tested the moderating role of ‘decarbonization capabilities’. With this model, the regression coefficient of ‘outsourcing scope’ was 0.236 (t=3.778, p<0.001), indicating that ‘decarbonization capabilities’ positively moderated the relationship between ‘outsourcing scope’ and ‘3PL-initiated LCSCI’, and therefore H3 was confirmed. The regression coefficient of ‘government regulation’ and ‘decarbonization capabilities’ was 0.362, indicating that ‘decarbonization capabilities’ negatively impacted the relationship between ‘government regulation’ and ‘3PL-initiated LCSCI’; hence, H4 was verified.

Notes: 1. Coefficients are standardized; 2. *** P<0.001; ** P<0.01; * P<0.1.

In order to reveal the moderating role of the variables, we set the average of ‘decarbonization capabilities’ as standard, dividing the sample into two groups: high level of decarbonization capabilities (high level) and low level of decarbonization capabilities (low level) in order to conduct a regression analysis of ‘3PL-initiated LCSCI’. Figure 2 shows that in the low-level group, the regression coefficients of ‘outsourcing scope’ and ‘government regulation’ were 0.409 (t=6.619, p<0.001) and 0.378 (t=5.7890, p<0.001), revealing a significant positive impact on ‘3PL-initiated LCSCI’. In the high-level group, the regression coefficient of ‘outsourcing scope’ was 0.526 (t=7.946, p<0.001), indicating that this variable also had a significant positive impact on ‘3PL-initiated LCSCI’, but the degree of impact was larger than in the low-level group. In addition, the regression coefficient of ‘government regulation’ was 0.058 (t=0.89, p>10%), showing that the impact of this variable on ‘3PL-initiated LCSCI’ was smaller than in the low-level group, and was not statistically significant. This analysis further verified H3 and H4.

Figure 2- The moderating role of decarbonisation capabilities

Conclusion and future research
Drawing upon three theoretical lenses - social network theory, institutional theory and RBV - this study develops a research framework for 3PL-initiated LCSCI, the constructs of which were verified by the empirical investigation conducted in China. The research results highlights the positive impact of 3PL-initiated LCSCI on corporate performance. It appears that, with the advent of decarbonized economies and societies, logistics service provision has been given greater environmental focus, distinct from traditional logistics functions. The emergence of 3PL-initiated LCSCI, to a large extent,
echoes Bowersox’s (1998) prediction that “the logistical mission of yesterday is being replaced by a broader concept driven by social responsibility” (p.2). This study shows that, as a strategic action, 3PL-initiated LCSCI is developed in response to a low-carbon economy. The findings of the current study provided evidence of 3PLs as supply chain orchestrators in decarbonized economies and their strategic benefits. Differing from many previous studies that focused on green SCI and 3PLs, this study provides a new perspective on 3PL-initiated LCSCI in consideration of the role of 3PLs as low-carbon supply chain orchestrators. Thus, the research results can contribute to knowledge development not only for SCI but also 3PLs. The present study also identified practical benefits for 3PLs in becoming supply chain orchestrators in a decarbonized economy and society. It suggests that, although the increasing pressure to outsource low-carbon services from both customers and government regulation, 3PLs be aware of their ability to initiate LCSCI, particularly their decarbonization capabilities. In order to gain the most from this initiative, 3PLs should optimize all their related processes, such as developing low-carbon logistics service design, techniques, and coordination capacity.

The empirical investigation can also provide scope for further exploration. Firstly, in relation to the factors that influence 3PLs to initiate LCSCI. This study assumed the degree of 3PL development to be at the same level. Given the negative role of decarbonization capabilities identified regarding the impact of government regulation on 3PL-initiated LCSCI, future research could examine the impact of these two factors on 3PL-initiated LCSCI in 3PLs at different stages. For example, when 3PL possess mature decarbonizing offerings, what is the impact of government regulation? Secondly, the empirical study was conducted in China; therefore, future research could investigate the differences between LCSCI initiated by 3PLs in cross-culture settings. Finally, the sample used in this study was relatively narrow, as data was only collected from one region. Future studies could expand the geographic coverage of the data.

Opportunities and limitations of blockchain based supply chain traceability

Oliver Bischoff (Oliver.Bischoff@uni-kassel.de)

Abstract
Blockchain is provoking significant disruptions, impacting supply chain management. We strive to progress the research regarding blockchain based supply chain traceability by identifying opportunities and limitations of the technology adoption. We a) reviewed concepts of supply chain traceability, b) conceptualised key elements of blockchain technology and c) highlight opportunities and limitations when implementing traceability using blockchain technology. Many of the blockchain’s characteristics represent incremental enhancement to current systems, when the technology features are adopted selectively, rather than the blockchains’ privacy model is embraced fully. Opportunities for disruptive change from disintermediation need to become focus of research.

Keywords: Supply Chain Traceability, Blockchain, Distributed Ledger

Introduction
Producers and customers alike demand verifiable evidence of traceability as an important criterion of sustainable products. Tracking data can aid demonstrating regulatory, social and environmental compliance. Stringent legal provisions and regulations, as well as high cost of product recalls provide strong reasons for traceability.

Furthermore, capturing the history of a product through the supply chain enables the optimisation of processes and the prediction of downstream time and quality issues, resulting in advantages in terms of costs, time and customer satisfaction (Abramovici et al., 2008). Traceability can accelerate innovation and sustainability within the organisation, leading to competitive advantage through differentiation. (Bosona and Gebresenbet, 2013).

Technological advances promise to ease challenges presented by traceability systems. Supply chains can benefit from the adoption of new technologies like the blockchain. Starting from the financial industry, blockchain incrementally is recognised in different industry applications, including supply chain management. Korpela et al. (2017) found that blockchain technology accelerates digital supply chain integration.

With the ability to perform peer-to-peer transactions in privacy, without third party intervention, blockchain can mitigate risks associated to the data manipulation, compromised privacy, or compliance with government rules and regulation. (Min, 2019)

However, alternative designs to a pure peer-to-peer model like public or private, permissioned or permissionless blockchains are discussed (Narayanan et al., 2016)
Several authors raise the concern that the pick and choose attitude towards blockchain technologies might result in blockchain being little more than the “new database tool” rather than the “next internet” (Jack Tatar, 2019). Consequently, private blockchain would just be confusing name for a shared database. (Narayanan, 2015)

Theoretical Background
Supply chain Traceability
Seuring and Müller (2008) recognise the sustainability aspect of supply chain management and extend earlier definitions to “sustainable supply chain management as the management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account which are derived from customer and stakeholder requirements.” Companies, Government and customers are building the core interest groups for supply chain traceability information.

Supply chain traceability is the capturing and analysis of custody, transformational and environmental information of material flows through the supply chain aiming to satisfy stakeholder needs regarding environmental, social and economic performance, compliance and quality. Traceability can be a source of competitive advantage through ensuring a transparent and sustainable supply chain. Traceability serves as an important component of business information system. With an efficient and effective system transmitting accurate, timely, complete, and consistent information, supply chain can significantly reduce the operation costs and increase productivity (Bailey, Bush, Miller, & Kochen, 2016).

Furthermore, companies need to cooperate to determine the requirements for tracking and tracing, so that all necessary information of the supply chain can be managed efficiently and effectively (van Dorp, 2002). Certifications and related documents are major means of validating product origins and sustainability fulffilments, which can be subject to falsification (Bailey et al., 2016) Customers are demanding more transparency from brands, manufactures and producers throughout the supply chain. Consumers focus strongly on the origin of products and show a preference towards sustainability. Therefore, customers and non-governmental organisations demand information regarding product origin, quality and sustainability.

“Traceability is required to recall what has already occurred in time; and that “It must be possible to trace from one entity to another” (Kim et al., 1995, p.109). Tracking is the determination of the current information that indicate the status, like the location, of an object being tracked downstream through the supply chain (Fritz and Schiefer, 2009). Tracking also referred to as forward traceability, being “the ability to follow the downstream path of a product along the supply chain, possibly according to some specific criteria” (Bechini et al., 2008)

Therefore, a clear identification of the products as well as the links between the components, combined in the internal processing, are required (Jansen-Vullers et al., 2003). To enable traceability, products, including materials, components, and assemblies, require to be uniquely identifiable. At each stage of the supply chain, the physical location of a specific object can be determined which facilitates logistical activities, recalls, and the provision of information to consumers and other stakeholders. (Moe, 1998; Opara and Mazaud, 2001)

Traceability system refer to all methods, procedures and routines used to manage traceability in its supply chains. Traceability systems are used by individual partners to increase visibility across their own organisation and contribute to end-to-end supply chain traceability (Global Standards One, 2017). Moe (1998) is separating chain and internal
traceability. Chain traceability focusses only on a subset of information, following the movement of the product through the supply chain from the source to the end customer. Internal traceability, within partners in the supply chain, allowing for more granular traceability information of the transformation process data. The different aspects of supply chain traceability are shown in Figure 1.

![Figure 1 - Supply chain traceability](image)

Capturing the history of a product through the supply chain enables the optimisation of processes as well as to demonstrate regulatory compliance (Abramovici et al., 2008). While Kim et al. (1995) saw traceability as being “backwards in time“ other authors recognise the importance of tracking data for predicting downstream events on the supply chain. Tracking data enables prediction of defects and adverse events (Skilton and Robinson, 2009), quality (Bollen, 2005) or arrival time (Biagioni et al., 2011).

Traceable information include supply chain trading volumes, address information like the origin and source of product, as well as dimension or chemical composition (Bosona et al., 2018). Additionally, continuous monitoring of conditions such as temperature, humidity, and vibration can be applied to assess quality”. The analysed information can be used to minimize quality loss or improve transportation services (Chaudhuri et al., 2018).

The data, generated continuously by multi-entities, has to be resilient against tampering or falsification. Integrity and reliability of the information has to be ensured. Handling the large amount of data generated along the supply chain in an efficient, secure, and economic way is a key challenge of traceability. (Qiao et al., 2018)

However, smaller scale companies often use manual, paper-based tracking, even though it limits the ability to accurately record, store, and query data to identify and track products. Pencil and paper systems present these companies a low-cost alternative to sophisticated information technology-based solutions (Karippancheril et al., 2017). Wilson and Clarke (1998) recognise product tracking information as incomplete, inaccurate, untimely, not useful and inaccessible.

Inaccurate storage and timely retrieval of, the high volumes of traceability data is problematic. Additionally, trust, privacy, security, and reliability of tracking data limits
the effectiveness of supply chain traceability systems. As systems are required to operate in complex supply chains, with large, dynamic groups of participants, cost can be high. (Thomas et al., 2015)

The use of information technology to ensure comprehensive product traceability throughout the supply chain enables companies to control cost and meet legal requirements. (Abramovici et al., 2008; Aung and Chang, 2014)

Petersen et al. (2016) state that decentralized, rather than centralized storage of the data generated in the decentralized process steps throughout the supply chain, is necessary to realize traceability in the context of the digitization of supply chain activities.

Figure 2 shows the different scenarios for the organisation of traceability data. In the centralised model all parties share their information to a central repository. The central database holds the complete set of is systematically enhanced traceability data. However, access rights might be set individually for all parties. In the networked scenario, the participating parties keep their individual data in local systems, providing supply chain partners query access to relevant information. In the cumulative model, the traceability data is enhanced as it moves together with the material downstream along the supply chain from one partner to the next. Here data is only shared with the downstream partners. For the decentralised scenario, as used in the blockchain technology, all data is systematically enhanced and shared with all supply chain partners. Each partner is managing a local copy of the complete set traceability data. While centralised and decentralised models provide a single traceability data set for a complete view, the cumulative scenario provides only local and upstream information out of the individual data set. For traceability in the networked scenario multiple, distributed datasets of the partners need to be queried. (Global Standards One, 2017).

![Figure 2- Distribution of traceability data](image-url)
Blockchain Technology
Blockchain, the base of Bitcoin, is a decentralised, distributed ledger “for electronic transactions without relying on trust” (Nakamoto, 2008). The application functions as an immutable ledger which allows transactions directly between anonymous parties to be performed in a decentralised fashion (Zheng et al., 2017). The information is stored transparently, chronologically and unchangeably (Schlatt et al., 2016). While blockchain ensures persistent storage and the consistency of the public data, the technology does not provide interfaces for retrieval, update, evaluation or management the users, data structure or the data itself.

However, database functionality like the management of large amounts of shared data, a coherent database state, protection against misuse, data recovery, security control for accessing and/or changing information, data set distribution and transparent access have been adopted since decades. (Abiteboul et al., 1996). Furthermore, smart contracts (Nick Szabo, 1994), hash trees (Merkle, 1979), digital timestamping (Haber and Stornetta, 1991) and cryptography (Diffie and Hellman, 1976) has been discussed since the second half of the last century.

Blockchain’s disruptive decentralisation and disintermediation characteristics can impact to supply chain management (Queiroz et al., 2019). By replacing the reliance on centralised architectures and trusted third parties, with blockchain’s decentralised privacy model, the technology introduces serious disruptive potential for traditional business processes (Casino et al., 2019). Furthermore, does blockchain enable “fundamental organisational changes in governance” and therefore “may be characterised as a disruptive innovation that breaks up established business models” (Fridgen et al., 2017).

In summary, blockchain has following four key characteristics:

Privacy Model
Blockchain’s disintermediation is reflected in the new privacy model. Nakamoto (2008) revises the privacy model, whereby the transactions are public, while the identities of the transacting parties are protected (Figure 3). Through the new design the element of trust between the identities or the entities and a third party could be eliminated. In the revised privacy model, all participants are equal, and all transactions are visible to the public. Privacy is achieved through protection of the transacting parties through the anonymity induced by public-key cryptography. However, to validate the public transactions of anonymous nodes, a new validation process needs to be revised (Nakamoto, 2008).

![Blockchain - Privacy Model](image-url)
In fact, “When we talk about replacing traditional systems fully or partly with technological alternatives, we are really talking about redistributing power from well-established legal, social and financial institutions.” (Narayanan et al., 2016, p.303)

**Anonymity**
Blockchain realises anonymity using changing pseudonyms and unlikability of participants and objects. Public-key cryptography (Diffie and Hellman, 1976) is applied, whereby private and public keys are used to preserve the privacy of nodes. Nodes are identified only by their public key address. Due to their anonymity there can be no trust relationship established between the nodes. Changing the public key address for each transaction prevents transactions to be linked to a participant. Additionally, the blockchain does not provide linkage to off-system assets.

**Decentralisation**
All participants are equal nodes in a pure peer-to-peer decentralized and distributed network, whereby “any single, arbitrary chosen terminal entity can be removed from the network without having the network suffering any loss of network service” (Schollmeier, 2002, p.102). The decentralized architecture leads to an increases resilience of the system, as it removes any single point of failure. However, the decentralisation requires participants to utilise resources for transmitting, storing and validating the data sets.

Due to the lack of a central governing party, a permissionless consensus mechanism allows nodes to coordinate the system status by mass collaboration. (Bogart and Rice, 2015). Consistency between the different nodes is ensured through this protocol.

Additionally to block formation and block validation, the propagation of new blocks through the decentralised network introduces delays in the processing of transactions (Sompolinsky and Zohar, 2013).

**Immutability**
Blocks of transactions are created when the blocks are timestamped, linked through a hash (Merkle, 1979) to the previously created block and signed (Haber and Stornetta, 1991). The network participants can verify the integrity of a transaction by recalculating and comparing the hash chain. Therefore, “to modify a past block, an attacker would have to redo the proof-of-work of the block and all blocks after it and then catch up with and surpass the work of the honest nodes.” (Nakamoto, 2008). Consequently, the chain becomes tamper resistant as manipulations can be detected and rejected by the network.

**Findings Opportunities and limitations**
The blockchain does not per se resolve cost, integration or information management challenges of supply chain traceability.

While the data transparency of the privacy model supports needs of supply chain traceability, the overall concept of anonymous identities performing in a pure peer-to-peer environment collides with traceability requirements. Firstly, producers, researchers, governments and consumers are key stakeholders in supply chain traceability. However, the blockchain privacy model aims at eliminating third party control. Secondly, most traceability systems are envisaged as a private or permissioned block chain. Nevertheless, this implies discarding anonymity in the peer-to-peer network, while introducing a permissioning authority. Thirdly, the publicity of the data calls for the anonymity of the transacting identities.

The identities in the blockchain are anonymous. The missing link between information and organisations allows companies to share internal data. Though, provenance and
Custody information are key interests of supply chain traceability. Furthermore, the unlikability of the transactions and pseudonyms an important factor in ensuring the overall anonymity. Furthermore, traceability aims at creating visibility of the flow of uniquely identifiable objects downstream the supply chain. In contrast, blockchain’s privacy model demands anonymity through pseudonymity and unlinkability to enforce participants anonymity.

Blockchain’s decentralisation mirrors in many aspects the organisation of supply chains. The fully decentralised approach, necessitated by the absence of a central third party, is at the core of the blockchain. However, supply chains, with heterogeneous capabilities and interests of supply chain partners, present challenges for the decentralised organisation of the system data. Specifically, companies financial and technical resources to distribute, store, validate, analyse or otherwise exploit large amounts of traceability data might differ greatly. Additionally, while supply chain traceability requires constant participation of all partners in the supply chain, Contrary, the blockchain’s pure peer-to-peer approach allows participants to join or withdraw from the network without impacting the blockchain. Latency in the block chain is introduced through block building, validation and network distribution. This latency hinders blockchain adoption when supply chain traceability requires real-time information.

Blockchains approach to tamper-proof the information supports the demand of supply chain management for trustworthy, immutable information. The error-prone manual recording and analysis of required information will introduce system complexity to maintain the data immutability characteristic within the blockchain. Requirements for archiving expired data out of fast-growing traceability pools are limited by the need to keep transaction chains for validation in the blockchain.

Conclusions
Not much of the revolution is left, once the blockchain is wrapped into an access controlled, distributed system. Decentralisation and disintermediation, as key drivers of the disruptive force in the blockchain, are relying on the anonymity of identities.

The absence of central control, mediator and system owner in the blockchain model, makes it hard to create business cases and therefore restricts companies’ exploration of the blockchain technology. However, public blockchains, with business models utilising blockchain information, could be path to utilize the technology in a commercial context. In the tension between disintermediation and business model lies an opportunity for researchers. Advancement of the privacy model, rather than focusing on technical aspects, could proof to be highly beneficial for traceability as well as overall supply chain performance. Supply chain spheres where institutional interest is lacking, supply chain partner struggle to coordinate their activities, individual infrastructure investment cannot be justified, or data privacy is a hard requirement, could be viable areas of research. Additionally, supply chain performance could be improved in areas where costly intermediaries are be replaced by approaches embracing blockchain’s new privacy model.

Abstract

This article aims to establish and describe the coexistence conceptual framework of the Short Food Supply Chains (SFSCs) and Supply Chains (SCs), at odds with the current polarisation of the literature on chain approaches. Based on a review of the literature, the paper draws on biology and market performativity notions to establish and describe a coexistence conceptual framework of SFSCs and SCs. This framework was arranged around two main criteria: i) convergence of interests; and ii) need to add value. Four types of coexistence were established and described with empirical evidence: i) competitive; ii) co-ordinative; iii) co-operative; and iv) unco-operative.

Keywords: Short food supply chains, Supply chains, Coexistence.

Introduction

A paradigm shift is observed in management theory, in which firms no longer compete as independent individuals, but start to act as Supply Chains (SCs) (Lambert and Cooper, 2000). On the other hand, new concerns have emerged from agricultural and agro-industrial practices in the areas of the environment, food safety and health, such as animal welfare and ecology (Renting, Marsden and Banks, 2003). Therefore, the development of Short Food Supply Chains (SFSCs) has gained prominence in recent years.

While these two approaches study similar phenomena, SCs and SFSCs are intertwined with different elements that regard both chain models as competing with each other. Clearly, in studies of SFSC one finds an attempt to characterize this model as an alternative to the conventional model of the SCs (Watts, Ilbery and Maye, 2005; Chiffoleau, 2009; Aubry and Kebir, 2013).

However, the focus - though shy - does not concern the replacement of long chains by short chains. Scholars (Oglethorpe and Heron, 2013; Schoenherr, Narasimhan and Bandyopadhyay, 2015) argued that the strategies should progressively strengthen the economic sectors and activities that allow the integration of increasing numbers of actors involved in both agrifood chains. It is possible to sustain that the propelling factors of SCs and SFSCs are present in the same space and period of time, showing that the two models coexist (Marsden, Banks and Bristow, 2000; Renting, Marsden and Banks, 2003).
Thus, this article shows how SCs and SFSCs are characterized and at which points they diverge and converge. Drawing on biology and market performativity, it establishes and describes the coexistence of the conceptual frameworks of SCs and SFSCs, instead of the current polarisation of the literature on chain approaches.

Given the analogy made by Nenonen et al. (2014) in market plasticity, it is possible to note that the application of the coexistence term is, in most cases, used in biological and ecological matters. The research objects in the coexistence aspects are based on a focus to analyse the competition or mutual existence between two agents (called species) in a certain time and place (environment), as stated by Schoener (1974). Thus, Chesson (2000, p. 343) affirms that “the most common meaning of diversity maintenance is coexistence in the same spatial region of species having similar ecology”.

According to Hanski (1981), the coexistence between two or more agents can happen through aggregation, and it can affect the environment and the relation among other agents in the same place and time. So, this perspective provides a positive outlook as a mutualistic relation by coexistence. However, “two like species may or may not coexist regionally, depending […] on the intensity of competition” (Hanski, 1983, p. 493).

Based on Rothschild (2004), the business ecosystem is a conjugation of species (firms, stakeholders, chains and other actors) doing business in the same space in a given period of time. In this case, the chains can coexist by integration, co-operation and competition, the latter being a predatory coexistence for survival.

Considering from a performativity perspective, Kjellberg and Helgesson (2006) argue that market practice is characterised by multiplicity. Hence, market actors do not necessarily act from the perspective of a single market, and may instead engage in divergent market practices (Kjellberg and Helgesson, 2006). Analogically to the chains, it can be understood that the actors do not necessarily focus on only a single chain, as empirically revealed by Benson-Rea, Brodie and Sim (2013). Thus, actors are able to operate in both chains (SCs and SFSCs), and, in case of such occurrence, this fact may characterise a new different type of coexistence.

Therefore, Kjellberg and Helgesson (2006, p. 849) state that “[…] different exchange, normalizing and representational practices may simultaneously perform different versions of the same market. Further, these versions need not be at odds with each other, but may more or less peacefully co-exist”. Given the multiple realities, it is recognised that actors can not only enact multiple (even conflicting) ideas, but that they can also participate in the formation of multiple market versions (Kjellberg and Helgesson, 2006). This notion can be transposed into the reality of the chains, given that each of the chains can establish itself (or may have already established itself) as a market (Flint, Lusch and Vargo, 2014).

Broadly speaking, “[…] the co-existence of multiple and potentially conflicting versions of the same entity does not imply conflict or indeed the necessity of any kind of coordination unless two or more of these versions encounter each other in a specific situation” (Kjellberg and Helgesson, 2006, p. 850).

Based on this perspective of coexistence, in the literature a competitive coexistence is highlighted, in which the SFSCs are established as an alternative to SCs. On the other hand, it is possible to recognise coexistence as pointed out by Hanski (1981), and even as co-ordinative, as presented in Kjellberg and Helgesson (2006).

In this aspect, the existence of chains is shown in a space-time dynamic in a contemporaneous scenario. Regardless of their particularities, both chains present established relations through the various actors in an arranged process that composes the chains for use of territories and value creation for the chains, actors and consumers. Thus,
SC and SFSC coexistence is characterised below, in order to understand how they converge and diverge.

Convergences and Divergences Between SCs and SFSCs
Sonnino and Marsden (2006) show that, while abstract, distinctions can be made between alternative and conventional food systems. There are, however, no clear boundaries between them. Therefore, the concepts, perspectives and dimensions suggest a possible intersection and coexistence between the theoretical frameworks at certain moments, but also highlight the difference between the models.

The convergent and divergent characteristics between SFCSs and SCs are synthesised in Table I. In particular, a comparison of focal components is presented, namely: objective, configuration, relations among the chain actors, interest, spatial relations and needs of the productive system and consumption.

Table I Comparison of SFSCs and SCs by focal components

<table>
<thead>
<tr>
<th>Components</th>
<th>SFSCs</th>
<th>SCs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Objective</td>
<td>Co-operation, integration and greater autonomy of actors; <em>generating value for the farmers and the consumers</em>, as well as alternatives and opportunities for rural and local development</td>
<td>Strategic co-operation for the <em>creation of value and efficiency</em> of the entire chain through the integration processes that are essential to the business of the chain actors</td>
</tr>
<tr>
<td>Configuration</td>
<td><em>Interactional network among actors</em>, mainly focused on bringing together producers and consumers</td>
<td>Gravitation actors around the focal firm, forming a <em>network of various businesses and relations</em></td>
</tr>
<tr>
<td>Relations among the chain actors</td>
<td><em>Proximity, formal and informal</em>, among the actors, mainly between farmers and consumers; relations based on trust building in the origin and quality of food products</td>
<td><em>Formality among actors</em>, moderate relations with trust features and institutional aspect among actors</td>
</tr>
<tr>
<td>Spatial relations</td>
<td><em>Relocation</em> Consumer knowledge about the location, production, product and spatial conditions of production; local and regionally-based</td>
<td><em>Delocation</em> Absence of spatial reference of the product; no incentive to understand the food origin; products without space/land/territory/place</td>
</tr>
<tr>
<td>Interest</td>
<td>Community, regionality, territorial development, <em>enable the farmer to capture greater value and generate added value to the consumer</em></td>
<td>Diffuse along the chain; in general, <em>generate added value for the various chain actors and the consumer</em></td>
</tr>
<tr>
<td>Needs of the productive system and consumption</td>
<td>Provide value to the chain actors; convergence of interests</td>
<td>Provide value to the chain actors; convergence of interests</td>
</tr>
</tbody>
</table>

It is sustained by Sonnino and Marsden (2006) that the current dichotomy between standardised and localised foods does not fully represent the reality of the food sector. In other words, there are no clear boundaries between these two approaches, despite the abstract distinctions between them.

Specifically, there is emphasis on the evolution in the conceptualisation of SCs, which has developed approaches partially similar to the structure of SFSCs; the relations among
SC actors require higher levels of interaction, characteristics that are similar to those of SFSCs in the Renting et al. (2003) model, such as in Schoenherr et al. (2015), which developed a framework for the assurance of food safety via relational networking.

With SC evolution, there is a redesign and repositioning of the supply chain and its actors (Folkerts and Koehorst, 1997). In this sense, new concepts emerge, such as sustainability (Carter and Rogers, 2008; Seuring and Müller, 2008; Pagell and Wu, 2009) and a green supply chain (Srivastava, 2007; Lee, 2015), without disrupting the main characteristics of SCs.

Such evolution has also happened in the SFSCs, and can be read in the concept model of extended SFSCs proposed by Renting et al. (2003) and applied in empirical cases by Oglethorpe and Heron (2013), which identifies supply chain barriers and constraints that occur in local food supply chains based on smaller producers when they seek to increase market penetration across a wider geographical area.

Thus, it is possible to notice a certain conceptual convergence of the SFSCs and SCs from a territorial and geographical perspective. In a certain period of time, they tend to take on co-ordinative functions, become co-operative and overlap, depending on the interests involved, opportunities and threats of markets and the needs for value that the chains may have in common. Therefore, the combination of adding value and convergence of interests by interacting factors is present in both SFSCs and SCs.

To deepen this discussion, the following topic emphasises coexistence, introducing the coexistence conceptual framework based on the combination of adding value and convergence of interests. In addition to the framework, empirical evidence is presented that characterises different types of coexistence between SCs and SFSCs.

**Coexistence and Empirical Evidence**

Schoenherr et al. (2015) highlight the current phase of the SC, due to awareness of food safety, product traceability, environmental impacts, among others. Therefore, some of the concerns that have led to the development of SFSCs are also reshaping the conventional SC. There is a collective reflection leading to a sustainability approach in order to reduce the negative impacts along the chain (Validi, Bhattacharya and Byrne, 2014).

As an outcome, the concept of sustainability is introduced in the SCs’ approach. Despite the focus on environmental/green issues (Srivastava, 2007; Seuring and Müller, 2008; Lee, 2015), there are also efforts to incorporate the social aspects of sustainability, demonstrating the relations among environmental, social, and economic performance (Carter and Rogers, 2008; Seuring and Müller, 2008; Pagell and Wu, 2009).

Thus, it is observed that conventional SCs are attentive to the new demands of consumers with regard to food safety, ecology and origin (traceability), highlighted by Ilbery and Maye (2005) and Renting et al. (2003) as drivers of SFSC creation, and may therefore constitute convergence points of interests and value.

The convergence of interests can be justified by Blasi et al. (2015) emphasising the need for an integrated perspective of the interests in the chain approach, namely the quality and value mechanism for the actors along the chain. On the other hand, the coexistence of the SFSCs and the SCs concerning the need to provide value is justified by the conceptual convergence presented by both Lambert and Cooper (2000) and Renting et al. (2003), who claim that the main focus of their approaches is the value to be created within the chains and provided to the consumers.

This paradigm shift points to a perspective of simultaneity among the chains, raising a model of coexistence that considers the combination of adding value and convergence of interests, as shown in Figure 1.
Taken together, these two dimensions create a conceptual space that allows mapping of a broad coexistence between SCs and SFSCs. In Figure 1, the need to add value is represented by the x-axis (horizontal), and the convergence or divergence of interests is represented by the y-axis (vertical). As it approaches the vertex between the two axes it means a reduction in the intensity of the coexistence factor, whereas distancing from the vertex indicates increased intensity of the coexistence factor.

The conceptual framework identifies four types of coexistence: unco-operative, co-operative, co-ordinative and competitive.

Unco-operative Coexistence
Initially, the unco-operative coexistence shows a reduction in both factors (convergence of interests and added value), having features, such as the absence or small convergence of goals by chains, which reflects a divergence of interests among the chain actors. Therefore, SCs and SFSCs offer their products and services without relations between them.

Based on the market performativity perspective, this coexistence can be understood as different versions of the same market, and, although potentially conflicting, does not imply conflict or even the need for any kind of co-ordination (Kjellberg and Helgesson, 2006). In this case, having a small need to add value to their products and services, the chains coexist in an independent manner from each other, with a relative absence of relations.

This type of coexistence is justified by the SFSCs’ initial emphasis based on alternative means in lieu of conventional ones, which explains the divergence of interests. Thus, this divergence had as an outcome the arrangement of alternative products in different forms of connection with consumers, and the smaller need to add value and maintain the absence of relations between the CSs and SFSCs. In this way, a focus on alternative products, such as organic ones, can be observed in the literature (Aggestam et al., 2017; Aguiar et al., 2018; Aubry and Kebir, 2013; Enjolras and Aubert, 2018; Galli and Brunori, 2013; Giampietri et al., 2016, 2018), in order to build a new market version that supports the
SFSCs, although the conventional SCs are present at the same time and in the same space supported by another market version.

In this example, it is emphasised that the SFSCs are closely linked to organic and local foods, and to traditional small-scale production (Giampietri, Finco and Del Giudice, 2016), where the concept of food is related to being: fresh, organic, slow, high quality, traditional and others (Galli and Brunori, 2013). Thus, organic production becomes a parameter in SFSC studies (Aubry and Kebir, 2013; Giampietri, Finco and Del Giudice, 2016; Aggestam, et al., 2017; Enjolras and Aubert, 2018; Giampietri et al., 2018) and is considered as a critical factor for the implementation of SFSCs (Sellitto, Vial and Viegas, 2018). On the other hand, conventional products are associated with SCs, and these are supported by the conventional market, the one that is already established, and commonly is not demanding added value, because it usually represents willingness to pay a premium price for the alternative product or the close relation with the farmer (Aschemann-Witzel and Zielke, 2017).

Co-operative Coexistence

In co-operative coexistence there is highly intense convergence of interests, and chains have a small need to add value. This coexistence features co-operation, association and dissemination of inputs and processes along the chains, as well as their relations due to the convergence of their actors’ interests.

However, there is no concern about or a common commitment to joint investment among the components of the chains, based on a greater need to add value. On the other hand, a small need to add value in the co-operative coexistence may be associated to products and services well established in the market, and based on chains with a high market share; in this case organisations and chains co-operate to maintain the status quo, which is also the result of the necessity/scarcity of resources and suppliers.

In this coexistence, the dichotomy among the chains is questioned, evidencing blurring among them. Thus, it is understood that farmers tend to combine different types of chains, rather than specialise in a single one (Aubry and Kebir, 2013). From this perspective, several systems and hybrid food spaces emerge, instead of two unique opposing approaches. (Ilbery and Maye, 2005; Aubry and Kebir, 2013; Aggestam, et al., 2017).

Studying the French SFSCs, Aubry and Kebir (2013) highlight that, in many cases, there is a link with the global market based on SCs. In this case, the complementarities between SCs and SFSCs “[…] enable farmers to complement their supply with additional products (in quantity and variety, according to the season) and to meet consumers’ demand” (Aubry and Kebir, 2013, p. 89).

Thus, "the majority of Ile-de-France farmers, including AMAP farmers, regularly use this type of long supply chain which, notwithstanding its drawbacks, does offer effective services with minimal commitment for selling or buying their products” (Aubry and Kebir, 2013, p. 90). This fact is also reported on the Scottish-English border. Ilbery and Maye (2005, p. 331) emphasise that, “[…] driven by a strong economic imperative, they often have to ‘dip’ into various ‘links’ associated with more conventional (commodity-based) food supply chains”.

In this case, “…‘alternative’ producers often have to resort to the use of ‘conventional’ abattoirs, carriers, wholesalers and commercial customers” (Ilbery and Maye, 2005). The authors also sustain that even organic meat producers have their animals slaughtered by the only local abattoir, stressing the need for co-operation. Thus, while actors create a context for closer social ties between farmers and consumers, it is evident that these still remain fundamentally rooted in commodity relations (Hinrichs, 2000).
The opposite is also observed in which SCs adopt sharing relations with SFSCs. Aware of consumers’ interest in knowing the origin of food, Aubry and Kebir (2013) evidenced that more and more supermarkets are looking for local suppliers, SFSCs’ actors.

In this sense, focusing on the coffee chain (certified), Raynolds (2009) highlights that, despite creating distinct ‘worlds’, in reality these chains are continually being negotiated within and between economic networks. Thus, it is based on the assumption that “‘alternative’ normative frameworks, qualification systems, and institutions mediate ‘mainstream’ commercial/industrial conventions in Fair Trade networks” (Raynolds, 2009, p. 1084).

However, despite these cases of SFSCs mixed with SCs, this fact questions the sustainability of the former. As evidenced by Ilbery and Maye (2005), by sharing inputs and suppliers, conventional food producers are not necessarily more sustainable.

*Co-ordinative Coexistence*

*Co-ordinative coexistence* is related to convergence of interest and high intensity of need to add value in chains. This coexistence is characterised by the integration of chains and actors, allowing full coexistence of chains through co-operation, joint action, integration and interaction of processes, structures, people, knowledge, technology and information, and it can act in formal and informal manners.

In this coexistence, the chain commitment to adding value can be the result of convergent interest of new chains in the market to achieve greater space and establish a competitive basis through collaboration and integration among chains (Bowen, 2010; Aggestam et al., 2017).

Through a broader view, it is possible to note that the sharing of practices and ideas that result in shaping the chains happens by means of an appropriation of principles from one chain to another.

In an empirical network, analyses based on different systems of direct sales in the South of France, Chiffoleau (2009, p. 221) highlights that “[…] the link with alternative chains is not evident: terroir products are today distributed just as much through long chains, even if their attendant image is associated more with market niche products intended for direct sale”.

In this sense, there are new strategies in contemporary SCs that are related, as highlighted above, to sustainability and location. One example is the geographical indications (GIs) that, although largely attributed to a local actor, are “[…] nested in wider regional, national, and international networks; and the passage from local to extra-local markets introduces new costs and benefits and new relations of power into the supply chain” (Bowen, 2010, p. 209).

In other words, “[…] the territorial embeddedness of GIs can serve as a link between local production systems and global markets, between increased competition and higher quality, and between economic and environmental sustainability” (Bowen, 2010, p. 238).

Thus, in co-ordinative coexistence, an attempt to shorten SCs is observed, improving traceability and integration with other supply nodes (food services) and non-food sectors, e.g. heritage tourism (Ilbery et al., 2004).

In the opposite case, one may also observe sharing of SC practices and ideas that are incorporated into SFSCs, as in scaling-up, revealed by Aggestam et al. (2017), where SFSC actors have intentions to scale-up. Being unlikely to restrict the specific market to solely one region, it is suggested “[…] a development that allows a ‘hybrid’ business model that combines abilities from both large mainstream producers and smaller regional producers to emerge” (Aggestam, et al., 2017, p. 70).
This picture emphasises the complexity of contemporary agrifood production. Murdoch and Miele (1999), not mentioning co-ordinative coexistence, illustrate this complexity through two Italian cases: in the first, the authors evidence a large egg producer company that participates in SCs, and has gone from standardised production to a plurality of new products imbued with quality and practices shared in SFSCs. On the other hand, the second case involves a group of small organic producers, established under the principles of SFSCs, who collectively establish a structure, standardising the 'dedicated' organic produce.

Another important case is the coffee sector, where, for a long time, it has focused on SCs (global chains) and on a standardised product (commodity). With the crisis and concerns related to quality, there is an emergence of voluntary regulatory systems (Muradian and Pelupessy, 2005). Specifically, a larger focus can be given to third party certification schemes, such as Fair Trade and organic certification, practices and ideas initially developed for SFSCs (Muradian and Pelupessy, 2005; Raynolds, 2009) and which were appropriate for the global coffee chains.

**Competitive Coexistence**

Finally, **competitive coexistence** is marked by a great need to add value in chains and a high degree of divergence of interests. In this coexistence it is notable that the chains are competitors, thus featuring a zero-sum game where chains compete for better market positions and more consumers (Oglethorpe and Heron, 2013).

In this coexistence, relations, technology, processes, people and chain structures are used in the competition against other chain components, given the divergence of interests and the intense need to add value and also capture it. This is the most illustrative coexistence in the literature involving the themes, and it is here that the highest stress in the polarisation takes place. It is necessary to say that the greatest emphasis on competition is found in the literature about the SFSCs (Aubry and Kebir, 2013; Hinrichs, 2000, 2003; Ilbery et al., 2004; Ilbery and Maye, 2005; Marsden et al., 2000; Sonnino and Marsden, 2006; Watts et al., 2005), and the competition occurs in positioning the other as a reference point that assists in the comparison to highlight the advantages/qualities/benefits of the chain that oppose the one already in position.

It is considered a coexistence with a difficult relation between SCs and SFSCs, which represents the difficulty in convergence and performance in networks involving these different chains. It is sustained by Aggestam et al. (2017, p. 70) that “[…] SFSC producers require innovative and entrepreneurial skill-sets that enable their brands to distinguish themselves from conventional products found on the mainstream market”.

In the same way, analysing the consumers’ behaviour towards SFSCs, Giampietri et al. (2016; 2018) emphasise an antagonistic view among the chains, where it considers the preference and the purchase of foods in SFSCs, instead of conventional markets or SCs.

Moreover, Sonnino and Marsden (2006, p. 181) affirms that, rather than viewing them as separate spheres, they see them as highly competitive, emphasising “[…] the need to explore the competitive relationships that alternative food networks have with the conventional sector to expose power imbalances and the effect these may have on wider rural development processes”. For this reason, Hinrichs (2000) stresses that, to develop an alternative to the market, a decommodification of food is necessary. Thus, this coexistence features the SCs and SFSCs stressing conflicts in relations.

**Conclusions**

This article has highlighted the divergent and convergent points between SCs and SFSCs, the concepts, perspectives and dimensions suggest a coexistence between them. In this
sense, it has established and described a coexistence conceptual framework of the SFSCs and SCs, arranged around two main criteria: i) need to add value; and ii) convergence or divergence of interests.

Consequently, the coexistence was arranged between divergence and convergence of interest and a greater and smaller need to provide value, thereby generating a conceptual framework expressing four types of coexistence, namely: i) competitive; ii) co-ordinative; iii) co-operative; and iv) unco-operative.

Thus, this article sheds light on new analysis of SFSCs and SCs from points of coexistence between them, creating opportunities for future researches. It is also emphasised that better understanding of coexistence is expected to have managerial implications regarding the retail food sector involving different forms of simultaneous chains.

Finally, research themes are suggested to advance the coexistence framework and analyse them in an integrated manner, and not only in a competitive mode, for instance: i) how chains develop their strategies for different types of coexistence; ii) performativity in chain coexistence, i.e., how the chain’s actions, assumptions and modelling perform in the other coexistence chain, and also how it impacts the previous chain; iii) assuming that this coexistence is not static, it is suggested that understanding be sought and their dynamics analysed.

Abstract

The proportion of bio and renewable fuels has recently increased, strongly affected by the biofuel legislation of the European Union. Simultaneously companies have been forced to optimize their increasingly complex supply chains in order to gain a competitive edge. This paper studies the benefits of deploying advanced supply chain analytics in this new business area. Decision recommendations provided by advanced analytics are compared to those obtained from the previously utilized heuristic tools and unstructured interviews of supply chain planners and managers are conducted. The findings suggest that the deployment of advanced analytics has brought substantial business benefits.

Keywords: Supply Chain Analytics, Model-Assisted Decision Making, Renewable Fuel Production Planning

Introduction

Neste Corporation is one of the world’s leading renewable fuel companies. It operates both in traditional oil products and base oils, and also in the rapidly growing business area of renewable products. The supply chain of Neste Renewable Products consists of feedstock supplies, storage facilities, refineries, blending facilities, retail outlets, and transportation. Most of the feed, including waste and residues, and vegetable oils, comes from farms and industry all around the world. These feedstock materials are transported to terminals and finally to refineries, where the raw materials are converted into the products of transportation fuels for automobiles, trucks, railcars, airplanes, and chemicals, such as plastic. Some of these products are transported to terminals before they are sold to customers.

Management of renewable fuel supply chain involves the planning and management of raw materials supply, manufacture of product, and logistics. The challenge to maximize the enterprise value involves supply chain related decisions, such as the selection of
feedstocks, products, and refinery operations. These decisions are constrained by the current price data and refining options. In addition, customer demands strongly steer the choice of feedstocks and product qualities. For example, requirements for supply chain traceability and for the mixture of processed feedstocks are typically defined by customers. Moreover, value maximization related decision making is strongly dynamic as the availability of feedstocks, demands with requirements, market prices, and refining capabilities change all the time (e.g., Kim et al., 2011; Awudu and Zhang, 2012). While most demands are fixed and steered by the EU biofuel legislation, some demands are uncommitted, thus increasing the volatility of the business. Currently, these kinds of supply chain related challenges are expanding as the growth of the renewable fuel business increases the number of potential feedstocks, markets, terminals, and different transportation options. Thus, the complexity of supply chain network continuously increases.

These complexities in the renewable fuel supply chains have motivated the development of different analytical tools to support management decisions. Especially uncertainties have highly been recommended to take into account while optimizing supply chains of renewable fuels (e.g., Awuzu and Zhang 2012; Dal-Mas et al., 2010; Kim et al. 2011; Labadidi et al., 2004; Sodhi and Tang, 2009). In addition, Che and Chiang (2010) have recommended to utilize multi-objective optimization models to include both financial and sustainability related objectives in decision making. Even the parallel processing of different optimization methods have also been considered applicable to renewable fuel supply chain optimization, as argued by Banos et al. (2011).

Despite there exists plenty of methodological research on supply chain analytics, only little research has focused on analysing the benefits which advanced analytics yields in practice. This research analyzes the benefits obtained from deploying advanced supply chain analytics to supply chain optimization in the business area of Renewable Products in Neste Corporation. The research hypothesis is that the deployment of analytics tools produce value by supporting to find the best match with the feedstock, demand, and refining capabilities. Therefore, supply chain analytics has been deployed for raw material planning and product portfolio selection in Neste Corporation. The analytics tools have been integrated with the corresponding ERP systems and business processes. This has led to significant value-add due to increased profits, and cost savings in supplies, logistics, and refinery processes.

**Study Methodology**

**Supply Chain Planning Process at Neste Corporation**

In the beginning of the Renewable Products business at Neste Corporation, heuristics supported by spreadsheet based tools were used to support the supply chain management related decision making. However, because of a large amount of potential supplies, sales, as well as production and logistics possibilities, the supply chain network of Renewable Products has developed a complex entity. Currently, 200 interesting supply-production-sales combinations are available based on business specific overviews and prospects. Therefore, the analytics tool Spiral Network has been utilized to support the effective supply chain management of Renewable Products with sophisticated map validation. The use of the optimization tool enables to consider multiple locations and complex logistic constraints by simplifying the complex supply chain network to find the optimal configurations between all possibilities.

The current supply chain management for Renewable Products is based on long-term planning for the following 15 months. The responsible supply chain planner updates the
plan every month by the Spiral Network optimization model to get financial forecast, planning guidelines, term deal strategies, and logistics network design. The model is configured so that all possible refining options in the varying business environment are evaluated in optimization to achieve an integrated solution instead of sub-optimal business solutions. Spiral Network tool is supported by Excel files and the reporting tool Tableau as shown in Figure 1.

![Network model update process](image)

**Figure 1 – Network model update process**

**Comparative study**
To analyze the benefits obtained from advanced analytics, the optimal plans generated by old spreadsheet based tools were compared to those obtained from Spiral Suite software. As the input to these models utilized real data set from the time period October 2017 – December 2018. This data set includes records of supplies, demands, including both forecast based plans and actual sales, and operations during the following 15 months starting from October 2017. Key figures of this data set are presented in Table 1.

</tbody>
</table>

**Table 1 – Data Content of Business Case Study from October 2017 to December 2018**

**Interviews**
In addition to the quantitative comparative study, unstructured interviews with supply chain planners and managers in the business unit of renewable fuels are also used to gain insights on the qualitative benefits obtained from deploying Spiral Suite for supply chain planning. The main themes covered in these interviews related to the benefits of using analytical methods in managing the renewable fuel supply chain and the advantages of supply chain analytics over the previously utilized tools. In addition, the profit increase enabled by the new tools were discussed, as well as the possible future challenges with the tools.

**Optimization Model**
Spiral Suite covers feedstock data management, trading, plant, and network optimization, as well as scheduling and process unit monitoring by the following three modules: Plan,
Schedule, and Network (Aveva, 2019). The Plan module provides the graphical flowsheet representation for fluent modeling with scenario analyses and reporting capabilities for the need of economics and engineering. The Schedule module focuses on short-term operations planning, whereas middle- and long-term strategic planning is performed by the Network module to manage a complex logistic network.

The Spiral Network model is based on nodes and transportation links between the nodes. Nodes can be divided into supplies, plants, terminals, and demands. A simplified network model representation is shown in Figure 2. Due to the business growth of renewable fuels, the amount of model nodes and transportation options has increased time after time. The management of this supply chain model by utilizing Spiral Network is demonstrated in Figure 3.

![Simplified Network model structure](image)

*Figure 2 – Simplified Network model structure*
**Findings**

We compared the profits made using the new and old tool and found out that both profit increase and cost savings are achievable with the more advanced supply chain optimization tool. The total profits identified based on the results of the new tools is 590 MEUR, which is 350 MEUR (+146%) more than with the old tools. The new analytical tools have contributed to bringing significant cumulative value from October 2017 to December 2018 to Neste Corporation due to higher sales profits and savings in raw material, logistics, and manufacturing costs.

Most significant strategic changes leading to the profit gains have been noticed in the following areas:
- Market shares
- Supply quality and suppliers
- Logistics network and transportation

Better use of big data largely explains the profit increase. As the new tools have managed to deal with the big variety of business options, new opportunities have been identified for market shares, supply and demand contacts, as well as logistics. This has led to significant profit gains and increase in the variety of sales. Today the company can identify a higher number of profit increase and cost saving opportunities as part of supply chain planning. For example, from the viewpoint of sales, earlier the deals may have been done based on the previous experience, and thus many potential deals and volatility of markets may have been ignored while lacking of advanced tools to include...
all potential customers in decision making. However, with the support of advanced supply chain analytics, even a complex supply chain network with multiple demand possibilities can be managed.

The findings of interviews support and extend the results of the quantitative study. It has been concluded in interviews as well that real practical value has been achieved from deploying supply chain analytics. Even the management of big planning data and business prospects were experienced challenging without the advanced tools. By advanced supply chain analytics, planning transparency has also increased due to the more integrated ERP systems. By a single source of knowledge, as demonstrated in Figure 4, decisions between diverse teams across global locations are shared and communicated regularly, simultaneously enabling to explore faster new business opportunities in a complex supply chain network and reduce operational risks. In addition, common systems ease the update of planning data and encourages learning across the organization instead of an individual level. However, despite all the benefits acknowledged from deploying supply chain analytics, future challenges were still seen with the full utilization of the new tools in daily work across the whole organization.

![Figure 4 – Differences of old and new enterprise architectures from the viewpoint of planning transparency](image)

**Contribution**
A promising research avenue stems from this research to support the practical use of advanced supply chain analytics in the novel applications of the bio and renewable fuels industry. This study suggests that advanced supply chain analytics can yield substantial benefits both in terms of profits and fluency of supply chain planning by reporting supply chain analytics related experiences in a real business context. The results contribute to existing literature by strengthening the link between researchers and practitioners in the field of operations management. Despite theoretical model development has been studied a long time, the value of deploying advanced analytics in the practical use in complex supply chain planning may have been underestimated (Little, 1970; Liberatore et al., 2000). However, the findings recommend to put more efforts on utilizing advanced analytical tools in decision making to achieve real increase in profits. This argument is also supported by Chevron (Kutz et al., 2014), which has promoted similar kind enhancements to its optimization models and obtained significant economic benefits from deploying advanced supply chain analytics.

The selected case study naturally affects the quantitative results while investigating the planning decisions and their effects on the profits made in the past. Thus, similar studies for multiple case studies in different time spans could be useful in the future.
research. In addition, despite the benefits of supply chain analytics may have been acknowledged, real challenges may have caused when implementing advanced analytical tools. Such benefits and limitations of model-based decision making have also been reported by Sodhi and Tang (2008).

Abstract
Supply Chain Risk Management (SCRM) has emerged recently, especially in globalised industries, such as the automotive one. Therefore, this article presents some results of research conducted in a large global automaker and one of its main global first tier suppliers. The purpose was to identify, systematise and analyse how these companies conducted the SCRM in their supply chains considering both operating environments in Brazil and Spain. The results show an essentially reactive posture from the companies regarding the SCRM and a great concern with the present momentum of the auto industry and the risks to its current business model.

Keywords: Supply Chain Risk Management, Automotive Industry, Brazil, Spain

Introduction
Over the past few decades implementing Supply Chain Management (SCM) and Just-in-Time practices has significantly reduced inventory volumes in many industrial segments. Outsourcing processes have also made industrial companies much more dependent on their suppliers. The logic of buying anywhere in the world, where it is most convenient, derived from the so-called "globalisation of the economy" has made companies much more dependent on suppliers located physically distant, thus increasing the risks of their logistics supply processes. Therefore, the effects of events such as natural disasters, political crises, factory and customs service strikes, company bankruptcies, etc., have had an unprecedented negative "domino effect" on supply chains.

Considering this, Supply Chain Risk Management (SCRM) has emerged and gained relevance in recent years, especially in highly globalised industrial sectors, such as the automotive one. Thus, avoiding any stops on final assembly lines has become a basic concern of the operations in the sector, especially by the automakers, where usually one-minute halts mean one less vehicle being produced. In this context, this article presents the main results of research conducted during 2018 in a large global automaker and one of its main global first tier suppliers aiming to identify, systematise and analyse how these companies identify, evaluate, mitigate and monitor the risks in their supply chains. Moreover, the study also considered two distinct operating environments of these two companies: in Brazil and Spain.
Supply Chain Risk Management

In one of the pioneering articles on the subject, Christopher and Lee (2004) defined Supply Chain Risk Management (SCRM) as the risk management through a coordinated approach among supply chain members to reduce the vulnerability of the supply chain as a whole. In addition, Tang (2006) defined it as the risk management in the supply chain through coordination or collaboration among partners in the supply chain to ensure its profitability and continuity.

With respect to the SCRM itself, Fan and Stevenson (2018) state that this process generally involves four steps: risk identification, risk assessment, risk treatment/mitigation and monitoring. These steps are the same as those used by Pires et al. (2013) and are shown in Figure 1.

![Figure 1: Main four steps of an SCRM process](image)

**Risk Identification**

Risk identification seeks to uncover all relevant risks and recognise future uncertainties to proactively manage them. This stage is critical to the success of SCRM because only after a risk is identified can any risk management activity be triggered. This implies that an early judgment is necessary in this identification to decide whether a risk is relevant, and therefore should be better evaluated, mitigated and monitored (Kern et al., 2012).

**Risk Assessment**

Authors, such as Fan and Stevenson (2018) consider that an effective SCRM requires a comprehensive, rapid, technical, and economically feasible evaluation. Assessing a risk is not usually a trivial task and usually covers both qualitative and quantitative aspects. They often also involve complex interrelationships, since removing a risk can help mitigate certain risks and at the same time create others. Roehrich et al., (2014) consider that although over the last years some studies have discussed risk assessment strategies, this is a topic where more research is needed. They affirm that risk assessments should take greater account of the intangible consequences and losses inherent in the occurrence of the risk being assessed, such as credibility, reputation, status, authority and trust. They also affirm that these immaterial consequences are often neglected by researchers.

Fan and Stevenson (2018) also argue that managers generally assess risks based on their own experience and business performance, but it is important to consider how other indicators or signs of change in the business environment can be incorporated (Hora and Klassen, 2013). Likewise, it is important to have a broader understanding of risk in the context of the supply chain. For example, not only direct risks need to be assessed, but the possible causes or sources of these risks also need to be examined at all significant links along the chain (Wever et al., 2012).

**Risk Treatment (Mitigation)**

The literature has adopted various terms for the types of risk treatment actions available, usually influenced by the business context of the study. However, the five most commonly reported types (strategies) of risk treatment are: acceptance, avoidance, transfer, sharing, and
mitigation. Overall, most research on the subject focuses on risk mitigation. Besides this, in the context of SCRM, the terms "risk treatment" and "risk mitigation" are often used interchangeably, although mitigation is in fact one of the options for treating with a risk (Fan and Stevenson, 2018).

**Risk Acceptance**: there are no standard guidelines for determining how much risk an organisation should accept. The acceptable level is dependent on the context and may be linked, for example, to risk propensity, i.e. the willingness of a person or organisation to engage in risk behaviours and to accept uncertain outcomes in decision making. However, the willingness to accept the risk does not mean that the risk should be ignored. It must continue to be considered and tracked to ensure that the consequences do not increase. Moreover, if the potential consequences of risk exceed a certain threshold, companies need to consider how to avoid, transfer, share, or mitigate risk (Park et al., 2016).

**Risk Avoidance**: organisations may choose to eliminate the types of events that may carry the risk. For example, a company may discontinue specific products, suppliers, or geographic markets if operations in the supply chain are unreliable. Thus, it will remove the cause of the risk (Fan and Stevenson (2018).

**Risk Transfer**: it seeks to transfer responsibility for risk to another party. For example, business interruption risks can be transferred through business interruption insurance. Risk transfer, however, seems to be more appropriate for interruption risks with a low likelihood and high impact (such as natural disasters and terrorist attacks) than for high probability and low impact operational risks (Aqlan and Lam, 2015).

**Risk Sharing**: it involves another party sharing some or all the risks. From the buyer's point of view, risk can be shared generally through contracts with clauses that account for possible changes in the associated risks and the development of collaborative relationships. Suppliers, for example, would pre-order inventory risk in the presence of financial constraints or increase capacity when orders were secured by customers. Similar to risk transfer, risk sharing seems appropriate to deal with risks that are low probability and high impact in order to reduce associated costs and increase levels of customer service (Fan and Stevenson (2018).

**Risk Mitigation**: it seeks to actively reduce risk to an acceptable level and applies both to reducing the likelihood of a risk event and its consequences. Mitigation strategies are typically adequate for operational risks with high probability and low impact. The selection of a risk mitigation strategy also depends on the type of risk and the organisation's budget. As risks are usually interconnected, relieving one type of risk can aggravate and/or mitigate another (positive and negative dependence). Therefore, mitigation strategies should be used carefully because at the same time mitigating one risk may increase another risk. (Tummala and Schoenherr, 2011).

**Risk Monitoring**

It is a fact that risk is not a static phenomenon and needs to be continuously monitored to assess how sources of risk are developing and whether any changes in treatment strategies need to be applied. It is important that risk monitoring is based not only on trial assessments, but also on formal processes. Moreover, although risk monitoring is an important part of SCRM, it has received little attention under the aspect of academic research (Hoffmann et al., 2013).
Researchers have mainly suggested the establishment of specific data management systems for risk monitoring. Managers, on the other hand, tend to incorporate monitoring tasks into existing management routines, such as performing them by monitoring company performance indicators (Fan and Stevenson (2018).

Concluding this topic, one can consider that different sets of risks may require different risk management strategies. As companies have limited resources, it is important to understand how they can best be used in the SCRM. Hence, investing in risk prevention seems to be necessary when there is a high probability that it will occur. Risk acceptance may be allowed for low probability and low impact risks. Risk mitigation appears to be more appropriate for high probability and low impact risks, while risk transfer and risk sharing seems more appropriate for low probability and high impact disruption risks, such as natural disasters and terrorist attacks. And above all, the situation needs to be continuously monitored and aligned with the strategy chosen to address the risk (Fan and Stevenson (2018).

**Methodology**

The research was conducted using an in-depth case study addressing a large global automaker and one of its main global first tier suppliers (dual approach) and their SCRM in two countries with distinct operating environments where they both have a strong presence and market share: Brazil and Spain. It is also worth noting that the supplier company is a major supplier of the automaker and, on the other hand, the automaker is a major customer of the supplier company.

In order to conduct the field research, a framework and a semi-structured questionnaire were devised, covering the stages of identifying, evaluating, treating/mitigating and monitoring risks. In terms of supply chain scope, operations were considered in the (1) internal limits of the company, (2) outside the company and internal to the supply chain and (3) outside the supply chain.

![Figure 2: The scope of the empirical research](image)

For the interviews, the main highest-level managers involved with the subject matter within the companies were interviewed. More details on the interviews and the qualification of the interviewees will be reported here later.
The empirical data collected from the interviews were complemented with visits to the company's facilities and all the company's documentation relevant to the research that was available was retrieved and analysed.

**Empirical Research**

The investigated auto parts company was a large European firm with a global presence. It has about 150 factories around the world, some of them in Brazil and Spain. The company defines it as “an automotive supplier and partner to automakers around the world, providing innovative mobility solutions with a particular focus on the intuitive direction and reduction of CO₂ emissions”. The company also provides and distributes spare parts to the dealers' distributors of automakers and independent aftermarket companies.

The interviews were conducted with a company's global corporate purchasing director, a purchasing director for Latin America and a Europe-Latin America sales director. They were conducted mostly in person at the company headquarters in Europe in April and May 2018 and a total of approximately eight hours of interviews was recorded. In this case, factors such as the position occupied within the company (global and regional directors), the experience and knowledge accumulated in the sector and the interest in the subject researched raised the level of interviews. Thus, in addition to discussing the issue in the context of Spain and Brazil, one can extrapolate the discussion to the practice of the SCRM within the company in all parts of the world where it acts as a major supplier of large automakers.

The auto parts company divides its operations into four business units: (1) thermo systems (radiators, air conditioning), (2) power train systems (alternators, starters, clutches), (3) visibility (headlights, windshield wipers) and (4) comfort assistance (arrow switch, stop control, sensors). In global terms, each of these business units practically contributes with 25% of the company's revenues, which is a balance considered internally as very positive.

In relation to the SCRM concerning the automakers, the biggest problem considered is the fluctuations in demand and the difficulty that this imposes on the management process as a whole. The drop-in production volume in the Brazilian market after 2013 is cited as an example, i.e., the whole industrial segment prepared for a production of around 5 million vehicles a year and demand remained well below this value, generating a large idle capacity in the segment. Another difficulty is managing more multipurpose (not dedicated) factories (such as those located in Brazil, Argentina and developing countries), which produce a greater mix of products and a smaller volume of each one. In turn, in Europe there are usually more dedicated factories, which meet a more stable demand from the automakers and with a reduced mix of products and high volumes of each product. Already in terms of risks, causing a stop at the final assembly line of the customer automaker is always a threat, something to be avoided due to the financial losses and credibility that this entails.

In the company, the supplies (materials) represent from 60% to 70% of the costs of the products and it buys a wide range of materials. Concerning this, and in terms of value in the global scope, approximately 20% are resins and plastics, 20% are steel and derivatives (forged steel, cast steel, stamping), 20% aluminium (parts and coils) and 20% electromechanical (motors, motor components, starting motors, copper wires) and 20% are electronics (embedded technology). In Brazil, computing all the factories of the company, electronics still represent about 3%, which illustrates well how much the local industry still has to go in terms of electronics used in their vehicles.

Moreover, supply management and inbound logistics are based on a categorisation of all materials purchased in about 40 categories, which have a global and local structure dedicated to their management, with strategies and procedures that consider the particularities inherent in
each one of them. For example, steel purchase management is quite distinct from electronics purchasing, and so on. The company maintains purchasing teams in its plants around the world, but the procedures for development, homologation, contracting and evaluation of suppliers are centralised at corporate headquarters. This allows for a greater standardisation of procedures and savings in the processes of purchases made in a consolidated (global) way. It also allows greater uniformity and consistency in the approval procedures of suppliers, in an industrial segment with several standards (such as VDA, IATF 16949, QS 9000, etc.) to be met.

In turn, risk management in supply chains is conducted within (jointly with) the management procedures of the approximately 40 categories of materials purchased, i.e., considering the particularities of each one of them. The basic (and simple) goal is to reduce material costs (and inventories) and minimise the risks of material shortages and non-fulfilment of customers’ requirements. However, the greatest difficulty lies in fulfilling this objective, especially with materials that are bought from single suppliers and centralised production in single factories, as is the case of a growing number of electronic components. Therefore, the proper definition of the supplier (or suppliers) of a given material still in the product development stage has become a key decision for risk management in the supply chain being created.

With respect to SCRM procedures per se in the company, they are still mostly reactive, that is, more focused on providing a quick solution to a risk situation that arises or is identified. Some proactive procedures, in the sense of anticipated identification of potential risks, are still considered timid and incipient by the directors interviewed. Moreover, the biggest justification for this procedure is the difficulty the company has to economically justify creating a dedicated team for a proactive risk management in its supply chains. However, despite this difficulty in allocating a dedicated internal team to perform such a task, the company has resorted to some services from external companies that provide analyses of economic scenarios and information about the economic performance of some of its suppliers. The main purpose here is to try “to view” a little beyond what the conventional supplier performance indicators usually show, and thus anticipate unpleasant surprises such as, for example, the unexpected bankruptcy of a supplier. In this example, it should be remembered that many of these suppliers belong to industrial groups and their financial results are generally disclosed in a grouped form, which makes it more difficult to identify any problems at the level of their productive units.

In turn, the automaker investigated belongs to a large European group that has more than one hundred factories around the world and operates in the market with some different product brands. In Brazil, the researched plant presents a relatively diversified range of products and assembly processes, ranging from complete (conventional) assembly of vehicles to assemblies in Completely Knock-Down (CKD) and Semi Knocked-Down (SKD) procedures. The main interview was held in January 2018 with the supply chain and logistics director of the factory and lasted about 5 hours. In Spain, a plant was investigated of the industrial group that produces vehicles with a brand different from that one researched in Brazil. This plant produces a relatively large range of vehicles geared specifically to the domestic and European marketplace. The interviews were conducted with an engineer and a manager from the logistics process development of the plant. They were carried out in November 2018 and in total had a duration of about 6 hours.

Following a corporate procedure, the two companies also manage their purchases of materials based on approximately 10 different groups of materials. For each of these groups, the company maintains a strategy and procedures for purchases and stock levels, which follow the guidelines of the automotive group to which it belongs. Thereby, there is a range of approaches ranging from materials where maintaining larger inventories can at certain times be considered "strategic" (steel, for example) to situations where stocks should be minimised to the extent
possible, with sequenced deliveries from suppliers (just in sequence) right into its final assembly line. In addition, as in the supplier investigated, the development, the homologation, the hiring and evaluation procedures of suppliers and the SCRM seek to contemplate the specificities of each of these groups of materials. In general, there are some normative procedures that are common to all categories and should be strictly followed as they are essential qualifying (homologating) elements for suppliers. Moreover, it is also necessary to consider the specific elements of each of the categories of materials. It should be emphasised that, because it involves the issue of human mobility and safety, the automotive industry (as well as the aeronautical, for example) is quite standardised and restrictive in relation to the homologation of suppliers. Thus, this creates a difficulty in replacing suppliers (at a time of failure of the original supplier, for example), since, for a basic cost issue, the preference of the companies is always to work with as few suppliers as possible for each item of product. Therefore, as single sourcing has become very common over the last two decades in the auto industry, a major negative effect of this dependence is clearly the increased risk of shortages of its product assembly lines.

A case in this sense occurred in 2016, when the supplier of a structural component classified as a security item, interrupted the supply to all the units of the investigated automaker in Brazil for a period of a relatively long time. Other automakers operating in the country also had the same problem. Because it involves an item that requires expensive homologation tests, the natural choice of the automaker was to decide on a single supplier. Moreover, this exclusivity turned out to be very harmful when the supplier suddenly ceased to supply, requiring a relatively long time for the development and homologation of a new supplier.

In terms of general SCRM procedures in the automaker company investigated, they remain predominantly reactive, with the formation of multi-departmental task forces to solve problems whenever necessary. In this case there is a kind of roadmap to guide the administrative procedures to be followed and with the basic purpose of normalising the situation as quickly as possible, even if the situation involves using a more costly mode of transportation, such as a dedicated air freight case. In more academic language, we can say that in this situation of abnormality, the company tries to be the most agile and resilient possible, even performing its operations at a higher cost. Furthermore, the rationale for a much more reactive rather than proactive approach in SCRM is the same as that of the supplier investigated, that is, the difficulty in economically justifying the creation and maintenance of an internal team to deal exclusively with SCRM. The company also understands that improving the visibility of operations and working with more stable production levels are essential to minimise the risks in their supply chains. Thus, the company in Spain is starting to work on a project that seeks to build a large computational tool and interface in the form of a large control panel (such as a cockpit) and with the purpose of increasing the general visibility of operations in all their supply chains. This project, still in its initial phase, should provide a more proactive character to SCRM within the company.

The auto parts and automaker’s data analysis also show that factors such as (1) using factories with a more diversified mix of products and lower production volumes, (2) the geographical location in the world, (3) the lower availability and higher cost of logistics infrastructure and (4) the customs bureaucracy, tend to make SCRM more complex in Brazil.

Therefore, these four factors have a more significant effect in identifying, evaluating, treating and monitoring risks under operational reality in Brazil. On the other hand, the main causes of line interruptions are generally the same across the geographic scope investigated (Brazil and Spain), i.e., facts such as the occurrence of a natural disaster, a failing supplier, a machine breakdown, etc. Moreover, the data from the field research (with the supplier and automaker)
shows a predominantly reactive posture of the companies with respect to the SCRM, since they consider that the allocation of a team working in a dedicated way still has a great difficulty to be justified under the economic aspect traditionally prevailing in companies. However, some initial movements were also identified in order to treat SCRM more proactively, such as contracting external risk monitoring services (in the case of the supplier company) and the construction of a system of cockpit visibility and monitoring of operations throughout the supply chain (in the case of the automaker).

Table 1 identifies some points regarding the SCRM in both companies and countries.

**Final Remarks**

The investigation results also show that the framework constructed to guide its conduction, although laborious, led to the results and knowledge of several real SCRM practices and cases that, when published in the near future in some articles, will certainly contribute to the knowledge on the subject. An example of these findings concerns the conduct of the SCRM in
companies according to the classification of groups of materials. To the best of our knowledge, we have found nothing reported in this regard in the academic literature available.

Furthermore, the research also highlights the turbulent historical moment that the automotive industry is currently experiencing, a fact that is more evident on the European continent. Therefore, although this was not the main purpose of the investigation, it was clear at the outset that the automotive industry is going through a period of great unease due to several elements that currently threaten the stability and status quo of its players. Among these elements are mainly the so-called autonomous driving, connectivity, electrification and travel sharing, which has led to new forms of mobility. Thus, topics such as cyber security, user interface technologies, telematics, gesture/voice recognition, parking and mobility optimisation, sensors and semiconductors, stand-alone solutions, electrification and energy storage, vehicle rental and fleet management, among others, are now on the daily agenda of the industry, especially of automakers and first tier suppliers.

Therefore, a research that began to focus only on the risks that could cause a stoppage in the final assembly line of both companies (supplier and automaker) ended up having to also consider the current moment. This means having to also consider the growth of risk for the automotive business as a whole, mainly due to possible breakdowns and/or disruptions in its technology and in its current business model in the near future. This risk can be well illustrated by a statement from one of the interviewees of the automaker investigated when questioning whether “the car of the future will be a car from our automaker with a software from Google or will be a Google car with the hardware of our automaker”?

Abstract

This paper clarifies the reality of supply chains involving automobile parts suppliers using natural materials. It identifies problems unique to natural materials and examines possible solutions through interviews with two Japanese tertiary suppliers of products using bamboo and leather. The research found the issues of unstable quantity and quality in material procurement, which inevitably prolongs the procurement lead time, resulting in larger inventory. The solution to this is inventory control through coordination of procurement and production, and process innovation by parts suppliers. This improvement could curb costs and contribute to making carmakers’ supply chains more efficient as a whole.

Keywords: supply chain

Introduction
The automobile market is changing rapidly due to the diversification of products, with parts suppliers, along with carmakers, being pressed to respond quickly to market conditions with flexible production systems. However, parts suppliers using natural materials have different problems from those using industrial materials in two aspects. The first is fluctuating demand from carmakers. In many cases, natural materials are used for luxury models as part of the companies’ product differentiation strategies. This causes fluctuation in demand. The second is unstable procurement, which is different from the cases where industrial materials are used. Considering these aspects, it can be expected
that parts suppliers using natural materials will design supply chains differently from suppliers using industrial materials.

This paper examines aspects of supply chains established by parts suppliers using natural materials through case studies of two tertiary suppliers of steering wheels for Toyota Motor Corporation. Until now, there have been few studies of supply chains focusing on material procurement by parts suppliers or procurement of natural materials by them. This study aims to offer a new perspective on supply chain diversity and enrich such knowledge by revealing the realities of supply chains developed by parts suppliers using natural materials.

**Literature Review**

Supply chains of natural materials present different challenges from those of industrial ones. Adding variations to supply chain models and viewpoints will contribute to the study of supply chain diversity. Therefore, this review focuses on different approaches to supply chain studies.

**Studies on product characteristics**

The first step in designing an efficient supply chain is to understand the essence of product demand. Products can be divided into two types: those with easy and those with difficult demand prediction. Each type is further categorized as to whether products are functional or innovative. Supply chains are designed according to the characteristics of each type. However, the same product can be considered to be both functional and innovative, and that is where difficulty in choosing the right supply chain lies (Fisher, 1997).

Problems arise from various types of demand according to product characteristics in an unpredictable market. However, they can be effectively solved by appropriately matching three managerial elements: strategy, structure, and process, with such characteristics. This enables intra- and inter-company supply chains to be integrated, thereby solving the problems and developing improved supply chains (Nakano, 2016). Studies on supply chains focusing on product characteristics have developed various measures to respond to unstable demand. However, there have not been enough supply chain studies concerned with material procurement to provide effective solutions to fluctuating demand.

**Studies on the coordination of demand and production**

Supply chains are designed to be lean or agile, depending on which type of demand pattern they face, effective or responsive. In either a lean or agile supply chain, responses to demand fluctuations can be controlled by where the decoupling point is set (Naylor et al., 1999). In many cases, whether a manufacturer can match demand and supply depends on the ability to flexibly control the amount of supply at the time demand information is obtained (Simchi-Levi et al., 2002). Studies of this nature concern themselves about where to put the decoupling point. There are only a few studies which discuss measures to coordinate production and procurement in response to demand fluctuations.

Mass-market cars and luxury models offer different values. In the case of steering wheels, for instance, the difference between classes of automobiles is often expressed through the use of different materials, which generates product characteristics with different demand. As a result, a differentiated product with fluctuating demand may exert influence on material procurement at the far end of the supply chain. Despite the close relationship between demand and procurement, the influence of demand fluctuation stemming from product characteristics has not yet been clarified.

Parts suppliers using natural materials issue procurement orders long before they obtain actual demand information. There is always a disparity between their annual plans and
firm orders they have received. To respond flexibly to demand fluctuation, suppliers are required to adjust not only their own production system but also their procurement system. Therefore, unless we investigate production-procurement coordination, and not just demand-production, the issues to be solved cannot be identified. Until now, there have been no such studies adopting this approach.

This paper aims to clarify aspects of supply chains in relation to differences in the materials used, not product differences. It also probes how production and procurement are coordinated in response to demand fluctuation. This study focuses on aspects of supply chains constructed to overcome problems peculiar to natural materials through an examination of automobile parts suppliers.

Research Design
Qualitative data was obtained through interviews at two Japanese automobile parts suppliers which use natural materials. Company X and Company Y manufacture steering wheels made from bamboo and leather, respectively. A total of five interviews were conducted with their purchasing managers.

Parts suppliers using natural materials need to address issues involving the instability of quality and quantity peculiar to the materials. This research suggests that the solutions to these problems could become a key to improving supply chains.

The question of differences in materials has hitherto been overlooked in supply chain studies. This new approach of focusing on such differences will help solve supply chain problems.

Case of Company X, bamboo steering wheel supplier
Company X in Kochi Prefecture is a tertiary supplier that was established in 1999 through a joint investment from a private hunting gun maker in Kochi, a major Toyota-affiliated automobile parts supplier and an associated company in Aichi Prefecture. Company X's unique skill of producing laminated bamboo parts by gluing and bending simultaneously enabled bamboo to be used as automobile parts for the first time. The company's bamboo steering wheels have been adopted for seven luxury models, including those in the Lexus and Crown line. Company X produces about 600 steering wheels a day in different shapes and colors.

Gaps between Advance Demand Information (ADI) and the supplier’s annual plan
Company X’s procurement lead time is four months and, in most cases, the ADI from the automaker, which is customarily issued three months in advance in the auto industry, is different from their plan for a given month based on their annual plan. With such a long procurement lead time, the company needs to place advance orders and maintain a certain amount of stock to respond to changes in demand. The disparity between the ADI and the annual plan for bamboo demand is 18.3% per annum on average. However, the fluctuation can grow more extreme, putting Company X at the risk of material stockouts throughout the year. In 2017, the disparity between the ADI and their plan ranged from 6.9% to as high as 72.4%.

These fluctuations are too large for small-scale enterprises to deal with. To reduce the burden on Company B, the upstream bamboo processor, Company X places a fixed order every month. Taking the material yield into consideration, Company X adjusts orders for the following month at the end of each month to minimize the effect of order changes on Company B as well as the bamboo provider, Company C. Without this adjustment, it would be difficult to maintain constant procurement from small-sized suppliers.
As seen here, the procurement lead time for natural materials is long, and therefore planning needs to be based on an annual plan, which often results in fluctuating disparities between the annual plan and the actual monthly plan. Unstable downstream demand has a greater effect on companies upstream. Company X compensates for such disparities by adjusting its orders to smaller enterprises so as not to pass on the burden. In addition to this instability in demand, natural materials have inherent problems of quality instability. Company X needs to deal with problems concerning both quantity and quality (Figure 1).

![Diagram showing production and information flow](image)

Figure 1: Company X's flow of production and information

Measures to prevent instability in material quantity
Bamboo contains more moisture than wood and its level of moisture differs depending on the season and the soil of the growing area. The best season for cutting is said to be during autumn and winter, and it is customary that bamboo used for processed goods is cut and dried naturally between November and February for a year’s use. However, bamboo procurement for automobile parts needs to meet the daily order requirement in the automaker’s just-in-time system. Therefore, Company X found two suppliers near Kochi City, Company C for material procurement and primary processing and Company B for secondary process of drying. The firm constructed a supply chain for bamboo steering wheels from scratch, realizing stable procurement of bamboo throughout the year.

When the company started manufacturing bamboo steering wheels in 2012, they were for only one model, the Lexus GS450h, and the total number shipped was small, at 1,300. However, a year later, this jumped to 23,000 as four Lexus models (ES, LS, HS, and RX) installed bamboo steering wheels, which made it impossible for Company X to procure enough bamboo material to catch up with demand.

Once parts suppliers have entered into a contract with an automaker, they have to meet the fluctuating amount of orders. However, procurement of natural materials with limited procurement routes cannot be flexibly adjusted at short notice when the amount vastly exceeds estimates. In addition, the long production lead time of the component material, laminated bamboo, is another factor making the adjustment difficult. On top of that, the amount required was significantly higher than that of the previous year, resulting in extremely large procurement shortages.
To secure stable procurement and avoid the risk of shortages, Company X asked Company C, a bamboo provider, to increase the number of professional bamboo cutters it employed and expand procurement routes by adding a local forestry association as a bamboo provider. Stable procurement of natural materials for industrial parts is an important issue in supply chain management.

Measures to prevent instability of material quality
Material defects are most often found at Company B, the secondary processor. When bamboo is peeled, some spots or uneven colored parts unexpectedly appear under the apparently perfect surface. In some cases, some inner parts are unusable due to insufficient specific gravity. These defects cannot be found before processing. Moreover, the bamboo harvested in spring contains more moisture because bamboo absorbs more water from the soil during its growing period. The quality of bamboo with higher moisture content is unstable even after artificial drying, resulting in yields of under 40% in some cases.

To solve this problem, Company X re-examined the moisture content of bamboo and reviewed the method of processing, and found that by adding a pre-processing drying stage, moisture content can be controlled to make the material consistent in quality. Pre-drying processing boosted the average yield to 65% from 45%. The company has continued to improve the processing method, eventually achieving a yield ratio of around 85%. It is crucial for a manufacturer using natural materials to keep improving material quality through industrial innovation after the start of mass production.

Effect of unstable material quality and quantity on production systems
The instability of bamboo procurement both in quality and quantity affects Company X’s production system. In terms of quality, even after the yield of bamboo lamina was improved to around 85% at Company B, unstable elements of bamboo still remained and appeared as in-process defects in Company X’s production. Bamboo has more water vessels than wood, which tends to cause variations in quality, and the rate of in-process defects was about 10% per month.

Concerning quantity, the amount of laminated bamboo which Company B delivered twice a day is not always the same as that required due to the unstable yield. To solve this problem, Company X maintains up to two months’ inventory volume after the acceptance inspection stage, in order not to stop their production line. Controlling the upstream supply chain in terms of quality and quantity is the most important task for parts suppliers which use natural materials.

Summary regarding Company X
Due to the fluctuating demand situation, a tertiary supplier such as Company X must perform an adjusting function to stabilize demand for the primary and secondary suppliers. The company devised a new supply chain management system and closely linked the supply chain to procure enough bamboo material in response to the huge surge in demand. Through process innovation, the firm also resolved the quality control issue regarding bamboo, which is susceptible to the weather and the season.

Following the situation at Company X, we will now explore the research data at Company Y, which faces the same quality and quantity problems involved in dealing with natural materials.
**Case of Company Y, leather steering wheel supplier**

Company Y, established in Aichi Prefecture in 1957, is a parts supplier which applies a leather sewing process to making interior automotive parts. The process is dependent on the dexterity of craftsmen to flexibly meet various requirements and their proficiency in stitching accurately. The company’s leather steering wheels come in 205 types and are installed in 14 models, mainly luxury cars. They produce about 3,000 leather-wrapped steering wheels a day in different colors, employing different sewing methods in accordance with specifications.

**Gaps between Advance Demand Information (ADI) and the supplier’s annual plan**

Company Y imports the leather it uses, and it takes about six months from material procurement to product completion. Therefore, the three-month prior ADI does not provide it with enough notice about demand. Company Y orders materials six months in advance, with seven months being the longest procurement lead time.

The procurement procedure and time durations are as follows. First, it takes two or three months for materials to reach a processing factory in Thailand by sea from Brazil. It then takes another month for primary processing there, which is followed by a three-week journey to Company Y’s factory in Japan. The total period of time necessary is at least five months, therefore it is quite difficult to shorten their procurement lead time.

The company orders materials for a given month at least three months before receiving the ADI. To fill the gaps between the ADI and their own monthly plan, based on their annual plan, Company Y adjusts their orders every time they receive the ADI and keeps its material inventory volume within a range of 1.5 to two months throughout the year to absorb any discrepancies. However, demand fluctuation is moderate compared to that of Company X, as leather steering wheels are built-to-order products with stable yearly demand (Figure 2).

**Measures to prevent instability of material quality**

The yield of leather Company Y procures is about 50% on average, with a large fluctuation rate of 25%. At the time of sewing, some defects, such as slight blemishes, stains and pinholes, can be detected on irregular surfaces of the leather. Such defects are difficult to find at the procurement stage before sewing.
Therefore, they set the estimated yield at 50%, and workers maximize the yield by visually checking the material piece by piece and carefully patterning it in a way to avoid defective areas. Taking advantage of importing whole hides, they have been improving the yield through patterning innovation.

Although the yield of leather changes depending on the quality of the lot they receive, Company Y is able to absorb the changes with their inventory volume of at least 1.5 months. Maintaining the inventory volume also helps avert the risk of stockouts related to the long procurement lead time. Appropriate inventory control is a crucial measure for suppliers of natural material products to maintain product quality and avoid stockouts.

Summary regarding Company Y
The procurement lead time of Company Y is longer than that of Company X, which results in greater gaps between the ADI and their estimates. Even though the demand fluctuation is smaller than that of Company X, the yield of the leather material is low and it fluctuates widely. To solve the problem of unstable quality, Company Y absorbs the discrepancy by keeping a minimum of 1.5 months of inventory volume as a buffer. Technical innovation to improve the yield was also observed at Company Y as well as Company X. Process innovation after mass production has started is an important measure to curb costs for suppliers using natural materials.

Results
Upstream parts suppliers have common problems to address with long lead times from material procurement to product completion and implement wide-ranging planning accordingly. To avert the fluctuation risk caused by the gap between their annual plan and the ADI, they need to be willing to maintain a certain amount of inventory. Inventory control is especially essential for natural materials since their yields are low and changeable because of their quality instability. As a solution to fluctuating demand from downstream and the instability of material procurement from upstream, both Company X and Company Y devised a unique function for themselves as a buffer, adjusting inventory in the middle of the supply chain.

Appropriate inventory control is necessary to link a supply chain in a stable way. Parts suppliers located in the middle of the supply chain can play a role in coordinating procurement, production and industrial technology to link the supply chain more effectively. The examples seen here show that reducing inventory is not always the best plan. The significance of case-by-case inventory control is crucial, especially when dealing with natural materials.

Findings
This study has made three important findings. First, we identified the influence that product characteristics have on material procurement. Bamboo steering wheels are differentiated products, installed in Lexus models for the first time, and have a greater range of demand compared to leather steering wheels. This fluctuating demand affects upstream primary and secondary suppliers more greatly than Company X. Thus, Company X adjusts the demand to minimize its influence upstream. We therefore, consider that product characteristics exert significant influence on material procurement as well as demand fluctuation.

Secondly, we recognized the importance of coordinating procurement and production to solve the problems related to the unstable quality and quantity of natural materials.
instability hinders flexible adjustment in procurement, resulting in larger inventory. Unlike with industrial materials, there are limits to the amount of inventory reduction that can be achieved with natural materials. As a result, maintaining a certain amount of inventory is unavoidable.

Thirdly, we observed parts suppliers have continued technical innovation to improve yields after mass production has started. Similar to cases involving industrial materials, process innovation relating to natural materials curbs costs, leading to greater efficiency of an auto manufacturer’s supply chain as a whole. However, technical innovation bears more importance in dealing with natural materials, which require greater inventory costs.

Theoretical contribution
This paper identifies problems unique to the procurement of natural materials, bamboo and leather, through case studies of suppliers which manufacture steering wheels, and considers solutions in constructing supply chains based on differences in materials.

This research points out the positive aspect of maintaining a considerable amount of inventory, which has been negatively evaluated as an obstacle to cutting costs in supply chains of industrial materials. Natural materials are not procured as flexibly as industrial materials because of their instability of quantity and quality. This difference generates differences in supply chains

The supply chain of a carmaker is constructed from smaller-scale supply chains. In the process of producing finished cars starting from material procurement and parts production, the chain is supported by the linkage of a multilayered structure of minor supply chains. Among them, the realities of small-scale supply chains at the uppermost part are revealed here. This study reveals the role of upstream parts suppliers from a viewpoint of natural material characteristics. This paper takes the first step in studying supply chains from this perspective.

Abstract

The objective of this paper is to analyse the mechanisms that integrate the functions related to the demand processes and their respective impacts on customer value delivery in payment method companies. A case study was carried out in a Brazilian payment method company. Fourteen in-depth interviews were conducted with managers from different areas. The most mentioned integration factors are informal in nature, however, some formal integration factors were able to stimulate the occurrence of other informal factors. According to the interviewees, integration can improve commitment with common goals, related to the achievement of agility and service delivery.

Keywords: Cross-functional integration. Demand Management. Customer Value. Payment methods

1. Introduction

Several studies about cross-functional integration have been developed since the 1960s (Lawrence & Lorsch, 1967; Ellinger, 2000; Enz & Lambert, 2015; Jugend et al., 2018). Cross-functional integration plays an important role in the generation, dissemination and delivery of customer value. One approach that studies this connection between integration and customer value is the Demand and Supply Integration (DSI). DSI seeks to improve the customer value proposition by addressing several concepts related to the integration of internal functions involved in demand management and supply management processes (Esper et al., 2010).

Customer value is the result of the set of costs and benefits desired with the purchase of goods and/or services during the delivery process by the suppliers (Grönroos, 2011). The integration of internal functions plays an important role in the existing connection between the organization and its clients. This is because, in addition to integrating process flows, it is also a way to internally disseminate market information (Grönroos, 2009). In order to put this into practice, integration mechanisms are necessary to join demand processes and supply processes. This initiative can
alleviate conflicts and improve the efficiency of the supply chain (Piercy & Ellinger, 2015).

It is important to analyze cross-functional integration and to understand how its practice can help in the planning and monitoring of demand (Santos & D'Antone, 2014). In addition, cross-functional integration has been poorly studied in the sense of uniting academic debates with practice, particularly in the context of demand management (Piercy & Ellinger, 2015). Hilletofth (2011) points out that organizations need to be aware of the process of creating customer value. For this author, the integration between marketing, operations and supply chain may facilitate customer value generation.

Therefore, the studied literature about demand management presents indications about the necessity of cross-functional integration to increase customer value. However, it is necessary to explore the operationalization of the integration mechanisms and their respective impacts in this context, in order to join the research and academic discussions with practice (Piercy & Ellinger, 2015). A sector that can provide examples of this issue is the payment method market. The creation of value in these companies depends on the agility and flexibility of the internal functions in order to meet the service processes (Chan et al., 1999). Based on this discussion, the following question is proposed as a research problem: How can cross-functional integration be operationalized in demand processes in order to create customer value in the payment method sector? The objective of this paper is to analyze the mechanisms that integrate the functions related to the demand processes and their respective impacts on customer value delivery in payment method companies.

2. Theoretical review

Value is a result of the set of costs and benefits intended by the customer with the purchase of goods and / or services and the process of delivery of that good and / or service by the suppliers. The final decision of a customer for a product is related to the perception of added value (Grönroos, 2011).

For Grönroos & Ravald (2011), customers are always value-makers and suppliers have the opportunity to influence value creation through interaction processes in which customer engagement and resource integration occur.

Still about value, Grönroos (2011) states that it should not be treated as an attribute embedded in the product, but from the perspective of the Dominant Logic of the Service, as a quality or offer created in and by the interactions of customers and suppliers. It is important to emphasize that this interrelationship is not exclusive to a single department within the organizations, but must involve all employees, putting into practice organizational strategies (Grönroos, 2009). It is understood, then, that internal and external relationships are decisive for the creation of business value.

The employees of an organization need to be aligned with the creation and delivery of value to customers, executing all business strategies (Grönroos, 2009). Creating value for consumers should be the reason for the company's existence and certainly for its success (Slater, 1997), and in this context, cross-functional integration is a fundamental tool in order to reach market alignment (Kohli & Jaworski, 1990, Jaworski & Kohli, 1993). For this, it is important to analyze the practice of integration, i.e.: how organizations interact internally and externally to carry out the planning and the monitoring of demand (Santos & D'Antone, 2014).

In this context, the Demand and Supply Integration (DSI) represents a strategic approach that seeks to improve the value proposition to the customer in order to create value in the market. This perspective interconnects several related concepts in the areas
of Marketing and Supply Chain, including: cross-functional integration and value generation (Esper et al., 2010). Mentzer, Stank and Esper (2008) report the importance of integration between Marketing, Logistics and Production for the efficiency of organizations in their external integration with the other links in the supply chain. This proposition is grounded in the following definition from the Council of Supply Chain Management Professionals (CSCMP): “in essence, Supply Chain Management integrates supply and demand management within and across companies”.

Demand management must be done through the connection between the areas of operations and marketing. This enables the understanding of the market, the development of actions aligned with the company's strategy and productive capacity, and also meet the needs of the customer (Jüttner et al., 2007).

Demand and Supply Integration (DSI) symbolizes a strategic approach, which seeks a customer value proposition, a process of value creation in the market (ESPER et al., 2010). According to these authors DSI is:

[...] the balancing of demand and supply market information and business intelligence through integrated knowledge management processes to strategically manage demand and supply activities for the creation of superior customer value. (Esper et al., 2010, p. 7).

The integration between the demand and supply processes helps the companies to fulfill their objectives and the customers’ needs in real time, besides identifying with more precision the limitations of the capacity of supply (Esper et al., 2010). The demand management must incorporate all the processes related to the creation and fulfillment of demand. Hilletofth et al., (2009) give some examples of demand processes, such as: strategic marketing planning, marketing research, market segmentation, product development, product marketing and sales, product life cycle management. Esper et al. (2010) also mention some examples of demand side processes: demand forecasting, branding, positioning, new product launches, advertising, selling.

From the definitions above, we can cite three common points between these demand management perspectives and customer value definitions, from Grönroos (2009) and Vargo and Lusch (2004): (1) coordination and collaboration between suppliers and customers; (2) International integration of demand and supply processes (3) a process flow perspective. Therefore, the nature of demand management perspectives, particularly DSI, is focused on integration of functions that are necessary to fulfill the demand and supply processes. In this sense, the next paragraphs are dedicated to explain concepts about cross-functional integration.

Integration can be defined as “the quality or state of collaboration that exists among departments that are required to achieve unity of effort by the demands of the environment” (Lawrence & Lorsch, 1967 p.11). Cross-functional integration can take place formally through the sharing of information, in order to empower the areas involved in decision-making (Gimenez & Ventura, 2005; Jüttner et al., 2007). However, integration may also occur informally on the basis of interpersonal processes (Kahn, 1996; Ellinger et al., 2006).

A difficulty when integrating functions is the fact that each internal function is concerned firstly with its own activities and objectives. Therefore, without integration, the behavior of the department tends to be individualistic, because the areas seek their particular interests, disconnected from the interests of the organization as a whole (Lawrence & Lorsch, 1967; Ellinger et al., 2006). To overcome these challenges, integration factors are necessary, as mechanisms that motivate the different departments
to cooperate with each other (Kahn, 1996). Some authors have studied integration factors as antecedents of cooperation between internal functions and, their respective impacts on the management of demand and supply processes (Turkulainen et al., 2017; Pellathy et al., 2019).

Pimenta et al. (2016) present a multidimensional framework composed by the following five tenets, systematically involved in the integration processes:

- **Boundary-spanning activities**: activities and processes that demand involvement of different functions to be performed;
- **Integration factors**: mechanisms that generate integration among functions;
- **Formality/ informality**: forms of operationalization of the integration factors (implemented by managers or spontaneously developed);
- **Level of integration**: intensity of the cross-functional relationship;
- **Integration impacts**: benefits and outcomes obtained as the consequences of integration.

This research focuses on the study of the application of integration factors as drivers of customer value in demand management processes. Thus, Table 1 shows the main integration factors shown in the literature, which supported the field data collection in this research.

3. Methodology

A case study was carried out in a Brazilian payment method company. The case study method was chosen because it makes it possible to investigate a phenomenon that is not yet clearly defined, and when the research problem contains questions related to why? and how? (Yin, 2001). From a theoretical point of view, it is justified because the integration within the processes of demand are still presented superficially in the literature and need further exploratory studies (Piercy & Ellinger, 2015). The company was chosen according to the following criteria: 1) It is a large company (more than 3 million issued cards and 115,000 accredited stores), 2) it has a complex supply chain, 3) it is dependent on several efforts of cross-functional integration for creating and delivering customer value.

Fourteen in-depth interviews were conducted with managers from different hierarchical levels of Marketing, Sales, Operations, Logistics and Planning areas. The interviews lasted 1 hour in average, with the support of a research protocol with the following script: 1) The interviewees were asked to describe the demand management processes in which they are most involved (Esper et al., 2010). 2) They were asked to define which internal functions are essential to fulfill the chosen processes. 3) They were asked to evaluate the integration factors from Table 1 in a 5-point Likert scale according to their perception of occurrence within the chosen processes, i.e: from “occurs very often” to “rarely occurs”. 4) They were asked to detail the operation of the integration factors evaluated as “occurs often” or “occurs very often” (4 or 5 in the scale). 5) Finally, the interviewees explained if these integration factors are able to generate customer value at some stage of the chosen process, and how it occurs.

Two additional data sources were collected in order to provide data triangulation. The questionnaire described in item 3 (integration factors) was responded by 33 people who are subordinate to the interviewees, as a trial of validating the existence of these factors. In addition, a qualitative questionnaire was applied to 21 current clients to identify the meaning of customer value. These responses were compared to the interviewees’ perceptions about item 5. The interviews were audio-recorded, transcribed and subjected to content analysis. The coded analysis obtained though the interviews was compared with the meaning of customer value according the perception of current clients.

4. Findings

The interviewees described the processes of demand management that they are most involved with. The most mentioned processes were: market strategy planning, market segmentation, product development, sales & marketing and product life cycle. Two other processes emerged from the data: marketing research and demand forecast, but according to the interviewees they do not have a cross-functional characteristic within the company. Marketing research is mostly performed by third parties and is not focused on the numbers of demand forecast. The process of demand forecast does not involve multiple internal functions, and is basically focused on the amount of sales from previous years.

The interviewees pointed out the internal functions that are essential to perform the activities related to the demand processes mentioned above: Marketing, Sales, Customer Relationship, Credit Analysis, and Operations (that comprises: Network Management, Logistics, Customer Care and Operations Management). The analysis of
4.1 Integration factors in the demand processes studied

In order to achieve the integration of the internal functions that comprise the demand management processes analyzed, the studied company presents several integration factors, according to Table 2. It presents all the factors identified in content analysis, as well as their frequency mentioned by the interviewees.

The most mentioned factors in Table 2 are informal in nature, which depends on people's willingness to integrate rather than on formal management intervention. Group spirit is related to a cooperative climate in the business environment, when work teams reach a behavioral pattern in pursuit of common goals.

When a large customer enters the company, for example. People are dedicated to meeting its demands. While some people do the development, other teams are giving support (Product Manager). Many areas engage in this group spirit, but not all of them (Sales Manager).

The longevity of relationships exists because of a low turnover, which makes it easier for people to interact and understand individual values.

If we have known each other for a long time, we have a certain agility to solve what we need, it gets easier to communicate (Product Manager).

The willingness and joint work to resolve conflicts represents the ability to work together to solve possible conflicts, establishing agreements between functions and the willingness of managers to adopt integrative behaviors. It is observed that this factor is related to group spirit.

In the past, when a product was going to be created, we would create the product, present it to the director and proceed with the project. Today we are restructuring this, involving other areas. We make a process, which involves legal, commercial, compliance, marketing, financial, controller, many areas of the company (Innovation Manager).
Consideration of informal working groups refers to the managerial attitude that supports the union of informal teams within the functions and stimulates joint work. Management should identify and adopt the collective behavior of the aggregate groups in order to obtain benefits for both the company and the employees.

There is support between areas and managers. It makes us see that everybody depends on each other to deliver the solution to the client. When the areas are integrated and we can make a delivery to the customer, he will see value in that (Relationship Manager).

In addition to these results, employees reporting to key interviewees were consulted on the existence of these integration factors. These respondents indicate that the most present factors are: Consideration of the informal working groups, Trust, Longevity in relationships, Non-conflicting objectives between functions, Willingness to work together to resolve conflicts, Mutual understanding about each other's activities and Group spirit. These complementary results indicate a good alignment of perception among the managers and subordinates, who realize that the integration occurs at several hierarchical levels, not only at the managerial and strategic levels.

4.2 Cross-functional integration as a driver of customer value

Before reporting which integration factors are able to generate customer value, a careful analysis was conducted in order to understand the meaning of customer value through the perception of three agents: managers interviewed, employees reporting to them and direct clients. It is important to clarify that the studied company offers different products in terms of benefits cards: meal cards, fuel cards, salary anticipation cards, pharmacy and dental benefits cards.

Both the managers and their subordinate people elected Agility and Service delivery as the most important elements of customer value within the demand processes. Service delivery is also related to the solving of operational issues from the demand processes. In their view, Agility and Service delivery mean a fast solution of problems related to the use of the benefits cards. There is an emphasis on solving operational problems, rather than understanding how the agility of this solution could bring benefits to the customers’ life.

On the other hand, the clients’ responses were more focused on the direct benefits of the service on their lives, in order to define what customer value represents to them. They affirm that a benefits card allows the company to value the employee.

The cards offer more credibility, tranquility and agility. It is a significant benefit, that in addition to an appreciation of the team, generates loyalty of the employees to the Company (Meal Card Client).

Another element related to customer value, according to the clients, is the ease of using the card instead of receiving the benefit through other forms. According to them, it is easier and safer for both paying (for the company that gives the benefit) and spending (for the employee who receive it).

One important element of customer value was mentioned by the clients of fuel cards and fleet control. According to them, the service is very good, mainly because the online information system, provided by the local company, allows them to perform a rigid control regarding how the vehicles are being used and fueled.
We need to have control of the fuel supply process of the vehicles and to avoid fraud (Fuel Card Client)

Finally, there are some points in common between the company and the clients with regard to customer value. Most of the customer value elements mentioned by the clients were not emphasized by the company's respondents. The latter agent, is focused on Agility and Delivery. These two elements were also mentioned by the clients, but less emphatically, because they are more concerned with the issues directly related to the convenience that the card brings them when carrying out daily activities. Thus, it is assumed that the interviewees did not demonstrate a very in-depth view of the concept of customer value, so as to transpose their concern with the execution of the demand processes in benefits related to the consumer behavior of their services.

In this case, a higher level of cross-functional integration could improve the awareness about customer demands. As mentioned by Grönroos (2009), cross-functional integration is a way to internally disseminate market information. Figure 1 presents the main characteristics of the studied case, with regard to the capacity of cross-functional integration to generate customer value on demand processes.

![Figure 1 – Main integration factors and impacts on customer value in the studied demand processes](image)

An important feature identified during the analyses is that the application of some formal integration factors, such as cross-functional meetings and Senior management support, stimulate the occurrence of other informal factors. For example, when there is joint planning between related areas with top management support, cross-functional meetings occur and, if they are regular, they can strengthen group spirit. In turn, these consequences increase the level of trust between people, which encourages...
greater information sharing. Therefore, according to the interviewees, Agility and 
Service Delivery can be improved. This occurs due to the greater responsiveness to the 
market achieved by internal integration.

Without integration, each one would think only of their problem or area, we 
would work individually, without thinking about the whole firm. The 
integration of the areas contributes to a broader understanding of the 
difficulties and functioning of the areas, strengthening team spirit and 
consequently, speeding up problem solving, minimizing negative impacts on 
customer value delivery (Regional Sales Manager).

According to OP3, when there is integration between the areas, there is affinity 
of thought and clarity. The members feel like part of a team, sharing the objectives and 
committing themselves to the goals delineated in value delivery.

When different functions are speaking the same language, with aligned goals 
towards the delivery to the customer, the perception about the client’s needs 
is much better, showing the synergy between the processes and deliveries of 
the company as a whole (Innovation Manager).

5. Conclusions

The field study presented the characteristics of some integration mechanisms, 
such as: Group spirit, Considerations of informal working groups and Longevity of 
relationships. The interviewees perceive a climate of cooperation between the internal 
areas. When people have known each other for a long time there is agility in resolving 
conflicts. There are problems of integration in demand processes management, which 
are mainly associated to the lack of the following integration mechanisms: information 
exchange, cross-functional training, adequate communication, proximity among 
departments and joint planning.

Regarding the impact of integration, the interviewed managers state that the 
integration among areas is responsible for agility in the resolution, delivery of customer 
service, solution of problems, resolution of conflicts and delivery of demands within the 
term. The managers agreed that agility is the most important capability towards value 
creation in the studied company. Finally, the analysis of the results shows that cross-
functional integration affects the creation and delivery of customer value, helping to 
increase satisfaction with the service, to create a sense of solving and to avoid setbacks.

This research is grounded on demand management and cross-functional 
integration literature. Specifically, this research aims to contribute to the advance of 
studies on value creation in demand processes, presenting concepts poorly discussed 
about cross-functional integration in this context, based on a case study in a company of 
payment methods. The results showed that it is possible to deliver more value to 
customers by practicing cross-functional integration, which means that the relations 
between internal areas are important and should be encouraged. Different areas of the 
company should be organized in order to generate harmony with each other. It helps to 
 improve the flow of the demand processes, and, consequently, to facilitate delivery of 
customer value.

Abstract

The present paper explores the environmental risk supply chain management through multiple case studies conducted in three Brazilian companies. We compare the literature findings with the business reality, bringing insights on how environmental risks are managed by industries and their supply chains, what the potential losses perceived by companies are and the strategies adopted to hedge against them. The case studies’ findings show that most of the risks found in the literature were considered by the companies and that two environmental risks highlighted by one of the companies can be added to the academic list.

Keywords: Environmental Risk Management, Supply Chain Management, Multiple Case Study

Introduction

Risk management is one of the most significant challenges faced by supply chains (Torres-Ruiz and Ravindran, 2018). Risks occur due to an interruption at some point in the chain, which successively clogs the flow of materials, funds or information among the entities of the supply chain (Bode et al., 2011). Global competition and outsourcing render supply chains more exposed to disruptions caused by several factors, such as uncertain economic cycles, consumer demands, natural and man-made disasters (Torres-Ruiz and Ravindran, 2018) and adverse environmental impacts (Levner and Ptuskin, 2018). Furthermore, supply chains are more vulnerable to stakeholder scrutiny, which might generate vulnerability to reputation damage (Christopher et al., 2011; Hofmann et al., 2014; Valinejad and Rahmani, 2018), access to capital and to regulatory compliance (Torres-Ruiz and Ravindran, 2018).
This paper focuses on environmental risks and presents a multiple case study on the topic, since the increase of diversity and the grow of the supply chains sizes, highlighted the importance of the environmental concerns in supply chain risk management research (Levner and Puskin, 2018), and the literature on supply chain risk management has largely overlooked ecological and social issues in their operations (Hofmann et al., 2014).

As suggested by Oliveira et al. (2019), case studies should be conducted across different companies in order to strengthen the practical field of environmental supply chain risk management and form a basis for comparability between academia and practice. Thus, in order to compare, validate and add new evidence to the findings of Oliveira et al. (2019), the present research aims to explore the environmental risks, the stakeholder effects and the consequences to the companies, as well as the environmental strategies adopted, by conducting multiple case studies across three large companies located in Brazil. The companies, here designated as companies A, B and C, are respectively a petrochemical company, an air compressor manufacturer and an agrochemical biotechnology company. More specifically, this paper aims to address the following Research Question (RQ): Are the environmental risks, consequences and environmental strategies found in the academic literature also found/relevant in a business reality?

The following section outlines the case study methodology adopted for this study. The results achieved through the conducted case studies are presented and discussed in Section 3. Section 4 presents the concluding remarks and suggestions for future research directions.

**Research Methodology**

The present research adopts the case study methodology proposed by Yin (2001), composed of six steps: planning, project, preparation, data collection, data analysis and sharing.

The planning intends to evaluate the relevant situation for the development of the case study in contrast to other research methods, justifying the choice of the case study method. Yin (2001) clarifies that the case study intends to investigate a contemporary phenomenon within its real-life context, particularly when the boundaries between phenomenon and context are not clearly defined. Thus, the case study method meets the need of this research which is to analyse environmental risk management in supply chains, since it uses several sources of evidence, and does not have a clear definition of the boundaries between the phenomenon to be studied and the context of the real life in which it is inserted.

Hence, the phenomenon to be investigated within a real-life context is the management of environmental risks in supply chains, addressing the consequences that these risks may generate for the organisations and the strategies adopted to hedge against these risks.

The project aims to elaborate on the research question, define the case study project (single or multiple) and define the criteria for interpreting the findings (Yin, 2001). Therefore, the main question of this study is centered around comparing and validating the environmental risks, consequences, and strategies proposed by Oliveira et al. (2019), with the real-life situations, observed and applied in the supply chains of three large companies located in Brazil.

Cauchick and Souza (2012) elucidate that, in the single case study, it is
expected that there will be greater depth in the investigation and less capacity of generalisation. On the other hand, in multiple case studies, there is a possibility of greater generalisation, with perhaps less deepening in the evaluation of each case. According to Herriott and Firestone (1983), the evidence resulting from multiple cases is considered more convincing, and consequently, the study is considered more robust. In order to provide greater robustness to the research, through the analysis of several organisational realities and the cross-referencing of these various cases, the present work undertakes a multiple case study.

The case studies were conducted in three large companies located in Brazil: a petrochemical company, an air compressor manufacturer, and an agrochemical and agricultural biotechnology company, chosen for being ones recognised for their sustainability visions and principles of generating positive impacts on communities and environment.

For the preparation, Yin (2001) proposes the development of a research protocol, which is extremely important to increase the reliability of the work, guiding the researcher in conducting data collection for cases. Thus, for this study, the research protocols were developed in order to guide the researchers in performing the collection of data from the multiple case studies.

Data collection considers multiple sources of evidence, such as: semi-structured interviews, documents, file queries, physical artifacts and direct observation (Yin, 2001). Yin (2001) recommends the use of several sources of evidence, since these multiple sources allow for greater detail in the collection of data. Considering the cases studies performed here, the data collection was conducted in the same way with the three companies under analysis. This collection took place in three different stages and used the following sources of data: documents provided by the company, semi-structured interviews and secondary documents sourced from corporate websites.

For data collection, a questionnaire was initially created based on a systematic literature review (SLR) performed by Oliveira et al. (2019) and was sent to the companies through the SurveyMonkey platform, in order to collect background information about their management of environmental supply chain risks. Then, three semi-structured interviews with different managers from the companies were performed in October and November 2018. Open questions based on feedback from the questionnaire were used in the interviews. Finally, the documents provided by the interviewees and secondary materials available on the companies’ websites were compiled and analysed.

The professionals considered in these interviews are specialised in dealing with management of environmental risks, and are: (i) Environmental, Health and Safety Engineer of Company A; (ii) Environmental Analyst of Company B; and (iii) Environmental, Health and Safety Engineer of Company C.

The data analysis, according to Yin (2001), is concerned with the examination, categorisation, tabulation, testing or recombining of evidence, in order to produce discoveries based on empiricism. This step can be driven by four different techniques: to construct validity, internal validity, external validity and reliability (Yin, 2001). In this study, the technique adopted is the internal validity by means of the adaptation to the standard, where the theoretical references of systematic literature review are used as prognosis and compared with the results of this empirical study, in order to reinforce the validity of the study (Yin, 2001).

The final step of the methodology, sharing, aims to transmit the relevant information of the study through the presentation of the results (Yin, 2001).
Results and Discussion

This section presents the results and discussion of the case studies conducted in the three Brazilian companies. The online questionnaire and the interviews allowed for the evaluation of the environmental risks along the companies and their supply chains.

Firstly, through the online questionnaire and the interviews, it was possible to understand how the environmental risks and consequences were perceived and managed by the companies. Among the environmental risks listed for the interviewees, the ones considered for Company A were: greenhouse gas emissions (GHG) and ozone-depleting substances (ODS); industrial ash and soot emissions; chemicals and toxic effluents released into water or groundwater and oil; inefficient use of water; inefficient use of energy; and explosions, fires, chemical accidents. The most cited consequences that the risks may generate for the company were reputational consequences. Thus, the company realises that the losses go beyond the financial consequences that these risks can cause.

Company B considered the following environmental risks: greenhouse gas emissions (GHG) and ozone-depleting substances (ODS); chemicals and toxic effluents released into water or groundwater and oil; inefficient of raw materials; inefficient use of water; inefficient use of energy; non-compliance with sustainable laws and regulations; and explosions, fires, chemical accidents. For Company B, the most frequent consequence was the reputational consequence. The Company understands that damage to the companies’ reputation can cause it irreversible losses.

Company C considered the environmental risks already mentioned, except the environmental risk related to industrial ash and soot emissions, especially as it is not closely related to its activities. With regards to consequences, those that were most frequent were financial and reputational consequences.

Respondents from Company C added two risks that were not previously included in the list of environmental risks related to the systematic literature review, with these being: inadequate disposal of hazardous solid waste and a risk of loss of biodiversity. These new risks should be added to the SLR list presented in Oliveira et al. (2019), as they may create critical environmental issues. However, the risk of loss of biodiversity is a specific risk related to the activity of Company C, which perhaps will not fit into the list of risks of all company.

Finally, regarding the strategies to deal with the risks, among the strategies identified in the literature, the most frequent strategies cited by the three companies were: wastewater and solid waste management; carbon and water footprint monitoring; efficient consumption of natural resources; substitution, precaution, and reduction in the consumption of chemicals and toxic waste; introduction of carbon emission reduction initiatives and practices (e.g., use of renewable energy, filters, freight consolidation, driver efficiency, etc.; auditing, monitoring suppliers and the use of sustainable criteria for supplier selection, encouraging suppliers and partners to promote a sound environmental policy.

It was observed that the companies have a robust environmental policy to deal with their environmental risks, once they consider most of the strategies identified in the SLR of Oliveira et al. (2019).

Regarding the consequences, the respondents of the companies reported that,
nowadays, organisations are becoming more aware of ecological issues, especially due to stakeholder pressures, legal requirements and environmental regulations. Thus, the companies perceived reputational losses in the same light as financial consequences. Furthermore, it was also concluded from the interviews that all the consequences are closely related since damage to a company's image directly affects the company's profits. The legal consequences are also associated with financial losses since fines and legal penalties minimise the company’s profits.

Environmental risks caused by supplier irresponsibility and their failure to abide by environmental standards are still poorly addressed by the Companies. Only recently have the risks arising from the suppliers become a perceptible topic in the field of supply chain management, as mentioned by Torres-Ruiz and Ravindran (2018). For example, recently Company A has developed voluntary engagement actions of suppliers with a focus on sustainability, requesting them to report their greenhouse gas emissions and water consumption, as well as the risks, opportunities and strategies related to these specific issues.

Company C also pointed out that it seeks to engage with its suppliers, promoting workshops in order to influence and engage them into sustainable management practices. The workshops are also intended to encourage them to participate in the Reforestation Program which seeks to balance the emissions of greenhouse gases generated in their transport processes. Company B also emphasised that it is engaging with its suppliers regarding environmental issues, but did not mention specific actions or programmes adopted.

However, despite the engagement policies mentioned by the Companies, they did not have a well-structured matrix of the environmental risks from the suppliers. Companies A, B and C only audit the contracted service providers for the destination, treatment and transportation of their chemicals effluents and waste. Thus, it is found that the companies do not have well-structured management of environmental risks that exceed the borders of companies (environmental risks of the suppliers). Thus, due diligence, i.e. the co-responsibility and diligence of the counterparties, is a topic that needs to be addressed and further explored.

Conclusion

This paper explored the environmental risks in supply chains. This was accomplished through a multiple case study conducted in three Brazilian companies. From these cases studies, it was possible to identify the environmental risks, consequences, and strategies presented in the companies and its supply chains. The results achieved allow to provide an answer to the research question of this paper. The findings indicate that several environmental risks presented in the literature coincide with the environmental risk considered by the studied companies. However, it is relevant to highlight that although the types of adverse environmental impacts are universal, the risk types should be specified for every individual industrial enterprise (Levner and Ptuskin, 2018). For example, the risk of loss of biodiversity mentioned by Company C may not apply to another company.

The contribution of the present study for researchers was to perform a comparison and validation between the business reality and the academic findings from Oliveira et al. (2019), showing that the environmental risks found in the academic literature are in line with the environmental risks presented in a business environment. From the case studies, we realised that the environmental risks from
the suppliers are still poorly addressed by the companies, as opposed to the environmental internal risks of the companies.

Furthermore, our findings contribute to the supply chain risk management field as this paper introduces the environmental perspective and addresses the consequences that can be felt by the companies and environmental strategies from a practical business environment.

For future research, case studies should also consider different country perspectives to yield interesting insights from other cultures. Moreover, case studies conducted in different economic and climatic regions may result in different perceptions and effects of environmental risks. The region in which the company is located, the exposure to the risk, the intensity of stakeholder pressure and the legal requirements of the region will certainly influence the management of the environmental risks in the supply chain.

Abstract
Sustainability is becoming a key aspect to compete in nowadays fashion market since customers, NGOs and governments are pressuring companies to become more sustainable. Having full knowledge of all actors and activities carried out along the supply chain is therefore becoming an essential factor for the fashion industry to ensure adequate levels of sustainability. In this context this study aims at investigating the issue of supply chain traceability. Secondary sources were analyzed to deepen the adoption of traceability, in particular by analysis the blockchain technologies, along fashion supply chain in order to support sustainability purposes.

Keywords: Sustainability, Traceability, Blockchain, Fashion

Introduction
Sustainability has become more and more a fundamental driver to the competitive success of fashion firms. In recent times, due to environmental and social scandals, as mistreating of animals, application of unequal working and payment conditions to employees, and the creation of eco-unfriendly collections based on polluting industry, we have witnessed the creation of a profound furrow in customers minds, dividing clearly companies which behave in a sustainable way and which are worth to be taken into account, form those which do not.

Literature maintains Supply Chains (SC) in Fashion Industry are tightly chained with the question of contributing to business sustainability (Caniato et al., 2012, Li et al., 2014). Many activities related to the production of fashion products are affected by critical environmental and social issues indeed, as the use of chemical reagents to obtain precise aesthetic features (e.g. tanning activities, Masilamani et al., 2017), or the lack of regulations for employees. Consequently, achieving a high degree of sustainability performances in SC has become strategically crucial for competing in the fashion markets. A review on the issue has showed how scholars evaluate diverse viewpoints on how to pinpoint the right SC strategy to reinforce the responsibility of company towards the environment and society. One of them is enhancing the visibility level along SC by mean
of a traceability system (Macchion et al. 2018; Moretto et al. 2018), to identify the sources of contamination, or defects or critical nodes, or to assure trust among the peers of the SC network (Marucheck et al., 2011), and to make decisions in a consistent manner with the own values.

In this perspective, the digital era has been providing companies with many opportunities offered by technology advancements to be exploited in operations. One example is blockchain technology (Casey & Wong, 2017; Tapscott & Tapscott, 2017), but how it can be practically useful for trace objects and elements along the fashion SCs is still missing in literature.

Based on these gaps, this paper aims at investigating the adoption of traceability practices along fashion supply chain in order to support sustainability objectives. In particular the blockchain will be investigated based on cases of application of this technology within the fashion supply chains.

This goal is tackled through the analysis of secondary sources, specialized in the fashion context, which describe examples of companies that have adopted, or are adopting, blockchain technologies to track their internal processes and supply chain for sustainability objectives.

**Literature review**

**Sustainability in the fashion industry**

The recent environmental and social scandals emerged across the world and the growing pressures by non-governmental organizations (NGOs) have brought under the public spotlight the topic of sustainability as an urgent issue to be addressed (Ageron et al., 2012).

Companies in several industrial contexts, therefore, have become always more sensitive to such challenge and started working on the internal processes and on the products/services they deliver. However, this is not enough, as the public community realized that managing environmental and social issues is not only confined to the boundaries of focal companies, but must be extended to the supply network (Krause et al, 2009) and through the distribution channels as well (Zhu et al., 2005). It follows that companies have now moved to address the emerging issue related to the challenge of sustainable supply chain management, which is defined as “the management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account which are derived from customer and stakeholder requirements” (Seuring and Müller, 2008).

The extension of these virtuous behaviours from focal companies through their supply networks might not be easy to accomplish and could rely on different strategies. For instance, some players, in several industrial contexts, have decided to abolish those current suppliers that are not proactive on sustainability, in favor of new ones more sustainable; in some other cases, the focal companies themselves developed sustainable capabilities to be forcedly extended to suppliers. In some other situations, the focal companies developed green and social capabilities, but in partnership with current suppliers; finally, there are also cases in which companies cooperate with competitors in order to develop sustainable standards and grow sufficient levers to exert such behavior to suppliers (Zhu et al., 2010). Notwithstanding such strategies, the extension of sustainability practices to an entire supply chain represents one of the most complex business challenges of the moment, as the globalization has brought to a fragmented scenario, in which suppliers are dislocated in different parts of the world, below different environmental and social regulations (Sarkis, 2012).

These issues are more than relevant for the fashion industry (de Brito et al., 2008), whose entire business model has been mainly built on the use of fragmented suppliers - often located in low-labour cost countries and where environmental and social regulations are not strict - and on
production processes highly polluting and consuming (Lo et al., 2013). The fashion industry, in fact, is now acknowledged as a business in which there is a high level of pressure on costs and prices, leading several fashion producers, in order to meet such requirements, to offset their workers’ rights and environmental emissions. This has attracted the attention of several NGOs, which have considerably raised their attention to such industrial context, starting numerous initiatives (such as the known Detox Campaign by Greenpeace) which aim is to inform the public opinion about the unpleasant aspects behind this industry.

**Traceability and blockchain in the fashion industry**

Notwithstanding the recent interest by academics on the issue of sustainability in the fashion industry, tracing all the actors in the supply chain still remains a discussion point.

In the fashion market, in which the identification of suppliers collaborating in the production is becoming a weapon of success, giving evidence (and therefore tracing) of the origin of supply chains is assuming a key role. However the development of traceability for the network remains an open challenge due to the difficulty of structuring traceability practices cross national boundaries to identify suppliers located internationally (Macchion et al., 2017).

In structuring traceability systems companies must define tools and mechanisms to transmit information, by focusing not only in their internal processes but on the development of a complete inter-organizational traceability that could align different actors of the supply chains and ensure the data exchange in a standardized way.

The development of traceability practices should be supported by proper tags, labels, barcodes, microchips or RFID, applied directly to each product or batch, but nowadays new tracking technologies are developing in the market thanks to the growing possibilities offered by new digital technologies: the blockchain.

The early blockchain concept was proposed by a developer hiding behind the pseudonym Satoshi Nakamoto, which has been fully validated through the bitcoin system implementations since 2009. Even if the blockchain was born for bitcoin contexts, paradoxically, it could also save the fate of fashion market, that increasingly requires the most complete traceability of garments and production, to guarantee both social and green supply chain sustainability. The blockchain, in fact, allows to check the history of the product along the supply chain, as well as the prevention, or at least the reduction, of the phenomenon of counterfeits, by leaving the final consumer the possibility to verify this information.

As stated by Fu et al. (2018) “The blockchain entries could represent transactions, contracts, assets, identities, or practically anything else that can be digitally expressed using smart devices. New versions of blockchain technology implementation offer support for the implementation of smart contracts encoded in ledger’s blocks, which implements different business rules that need to be verified and agreed upon by all peer nodes from the network. When a transaction arrives, each node updates its state based on the results obtained after running the smart contract. Such replication process offers a great potential for control decentralization”. Based on this structure composed of nodes, it represents a weapon to protect the consumer on one side, and the brand itself on the other side, considering the possibility that some stocks end up in the so-called Gray market (i.e. the parallel sales market outside official circuits of the brand). Moreover, its development could be supported by greater consumer demand for tracked products. According to a recent Pwc report, customers would be willing to pay 5 to 10% more than the list price to buy traced products.

**Research aim and research methodology**

This paper revolves around the role of technology advancements to achieve higher level of sustainability within supply chains, by understanding to which extent they could be catalysts of a progress in the sustainability performance of SCs. In light of this consideration, the following research question is formulated:
RQ: How advanced Digital Technologies, such as Blockchain, might improve SC sustainability?

In pursuance of our aim, for the exploratory nature of the topic under investigation this paper is based on a secondary data qualitative analysis methodology on five different companies. This methodology provides the opportunity to understand complex phenomena in their whole facets by examining companies’ documents and code of conducts, newspaper reports and sustainability and CSR reports available on the company’s website and represents an important source for empirical studies (Harris, 2001). In fact, in order to plan how to select and invest on technologies to address the sustainability journey at a SC level, a profound understanding of all the practices undertaken in the field is needed. Thus, to explore our research question we embraced a supply chain perspective, and we selected five important firms consistent with the following eligibility criteria:

1. The selected company is the focal firm of each SC and is large size brand owner. Hence, it has sufficient levers to structure and influence its entire supply chain;
2. The selected company delivers products at the international level; therefore, the whole supply chain has to be compliant with different national and international sustainability regulations.
3. The selected company must have begun the path of digitalization and sustainability to study sustainability implications due to technological changes over the years.
4. The selected company must publish available information related to their commitment to sustainability and digitalization also in their online site as evidence of their sustainable path.

In order to collect data, we focused on gathering two diverse type of information consistently to the researched field. First, the different digitalization practices and projects to assess and measure the digital maturity of companies, and in particular of their SCs (Plomp, 2010; Schumacher, et al., 2016; Bienhaus and Haddus, 2018). Second, the environmental and social strategies and practices adopted by the companies during the considered years. All the collected practices of digital transformation and sustainability have been catalogued in a spreadsheet and they have been analyzed. The whole analysis has been conducted during the years 2018 and 2019 and information were collected starting from the first implementation of digital transformation and sustainability principles and practices within the supply chains. As specified, the research was conducted on a group of 5 international companies belonging to different SC networks and market segments. The selected firms all belong to the fashion industry; they are positioned in different market segments; they are homogeneous in terms of size (i.e. more than 1bn revenue), brand longstanding existence (i.e. 150 to 50 years); they show a high level of world-class operational and organizational practices; they state to pay attention to sustainability (i.e., mentioned as a competitive priority); and they are at diverse stage in the approach to digital transformation, showing to have conducted explorations on the chance offered by technology to digitalize their SCs.

Moreover, the selected companies are heterogeneous per type of products (i.e., clothes, accessories and jewelry) to cover the variety of products of the fashion industry and per country of origin of the headquarter, to understand the impact of country of origin in the approach to digitalization and sustainability.

The selected companies

- LVMH is a French luxury company founded in 1987 as a result of the merger between Louis Vuitton and Moët Hennessy. Over the years, it has progressed by acquisition, adding to its portfolio more than 60 brands such as Bulgari, Céline, Christian Dior, Givenchy, Loro Piana or Sephora. LVMH group has produced 46.8 bn € revenue in 2018 (+10% on 2017) and it counts 150,000 employees. Besides the fashion industry which amounts to 40% of the revenues, its business comprises also selective retailing, wine, cosmetics, and jewelry. (LVMH, 2019).

LVMH in 2017 has created a blockchain-dedicated team to develop MVP of a blockchain-based traceability system. The platform AURA leverages on Quorum by JP Morgan, an industrial adapted version of Ethereum. Within the network of companies, Louis Vuitton and Parfums Christian Dior have been elected to test the MVP with the purpose to scale-up the solution to the entire company. The strategic idea at the bottom is to co-opt inside this network not just the entire SCs but also the competitors as well. However, the project is still in its infancy and it has not been officially confirmed by LVMH. (Coindesk, 2019)

- De Beers and Alrosa are two leaders of the diamonds industry. Their business owns the entire Supply chain: from the exploration in search mineral deposits, to the mining process, and to the production and B2C selling of jewelry.

Since its foundation in 1888, De Beers has been based in South Africa. Its business spreads toward 35 different countries with a revenue of 6.1bn € in 2016 and more than 20,000 employees. (De Beers, 2019). The Russian Alrosa, founded in 1954, follows De Beers as the second largest player of the sector, with revenues audited around 4.09 bn € in 2018 (300bn Rub) (Alrosa, 2019).

De Beer and Alorsa have joined their forces on the development of a traceability system to combat the illegal diamond trafficking and forgery. From their union rose Tracr, a blockchain system with the purpose of tracking the gems status form the mining process to the customer ownership. Ensuring the quality and the history of a diamond is important also to safeguard the overall value of the market. Indeed, incumbent as De Beer or Alorsa are continuously threatened by innovation in chemistry like the synthetic diamonds, or changes in customers priorities. (Trackr, 2019)

- With 5.5 bn€ revenue divided between more than 110 countries, Levis Strauss is a US global general-purpose clothing producer and seller. Its brand is worldwild recognized mainly for its historical leadership in jeanswear. The origins of the company date back in the 1853’s California, and to date the company comprises more than 15,000 employees. Recently, the firm has signed a partnership with
Harvard University to investigate how blockchain may be used to reinforce the workforce welfare. The project pilot has gained the sponsorship of the U.S. Department of State, and it aims at monitoring the workers’ condition within the entire Supply Chain (Coindesk, 2019).

- Hugo Boss Group is one of the world market leaders in the premium segment of the apparel market that accounts almost 14000 employees and in the fiscal year 2018 it achieved net sales of 2.7 billion euro. The actions of the company are guided by the vision of being the most desirable fashion and lifestyle brand in the premium segment, and by the believes that the desirability of its brands will be the most important factor in the group’s long-term success. Hugo Boss’s management has claimed in diverse occasion to foresee Blockchain as a disruptive technology, which potential need to be explored. In particular, it is currently studying how to leverage on a blockchain-based system to track products along their Supply Chian (SCF Briefing, 2019).

Results and discussion
Thanks to the analysis of secondary data from companies listed above, the potential contribution of visibility and traceability through blockchain for sustainability was hinted.

The term Digital Supply Chain (DSC) refers to the data exchanges between actors involved within a supply chain. As stated by Büyüközkö and Göçer (2018), DSC is about “how supply chain processes are managed with a wide variety of innovative technologies”, as IoT, Big Data Analytics, cloud computing and blockchain itself.

This great volume data shared between actors in a supply chain is increasingly growing and offers a wide range of opportunities for enhancing the chain efficiency and effectiveness, yet creating complexities, uncleanness and issues in data management. Moreover, many supply chains still suffer from lack of integration between parties, many documents are still paper-based, and a lack of visibility on processes is still evident. Businesses are therefore trying to focus on integrating processes and transactions, which generates a huge challenge. According to Santos and Eisenhardt (2005), supply chain integration constitutes a key driver for minimization of network’s governance costs, in particular the costs associated to information exchanges with other actors in the ecosystem. Scholars agrees in recognising that integration between participants in a supply chain builds supply chain efficiency.

The key area in which supply chain digitalization can provide benefits is integration between actors, in complex supply chains.

Blockchain technology can create a support towards supply chain integration. According to Korpela, et al. (2017), blockchain can address DSC limitations thanks to the following features:

- A distributed ledger of transactions replicated to every node of the blockchain network. As already discussed, the distributed ledger is open to all nodes (which may have restrictions depending on the permission level). Transactions create new blocks that are chained to the previous, and everyone who has read permissions can verify the validity of transactions (for instance, the seller can notify the buyer about a transaction, and verify the existence directly from the ledger).
- The possibility to develop smart contracts, for automating business transactions and document exchanges between parties within the supply chain. Smart contracts are
developed on blockchains and can be used to “automate DSC transactions at a very detailed level” (Korpela, et al., 2017). As an instance, smart contracts could enable automated transactions in dependence of pre-determined agreements between parties.

- The use of public key cryptography (PKC), to encrypt and decrypt a transaction. This feature ensures a high security level, as well as sustaining the whole architecture.

As a result, blockchain could enable a quick, reliable and efficient execution of transactions and document exchanges, in a secure way and at low cost (Korpela, et al., 2017).

According to evidences provided by secondary case studies, blockchain adoption in business transactions is not supposed to replace enterprise systems, but to be integrated with them in order to receive and store data in ERP’s relational databases, while leveraging distributed ledgers properties to provide trust and accountability to business processes.

An insight on some benefits that can be achieved by integrating enterprise applications with blockchain is provided by Banerjee (2017).

- ERP store information about purchase, storage, production or shipment of a product. Integrating with blockchain can provide a copy of this information into the network, which is indelible, immutable and trackable at any time.
- ERP generate financial transactions. Integrating with blockchain can make transaction transparent and reliable.
- ERP holds procurement information, like purchase order and purchase agreements. These can be registered in digital formats in a blockchain and made available only to the intended parties through their private key. This would harshly reduce the need for emails or other means of communication.
- Integrating ERP with blockchain can reduce disputes over invoices. From the results of an IBM survey (Guarini, 2016), over 100 million of dollars of invoices worldwide are subject of disputes. According to IBM estimations, blockchain could avoid this kind of disputes in 90-95% of cases.
- Integrating ERP with blockchain can replace Electronic Data Interchange protocols (EDI). Messages can be transferred across members via blockchain nodes, with confidential data stored and accessible with a private key.

Pandey (2019) proposes a framework for implementing blockchain in company’s ERP databases, with the purpose of solving the issue of inconsistencies in data flows. The solution is proposed in the case of two actors (a buyer and a seller), within a generic interaction based on contract, order, payment and delivery. If records are correctly uploaded on a blockchain platform, this becomes a single source of truth, and both actors can access to relevant information in real time. This approach can be followed also at a full supply chain perspective, with more actors involved. In the same way, blockchain provides a ledger where to keep record of all transaction and information exchanges.

Cases have also allowed to identify where blockchain could play a stronger role to increase transparency within companies’ processes and along the supply chain. The main potential benefits are the following:

- **Transparency and auditability**: The distributed ledger is replicated to every active node, capable of communicating with ERPs. The ledger is immutable, and each
member of a transaction channel can have access, read or write according to their permissions. Moreover, auditability is made easy thanks to data integrity: for instance, financial audits are immediate and certain.

- **Transaction processes**: The most important information transactions occurring between actors are automated thanks to smart contracts, making the process smoother, more efficient and less subject to errors.

- **Visibility**: Data about the status of purchase orders are constantly updated, and information is available almost in real time.

- **Trust**: The adoption of smart contracts and of a shared ledger provides the highest possible level of trust between parties. Data are shared and immutable, and each involved party has access to the same version of truth. For this reason, it is expected to reduce disputes on orders or invoices.

- **Multi-party collaboration**: Actors can easily exchange digital information and access to shared data uploaded on blockchain.

- **Document exchange**: Paper flows are replaced with digital data exchanges, which can easily synchronize data that were previously spread across systems. Moreover, documents can be digitally stored in dedicated databases and are fully auditable.

- **Failures identification**: Thanks to the increase in visibility on flows, and the reduction of information asymmetry, detection of issues is easier and faster.

- **Lead time**: Increase in visibility and data sharing efficiency could reduce downtimes due to slow exchanges of information. However, no evidences that time savings are expected to be significant, if compared to the overall process lead time, can be obtained.

- **Cost**: Increase in process efficiency is expected to reduce time required by operators in repetitive tasks, which can be dedicated to more value-adding activities. However, due to the high costs implied by the blockchain service provision, these cost savings are not relevant.

Thanks to the preliminary analysis of secondary case studies, we were also able to link benefits of blockchain listed above with sustainability practices, to understand for which practices blockchain could also become an enabler of sustainability practices.

- Cost

Conclusions and future developments

This paper investigates the topic of traceability for supply chain sustainability, with a main focus on the contribution that blockchain technology could play to foster these benefits. Whether the relevance of sustainability for the fashion industry is well recognized by both practitioners and scholars, companies are still struggling in identifying methods to enable and foster sustainability at the supply chain level. Literature presents visibility and transparency as key drivers to push sustainability, and blockchain technology appears as one of the most promising tools to enhance transparency. Through the analysis of secondary data from leading fashion companies, this paper identifies the main potential benefits of blockchain technology and makes a possible link between these benefits and the main supply chain sustainability practices.

This paper is just a preliminary step of a broader research project, oriented to investigate how blockchain technology could enable the achievement of sustainability in the supply chain. Further steps have the purpose to make direct interviews with selected companies, to triangulate data collected through secondary resources. Moreover, future research aims at assessing the potential contribution of blockchain, selecting cases that already implemented the technology to compare the ex ante and the ex post performance in terms of sustainability and the consequent level of implementation of practices.

Abstract

This paper investigates supply chain strategies empirically, analyzing the adoption of
lean, agile, leagile and traditional SC concerning product characteristics, environmental
uncertainty and business/innovation performance. The exploratory analysis was carried
out based on a sample of 329 companies from Portugal and Brazil. Hierarchical cluster
analysis and ANOVA were conducted and many differences between the clusters were
identified, highlighting that companies with leagile SC present the highest performance,
while those with a traditional SC present the lowest; companies with agile SC compete in
the most complex environments, while those companies with lean SC present a clear
predominance of functional products.

Keywords: Supply chain strategies, Business conditions, Performance

Introduction

Supply chain (SC) strategy has attracted attention from academics in the last years due to
its potential to help companies to improve performance and obtain competitive advantage
(Naylor, Naim, & Berry, 1999; Perez-Franco & Phadnis, 2018; Qi, Boyer, & Zhao, 2009). The
choice of the most appropriate SC strategy is a challenge to managers, as such a
choice needs to consider the various features of companies and their environments
(Fisher, 1997; Lee, 2002).

Previous studies have theoretically and empirically discussed and tested different
patterns of the adoption of SC strategies and the importance of their alignment with a
variety of aspects (Fisher, 1997; Prajogo, Mena, & Nair, 2018; Qrunfleh & Tarafdar,
2014; S.M. Wagner et al., 2012). Product and environmental characteristics are often
viewed as antecedents to SC strategies, as they help to understand the choice of a
particular strategy, while performance can be understood as a consequence of the chosen
strategy (Arora, Arora, & Sivakumar, 2016; Prajogo et al., 2018; Qi et al., 2009). However, the relationship between SC strategies, the nature of the products and performance is not consensual, as some authors have studied different aspects and have found different results (Lo & Power, 2010).

In this sense, the aim of this study is to add to the knowledge about the role of SC strategies within companies by means of an exploratory analysis of their relationship with product characteristics, environmental uncertainty, business performance and innovation performance. Part of the paper is developed as a complement to previous studies, contributing to the generalizability of the previous findings, while assessing the same subjects under different conditions (Goldsby & Autry, 2011). As stated by Goldsby and Autry (2011) and by van Weele and van Raaij (2014), replication of previous studies should be more frequent in SCM research, as it helps to increase the validity, credibility and relevance of theory developed in the field.

Moreover, this study will try to go further by contributing to extending the knowledge regarding the role of SC strategies by including an assessment of the adoption of the different strategies with respect to environmental uncertainty and innovation performance. Thus, the objectives of this study are: (1) to assess/confirm the taxonomy of SC strategies adopted by companies; (2) to assess/confirm the link between product characteristics and SC strategies; (3) to assess the link between environmental uncertainty and SC strategies; (4) to assess/confirm the impact of SC strategies on business performance; and (5) to assess the impact of SC strategies on innovation performance. The following question will be addressed: what differentiates the companies that adopt each type of SC strategy in terms of product characteristics, environmental uncertainty and performance?

This paper contributes to theory, as it analyzes a set of characteristics related to the adoption of the different SC strategies that have not been tested together before; and to practice, as the results may help managers in the challenging task of choosing the most appropriate SC strategy. Resource-based view (RBV) constitutes the theoretical foundation for this paper as it has been applied to supply chain management in recent years (Sjoerdsma & van Weele, 2015) and, according to the RBV, the resources and capabilities of companies are the key sources of sustained competitive advantage (Menguc, Auh, & Yannopoulos, 2014).

**Theoretical background and literature review**

The competitiveness that characterizes today’s business environments leads companies to incorporate strategic SCM in their competitive strategies (Arora et al., 2016; Narasimhan & Narayanan, 2013; Zimmermann, Ferreira, & Moreira, 2016). The choice of an SC strategy is a complex and dynamic process, as the main elements that constitute the nature of the SC, such as product life-cycle, product demand and product variety, can be dynamic as well (Christopher, 2000). Companies have to adapt their strategies and practices constantly to maintain the fit with changing contextual aspects and to obtain higher performance (Perez-Franco & Phadnis, 2018; Prajogo et al., 2018). Thus, the SC strategy adopted must help to overcome the (more or less) volatile environment and influence the competitiveness of companies positively.

To respond to the different requirements of the environments where companies compete, two main approaches are presented and discussed in the literature: increasing efficiency (usually described as a lean or efficient SC) and/or responding quickly to market demands (usually described as an agile or responsive SC). Although each SC strategy demands different and specific requirements, the complexity of the business environment makes the existence of conditions that require purely lean or agile SCs
unusual. Companies adopt different levels of leanness and agility to meet the specific needs of their business conditions (Mason-Jones et al., 2000; Naylor et al., 1999). The combination of the two paradigms is often called leagile (or lean/agile) (Qi et al., 2009). On the other hand, when companies do not emphasize either lean or agile principles, they adopt what is known as a traditional SC strategy (Qi et al., 2009).

Among the most relevant aspects that guide companies to choose the right SC strategies, it is possible to point out a set of characteristics that influence a company’s conditions to compete and perform its business, such as product characteristics (Christopher & Towill, 2002; Fisher, 1997; Qi et al., 2009), supply and demand uncertainty (Lee, 2002), the dynamism and competitiveness of the business environment (Prajogo et al., 2018), technological and marketing turbulence (Arora et al., 2016), supplier management practices (Prajogo et al., 2018), among others. In this study, besides product characteristics, the relationship of environmental uncertainty with SC strategies is analyzed.

Product characteristics is a concept traditionally linked to SC strategies (Fisher, 1997; Qi et al., 2009) as it is one of the main features that has to be considered when defining a strategy. To choose the most suitable SC strategy, companies have to consider characteristics such as product life-cycle length, predictability of demand, product variety and market standards for lead times and services (Fisher, 1997; Qi et al., 2009). Two types of products are considered in this study: functional and innovative, replicating the measures used by Qi et al. (2009).

The second aspect assessed as an antecedent of SC strategies is environmental uncertainty. The definition of environmental uncertainty encompasses the inability, at different levels, to establish the probability of future events and to predict the consequences of the decisions accurately (Sia, Teo, Tan, & Wei, 2004). Environmental uncertainty is adopted in this study according to the model proposed by Aldrich (1979) and Dess and Beard (1984), who classify the concept in three dimensions: environmental munificence, environmental dynamism, and environmental complexity. Environmental munificence refers to the extent to which the environment where companies compete can support sustained growth (Aldrich, 1979). Environmental dynamism is related to the extent that the environment is characterized by changes that are hard to predict and that heighten uncertainty for key organizational members (Aldrich, 1979; Dess & Beard, 1984). Environmental complexity refers to the complexity of the environment, measured by the extent that the environment is characterized by great uncertainty and a great information-processing requirement (Dess & Beard, 1984).

Considering the characteristics of each one of the three dimensions, it is expected that companies which compete in environments with high degrees of dynamism and complexity tend to adopt agile SC characteristics, while companies in an environment with low degrees of dynamism and complexity tend to adopt lean SC characteristics. Environmental munificence, on the other hand, is expected to have a lower level of correlation with the choice of the SC strategy, as munificence can be found in different types of environments, both more or less dynamic and complex (Pan et al., 2018).

The impact of the adoption of SC strategies on business performance and innovation performance is analyzed. Business performance has been used in a great variety of ways (Gonzalez-Benito, 2007; Rauch, Wiklund, Lumpkin, & Frese, 2009). There are several possible dimensions to measure performance, which may differ for business managers and for researchers, and a consensual model does not exist (Franco-Santos et al., 2007). A measure of business performance can be understood as a set of metrics used to quantify both the efficiency and effectiveness of companies’ actions (Franco-Santos et al., 2007; Neely, Gregory, & Platts, 1995).
The performance of innovation is included in this study as a way to contribute to theory and practice, evaluating whether or not SC strategy is related to the performance of innovation and complementing the idea behind the relationship between SC strategies with product characteristics (functional or innovative products), previously evaluated by Qi et al. (2009). Innovation performance is a complex and non-consensual issue. In this study, the concepts of product and process innovation effectiveness are used, following Alegre and Chiva (2008), who based their model on the Oslo Manual (OECD & Eurostat, 2005). Nowadays, many innovation studies use this widely validated scale (Alegre & Chiva, 2013). Figure 1 shows the research model adopted in this study.

Methodology
Data were collected from firms operating in Portugal and Brazil. The questionnaire was developed from a variety of references. The reliability and validity of the instrument was ensured by means of a set of actions, including preliminary interviews with experts, translation and back translation to Portuguese and English and pilot test (Zhao, Flynn and Roth, 2007). The questionnaire was made available in an online platform and an invitation was sent to 1.000 firms and Portugal and 1.000 firms and Brazil, encompassing firms from various sectors. The total number of responses was 329 (179 from Portugal and 150 from Brazil) and the return rate was 16.5% (17.9% in Portugal and 15.0% in Brazil).

Following the guidelines proposed by Craighead, Ketchen Jr. and Dunn (2011), the questionnaire was answered by two respondents in each firm, improving the reliability of the data and minimizing the risk of common-method bias. Nonresponse bias was assessed by contacting a random sample of nonrespondents and examining the differences between early and late respondents – the analyses indicated that nonresponse bias does not appear to be a concern. Secondary data were also used to triangulate survey data, reducing the risk of common-method bias (Montabon, Daugherty, & Chen, 2017).

Hierarchical cluster analysis was used to identify patterns among the firms and define the different groups of SC strategies and one-way analysis of variance (ANOVA) was applied to test the relationship between SC strategies, business conditions and performance.

The main measures used in the exploratory analysis are: SC strategies (Qi et al., 2009), product characteristics (functional and innovative) (Fisher, 1997; Qi et al., 2009), environmental uncertainty (munificence, dynamism and complexity) (Aldrich, 1979; Dess & Beard, 1984), business performance (Gonzalez-Benito, 2007) and innovation performance (Alegre and Chiva, 2013).

Results and discussion
A set of methods was applied to assess the reliability and validity of the constructs. First, exploratory factor analyses were conducted for each construct as proposed by Qi et al. (2009). The first analysis was made according to lean and agile SC characteristics. All the items were maintained as they presented factor loadings greater than 0.5 in the factors they were supposed to measure.
The second factor analysis was made for the items of product characteristics. One item (DC5) was excluded from the final construct, as it presented high cross loadings (higher than 0.4), following the suggestion of Hair, Black, Babin and Anderson, (2010). The next factor analysis assessed the constructs for innovation performance. Three items (DIPS8, DIPS9 and DIPS10) were excluded due to the presence of high cross-loading values (higher than 0.4).

Cronbach’s alpha for SC strategy, business performance and innovation performance were also tested as they help to assess the internal consistency of the constructs (Hair et al., 2010; Peng & Lai, 2012). All the Cronbach’s alpha results are greater than 0.8, suggesting that the constructs have sufficient reliability (Peng & Lai, 2012). Eigenvalues were also analyzed for the constructs. The analysis of the constructs for SC strategy showed that the scale for agile explains 27.0% of the variance (eigenvalue = 3.78/7 items) and the scale for lean explains 25.8% of the variance (eigenvalue = 3.61/7 items). The factor analysis for business performance also resulted in two factors – commercial performance – which explains 34.65% of the variance (eigenvalue = 2.43/4 items) – and economic and productivity performance – which explains 31.98% of the variance (eigenvalue = 2.24/3 items). Innovation performance also presents two factors, where product innovation performance explains 32.1% of the variance (eigenvalue = 4.17/5 items) and process innovation explains 26.2% (eigenvalue = 3.40/7 items). Regarding product characteristics, the scale for innovative products explains 38.1% (eigenvalue = 1.52/2 items) and the scale for functional products explains 26.9% (eigenvalue = 1.08/2 items).

The fit indices of the structural model were also tested, and the results obtained are satisfactory (p < 0.001, IFI = 0.926, TLI = 0.912, CFI = 0.924 and RMSEA = 0.054), providing support for the nomological validity of the structural model hypothesized.

**Adoption of different SC strategies**

Hierarchical cluster analysis (Ward’s method, squared Euclidean distance) was conducted based on the constructs for lean and agile. The analysis of the number of clusters followed the method proposed by Frohlich and Dixon (2001). Lehmann (1979) suggests that the number of observations in each cluster should be between 30 and 60. Considering the size of the sample (N = 329), the number of clusters in this study should be between 5 and 10. However, taking into consideration that the choice of the final number of clusters is subjective, and after analyzing solutions with four and five clusters, the solution with four clusters was chosen as it provided a better understanding of the characteristics of each cluster. Moreover, the solution with four clusters matches with the solutions applied by Qi et al. (2009) and, for that reason, the clusters were named according to this study, where the four clusters are defined as: lean, agile, leagile and traditional.

Next, a one-way analysis of variance was conducted to test for differences in group means. The ANOVA and the Scheffe post hoc tests of mean differences helped to analyze the specificities of each cluster and interpret the results (table 1).

| Table 1 – Analysis of variances of the SC strategies using hierarchical cluster analysis |
|---------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Cluster 1 – Leagile N = 90 | Cluster 2 – Agile N = 40 | Cluster 3 – Traditional N = 74 | Cluster 4 – Lean N = 125 |
| Mean* | SE | Mean* | SE | Mean* | SE | Mean* | SE | F Value |
| Lean SC | 5.55 | (2.3) | 2.95 | (1.3,4) | 4.14 | (1.2,4) | 5.72 | (2.3) | 156.02** |
| Agile SC | 5.39 | (2.3,4) | 5.83 | (1.3,4) | 4.81 | (1.2,4) | 3.71 | (1.2,3) | 308.66** |

SE = standard error; * Based on a seven-point Likert scale; ** p<0,001; Numbers in parentheses indicate the cluster from which this cluster is significantly different at 0.05 level of significance based on the Scheffe pairwise comparison.
The four clusters identified present very well-defined features when analyzing the constructs for SC characteristics, which can be seen by means of the results of Scheffe’s multiple comparison test, which indicates significative differences among the clusters.

As showed in table 1, the companies which are part of the leagile cluster present high means for the characteristics of lean and agile SCs, which means that they demonstrate a balance between leanness and agility in upstream and downstream SCs, according to the environment where they compete (Mason-Jones et al., 2000). Companies in cluster 2 present the highest means for agile SC characteristics among all the groups and the lowest value for lean, meaning that this group clearly prioritize characteristics such as: a quick response to the changing market environment, high capacity buffer and personalized products (Qi et al., 2009). On the other hand, companies in cluster 4 present the highest values for lean, and the lowest values for agile. This group has a clear predominance of practices that focus on predictability and reduction of waste, reducing costs through mass production and providing customers standardized products. Finally, cluster 3 group companies do not present a clear focus on leanness or agility, as they show low levels of both strategies. This group is called traditional SC (Qi et al., 2009).

The characteristics of each cluster were analyzed with respect to demographic characteristics of the companies that are part of each cluster. Two aspects were analyzed: company size and industry sector. Tables 2 and 3 show the results of the analyses.

Regarding the size of the companies, no significative difference was found among the clusters, indicating that the choice of the SC strategy does not depend on this feature. This result is similar to previous studies.

Concerning the industrial sector, some interesting findings can be highlighted. Companies in the food and beverage sector (the most common among the respondents) adopt lean and leagile SC strategies predominantly. Although food and beverage is a highly diverse and heterogeneous sector, the results indicate that part of this group can be

characterized by mass production and relatively low variability. Moreover, more than 50% of the companies in the automotive and parts sector and 45% in the construction and material sector adopt a lean SC strategy, indicating a predominance of this strategy among companies in these sectors, which can be explained by the characteristics of these sectors, especially mass production, when compared with other sectors. Among the companies that adopt an agile SC strategy, it is possible to note the presence of those from the textile and apparel sector, although this sector presents a relative homogeneity regarding the choice of SC strategy.

**Antecedents to the adoption of SC strategies**

One-way analysis of variance was also conducted to analyze the differences between the clusters regarding product characteristics and environmental uncertainty (table 4).

SE = standard error; * Based on a five-point Likert scale; ** p<0.001; *** p<0.01; Numbers in parentheses indicate the cluster from which this cluster is significantly different at 0.05 level of significance based on the Scheffe pairwise comparison.

The results show significant differences among the clusters, especially when it comes to product characteristics and environmental complexity. It is possible to highlight the frequent significant differences between agile and lean. Companies in leagile group have relatively high levels of functional and innovative products. Considering that leagile is a combination of lean and agile and that lean is more related to functional products and agile to innovative products (Fisher, 1997; Wagner, Grosse-Ruyken, & Erhun, 2012), the findings confirm the theory developed in previous studies. The environment where companies in this cluster compete is characterized by high levels of munificence and average levels of complexity and dynamism (well below agile but above lean and traditional strategies). To cope with this relative uncertainty, this group needs to be able to respond quickly to changes, which explains the need for a certain degree of agility.

The results show a predominance of innovative products among the companies in cluster 2. This can be explained by existing theory as an agile strategy is often linked to innovative products (Fisher, 1997; Wagner et al., 2012), and product characteristics can be considered one of the main antecedents to an SC strategy (Qi et al., 2009). Complexity and dynamism characterize the environment of these companies, which helps to explain their choice of this strategy, while munificence is relatively low. Cluster 3 shows a relative balance between functional and innovative products, which may help to explain their apparent lack of focus (Qi et al., 2009). The environment where this group of companies competes is characterized by average munificence and low complexity and dynamism. In cluster 4, there is a clear predominance of functional products, rather than innovative products, confirming the theory that a lean strategy is related to functional products (Fisher, 1997). The environment of this group is characterized by low complexity and dynamism, which helps to understand the cluster’s strategic choice, and relatively high munificence.
Impact of the SC strategies on business performance and innovation performance

The impact of the adoption of the different SC strategies on business performance and innovation performance was also assessed by means of one-way analysis of variance, as presented in table 5.

SE = standard error; * Based on a seven-point Likert scale; ** p<0.001; Numbers in parentheses indicate the cluster from which this cluster is significantly different at 0.05 level of significance based on the Scheffe pairwise comparison.

These results show that companies with a leagile SC strategy achieve the best performance among the clusters in the four parameters analyzed. It can be said that this group is the most well-prepared to face different types of environments, as they are able simultaneously, and depending on, different challenges, to reduce waste and improve efficiency and respond quickly to changes in demand (Qi et al., 2017). Companies with an agile SC strategy present relatively high levels of economic and productivity performance, as well as product and process innovation performance, but a lower level of commercial performance. Companies that follow a lean paradigm presented higher levels of commercial, economic and productivity performance compared to innovation performance. The group of companies that adopt a traditional SC strategy has the lowest levels of performance in all the parameters observed.

Implications and conclusions

The aim of this paper was to discuss and test the antecedents and consequences of the adoption of different SC strategies. The study replicated and confirmed previous studies (especially Qi et al., 2009) in some respects and added to the existing knowledge in others. The hierarchical cluster analyses carried out demonstrated that the four types of SC strategies observed by Qi et al (2009) in Chinese companies are also adopted by the companies analyzed in the Portuguese and Brazilian context. Significant differences among the clusters were found in a variety of aspects.

Product characteristics and environmental uncertainty were analyzed as antecedents of the adoption of SC strategies. The results confirmed previous studies regarding product characteristics, clearly showing that companies with primarily functional products tend to adopt a lean strategy, while those with primarily innovative products adopt an agile strategy. Companies with traditional and leagile SC strategies present both functional and innovative products to a similar degree, although leagile has higher levels of innovative products. These results confirm the model proposed by Qi et al. (2009), contributing to provide validity and credibility to this previously developed theory.

Environmental uncertainty was assessed with a view to adding to the present knowledge about the factors driving the adoption of SC strategies. According to the results, companies that compete in environments characterized by high levels of complexity and dynamism tend to adopt an agile SC strategy, while those in environments with higher munificence adopt leagile and lean strategies. These results help to explain the strategic choices made by companies, along with product characteristics, as the
analysis was able to support and extend the theory regarding the relationship of the
different SC strategies to the different internal and external features of companies,
especially concerning the various aspects of uncertainty.

The results showed that the companies that adopt a leagile SC strategy present better
business performance, contrary to previous studies, especially Qi et al. (2009), who do
not find significant differences among the performance of lean, agile and leagile ones.
Moreover, the group using a leagile strategy also perform better in terms of innovation,
which had not been tested before. According to the results, a traditional SC strategy leads
to the worst results, confirming the results obtained by Qi et al. (2009). The similarity of
the performance between lean and agile, also verified in previous studies confirms the
idea that there is no best SC strategy.

This study makes a theoretical contribution to the literature on the characteristics of
companies with a lean and agile SC strategy and presents a variety of managerial
implications. Companies need to adopt not only the right SC strategies related to their
product characteristics, but also to the variety of features of their environment. The results
can be used to guide managers in the adoption of their SC strategy as it clearly
demonstrates that each strategy fits better with different characteristics of companies and
environments, and produces different results.

Although this study provides interesting findings on the relationship between strategy,
business conditions and performance, the limited sample size and geographical coverage
of the sample means that any generalization of the conclusions should be made cautiously.
Future research using data from different countries could contribute to discussing
similarities and differences among different cultures further, following a logic of
replication, as advocated by Goldsby and Autry (2011). Considering the significative
lower level of commercial performance compared with economic and productivity
performance in all the clusters, future research could use different scales and metrics
(such as primary data) to explore and discuss the reasons and effects of this characteristic.

Abstract

Sales and Operations Planning (S&OP) is an emerging topic, as reflected by the increasing interest of both practitioners and academics. Current studies highlight that many companies are experiencing challenges in implementing and executing S&OP processes successfully. This paper offers a first investigation on the applicability of reference modelling, a concept from the Information Systems community, as a novel approach to address current S&OP challenges. The analysis builds on a systematic literature review and interviews with three executives. The paper identifies benefits and challenges for applying reference modelling to S&OP and offers an overview of existing reference models in S&OP-related areas.

Keywords: S&OP, Reference Model, Information Systems

Introduction

Sales and Operations Planning (S&OP) is a business process, which has the aim to synchronise demand and supply, by connecting different functional areas within a company, and to bridge the strategic business plans with the operational plans of a company (Blackstone, 2010; Thomé et al., 2012). S&OP has become a topic of great importance for academics and practitioners, as indicated by an increasing industrial interest and a growing body of research (Tuomikangas and Kaipia, 2014; Kristensen and Jonsson, 2018). Despite the seemingly simple S&OP process, many companies are
currently experiencing challenges in implementing and executing S&OP processes successfully (Tuomikangas and Kaipia, 2014; Scavarda et al., 2017; Kristensen and Jonsson, 2018). Qi and Ellinger (2017, p. 1320) state that a reason for this is that “the process is not well understood”. Although different aspects of S&OP have been investigated and the literature provides a variety of frameworks, a complete characterisation of the process is still missing (Pedroso et al., 2016). This is associated with a lack of detailed guidance to implement S&OP (Pedroso et al., 2016; Danese et al., 2017). A complete process characterisation could help companies in implementing and designing their S&OP processes.

This paper introduces reference modelling, an approach from the Information Systems community, as a possibility to address this issue. Reference models are information models constructed with the intention to be reused to support the development of company-specific models (Becker et al., 2007). They can serve as an initial point for process implementations, but also as a template for improvements by showing how processes can or should be designed (Fettke and Loos, 2007; Rehse et al., 2017). Reference models have been successfully applied in Operations Management, for example, SCOR in Supply Chain Management (Supply Chain Council, 2012). However, to the best of the authors’ knowledge, a reference model for S&OP does not exist in the literature, and an analysis of the reference modelling approach to address current S&OP challenges has not been carried out yet. Therefore, the purpose of this paper is to conduct a first analysis in this regard. Furthermore, the paper aims to identify existing reference models in S&OP or its related functional areas and to analyse their application potential for the design and support of S&OP processes. Consequently, the following two research questions are investigated:

- **RQ1**: Can the reference modelling approach support S&OP design and implementation challenges and provide complete process characterisation?
- **RQ2**: Which reference models exist in S&OP-related areas and in how far can they be applied to S&OP?

To answer the first question, the authors of this paper conducted three interviews with industry executives, who have a long experience in working with S&OP. Furthermore, to identify reference models and to answer question two, a systematic literature review is conducted. By this, the paper takes an initial step for investigating reference modelling as a potential solution for S&OP challenges.

The paper is structured in the following way: In the next section, the literature background on S&OP and reference models is presented. Afterwards, the methodological approach for the interviews, literature search and reference model classification is explained. This is followed by a presentation and discussion of the findings. The paper finishes with a conclusion in the final section.

**Literature background**

*Sales and Operations Planning*

S&OP is a “cross-functional and integrated tactical planning process within the firm” (Thomé et al., 2012, p. 2). According to the APICS definition, it “brings together all the plans for the business (sales, marketing, development, manufacturing, sourcing, and financial) into one integrated set of plans” (Blackstone 2010, p. 133). S&OP combines horizontal with vertical integration (Tuomikangas and Kaipia, 2014; Kristensen and Jonsson, 2018). While horizontal integration refers to an alignment between different functions within a company as well as across several actors within a supply chain, vertical integration relates to the alignment of objectives and plans throughout the different levels in a company (Kathuria et al., 2007; Thomé et al., 2012; Tuomikangas and Kaipia, 2014).
S&OP usually follows a five-step process that is conducted in a monthly cycle (Wallace and Stahl, 2008), as depicted in figure 1.

Wallace and Stahl (2008) describe the five S&OP steps as follows: (1) Data Gathering, in which files are updated with the most current data and generated information; (2) Demand Planning, in which the sales and marketing department uses the information to generate the demand forecast; (3) Supply Planning, in which the operations department creates a supply plan that is based on the forecast from step three; (4) Pre-Meeting, in which conflicts are addressed and decisions to balance demand and supply are taken; (5) Executive Meeting, in which executives review the results from the previous step and change or verify the S&OP plan. Although the S&OP steps are often described similar to the ones presented in figure 1 (e.g., Lapide, 2004; Ivert et al., 2015; Hulthén et al., 2016), many studies report that how the detailed process is designed and executed depends on several contextual factors like industry, company size, or manufacturing strategy (e.g., Thomé et al., 2012; Ivert et al., 2015; Kaipia et al., 2017; Dreyer et al., 2018; Kristensen and Jonsson, 2018).

Reference modelling
A reference model represents “a special form of information models” (Becker and Schütte, 1997, p. 428), and can be used for the development of other, specific information models (Hars, 1994; Becker and Schütte, 1997; Fettke and Loos, 2007). Reference models can be seen as the result of the construction of a developer, who describes information on universal elements and relationships of a system by means of a formal language and thus creates a point of reference (Schütte, 1998). On the one hand, reference models could lead to “off-the-shelf-applications” (Fettke and Loos, 2007, p. 5) and be applied completely. On the other hand, it is also possible to reuse the reference models only partly, extend them in various aspects, aggregate their different parts, or transfer several of their patterns to analogous situations (vom Brocke, 2007).

Even though a large body of literature has been published on reference modelling, no unanimous definition of the term “reference model” exists (Thomas, 2005; Fettke and Loos, 2007; Rehse et al., 2017). Several authors present different characteristics that reference models should embrace, which are debated in the literature. Reference models should, for example, be reusable to create organisation-specific models and have a certain degree of universal applicability (e.g. Fettke and Loos, 2007). To apply reference models in different, more specific application contexts, Becker et al. (2007) highlight the importance of reference models to be adaptable. Moreover, reference models should provide recommendations for the modeller and can offer examples of actual implementations and best practices (Schütte, 1998; vom Brocke, 2003; Becker et al., 2007).

Several benefits are associated with the use of reference models. They offer a general description of a company (Fettke and Loos, 2007), and can thus foster a common understanding of the modelled objects. For the creation of company-specific models, the reuse of existing knowledge can lead to a decrease in development time and costs (Hars, 1994; Thomas, 2005; Becker et al., 2007). Furthermore, the quality of a model can increase when constructing it based on a reference model (Hars, 1994; Thomas, 2005).
Besides, the risk of failure can be reduced when applying an already proven solution presented in a reference model (Hars, 1994; Fettke and Loos, 2007). An adapted or partly usage of reference models could also yield the described benefits.

**Research methodology**

This paper follows a two-step methodological approach. In the first step, interviews with three S&OP executives were conducted to obtain empirical insights regarding the use of the reference modelling approach for S&OP. The executives were chosen because they have long experience in working with S&OP in different manufacturing industries in Germany and Brazil. The interviews were conducted in a semi-structured form, following the guidelines of Myers and Newman (2007).

In the second step, a systematic literature review was conducted, based on the approach of Tranfield et al. (2003). ScienceDirect was selected as the database and searched with the following keywords: “reference model” AND (“S&OP” OR “sales” OR “operations” OR “marketing” OR “product development” OR “manufacturing” OR “production” OR “sourcing” OR “financial” OR “finance”). The search terms were chosen to represent all functional areas described in the APICS S&OP definition presented in the second section. Moreover, “production” was added as a synonym of “manufacturing” and “finance” as a synonym for “financial”. The term “product development” was chosen instead of “development”, as otherwise, many reference model development techniques appeared in the search, which is not the focus of this paper. For the study selection, two exclusion criteria were defined: (i) studies not presenting a reference model (i.e., only superficially touching the topic); (ii) conference papers that present similar contents, which are later published in a journal. As this paper is not intended to contribute to the debate regarding formal reference model definitions, it is, therefore, referring to a “reference model”, when it is declared as such by the authors of the analysed papers.

The search was conducted in December 2018 and without time restrictions. It returned 517 papers in total, which abstracts were read. After reading the abstracts and applying the exclusion criteria, 44 papers were selected for a full-text review. After the full-text reading, 29 papers remained for the final analysis. To classify the reference models in these publications, the following criteria from the reference model classification methodology by Fettke and Loos (2004) have been adopted: origin, modelling language, construction method, application method, evaluation, and application domain.

**Findings**

The following section firstly presents the findings from the interviews, and the secondly offers the investigation of the studies from the systematic literature review.

**Reference modelling as a potential solution for S&OP challenges**

The interviews with the executives confirmed that companies are often struggling to implement, maintain, and execute successful S&OP processes, and that one reason for this is a lacking homogeneous understanding of the S&OP process. All three executives are not aware of a reference model for S&OP. However, they acknowledged that such a model could potentially provide benefits for the current S&OP challenges, and support the implementation and execution of S&OP processes. Executive 1 highlighted that “a reference model for S&OP could be very useful and add value, as it could help to overcome some challenges and difficulties”. Executive 2 confirmed this view and stated that a reference model could serve as “best practice” for the S&OP application and “could help to make the process more effective and cost-efficient”.

However, despite the potential benefits, all three executives emphasised that they see...
difficulties with the development of a reference model for S&OP, which are mainly related to its context-dependent nature. The executives stressed that, according to their experience, S&OP processes are highly company-specific and that their design can be influenced by many contextual factors. Examples of such factors that were mentioned during the interviews include the industry sector, company structure, type of products, amount of stock keeping units, available information technology (IT), or outsourcing decisions. Additionally, “the state of the S&OP implementation plays an important role”, as indicated by Executive 3.

Even though the interviewees expressed the contingent specificity of S&OP, they believe that the contextual influence depends on the level of detail of the S&OP process. Executive 1 pointed out that “the five core S&OP steps stay the same for different companies, but looking onto the lower level could become a ‘nightmare’, as there will be an extremely high number of contextual variables”. Executive 2 confirmed this by stating that “the question is, how detailed you want to describe the S&OP process. I think you will fast reach a level, where it will be very company specific.” The executives expect S&OP processes to be comparable across different contexts on a higher level, which has been emphasised especially by Executives 1 and 2.

Furthermore, the executives highlighted that solely presenting the S&OP process in a reference model would not be sufficient to describe S&OP completely and address its challenges. Executive 2 often used the expression “S&OP management” in this regard, indicating that a successful implementation embraces more than simply introducing a well-structured business process. All three executives accentuated the importance of people for a functioning S&OP process. Executive 1 stated that “considering the role of people is especially important for S&OP as different stakeholders are working together, who often have conflicting motivations and goals.” To have a functioning process, the different S&OP actors need to have the “competency and understanding” (Executive 3), but also the “commitment” (Executive 1). The communication among each other is vitally important to solving the conflicts, which cannot directly be depicted in a model, as Executive 2 stated. Another factor that is crucial for S&OP is the supporting role of IT, as stressed by the executives. IT can influence the S&OP process in several ways and be an important enabler for a successful S&OP, as it can, for example, increase the forecasting process or make scenario planning possible (Executive 1). Other examples of the positive effects of IT on the S&OP process that were mentioned in the interviews are data management support and the provision of a “communication platform” (Executive 2). Besides describing the process, a complete characterisation of S&OP should, therefore, embrace these two dimensions.

Reference models in S&OP-related areas
The systematic literature review revealed no S&OP reference model. The 29 selected papers present 23 different reference models from S&OP-related areas. Seven of these papers focus on the Supply Chain Operations Reference (SCOR) and are therefore summarised under the term “SCOR” in the following.

The results of the classification according to the criteria of Fettke and Loos (2004) show that the identified reference models are highly diverse in nature. Despite SCOR, all reference models are developed in scientific publications and hence do not have their origin in practice. Only some of the models are developed by applying a modelling language such as flowcharts (Kovacs et al., 1994), Petri Net (Mendéz et al., 2000), IDEF0 (Kalpic and Bernus, 2002), or eEPC (Molina and Medina, 2003). Models in other publications are mainly described textually. Furthermore, only a few authors specify the construction method, by which the reference model is developed. While Gerosa and
Taisch (2009) apply the construction method of Fettke et al. (2005), Kovacs et al. (1994) and Brilhuis-Meijer et al. (2016) develop and apply their own approaches. Kalpic and Bernus (2002) and Zapp et al. (2012) use information gained by companies to construct their reference models and thus develop their model inductively. Other authors develop the reference models in a deductive way based on literature (e.g. Brilhuis-Meijer et al., 2016). Regarding the application method, most authors do not suggest an approach on how to use the reference model for developing company-specific ones. Only SCOR, Eversheim et al. (1997) and Wang et al. (2004) provide concrete suggestions for the application of their model. Moreover, not all of the presented reference models are evaluated. Most of the evaluations are conducted through practical case studies (Mendez et al., 2000; Kalpic and Bernus, 2002; Ng and Jiao, 2004; Oztemel and Tekez, 2009; Brilhuis-Meijer et al., 2016). SCOR is a step further and considered an established reference model that is often applied in practice (Supply Chain Council, 2012).

The identified reference models cover a wide range of application domains, e.g. Supply Chain Management (SCOR; Pereira et al., 2018), product development (Eversheim et al., 1997; Kalpic and Bernus, 2002; Brilhuis-Meijer et al., 2016), or capacity planning (Zapp et al., 2012). Most of the reference models focus on the manufacturing context. However, in terms of goals and concepts, even these reference models are highly diverse. Chalmeta et al. (1997) use an object-oriented perspective to develop a manufacturing system, whereas Macedo (1994) and Oztemel and Tekez (2009) describe the use of artificial intelligence techniques to design a manufacturing system. Kovacs et al. (1994) focus on designing and operating a computer-integrated manufacturing system. Wang et al. (2004) deal with integrating enterprises based on a business logic perspective. Biemans and Vissers (1989) have another focus and describe specific tasks of components in a manufacturing planning and control system.

Most of the identified reference models have a functional-specific intention (e.g. manufacturing or product development) and do not address cross-functional issues between different departments. Three reference models address the synchronisation of the demand and the supply side. SCOR aims to model, analyse, and improve the communication between supply chain partners and the supply chain management activities of a company (Persson, 2011; Supply Chain Council, 2012). Pereira et al. (2018) develop a reference model to handle a demand-supply synchronisation in omnichannel retailing environments, and Zapp et al. (2012) construct a reference model for a collaborative capacity planning between two supply chain partners.

**Discussion**

The statements during the interviews, based on the executives’ practical experiences, reinforce several issues that are currently discussed in the S&OP literature. The mentioned challenges related to S&OP implementations are in line with several studies (e.g., Pedroso et al., 2016; Danese et al., 2017) and emphasise the need for practical support. By highlighting the context-dependent nature of S&OP, the executives confirmed the findings from the literature (Ivert et al., 2015; Kaipia et al., 2017; Dreyer et al., 2018; Kristensen and Jonsson, 2018). Furthermore, the necessity to view S&OP from a more holistic perspective and consider the people and IT together with the process to characterise S&OP corroborates Kristensen and Jonsson (2018, p. 21), who state that one should also consider “the human, technological and organisational (HTO) characteristics, which can ease or hinder the use of S&OP”.

Regarding the application of the reference modelling approach to S&OP, the executives believe that the features of reference models can help to address current S&OP challenges. The potential benefits of a reference model for S&OP, that were highlighted
during the interviews, are in line with the generic benefits described in the literature (Hars, 1994; Thomas, 2005; Becker et al., 2007; Fettke and Loos, 2007). All three executives state that currently no reference model for S&OP exists, which corroborates the systematic literature review results. Also, the identified reference models from S&OP-related areas have limited applicability to S&OP. None of the reference models covers the five steps of the S&OP process described by Wallace and Stahl (2008). Furthermore, most of the models are either too function-specific or have largely operational planning foci. Thus, they do not combine vertical and horizontal integration and match the cross-functional and tactical planning characteristics of S&OP. Most of the authors do not raise the issue of their models being adaptable or applicable to other contexts than the ones for which they were designed. Even those models that address demand and supply synchronisation do not appear to be directly applicable for an S&OP reference model. The SCOR model found in the literature review was also mentioned during the interviews, but it was described as being “too generic to serve as a reference for S&OP” (Executive 1). The model from Pereira et al. (2018) is too specific, with a focus on omnichannel retailing. Zapp et al. (2012) specifically focus on the planning between the automotive and the semiconductor industry and provide recommendations instead of a process model.

Regarding the comparison of the identified reference models, it is important to highlight, that many authors of the papers have a significantly diverging understanding of what a reference model is. This leads to the fact that their developed reference models are highly heterogeneous. While some provide detailed process model (e.g., Kalpic and Bernus, 2002; Brilhuis-Meijer et al., 2016), others only describe more general recommendations verbally (e.g. Gerosa and Taisch, 2009; Zapp et al., 2012). Also, the degree of detail to which the reference models are described varied significantly. While most of the reference models were just described in a few pages (e.g., Macedo, 1994; Méndez et al., 2000), SCOR comes along with an extensive and detailed description (Supply Chain Council, 2012). These differences among the models made their comparison challenging.

Despite the potential benefits of an S&OP reference model, its development appears to be a very challenging task. This has mainly to do with the fact that the design of S&OP processes is highly context-dependent. Even though a model could serve as a reference for different companies at a high level of detail, it would need to be severely adapted to address company-specific needs, which are particularly important on a more detailed level. Executive 1 highlighted that the development of an S&OP reference model would have to be conducted “in close collaboration with practitioners to capture challenges from real-life”, indicating that it would have to be conducted inductively to a large extent. Executive 3 highlighted that especially for S&OP a reference model could and should not be used dogmatically, as it would be very important that the practitioners have the possibility to shape the process according to their specific needs. Furthermore, a process model alone could not capture the essential S&OP dimension as especially the people and IT play a crucial role for S&OP. Therefore, a reference model for S&OP would need to be highly adaptable to different contexts and able to embrace the dimensions of people and IT. Another possibility could be to apply reference modelling as part of a bigger, more flexible solution for S&OP management.

Conclusion

By borrowing the reference modelling approach from the Information Systems community, this paper offers a novel approach to address current S&OP challenges. The paper aimed at investigating if reference modelling can support S&OP design and implementation challenges and provide a complete process characterisation (RQ1), and
identifying existing reference models in S&OP-related areas and examining their applicability to S&OP (RQ2). To address the research questions, firstly, interviews with three executives were conducted, and, secondly, a systematic literature review was carried out.

Concerning RQ1, the executives emphasised that a reference model could help to address the S&OP design and implementation challenges and provide a process characterisation. However, it was highlighted that more dimensions than just the process would need to be considered for a complete S&OP characterisation and management. The role of people and IT are essential factors in this respect. Furthermore, in regards to the importance of contextual factors for the design of S&OP, findings from the literature were reinforced in this study, emphasising that a comparison on a more detailed level of the process appears difficult. Concerning RQ2, an S&OP reference model was not identified, as indicated by the executives and the results of the systematic literature review. Twenty-three reference models from S&OP-related functional areas have been identified and classified according to the methodology of Fettke and Loos (2004). The analysis revealed that none of the reference models can solve the S&OP implementation and design challenges or provide a process characterisation. The three identified models that address demand and supply synchronisation, have either generic (SCOR) or too narrow foci (Pereira et al., 2018; Zapp et al., 2012). The development of a reference model for S&OP is considered to be a beneficial, but highly challenging endeavour, especially due to the context-specific nature of S&OP.

This paper has some limitations and offers directions for future research. For the literature search process, only one database was used. Searching more databases could have led to an identification of further reference models. Furthermore, the search was focused on identifying reference models in S&OP-related areas based on the APICS definition. Keywords such as “integration”, “collaboration”, “coordination” or “alignment” might be promising as well, but were outside the scope of this paper. Analysing the papers identified in the systematic literature review demonstrated the wide variety of interpretation of what a reference model is and what goals it should achieve. Further research should be conducted to develop a common understanding of the term reference model in the investigated areas. Moreover, as only three executives were interviewed for this work, a deeper investigation to validate the findings appears promising for future studies. In spite of the limitations, the insights gained from this paper could be used as a starting point for the development of an S&OP-specific reference model. This would address current research gaps and at the same time be of high practical relevance. As it is challenging to address the context-dependent aspects of S&OP and at the same time embrace the dimensions of people and IT with a reference model, the application of reference modelling as part of a bigger, more flexible solution should be investigated further. The examination to combine other concepts with reference modelling would, therefore, be helpful. Especially the investigation of other approaches from the Information Systems community appears promising, as IT plays an important role for S&OP management.

Balancing Supply and Demand and its Impact on Operational Performance: Evidence from Complex Retail Operations

Abstract

Matching supply and demand is an important aspect of the supply chain management discipline. Yet, there is little research focused on validating the primary claim that improvement of such matching leads to operational performance benefits. This research addresses this lacuna by exploring the impact of the Bullwhip Effect Coefficient (BEC), a proxy of supply and demand matching, on Gross Margin Return on Inventory (GMROI) in the complex setting of cruise ship retail operations. The findings show that in this setting BEC has only a limited effect on GMROI, which can be partially attributed to the complexity of the case organisation.

Keywords: Retail Supply Chain, Bullwhip Effect, Supply Chain Performance

Background

It is widely acknowledged that the concept of Supply Chain Management (SCM) encompasses a network of interrelated entities involved in flows of materials, finance, and information in order to deliver customer value at the optimal network-wide cost (Ellram and Cooper, 2014). However, from its inception in the 1980s it has been emphasised that the balancing function of supply and demand is the key objective of SCM (Oliver and Webber, 1982). Subsequent thinkers have confirmed the importance of this function (Cooper et al., 1997; Christopher and Ryals, 2014).

In order to fulfil this balancing function a number of general ideas have been adopted by management practitioners, such as Lean (Womack et al., 1990), Agile (Nagel and Dove, 1991), and Leagile (Naylor et al., 1999); followed by more specific frameworks, including Virtual Organisations, Six Sigma, and Total Quality Management. These developments were expected to provide the supply chain participants with tangible improvements in terms of operational and organisation wide performance (Tan et al.,
It can be argued, therefore, that a level of matching supply and demand in a supply chain should be directly linked to operational performance (Lee et al., 1997).

**Research Purpose and Setting**

Researchers generally agree that the SCM approach provides an added value for all involved partners, such as suppliers, focal companies, and customers (Lambert and Enz, 2017). These benefits are expected to be manifested in improved operational performance and achieved competitive advantage. Regarding performance the literature discusses both generic metrics such as quality, delivery, cost, and flexibility (Hallgren et al., 2011), and more specific metrics such as fill rate, on-time delivery, and lead time (Beamon, 1999).

In retail organisations it is particularly important to recognise that traded goods are assets which provide the means for those organisations to operate. Traditionally, therefore, the main performance measures in the retail industry include stock turns, return on investment (inventory), and cash-to-cash cycle. It has been acknowledged, however, that there is no single unified set of SCM performance measures which are able to completely assess operational performance (Anand and Grover, 2015).

There is still relatively little research focused specifically on validating the main premise of the SCM concept that balancing supply and demand leads to improved operational performance (Geary et al., 2006). Furthermore, existing studies focus predominantly on settings with relatively stable and predictable patterns of demand and supply, such as manufacturing and retail (Lee et al., 1997; Jin et al., 2015). The research reported in this paper attempts to extend existing knowledge by analysing if there is a link between supply and demand disparity, represented by the bullwhip effect coefficient (BEC), and Gross Margin Return on Inventory (GMROI) in a more complex and dynamic setting – cruise ship retail operations. These two measures have been selected purposely because of their significance for the retail industry (Gaur et al., 2014; Jin et al., 2015). The BEC enables one to measure how strongly supply and demand are matched in any given period of time, and in general it is a result of the quality of supply chain management practice (Lee et al., 1997). GMROI, on the other hand, combines two important aspects of performance, Gross Margin and Average Inventory Investment, and it has been long recognised as an important factor for retail organisations (Sweeney, 1973; Levy et al., 2012).

By analysing if there is a correlation between BEC and GMROI over prolonged period of time we aim to explore how matching of supply with demand affects the performance of a company operating in a dynamic and complex retail setting.

The research follows the principles of the case study approach, which is suitable for in-depth exploration of contemporary phenomena in a real life context (Yin, 2014, chap.1). A retail organisation operating in the cruise ship industry was selected as the case study. The main motivation for selecting this particular firm is that their supply chain has characteristics that make it highly complex and unusual. The case study design is seen as particularly suited to examining unique settings (Eisenhardt and Graebner, 2007; Yin, 2014, p.52).

The uniqueness of the chosen cruise ship retail organisation is manifested in several characteristics. Firstly, the firm is part of a complex supply chain consisting of three distribution centres located on three different continents, over 200 shops located on
board more than 50 sailing ships and selling products sourced from over 600 suppliers. Secondly, the case organisation manages a very wide variety of products ranging from food, cosmetics, and clothing, to jewellery and gifts. Furthermore, the number of unique items sold by the case organisation exceeds 150,000, which is considered significant compared to manufacturing organisations, or even many large land-based retailers. Thirdly, a unique feature of retailing on cruise ships is the requirement to deliver goods in tightly fixed delivery windows, which demands a specific focus on delivery system robustness. It has to be emphasised that failing to deliver goods to a ship in the specified delivery window is likely to result not only in significant commercial losses but also reputational damage. Fourthly, unlike in many other types of businesses, in the case study organisation two critical aspects of the supply chain replenishment system vary significantly, namely lead time and the reordering cycle. This is a result of the fact that the ships are sailing around the world, which means that the delivery ports are changing, and the lengths of voyages are changing. Furthermore, the case study organisation faces other challenges in its management of the supply chain, including uncertainty regarding law and regulations in different parts of the world, fast changing customer profiles, and very limited storage space on board the cruise ships.

**Methodology**

The process of the research consists of three parts: selection of units of analysis, data collection and preparation, and statistical analysis of the data.

For this study ‘product groups’ were selected as the unit of analysis. Each product group consists of two elements: a category and a supplier. This reflects an entity used by the case firm to manage their replenishment processes. The selection of the product groups followed the theoretical sampling approach (Eisenhardt and Graebner, 2007), with particular focus on those product groups that ‘can bring the greatest theoretical return’ to the study (Strauss and Corbin, 1998, p.202). A main criterion used to select the product groups was their contributions to the firm’s revenue. Twenty-one product groups have been selected, with a combined contribution to the company’s revenue in 2014 in excess of 40%. Moreover, the selected product groups contain a wide variety of products such as food, clothing, jewellery, watches, and beauty products.

Numerical data required to calculate the BEC and GMROI for these product groups were collected from the case organisation’s Enterprise Resource Planning (ERP) systems for a four-year period (2012-2015), but for each year separately. These data included ERP records regarding:

- purchase orders
- sales orders
- gross margin
- inventory levels.

The authors adopted a commonly used formula for calculating the bullwhip effect coefficient (Chen and Lee, 2012; Bruccoleri et al., 2014):

\[
BEC = \frac{VO}{VD}
\]
where:
VO - variance of purchase orders
VD - variance of sales orders
These measures have been calculated using standard formula for statistical variance (Field et al., 2012):

\[ s^2 = \frac{\sum (x_i - \bar{x})^2}{n - 1} \]

where:
\( x_i \) - individual observation: for purchase orders it is monthly cost of purchased goods, for sales orders it is monthly cost of sold goods for a specific product group
\( \bar{x} \) - mean of observations: mean of monthly purchase costs, and costs of sold goods respectively
\( n \) - number of observations: twelve per year for each product group

GMROI, on the other hand is calculated using the following formula:

\[ GMROI = \frac{GM}{I} \]

where:
GM - gross margin
I - average inventory at cost

Table 1 shows an extract from the data format used in the study for four product groups. Lower values of BEC indicate better match between supply (purchase orders) and demand (sales orders). Even in this short extract it can be observed that there is substantial variability of this measure. For example, for Cigarettes - V01977 in 2012 the BEC value was 17.1 (poor match), dropping to 1.8 (good match) in 2014. Even greater discrepancies can be observed between product groups, with highest for Accessories - V02046, and lowest for Cigarettes - V01977. GMROI values also vary on yearly basis within product group, and although the differences might not look large they have significant effect on profitability. However, much greater dispersion can be observed between product groups, for example, for Accessories - V00727 GMROI ranged from 1.45 to 1.98, whereas for Cigarettes - V01977 its values were higher and achieved between 4.99 to 6.97.
Based on the BEC and GMROI data and using R Language software (R Core Team, 2019) to conduct correlation analysis, the strength of association between the supply-demand matching (bullwhip effect coefficient), and operational performance (GMROI) was examined.

**Findings**

The results of the correlation analysis are presented in the scatter plot shown in Figure 1, where each point represents a product group in each year. There are 83 points, because 1 outlier due to an error in the ERP data has been removed from the analysis.

</tr>
</tbody>
</table>

From Table 2 it can be seen that the product groups with a GMROI above 5.0 belong to categories that traditionally are associated with a high profit margin. Furthermore, these products were delivered by one vendor (V01977) and they achieved low BEC scores, which indicate a relatively close match between supply and demand.

On the other hand, there are a number of product groups where BEC scores are quite high, even exceeding 60 (Table 3).

<table>
<thead>

<td>1.71</td>
</tr>
<tr>
<td>Fashion Watches - V01165</td>
<td>2015</td>
<td>66.8</td>
<td>1.19</td>
</tr>
</tbody>
</table>

Most of the product groups with high BEC scores are what Fisher (1997) described as ‘innovative products’, which are inherently affected by high variability of demand. Furthermore, almost all of these product groups (with exception of Fashion Watches - V00621) are sourced from overseas, mainly from the US or China with long delivery lead times. Therefore matching supply and demand for those products is likely to be more challenging.

The scatter plot (Figure 1) also shows an inverse linear relationship between the BEC and GMROI. However the slope of the regression line is rather shallow, which indicates only a moderate negative correlation. Further statistical analysis of the correlation between BEC and GMROI was conducted using R Language software (R Core Team, 2019) to determine the precise strength between these variables and the statistical significance of the results. The outputs of the analysis are presented below in Table 4 (R Language code is included in the Appendix).
Table 4 Pearson's product-moment correlation

</tbody>
</table>

The low p-value (0.002873) reported in Table 4 indicates that the analysis is statistically significant - below the level of 0.05 recommended for social science studies (Silver, 1997, p.100). The correlation coefficient value -0.323282 confirms our interpretation of the scatter plot and regression line, that the negative relationship between the BEC and GMROI is only moderate for the product groups analysed (Field et al., 2012). These results suggest that although improvements in operational performance can be achieved by matching supply and demand more closely, these improvements may not be significant in complex supply chain settings like that examined in this study.

**Conclusion and Limitations**

This research provides new insights into an important aspect of the supply chain management concept of the relationship between supply and demand matching and operational performance, measured in this study by the BEC and GMROI respectively. The correlation analysis undertaken in this study allowed us to draw the conclusion that there is a statistically significant link between these two variables, but that the strength of this link is only moderate in the case study organisation. We suggest that these results can be explained to some extent by the complex and highly dynamic characteristics of cruise ship retail operations, such as rigid delivery windows, variable lead times and replenishment cycles, changeable customer profiles, limited storage space.

Fixed delivery windows demand from the organisation to deliver goods to ships on specific days, which from one side requires robust distribution and from the other reliable supply process. Although the company operates dependable delivery system the supplier base varies in their delivery quality, which in turn negatively impact stock availability and its level, further affecting both BEC and GMROI measures. Variable lead times and replenishment cycles are unique to the cruise industry. In addition to experiencing difficulties with forecasting and planning inventory levels and demand, there are also challenges with short term replenishment especially for products with long lead times, resulting with stock-outs and overstocks. Unlike other ‘land’ retailers, where customers base is rather consistent, in the case of cruise ship industry there is greater variability of customer profiles, which is further reinforced by increasingly frequent price discounts and promotions offered by cruise liners, which disturbs the regular pool of passengers from a demographic perspective. As a result, cruise ship retailers have greater difficulties with planning their offerings and providing sufficient level of stock. Finally, an important aspect of retail operations is a storage space in shops, which should allow to temporarily warehouse stock for which there is no sufficient space on shelves. In the cruise industry the main focus is on providing
passengers with primary services such as accommodation, entertainment and retail experience. Other spaces, including storage backrooms are limited to minimum, which inevitably affects stock availability, especially of products with high demand variability, causing stock shortages. There are several other challenges the retail operations of the cruise ship industry face, however those listed above significantly affect both BEC and GMROI measures.

We argue that the scope to generalise our findings to other less complex and dynamic supply chain settings is likely to be limited therefore. More empirical research comparing the relationship between supply and demand matching and operational performance in different kinds of supply chain settings is needed, however, to evaluate this argument.

Early supplier involvement in the automotive industry: 
a study from the supplier perspective

Abstract

Product Development (PD) is a critical process in the automotive industry. The Supply Chain Management (SCM) practice of Early Supplier Involvement (ESI) may provide a competitive advantage for the sector, but to obtain its benefits it is necessary to meet prerequisites and overcome challenges. This article seeks to understand, through a case study, how the ESI is conducted from the perspective of a Brazilian auto parts supplier. Results indicate that the benefits from ESI are beneath its potential, application of SCM and PD practices is still incipient and there is a gap in ESI theory concerning to the supplier's perspective.

Keywords: Early Supplier Involvement, Supply Chain Management, Automotive Industry

Introduction

Product development has become a critical process within Supply Chain Management, especially in the automotive industry, which carries a high degree of complexity and usually involves a significant diversity of materials and technologies. For such, the involvement of key suppliers in the early stages of the product development process, by the practice of ESI, can promote reduction of development time, quality improvements, and innovations into the products and the production processes, as well as can leverage costs and time-to-market reductions to the entire supply chain, by incorporating into the project the knowledge and skills of suppliers. Therefore, the ESI can strengthen the integration between company members of the supply chain. However, in order to properly carry out the development process and to effectively obtain the benefits of ESI, it is necessary to meet a series of prerequisites, such as technological capability, open communication, management structure and performance measurement systems of the companies involved. Additionally, the challenges encountered in the process must be overcome, such as lack of trust between the companies, unawareness of the advantages of ESI and lack of sharing of gains from its implementation. In this context, an extensive review on the ESI literature showed that the vast majority of reported studies was conducted from the perspective of the customer companies and that the implementation and management of ESI analysed from the perspective of suppliers is still an incipient
subject in the literature. Therefore, this article reports on an empirical research carried out in a supply chain of the Brazilian automotive industry, conducted from the perspective of a supplier of casting aluminium components for engines and automotive transmissions, and that had as main purpose to investigate how the practice of ESI has been conducted from the perspective of this supplier company.

Supply Chain Management
According to Pires (2009), a supply chain (SC) can be understood as a set of interlinked organizations. From the standpoint of a focal company within the supply chain, organizations located upstream are the direct suppliers, also known as tier-1 suppliers, and sub-suppliers (tier 2, tier 3, etc.). The companies downstream are the customers, the dealers and the final consumer.

The Council of Supply Chain Management Professionals (CSCMP, 2015) considers the SCM as a model that integrates key functions and business processes along the supply chain, seeking high performance of the supply chain and its members. Lambert & Schwietertman (2012) identified eight business processes in SCM: (1) Customer Relationship Management; (2) Supplier Relationship Management; (3) Customer Service Management; (4) Demand Management; (5) Order Fulfilment; (6) Manufacturing Flow Management; (7) Product Development and Commercialization and (8) Returns Management. Each of these processes is divided into strategic and operational sub-processes that relate to the other processes, involving cross-functional teams with representatives from the areas of sales & marketing, purchasing, logistics, operations, product design, finance and information technology, as well as customers and suppliers (Rogers, Lambert, & Knemeyer, 2004).

Pires (2009) states that the effective implementation of Supply Chain Management (SCM) involves the development of initiatives and managerial practices, such as: restructuring and consolidation of supply chains; suppliers development; planning and collaborative management, including electronic data interchange (EDI), efficient consumer response (ECR), vendor managed inventory (VMI), continuous replenishment (CR), collaborative planning, forecasting and replenishment (CPFR); outsourcing; in-plant representatives; postponement; and early supplier involvement (ESI).

Product Development Process
The Product Development (PD) process is critical for the SCM effectiveness (Matos, Pires, & Vivaldini, 2014) and may provide sustainable competitive advantage for organizations, since the reduction of time-to-market is a key element to the success in innovation and product profitability. PD requires a multidisciplinary approach and integration with customers and suppliers as well as the increasing integration of services and products, a practice currently used as a way of adding value to the product and a valuable source of market differentiation (Rogers, Lambert, & Knemeyer, 2004). Like other SCM processes, PD consists of strategic and operational sub-processes, which relate to the other processes and are developed by multifunctional teams, including managers from the areas of product engineering, research and development, marketing, finance, purchasing, logistics, and representatives of customers and suppliers, which permits the alignment of objectives across the different functions involved in the process (Tsai, Fang, & Hsu, 2012).

The PD in the automotive industry is part of a strategic effort to enhance the SCM performance through the establishment of best management practices (AIAG, 2012). The instrumentalization of the PD process occurs mainly through the application of product quality planning methodologies, especially the Advanced Product Quality Planning
(APQP), which involves the various levels of the supply chain and starts even before the formal closing of the purchase order. One of the APQP premises is concurrent engineering, which is a process carried out by cross-functional teams of supplier, customer and sub suppliers, who must work together in order to develop quality products in the shortest time possible. In concurrent engineering design phases overlap over time, rather than being performed sequentially. The APQP is aligned with the concepts and practices of SCM, especially the ESI, since it advocates the involvement of supply chain members in the PD process and considers not only aspects of product design, but also the production process and logistics issues (AIAG, 2008).

**Early Supplier Involvement**

The PD process requires the integration of an internal development team with other members of the supply chain (Rogers, Lambert, & Knemeyer, 2004). ESI is a practice of SCM that suggests the involvement of the supplier with the customer since the early stages of PD so that supplier’s skills are incorporated into the project with the goal of developing higher-quality and lower-cost products more quickly (Pires, 2009). ESI is also aligned with the principles of lean manufacturing, as both aim to reduce waste, risk, cost, and time-to-market (Forno, Forcellini, & Bornia, 2013).

In order to be successful, the ESI program must be structured to integrate tactical and strategic operational factors. Dowlatshahi (1998) proposed a conceptual framework to support the implementation of the ESI that includes four blocks: (1) Design, that recommends the participation, beyond the project area, of other areas and functions of the company and of the suppliers in the definition of critical project tasks. (2) Procurement, where the role of the purchasing area should not be restricted to be a mere facilitator in the implementation of the ESI. Purchasing should also be involved in product design so that their concerns are considered in the product development process. (3) Suppliers, since the development of a long-term strategic relationship between the organization and the supplier enables the achievement of mutual gains. (4) Manufacturing, to ensure that the products can be easily manufacturable.

The degree of involvement of each supplier in the PD depends on a series of factors, among which stand out the degree of responsibility of the supplier in the project and the degree of risk involved. The interaction between customer and supplier in the development phase is a function of the risk and responsibility of the supplier in the project (Calvi, Le Dain, Harbi, & Bonotto, 2001). The interaction may be classified as black box, when the product project has integral responsibility of the supplier and is divided into two involvement types: (1) global development based on specifications, when the supplier has technical knowledge and autonomy to integrally develop the product based on the required performance expected by the customer; (2) strategic co-development, a critical situation that requires greater interaction between customer and supplier, as in the case of systems and modules manufacturers. In the gray box involvement, also called (3) critical co-development, neither the customer nor the supplier has the total knowledge required and demands strong interaction between the customer and the supplier, which share responsibility for the project. In the white box involvement, the supplier follows the customer specifications and also is divided into two types of involvement: (4) classical subcontracting based on technical specifications, where the suppliers role is limited on defining the productive and logistic processes necessary to meet specifications at the lowest possible cost and (5) coordinated development based on technical specifications, where the product design is responsibility of the customer that has a strong influence and controls the development process. In this case the supplier must absorb the project changes during the development (Pires, 2009).
After the establishment of ESI management structure and determination of the degree of supplier involvement in the project, the implementation phase of ESI begins, when the effective integration of the supplier to the project occurs. If the program prerequisites are met and the challenges overcome, the expected benefits of the practice are then obtained. The interaction between customer and supplier in PD can occur in different phases of the project, and it is a function of several factors, among which the degree of responsibility and autonomy of the supplier on the project and the degree risk involved in the project (Petersen, Handfield, & Ragatz, 2008).

In medium or high complexity products, the benefits of ESI tend to be greater when the integration of the supplier occurs at the beginning of the project. The leverage effect of investments on profits is due to the fact that design changes are generally more costly and complex when investments are made closer to the beginning of the mass production (Eisto et al., 2010).

Although the benefits of ESI practice have been widely documented through qualitative and quantitative studies, a successful ESI implementation depends on a number of prerequisites, without which the expected benefits will not be fully achieved, what makes the application of ESI to be below its potential. This gap is due, among others factors, to the difficulties and challenges found in the implementation. The main benefits, prerequisites and challenges in ESI implementation are shown in Figure 1.

Figure 1 – Benefits, Prerequisites and Challenges in ESI Implementation (Source: Authors)

These benefits, prerequisites and challenges in ESI implementation were identified after an extensive review of ESI literature, summarized in Table 1, that includes the authors consulted, the classification of the articles analysed regarding the perspective adopted (customer or supplier) and the research method (qualitative or quantitative). Concerning the research methods, there is a balance between qualitative and quantitative studies. Most of the studies are conducted from the customer's perspective and studies that consider the ESI from the supplier's perspective are still uncommon.
Among the evaluated publications, a representative case stands out (Eisto et al., 2010). The case deals with the ESI practice in casting customers and suppliers – as is the business focus of this research – proposes a framework for ESI implementation and considers the supplier's perspective in more depth than the other works consulted.

**Methodology**

The research was conducted through the in-depth unique case study using a multi-tier approach within the supply chain, what allows the researcher to capture more fully the context in which the phenomenon under study occurs (Yin, 2010). Nowadays there is a growing trend to use qualitative methods in operations management studies due to its contribution to the development of the theory and construction of knowledge, because these methods examine concepts in terms of its meaning and interpretation in specific
contexts of research (Barratt, Choi, & Li, 2011) and beginning from the confrontation of theoretical propositions with the idiosyncrasies of the analysed case, there may be theoretical implications that contribute to the creation of knowledge in the chosen field of study (Ketokivi & Choi, 2014; Siggekow, 2007). One of the main aspects that make the case chosen unique is the fact that the focal company is a manufacturer of aluminium castings for the automotive industry, what requires a high-quality level and technical knowledge of casting process that few companies worldwide currently have, making the company a strategic supplier to its customers. Besides the focal company, its three main customers (which together account for about 90% of its revenues) and its three main suppliers were also investigated, as shown in Figure 2.

Data were collected through interviews with key executives involved in SCM, PD and ESI in the focal company. To guide the case study a semi-structured questionnaire was developed, covering issues related to SCM, PD and ESI in the investigated companies and for the data assessment were established, based on the literature review, twelve variables divided into three categories of analysis: benefits, prerequisites and challenges of ESI. The empirical data collected in the interviews were complemented with visits to the company’s facilities and the company’s documentation available were gathered and analyzed. Moreover, in order to increase reliability, transparency and replicability of the case study, a research protocol was previously established.

Case Study
The case study was conducted in a Brazilian medium-sized company, supplier of components for the automotive industry, its three main customers and three suppliers involved in PD process, whose main characteristics are shown in Table 2.

Most of the products produced by the focal company can be classified as gray box and the projects are customer responsibility, but with the growing participation of the focal company, consulted to ensure product manufacturability, since the increased use of aluminium in vehicles is a global trend, due to its low density, high strength and virtually unlimited recycling. The tooling is customer property, as usual in the automotive industry, what introduces an important variable to the process, because the supplier should be transparent to the customer, but also protect its know-how. The PD process is based on APQP manual and closely monitored by the customer. The project is developed by a cross-functional team with members from Project, Process Engineering, Tooling, Manufacturing and Quality areas. The design and construction of the casting tooling are considered critical activities to the success of the project and consume most of the time and program resources, having a major impact on product quality and productivity. The Engineering area develops the projects of the moulds using technological tools in line
with global best practices, such as CAD, CAE and CAM systems. Engineering simulations using CAE system are outsourced.

The results from the interviews and documentation review in focal company related to SCM indicate a number of important gaps in the management system, which does not meet fully and consistently the requirements of the SCM processes, and the main gaps are in the processes of supplier relationship management, demand management and product development and commercialization. Regarding the SCM practices, none of them are fully implemented in the company or its suppliers and has not even been considered in a systemic way in the development of internal processes of the company. The practices that were found in the company were implemented by imposition of customers.

The results of the PD process indicate a high degree of compliance with the requirements of the sector, particularly with APQP process, but still with gaps in the processes of generation and selection of ideas, design and prototyping, decision make-or-buy, performance indicators system, implementation of concurrent engineering with participation of suppliers and treatment of logistical issues. A positive point is the intensive use and exchange of electronic data, especially CAD, CAE and CAM.

The results of ESI practice also indicate several important gaps. The development time, one of the main benefits of ESI, had no significant gains in last developments, due to the late involvement of the company on the projects and to the customer’s resistance to design modifications suggested by suppliers. The reduction of costs and improvement of product quality can be considered together as they are due to the same factors, like geometry or materials changes of the product that allow gains by reducing failure rates and increasing productivity. Implementation of changes to the product are more difficult when they occur later in development, because once a product concept has been approved, changes require new validation, which can be extremely time consuming and costly. No product innovations were identified, but an innovation in PD process was observed in one project, that is the stress simulations made by the customers in parallel with the simulation of casting process by focal company. Strengthening the customer-supplier relationship is also positively affected by the practice of ESI, but it is necessary to the company to be represented by technically trained staff, with negotiation skills and decision-making power sufficient to respond to the project and the customer's demands.

The prerequisites to ESI were also investigated. In the current environment of the automobile industry the intensive use of technology is an imperative for product
development, with major impact to its success. The exchange of electronic data between supply chain members shortens the process and reduces the amount of errors and design changes. The technological capability is not restricted to the availability of systems such as CAD, CAE and CAM, and requires the necessity of trained professionals and the continuous monitoring of technology trends to identify opportunities and risks resulting from rapid technology obsolescence. New trends, such as rapid prototyping and 3D printing, have potential to quickly and dramatically change PD process. Communication plays a central role in ESI and the focal company has established a cooperative communication with its customers and suppliers. The main deficiency of the process is the little emphasis on strategic and commercial issues, staying focused on technical issues. As the management system of the focal company is not structured to the practice of ESI, significant shortcomings were found. APQP procedure includes simultaneous engineering, but does not establish criteria for development risks analysis, or to determine the degree of involvement of suppliers, nor to seek a proactive participation in product design phase. The performance measurement system is insipient and current indicators do not measure the impact of ESI on the results of developments. It is noteworthy that neither the literature of PD establishes suitable indicators for ESI.

Finally, the challenges in ESI implementation are presented. As customers do not establish any formal contract with suppliers that provides a minimum of certainty of return for supplier participation in the project, the business confidence level is low, what reduces the supplier willingness to share the expertise with customers. However, the focal company often takes the risk to participate without guarantees, because their participation increases the chances of winning the purchase order. The awareness of ESI benefits is widespread in the supply chains of the automotive industry, but only in relation to its potential benefits. The lack of clarity about the prerequisites and implementation challenges is one of the factors that make it difficult to obtain the desired benefits, because the process complexity requires a structured approach, including support from higher hierarchical levels, so that they can overcome the barriers and difficulties inherent in the process. The lack of sharing of gains is another feature clearly identified in the research. As the customers' PD process is structured considering the traditional method of sequential development, where engineering area designs the product and purchasing area selects the supplier based on final product specifications and quality requirements, logistics and price, the ESI is not included in the procedures and purchase contracts, so the sharing of gains with suppliers of gains from ESI practice is not considered. On the other hand, the focal company also has a passive attitude and does not include the issue of sharing of gains or development cost recovery in negotiations with customers in cases of application of ESI.

**Final Remarks**

Within the scope of the SCM the results show that the supplier relationship management processes conducted by the focal company are relatively undeveloped, presenting several opportunities for improvements, and the definition of its supplier base is carried out based mainly on assessments of the quality and the production processes systems. Regarding the PD process, the focal company practically does not have a formal framework to develop proactively products on its own initiative. The company develops products only when it is triggered by a customer company and it does not have even a structure for the development of prototypes, which is becoming a supplier’s qualifying criteria in the sector. Somehow, this seems paradoxical because the focal company has a recognized expertise in auto parts of casting aluminium, whose global demand has grown significantly during the last years, especially due to the processes of engines downsizing.
Regarding the practice of ESI, despite being increasingly applied in the PD of the focal company, it is still performed in an unstructured and passive form, i.e., always seeking to meet customer needs. Also, when carried out, the focal company does not usually have a contract that guarantees that it will be later the supplier of the component to the customer company, and it has no guarantee that its expenses will be reimbursed if it does not become the component supplier. This makes the ESI practice a "risky operation" to the focal company, but the company considers it would be worse nowadays if it does not get involved in ESI of its major customers. The creation of opportunities for developing new business and of a privileged channel of communication with the customer companies are the two main reasons identified for such procedure. Another remarkable point is that there is no formal, or even informal, compromise (between the focal and customer companies) concerning the sharing of benefits arising from the ESI implementation, and they mostly stay with the customer companies. To the focal company usually is only possible to obtain gains in technological development and reduction of production costs arising from the better manufacturability of developed components. Another noteworthy fact identified is that, from the perspective of the focal company, the ESI tends to be more easily implemented and managed in the case of customers who are "systemists" (key first tier suppliers), than the case of customers who are automakers.

The results indicate mainly that the benefits arising from the application of ESI for the focal company, its customers and suppliers are below the potential of the practice, which are due to not fully meet the prerequisites and the difficulties to overcome the challenges of its implementation. Furthermore, the research found and sought to contribute to fill a significant gap in the literature about ESI, which deals with the practice predominantly from the customer's perspective, with little consideration from the supplier's perspective, as would be required for the development of a truly and win-win collaborative practice as it has been contended in the basic tenets of SCM.

Abstract

One hypothesis identified as cause for the traditional automotive companies to become unable to compete with new incoming assemblers is an inefficient supply chain. This paper aims to crosscheck the supply chain structure of the traditional automotive industry installed in Brazil with South Korean and Chinese supply chains. Based on strategic decision making and transaction cost theory, this comparison exploits the factors that lead to the inefficiency of traditional automotive supply chains. It was used a multi-method research, leading to the proposition that automakers recently installed have lower transaction costs than traditional ones due to their vertical supply chain structure.

Keywords: Supply chain management, Supply network design, Operations strategy

Introduction

The automotive industry is very strong in the Brazilian economy: it represents 23 per cent of industrial GDP and 5 per cent of total GDP (Anfavea, 2015). Brazil is the fourth largest market and the seventh largest manufacturer in the world, with 31 automakers installed, 64 industrial plants, more than 500 direct automotive parts (first tier of the supply chain), 5,533 resellers spread throughout Brazil, involving almost 200 thousand companies directly or indirectly linked with the automotive supply chain. This industry contributes to the national economy by generating around 1.5 million direct and indirect jobs; tax collection of approximately US$58 billion; and annual revenues of roughly US$110.9 billion (Anfavea, 2015).

There are some hypotheses that may explain the inability of the Brazilian automotive sector to compete with imported or newly locally produced vehicles, such as outdated product technology; delayed manufacturing technology; inefficient supply chain; low skilled labor in the development of high technology products and processes (Agénor, Canuto, & Jelenic, 2012; Eichengreen, Park, & Shin, 2011; Felipe, Arnelyn, & Utsav, 2012).
This research aims to explore one of the hypotheses listed above: supply chain inefficiency is a cause for the low competitiveness of the domestic automotive industry. Supply chain is a set of companies that continuously relate to the goal of delivering products or services to the consumer market (Lambert, Stock & Ellram, 1998). The focus company considered in this research is the automaker. Direct suppliers are called Tier 1, and suppliers of automakers’ suppliers are called Tier 2.

Starting in the 1970s, the automakers installed in Brazil started a vertical disintegration movement stimulated by the need to reduce production costs, made necessary to face the Japanese model (Vanalle & Salles, 2011). As a result, there was an increase in suppliers in the supply chain, replacing domestic production, which reduced production costs, but increased the incidence of transaction costs. The South Korean and Chinese automobile factories recently deployed in Brazil present a different arrangement of the supply chain, with a strong verticalization. These new incoming assemblers took over the development and production of the main parts, outsourcing some of them to suppliers that they have stock control or shareholding.

Given this context, in which there are different supply chain arrangements with different results, the question that we intend to answer herein is: What are the factors that differentiate the structure and management of the supply chain of the national automotive industry from countries such as South Korea and China?

The objective is to evaluate the impact of the supply chain structure of the national automotive industry on its competitiveness, crosschecking it with supply chains of other two countries that have stood out in the automotive industry over the past decade, South Korea and China. This comparison allows to highlight the similarities and differences that can contribute to the understanding of the problem, and thereby redirect the long-term competitiveness of the national industry. The research is based on supply chain, strategic decision making, and transaction cost theory literatures. A multi-method methodology based on a qualitative approach is used.

The next sections detail the theory and methodology used, to finally present the results and conclusions of the research.

**Literature Review**

Supply chain management as an integrated discipline gained force in the 1980s, mainly due to the successful implementation of the lean program developed by Toyota (Holweg, 2007). At that time, Toyota and Honda outsourced about 80% of the value of the cars they produced, using collaborative relationships with few suppliers for each automotive part, while US automakers outsourced only about 30%, denoting a high vertical integration (Corrêa, 2010). The American automakers followed the original model of the automotive industry, based on an intense verticalization. This example shows how the supply chain arrangements can be different within a single industry.

In this research, we will emphasize the decision of the supply chain arrangement using strategic decision making and transaction cost theory.

**Strategic decision-making**

The boundaries of a company are a long-term strategic commitment, which has consequences in its performance (Novak & Stern, 2008). The decision about the organizational boundaries can be divided into making internally (vertical integration) or buying in the market (outsourcing or horizontal integration). To make or to buy a determined product or service is not only an economic decision based on the best cost; it is a strategic decision for the company (Prahalad & Hamel, 1990; Quinn & Hilmer, 1994).
There is a diversity of research that explores the nuances and consequences of vertical integration and outsourcing (Nickerson & Silverman, 2003; Baker & Hubbard, 2004; David & Han, 2004) with different points of view. Some companies consider outsourcing a critical element of their strategy (Holcomb & Hitt, 2007), since outsourcing can be a way to reduce costs and improve performance, leaving the activity in the hands of experts (Gilbert, Xia and Yu, 2006). However, outsourcing should always be viewed from a strategic perspective. The eagerness to reduce costs can lead to the loss of company skills (McIvor, 2009, Prahalad and Hamel, 1990).

Outsourcing facilitates access to state-of-the-art technology and the use of performance contracts. On the other hand, vertical integration allows companies to adapt to unforeseen contingencies and customer feedback to maintain incentives that are more balanced and develop company specific capabilities. These effects suggest that outsourcing will be associated with higher levels of initial performance, and that vertical integration will be associated with improved performance over the product life cycle, enabling the development of specific capabilities (McIvor, 2009).

**Decision based on the theory of transaction costs**

The transaction costs theory is based on the premise that one must analyse not only the economic costs of production but also the transaction costs in intercompany operations (Coase, 1937). A transaction cost occurs when a good or service is bought or sold from one company to another in well-delineated processes, surrounded by several sources of inefficiencies as limited rationality, opportunism, uncertainty and complexity, and information asymmetry (Williamson, 1975, 1979, 1983).

Transaction costs are the expenses that companies face when they buy and sell in the market. Some examples are the process of seeking the best technical and economical option, the preparation and negotiation of contract terms and the control of delivery performance in the required time and quality, among others (Williamson, 1985).

Williamson (1979, 1983) draws attention to the fact that the expansion of company boundaries tends to increase the costs of administrative coordination, reaching a point where, with high levels of coordination costs, the internal execution of activities becomes practically prohibitive. Phenomena such as bureaucracy and isolationism from competitive market pressure are other difficulties experienced (Geyskens, Steenkamp, & Kumar, 2006). In this case, the company can use the external market and obtain the same product or service at a lower cost through an outsourcing movement.

On the other hand, there are situations in which transaction costs with suppliers are high. Williamson (1975, 1985) considers three dimensions that combined indicate the timing of integrating an activity: frequency of transactions, specificity of assets, and uncertainties related to the environment before the contract and with the behavior after the contract.

The central issue of transaction cost theory is whether a transaction performs more efficiently within the firm (vertical integration) or by autonomous third parties (market governance) (Geyskens, Steenkamp & Kumar, 2006).

Dyer (1997) makes an important counterpoint, suggesting that transaction costs do not necessarily increase with the growth of specific investments in one supplier. In his study, the Japanese automakers present high specific investments with suppliers, but still have lower transaction costs than US automakers.

**Methodology**

The methodology of the research is qualitative, using a multi-method approach (Minger & Gill, 1999). Data were collected through interviews and secondary data, allowing the
identification of aspects that support the clarification of the research objective (Guerin & Runfola, 2008; Yin, 1994).

The context of the automotive industry justifies the use of a multi-method approach, since it is a complex environment, highly competitive and globalized, with great secrecy of information, which also grounds a four-stage process (Minger & Gill, 1999):

(1) First stage: Secondary data were used to understand the current structure of the automotive sector, supply chains and financial performance, with a focus on three countries, Brazil, China and South Korea. Data were collected from automakers and Anfavea (National Association of Automotive Manufacturers in Brazil) reports and published by the press in the internet.

(2) Second stage: At this stage the authors developed a semi-structured interview script, based on literature review and findings from the first stage to deepen data analysis. The script was validated by one of the authors, who has more than 25 years of experience in product development and interface with suppliers in the automotive industry, and by two other executives in the industry. The main interest of the authors was to understand the structure of the supply chain and how each assembler relates to its first and second tiers. Six executives with extensive experience in the automotive market were interviewed, with two executives working in newly installed assemblers in the country, while the others work in traditional assemblers in the Brazilian market. The interviews lasted about 80 minutes. For reasons of confidentiality, it is not possible to name the assemblers interviewed.

(3) Third stage: The authors organized a workshop with executives and specialists from assemblers, automotive suppliers and universities to discuss the automotive industry. The workshop brought together 145 representatives from distinct sectors of the automotive and academic industry (Fórum de Inovação, 2015). In addition to collecting general information compiled in the discussions, individual interviews were conducted with eight executives who participated in the event. These executives occupy positions of management or board of directors in assemblers installed in Brazil or new incoming.

(4) Fourth stage: In this last stage, we worked on tabulation of results, organization of tables and establishment of relations with theoretical aspects.

Results and discussion
As a result of the fourth stage, the authors tabulated a summary of the analysis of the secondary data (first stage) and information collected in the interviews with the executives of the assemblers and the individual discussions of the workshop (second and third stages) (Table I).

We compare the financial results of some automakers to discuss their competitiveness (Table II). Through the global profit margins, we highlight some trends:

. U.S. automakers (GM and Ford): they have average profit margins around 4%, with standard deviations higher than other companies;

. Japanese automakers (Toyota and Honda): Honda has a constant value of 4% while Toyota consistently exceeded 7%;

. Korean automaker (Hyundai): a global competitor with recent global expansion systematically shows a profit margin above all other world competitors (around 9%);

. Chinese automaker (Geely and SAIC): new entrants to the global competition, Geely has a profit margin close to 8% and SAIC a constant margin of 4.5%.

It is possible to highlight some differences between the characteristics of the traditional assemblers in Brazil and the newly installed Korean and Chinese assemblers. The analysis of the primary data allowed its correspondence with the literature concepts and their comparison among the different structures of supply chain (Table III). It was possible to
compare the same concept from the perspective of each supply chain model, qualifying it according to the perception of the interviewees and connecting theory and findings. Below it is presented a discussion of the findings by nationality of the assembler:

**South Korea**
According to the executive of the Korean company, Korean automakers follow the concept of chaebol, which can be defined as a large business group that is controlled by a family or by members closely related to that family. Government support is common to leverage business growth (Choi, Michell, & Paliyawadana, 2008). The main characteristics of a chaebol are centralized planning; the vertical structure of the organization; family participation in each chain business and high capital investments (Choi et al., 2008; Jwa, 2002).

The assembler interacts with all major first tier suppliers through stock or equity control. These suppliers have autonomy to supply their auto parts to other customers and especially to competitors, thus obtaining economies of scale that result in lower costs for the parent company.

The centralized governance in the supply chain provides high reliability between the automaker and its suppliers, providing conditions that reduce transaction costs: the long-term relationship and the possibility of expanding the return on investment of specific assets reduce opportunism; in turn, the greater exchange of information reduces the uncertainty and asymmetry of information, minimizing transaction inefficiencies (Williamson, 1979, 1985; Gulati & Singh, 1998; Dyer & Chu, 2003). Economy of scale and, especially, transaction costs minimization along the production chain are factors that make South Korean companies more profitable than the industry average.

**China**
Automotive companies in China are nationalized, as well as a large part of the supply chain, with a strong fiscal incentive and investments in research and development, so they can develop high value-added products quickly.

The entire supply chain operates cooperatively with parent companies (assemblers). Both first and second tier suppliers are under control of the automaker (fully nationalized control; mixed control between government and private sector; or stock control of the automaker), ensuring a relationship with centralized governance (Williamson, 1979, 1985). The stability of the relationship ensured high reliability between the automaker and its suppliers, providing conditions that reduce transaction costs (Dyer & Chu, 2003; Gulati & Singh, 1998). Long-term relationships imply long-term return on investments in specific assets, thereby eliminating opportunism in negotiations (Dyer, 1997). In addition to consistent information exchange, inefficiencies in transactions and consequently transaction costs are minimized. Western and Eastern (Japanese and Korean) companies, to gain access to the Chinese market, must necessarily constitute a joint venture with a local state-owned enterprise, conducting all steps from project development to full manufacturing internally at the Chinese enterprise, thereby transferring all technology and expertise.

There is a government policy focused on technological development in two ways: incentives for investment in research and development and joint venture policy in the country. The internationalization of the company tries to follow this same model. In Brazil, the main Tier 1 suppliers are Chinese, with state or mixed stock control, ensuring greater stability in the relationship and a verticalization of the supply chain. Chinese companies with shareholder control of the automaker or with state or mixed investment form the layer of the second-tier suppliers, whenever possible.

Brazil

Brazil has a sui generis automotive sector as it has only multinational automakers. Tier 1 suppliers are also mostly multinational. The choice of these suppliers has a strong dependence on the values of transacted products. There is no shareholder relationship between automaker and suppliers, and there is no participation of the national government in these companies. As there are few good suppliers in the country, there is a strong dependence on first tier suppliers.

Tier 2 is formed mostly by small and medium-sized domestic companies with family control. Respondents said that this is a weakness of the local industry. It is common that second tier suppliers have financial difficulties, affecting the production of the automaker. Such distancing hinders the exchange of information and knowledge in a fluid way in the chain, negatively affecting transaction costs (Dyer, 1997; Dyer & Chu, 2003).
The creation of local models of the productive chain, such as modular consortium and industrial condominiums, sought to bring the automaker closer to the main first tier suppliers. The modular consortium was implemented by “Volkswagen Caminhões” (trucks) in the city of Resende (Rio de Janeiro State). Industrial condominiums are characterized by the proximity of Tier 1 suppliers, who provide modules directly on the assembly line.

Discussion
The traditional assembly plants installed in Brazil for many years have a production structure focused on the assembly line with a high level of outsourcing. This outsourcing led to a predominance of multinational suppliers in Tier 1 in the last two decades, due to the lack of competitiveness of the national auto parts industry.

Tier 1 assumed the responsibility for Tier 2 suppliers, which are predominantly domestic and family-owned companies with many management problems and unable to cope with the country’s frequent economic and political instability. As a result, they generate supply problems, costs and sometimes culminate in bankruptcy. Also, Tier 2 has a low level of innovation. This is a weakness of the traditional automotive supply chains in Brazil pointed out by the research: the detachment of the automakers from their Tier 2 suppliers, which are much smaller and unable to absorb large variations in demand, has affected the automaker’s relationship with Tier 1 and increased costs in the supply chain.

On the other hand, the automakers that settled later tried to adopt different strategies:
- Hyundai has been introducing the Korean model in the country, with a strong vertical integration in the supply chain. The company has equity control of suppliers that develop and produce the main auto parts and components. Tier 1 suppliers are part of the chaebol;
- Chinese assemblers are building their first factories in Brazil, bringing the mode of operation from the country of origin: assemblers and suppliers are companies under the economic domain of the government, with an intense connection between them.

The outsourcing of productive competencies of most Western automakers enabled the development of these competencies in multinational suppliers, driven in recent years by the accelerated advance of information technology, electronics, telecommunications, among other technologies. The benefits of the new technologies are undeniable, but the required levels of investment have been growing at a rapid pace. At the same time, the obsolescence of these technologies happens at a faster rate than the return of the investments, forcing a transfer of investment costs from supplier to the automaker in shorter terms.

Two of the executives interviewed pointed out that the technological developments of suppliers generate several intellectual properties and patents, essential for the development of new vehicles; however, the investment costs in specific assets are passed on to automakers within short periods. Thus, there is an increase in transaction costs between suppliers and automaker (Dyer, 1997), strongly affecting the performance of horizontal supply chains. It is possible to notice there is a pressure from patent holders, which is one of the forces driving a company to consider vertical integration (Cacciatori & Jacobides, 2005).

Companies with a higher level of vertical integration in the supply chain had the best financial results and have been expanding their operations to other countries over the past decade, such as the supply chains controlled by Korean and Chinese automakers. High investments in research and development in these countries, as a result of their macroeconomic policies, support the development of competencies in technology.

</table>
To adapt to the new competitive arena, some aspects indicate the need for a change: a globalized and extremely competitive market, new low-cost competitors vertically integrated, new technological skills overlapping traditional ones, heterogeneity of countries regarding economic and political stability and wealth generation.

Based on the results of the research and the qualitative analysis of each concept, we make the following proposition: automakers recently installed in Brazil have lower transaction costs than traditional automakers due to their vertical supply chain structure.

The structural reorganization of the traditional automotive industry in Brazil requires the reduction of transaction costs through the integration of activities upstream of the supply chain. It is not necessary to follow the oriental models analysed herein, which are based on intense vertical integration. One cannot affirm, as in the model proposed by Lin et al. (2014), that vertical integration will always be beneficial. However, one can opt for hybrid models, integrating vertically the items whose competence is essential for the company's competitiveness, and outsourcing other items in the market (David & Han, 2004; Williamson, 1985). It is necessary to focus on identifying the necessary competencies to stay technologically up-to-date and at the same time reduce the current problem with the cost pressure of suppliers that hold patents (Cacciatori & Jacobides, 2005).

Conclusions and final considerations
This research compares the traditional automotive industry installed in Brazil with the automotive industry of two other countries, South Korea and China, recently installed in the Brazilian market and examples of growth over the past decade. The aim is to understand the factors that differentiate the structure and management of the supply chain of the traditional automotive industry in Brazil with those countries, which may pave the way for understanding the problems and for the long-term competitiveness of the Brazilian industry.

We conclude that horizontal automakers must rethink the limits of their company and study a plan of re-verticalization, focusing on the parts whose competence is important for their competitiveness. It is an opportunity to identify competencies in automotive parts that have a high impact on cost and especially on rapidly evolving technologies, which, being absorbed internally, can reduce transaction costs and improve quality. This is a practical contribution of this study, which is to encourage managers of the automotive chain to rethink the current management model of the supply chain.

Abstract

Procurement is a key function within Automotive supply chain, especially during the Brexit period. Supply Chain integration has been widely applied with in manufacturing/automotive industry. However, the extant literature lacks exploration of its impact on procurement performance. And this relationship closely correlated with trust between suppliers and buyers. This research explores a three-way moderation effect among supply chain integration, supplier-buyer trust and procurement performance empirically via 126 responses by UK automotive manufacturers.

Keywords: Supply Chain Integration, Procurement Performance, Supplier-Buyer Trust.

Purpose

The automobile manufacturing industry comprises the manufacture of components, bodies and trailers for cars and commercial vehicles (Brown and Rhodes, 2018). It has become an essential part of the UK economy, accounting for more than £82 billion turnover and £20.2 billion value added (SMMT, 2018b). As one of the most crucial features of supply chain management (SCM), supply chain integration (SCI) has been widely researched and tested from different perspectives (Armistead and Mapes, 1993; Das et al., 2006; Ebrahimi, 2015; Marquez et al., 2004; Rosenzweig et al., 2003; Sezen, 2008; Vickery et al. 2003). Also, Van der Vaart and Van Donk (2008) indicated that the SCI plays a sustainable role in improving the competitive edge of organizations. Therefore, SCI has been widely applied with in manufacturing/automotive industry, which plays a foundation role to guarantee the fluency of the Just-in-Time implementation. Within SCI, trust between suppliers and customers is a key role, which could significantly affecting the collaboration, communication, and engagements among suppliers who are in the same supply chain networks, and further affect the benefits of stakeholders (Darma, 2016; King and Burgess, 2008; Zhu and Sarkis, 2004). In addition,
procurement is a key function within automotive supply chain as well, especially during the current Brexit period. Nowadays, more than half of the sales turnover is spent on purchased activities in companies, hence, procurement performance (PP) has become a crucial and strategic significant dimension of performance measurements, which closely involved in the SCI and the cooperation and activities among suppliers (Van Weele, 2010).

However, most research to date has focussed on exploring the relationship between SCI integration and overall business performance (Das et al., 2006; Germain et al., 2008; Gimenez et al., 2012), lacks exploration of its impacts on procurement perspective. And these impacts could be closely correlated with trust between suppliers and buyers, which is a blank area within the extant literature. Therefore, this research aims:

*To explore a three-way moderation effect among supply chain integration, supplier-buyer trust and procurement performance.*

**Conceptual Framework and Hypotheses**

![Figure 1 Conceptual Framework](image)

Through the systematic analysis, Flynn et al., (2010) classified SCI into three dimensions, customer integration, supplier integration and internal integration (manufacturer), which can ultimately be accepted as the commonly recognized SCI dimensions (Alfalla-Luque et al., 2014; Boon-itt and Wong, 2011; Gimenez et al., 2012; Kim, 2013; Zhao et al., 2011). However, whether or not to regard external and internal integration as having the same level of significance has engendered strong debate in this SCI dimension research. Therefore, Vander Vaart and Van Donk (2008) raised SC practices, patterns and attitudes based on the external factors of integration. In this research, the SCI focuses on the external integration which is more about interaction of suppliers. Therefore, the dimensions of Van der Vaart and Van Donk (2008)’s on SCI has been adopt in this research.

As shown in Figure 1 the conceptual framework, even though the extant publication did not justify the relationship between SCI and procurement performance, but the it does show a clear positive collaboration between SCI and financial performance (Das et al., 2006; Germain et al., 2008; Gimenez et al., 2012). For example, Vickery et al. (2003) recognized SCI as an essential strategy to integrate supply chain, meanwhile, examining the customer service and financial performance. As the key interactive activity among suppliers and customers, this research assume the SCI would have a positive correlation...
with procurement performance. Saad et al. (2016) proposed a comprehensive model and provided insights into procurement performance for manufacturers in automobile industry, including efficiency and effectiveness two dimensions, which have been adopt in this research. Therefore, as shown in Table 1, the main hypotheses (main effect) have been displayed in detail to illustrate the proposed relationship between SCI and procurement performance.

Looking for a long-term and stable cooperative relationship is largely based on trust between buyer and supplier, which has been acknowledged as a key objective in different business. Following to the theory of resource-based view that to utilize and balance unique firm resources, such as capital assets, specific capabilities, or processes, to enable a firm a well executive of their strategies and thus assist to better efficiency (Barney, 1991), the buyer-supplier trust is an acknowledged firm resources as well. Even it is physically invisible, it plays a significant role and place great impacts on operations. Moon et al. (2017) suggested that trust enables to lubricate social friction and facilitate collaboration, the area with strong demand of collective actions in particular. Accordingly, Ahimbisibwe, et al. (2012) found that cooperation based on trust enables partners to accumulate accessible resource, and Ryu et al. (2008) justified the companies usually have a more positive outcomes with collaboration with partners is also involved in trust, rather than there is no interference between each other. Therefore, in order to achieve an effective relationship with suppliers and higher procurement performance, trust is an essential precondition in this base. Therefore, this research hypotheses the trust would moderate the relationship between SCI and procurement performances. As shown in Table 1, the moderations hypotheses (interaction effect) have been displayed in detail to illustrate the proposed relationship that the Buyer-Supplier Trust moderate the correlation between SCI and procurement performance.

Therefore, a summary of all the hypotheses were presented from Table 1, aiming to build the connection and make sense of multiple research concepts based on established model.

Methodology

Data Collection

Informed by the conceptual framework, a survey approach was adopted in order to collect the primary data and test the statistical relationship among the variables in Figure 1. As the dependent variables of this study, PP is the key research sector to examine, and hence, the participants for this survey are procurement-related staffs in manufactures in the UK automobile industry. And the suppliers from different tiers are also contained into the investigation due to the numerous repeated cross-border transactions existing in the international trade, automobile industry in particular, and the suppliers might also import the raw materials from the Continental Europe. The survey adopts 7 Likert-scale, and all the measurement items for each variable are adopt from the previous research. The survey is conducted through an online questionnaire statistics system, enabling to collect and manage information efficiently. Moreover, social medias, (such as Linked), is the may channel to search for the appropriate participants and collect the primary data from. In addition, the author also collect data for this survey via industrial visitings and industrial conference, social activities, targeting the UK automotive manufacturers covering tier1, 2, 3 and OEM. The collection starts from April 2018 and end up with 126 as the sample available to use for further statistical analysis.

Measurements

All the measurements related to the variables within the moderation model were adopted from previous research. For the three independent variables (IVs), there are seven items to measure SC Practices: schedule deliveries together with key suppliers, key suppliers deliver to us at short notice, key suppliers deliver to us frequently, share information electronically, share information about the production plans and forecasts to key supplier, high degree of strategic partnership with suppliers, high degree of joint planning, key suppliers are involved in our product development processes (Boon-itt and Wong, 2011; Flynn et al., 2010; Gimenez, 2011); three items to measure SC Patterns: high-corporate level communication on important issues, face-to-face communication frequently, online communication frequently (Vallet-Bellmunt and Rivera-Torres, 2013; Gimenez, 2011); four items to measure SC Attitudes: the parties are willing to work out a new deal when some unexpected situation arises, jointly treat problems when they arise, always jointly responsible for making sure that tasks are completed, be open to modifying their agreement if unexpected events occur (Gimenez, 2011). For dependent variables, there are seven items to measure procurement effectiveness: the materials quality fit to precise production requirements, receive order within request time; suppliers are able to fulfil an urgent unexpected demand, have a globally integrated procurement process, procurement process is mainly integrated to the Continental Europe suppliers, suppliers are able to help company to reduce procurement cost, suppliers have awareness of available prices for a product or service all the time (Kim et al., 2015; Saad et al., 2016; Wen-li et al., 2003); five items to measure procurement efficiency: supplier has a good network of known contract and reputation in automobile industry, able to keep continuous supplier collaboration, development and evaluation since supplier selection, we use e-procurement and paperless systems to manage procurement processes, we have achieved a great success from the utilization of e-procurement or digital system, suppliers and the company develop environmental friendly procurement with less resource wastage or CO2 emissions (Abolbashari et al., 2018; Kim et al., 2015; Saad et al., 2016). In terms of the moderator buyer-supplier trust, the measurements include: both parties are willing to make mutual adaptions, our firm can count on the supplier to be sincere, we believe that the supplier will be ready and willing to offer us assistance and support, we will
endeavour to keep original suppliers even in the stage of external environment change, (e.g. post-Brexit) (Ahimbisibwe et al., 2012; Fynes and Voss, 2002; Ryu et al., 2008).

**Analysis Methods**

To begin with, the descriptive analysis attempts to illustrate the demographic of target respondents in the UK automobile industry, enabling to reflect visible patterns, and probably, it is also accessible to detect the potential connection between the targeted factors. Furthermore, factor analysis, validity test and multiple linear regression are conducted step by step. Through the exploratory factor analysis (EFA) examining, unreasonable measures have been eliminated for the six variables, which confirm the convergent validity and discriminant validity for the data sample. The Cronbach’s coefficient α of the scale, SCI, buyer-supplier trust and PP is ranging from 0.712 to 0.901. Hence, these results confirm that this scale is reliable, and the theoretical variables are acceptable. Following, the multiple linear regression aims to detect the correlation relationship between variables as well as the moderation effect (Schumacker and Lomax, 2010).

**Findings**

After data cleaning, the descriptive analysis, factor analysis, correlation analysis and multiple linear regression has been conducted step by step. The key results and findings have been shown below.

The background characteristics of samples and descriptive demographics were briefly introduced in Table 2. It can be seen the samples have a good varieties and diversities, even though not able to get responses from Northern Ireland.

Table 2 – Descriptive Analysis Result
As the truth that majority UK automotive manufactures have close businesses with European suppliers, therefore the survey ask how long and the procurement amount from Continental European suppliers. The Figure 2 displays the connection between UK companies and Continental Europe suppliers. Nearly 90% samples have long-term cooperation with European suppliers and most companies import more than 40% of total volume from the EU.

The regression analysis results of main effects between SCI and PP have shown in the Table 3 below. If taking the significant level at 0.05, it can be clearly see that all the hypotheses about main effects (H1, H2, H3) have been supported. It means the SCI (including SC practices, patterns, and attitudes) does have a positive correlation with procurement performance (including effectiveness and efficiency). This result is alignment with the current literature that the effect of SCI on performance has been extensively recognized in different industries (Das et al., 2006; Germain et al., 2008; Gimenez et al., 2012).

In terms of the moderation effects, as shown in Table 4 below, not all the hypotheses have been justified, however, three clear significant results have been defined, which justify that the buyer-supplier trust significantly moderates on the relationship between SCI (practices, patterns, attitudes) and procurement effectiveness. This clear shows the close correlation of SCI and Trust on the effectiveness. This could due to that the trust will directly affect on the information sharing among different suppliers and avoid “Bull
“whip” effect (Carnevale and Isen, 1986; Li et al., 2006), which will positive improve the accuracy, timeliness and the integrity of purchase effectiveness. In addition, Dyer and Chu (2003)’s study on 344 automobile buyer-supplier relationship from the US, Japan and Korea, and they found that trust enables to decrease the cost of transactions, which is relevant to the information sharing in procurement. This outcome is consistent with Krause et al. (2007)’s study, that buyer-supplier trust tends to improve the length and depth of integrative relationships. Therefore, with a good trust, the integrity and cost reduction of purchase effective will be clearly improved.

From the results, however, buyer-supplier trust has no moderation impact on the relationship of SC practices, patterns and procurement efficiency. This could due to the efficiency was defined by selection and purchases decision in this research, which is a more complete process and may be affect by more factors in practice, and trust may not be the significant one. In details, for SC practices, one possible explanation for this is
associated with the definition of procurement efficiency. For example, E-procurement is an approach that focal companies choose to simplify their procurement activities. It depends on companies’ decisions through the evaluation of investment and outcomes. Although SC practice can facilitate procurement efficiency by developing limited system and ensuring the reliability of information sharing with joint efforts, focal companies can choose the appropriate system based on their practical demand and it will not be impacted by buyer-supplier relationship. Common sense suggests that buyer-supplier relationship will be impacted on mutual trust. Nevertheless, it is necessary to detect the relationship between trust and joint efforts. If the relationship is significant, it confirms that trust plays an indirect impact on procurement efficiency, if not, the relationship between SC practices and procurement efficiency will not be influenced. In addition, SC patterns focuses more on the communication between buyer and suppliers, including the negotiation, regular meeting and revisit, conference in special period and order in daily business. Trust significantly relates to buyer-supplier relationship, reflecting and functioning on the outcome of transactions. In SCI, buyer and supplier can share more information or technology support based on mutual trust, facilitating to satisfying transactions, whereas procurement efficiency, associated with procurement approaches, seems to be impacted less. Because procurement efficiency concentrates more on the company’s willingness of appropriate procurement, and it will be adjusted according to the practical situation in SCI. Therefore, buyer-supplier trust has almost no influence over the study result. More interpretation on the moderation effect may need to draw and review the plots based on the results from Table 4. However, due to the time limitation, the plots have not been included in current work, which will be further improved in the future journal paper publication.

Conclusion and Contributions

From a theoretical standpoint, this work contributes to the extant literature by covering the gap between SCI and procurement performance, as well as the moderation effect of Trust on the correlation between SCI and procurement. When it comes to practice, this research will provide several implications for automobile manufacturers in the UK. First of all, the buyer-supplier trust still plays an important role in maintaining supply relationship. Closer connection within SCI enables partners to share information on the basis of seamless and multiple-channel communication, and this is crucial for enhancing procurement effectiveness, especially understand the JIT system. Due to the practice that around half of the UK automotive manufacturers buy in from European suppliers, faced with the potential uncertainties of the outcome of Brexit negotiations, mutual buyer-supplier relationship might be changed because of risks of cost increasing, commutative barriers, etc., and further, the PP probably is influenced along with the procurement activities transformation. Therefore, enhancing trust could also be a fundamental solution that company could do as an approach to mitigate the uncertainties brought by Brexit.

Abstract

The purpose of the paper is to extend the social media analytics frameworks reported in the existing literature to create value from the data captured from heterogenous social media and IoT sources in a global supply-chain. The paper will aid the practitioners to understand the importance of focussed analysis and the key requirements for this analysis by offering a guide to organisational needs. The framework and requirements proposed in the paper will aid managers to capture value from the data (i.e. gain key insights) and augment human decision-making.

Keywords: Social Media, Analytics framework, Value creation

Introduction

Social media has become a major phenomenon for different organisations globally, and the field of supply chain management has slowly recognised its value for organisations (Chae, 2015). Companies are creating their own online platforms to interact with customers (Correia Loureiro, Serra, & Guerreiro, 2019) or collecting information to use it to enhance customer loyalty (Gamboa & Gonçalves, 2014) and to improve the products offered to consumers. The purpose is to “win with data” (Hopkins & Lavalle, 2010). This perspective is very appealing because technological advances and the increase use of social media by customers.
How to properly harness the benefits of social media in supply chain management, however, it is still a growing area. Information from a multitude of sources is collected and analysed to take advantage of it, but that can become a complex and time-consuming task because of the large volume, variety and velocity of the data, along with its unstructured state (Singh, Shukla, & Mishra, 2018). This is an important consideration because poor quality of data can render the data useless (Hazen, Boone, Ezell, & Jones-Farmer, 2014). This paper states that a different approach is required. Instead of only looking at the volume and the quality of the data, it is important to start looking at the question that the data is trying to answer.

Current analytics frameworks assume that value is created at the final stages, once analytics are applied to the information to find some trends/insights. This article presents a review of two case studies in supply chain management to identify the important elements that create value from the use of social media and redefine current analytics framework. From a more practical perspective, this paper is looking at the most beneficial approach to create value for decision-makers. The objective is to offer a conceptual framework that can be used by stakeholders to take advantage of social media for value creation.

The contribution of this paper is to change the current paradigm from a more “exploratory” analysis of social media data to a focused process introducing “value creation” as a stage defining and guiding the analysis. This shift can become beneficial to address several of the shortcomings identified in the literature about the use of social media in organisations. The paper is also providing a guide with the value creation requirements and organisational needs to exploit the benefits of social media.

**Cases**

Currently, the role adopted by the social media is increasing world-wide with the advances of cross-platform Web 2.0 applications and services (Palen, Starbird, Vieweg, & Hughes, 2010). To analyse the impact of social media in the supply chain and to identify the needs to exploit its potential impact, this research is looking at two different supply chains: retail and humanitarian. Both supply chains have similar components, but the objectives and strategy of each one of them exhibit significant differences, allowing the authors to identify the common elements to exploit social media in supply chain management.

**Case study: Zara**

Zara has been a very interesting case in operations for a long time because of the fast response and flexibility stemming from their practices (Kasra Ferdows, Machuca, & Lewis, 2015). The concept of fast fashion and the high level of vertical integration applied by this company has shown the value of staying at the forefront of operations and its impact on performance. Zara is part of the Inditex group, with more than 650 stores over 50 countries (K. Ferdows, Lewis, & Machuca, 2004) which has led them to achieve nearly 75% of sales of the whole group (Kasra Ferdows et al., 2015).

Speed is an essential quality in the fashion industry. Responsiveness is one of the goals of different companies, but Zara is able to claim achieving responsiveness because of the agility embedded in its supply chain (Kasra Ferdows et al., 2015; Martínez, Errasti, & Rudberg, 2015) as a result of the high level of control rom the supply of materials until the customer purchases the garments (K. Ferdows et al., 2004). For instance, Zara has
been able to introduce new items of clothing to its different stores in around two weeks, from design until delivery (Kasra Ferdows et al., 2015).

Zara has been able to thrive by leveraging new technologies to support its fast fashion approach. The high degree of control over the different links of the supply chain has allowed Zara to have better information sharing as part of their supply chain. Knowledge from the links directly in contact with the customer in the supply chain have allowed the company to be more responsive, using private systems to reduce delays, and enhance the quality and attractiveness of the garments.

With the development of Web 2.0, e-commerce has become a valuable channel to sell products and services. Zara has taken advantage of that opportunity to make their products available to consumers (Fondevila Gascón, Del Olmo Arriaga, & Bravo Nieto, 2012; Gamboa & Gonçalves, 2014) and leveraging from brand enhancement from electronic word of mouth (Correia Loureiro et al., 2019). Similarly, consumers are taking a more prominent role through new communication channels opened by Web 2.0. The introduction communication channels supporting many-to-many interactions have allowed consumers to participate and even collaborate with companies (Gamboa & Gonçalves, 2014). Therefore, several companies are using online platforms in which customers can take part to become closer to the company (Correia Loureiro et al., 2019).

Social media has become a new battlefield for fashion companies because it has become essential to shape the reputation of the brand and achieve customer loyalty (Fondevila Gascón et al., 2012). Zara is the example of an organisation that has embraced social media, as it is one of the fashion companies with the highest number of fans on Facebook (Gamboa & Gonçalves, 2014), which allows them to enhance the engagement with consumers (Fondevila Gascón et al., 2012) and advertise new products and relevant updates about the brand (Correia Loureiro et al., 2019).

Zara’s engagement in social media involve constant interaction with customers and posting photos and videos with relevant content (Correia Loureiro et al., 2019), which has paid-off with an increased level of customer loyalty (Gamboa & Gonçalves, 2014) and improved advertising strategies, but it has also carried some challenges. For multinational organisations it is important to consider decentralisation, language, culture and campaign coordination across markets (Fondevila Gascón et al., 2012). The evolution of the content provided and aligning social media to the strategy of Zara is essential to continue enjoying the benefits of social media.

**Occupy Sandy: Social media for disaster relief**

U.S. Congresswoman Susan Brooks stated in 2013 the importance of social media and technology in disaster management, as well as the value of digital volunteers to enhance the potential of social media and increase situational awareness (Kirac & Milburn, 2018).

A good example of the potential of social media in disaster management is the situation occurred after Hurricane Sandy hit the US. Hurricane Sandy has been one of the costliest disasters that have affected the United States of America. The disaster had devastating impact in several states of the country after growing into a category 3 Hurricane (Yoo, Rand, Eftekhar, & Rabinovich, 2016), striking the East coast in October 2012. It was challenging for FEMA to cope with the situation because of the scale of the disaster, which allowed a small group stemming from the Occupy movement to show the potential of social media to support disaster management with their activities in Brooklyn (Feuer, 2012). In fact, disaster response from the Occupy movement was quicker than larger and more established organisations such as FEMA and Red Cross (Kavner, 2012).
Social media has been heavily linked to disseminating information in disaster situations and to target search and rescue activities (Panagiotopoulos, Barnett, Bigdeli, & Sams, 2016), but the potential of these tools go beyond that. FEMA has recognised the value of social media have a two-way conversation with people and to look at them as resources (Tobias, 2011). This was experienced after Hurricane Sandy hit the US, because the occupy movement was able to set-up communication hubs to re-establish communication and use it to create an emergent supply chain.

Procurement was performed appealing at donations from citizens in two ways. Financial donations using Webpay (Webpay, 2012) were collected to finance response activities and projects, with a total tally of $1,361,337.19 (Occupy, 2013). On the other hand, in-kind donations were also encouraged through the use of Amazon’s wedding registry (Occupy, 2012). In this alternative, an updated list of the most needed items in ravaged areas was posted online for donors to but the items directly and use Amazon retail services to deliver the items to one of the outposts from the movement (Feuer, 2012). The collection of in-kind relief was successful as well, as shown by the delivery of over 35,000 items in few weeks after the storm hit (Islam, Vate, Heggestuen, Nordenson, & Dolan, 2013). They used Sahara Eden to request assistance, to print waybills with items and delivery areas, and to track requests (Homeland_Security, 2013).

Exploiting both supply channels represented operational challenges to manage the relief. The relief was delivered to Occupy Sandy distribution sites split between two churches in Brooklyn, which were the facilities used to deploy relief end volunteers to affected areas (Kavner, 2012). Coordination of these volunteers and relief can become problematic task, especially with numbers between 5,000 and 10,000 volunteers (Homeland_Security, 2013). The Occupy movement used communication systems to enable collaboration by matching human resources with the required activities (Kavner, 2012; Occupy, 2012). That way, a set of borrowed cars and trucks were used to move items and people from the distribution hubs to the affected areas (Feuer, 2012) with the purpose of providing further support to the victims and distribute the relief available.

The size of the occupy movement, however, was not enough to supply all the affected areas. The integration of different organisations and initiatives quickly became a priority to manage operations. That is the reason a link between formal and informal response efforts was essential. Geeks without Bounds became that link for Occupy Sandy, allowing them to coordinate with FEMA and other formal organisations to make operations more efficient (Homeland_Security, 2013). Additionally, they provided situational awareness through crowd mapping. They worked with Hurricane Hackers NYC to provide a map of the affected areas (Homeland_Security, 2013). Therefore, the Occupy movement was able to use public social media as an enabler to create an emergent organisation to provide support online and on the ground (Kavner, 2012). Overall, Occupy Sandy was able to leverage social media across different parts of the supply chain to support disaster affected areas. The collaboration among different links of the supply chain, the constant monitoring of physical and financial aid, the ability to match supply and demand to coordinate different stakeholders, and the use of crowdsourcing to enhance information during the event are some of the examples of the potential of social media in these situations.

Framework
In this section, we extend the existing social media analytics framework (Figure 1) to include a value creation stage, which will aid the decision-makers and relevant supply-
chain entities to understand the purpose of using the analytics for processing the big data captured from social media sources. The key challenge with the voluminous and heterogeneous data collected from different sources are lack of focussed analysis (i.e. what do we want from the data) and trying to find a pattern (generate insights without knowing what exactly we are exploring). Thus, the proposed framework extends the existing social media analytics frameworks reported in the extant literature (Lee, 2018; Stieglitz et al., 2018; Holsapple et al., 2018; Chae, 2015)

**Inception:** The primary activities in this stage are collecting the data, followed by cleaning it (i.e. formatting with suitable annotations), then storing it in a structured-way for future use. The primary deliverable is not only a data repository but a report that can guide the next stage, where managers will identify the value of the stored data for purposeful use.

**Value Creation:** This stage is essential to the outcome of the analytics and a component that has seldom been considered in the existing analytics frameworks. The main idea is for managers to use the inception report to understand what data is available from various social media sources and define the questions that they would like to pose to make the analysis focussed. The focussed analysis will aid in capturing value from the process and aid human-decision making.
• **Aggregation:** The relevant data from the inception stage will need to be integrated into a consistent format suitable for analysis (basic analytics and advanced analytics). The data selection will depend upon the problem (questions posed by the decision-makers), thus making the both the analysis and outcome focussed and purposeful (Govindan et al, 2018).

• **Sense-making:** The sense-making stage will employ algorithmic procedures depending upon the questions posed by the managers (in the value creation stage). This stage will include two deliverables: (1) a summarised snap-shot of the data which will help to gather suitable information from the data (which is likely to be voluminous and gathered from heterogeneous sources); (2) output of the analytics employed (such as predictive, prescriptive) using machine learning techniques (Fan and Gordon, 2014). The summary and output will help the managers to capture value from the data, i.e. gain suitable insights for the problem/question identified in the value creation stage, which in-turn will aid in formulating recommendations thus reducing the information and cognitive overload.

• **Sense-giving:** This final stage will present the information (summary and output of the analytics) in a visual form, which is intuitive and easy to understand using suitable pictorial representation (such as linked-graphs, trees, filters). The visual representation will help the mangers to have a high-level understanding of the output and offer further drill—down to understand the rationale behind the recommendations (for a recommender system), which ought to depend upon historical information (data bias), heuristics used in the analysed (factor weighing) and source as well as type of data (textual, numerical values, audio and videos).

Overall, the proposed framework demonstrates the importance of value creation stage, which drives all the other stages in the analytics framework towards a focussed analysis. The outcome of the analysis will aid managers to understand the value of the data and have the potential to optimise business processes.

**Organisation Needs**
This section will discuss the key needs for an organisation to use the proposed framework for creating value and eventually capturing it through the analytics process. The key elements comprise of resources and activities that will aid organisations to build capabilities (such as technology, tools, skills) for successful deployment of the initiatives. The key elements (Figure 2) for consideration are as follows.

• **Organisation culture:** This represents the willingness and attitude of the business organisation (managers and team) to invest in contemporary initiatives (data-driven vale creation), appreciate the associated long-term and short-term risks, and evolve the process over time (i.e. remain agile to the advent of technology and novel data contribution platforms). The mindset of the organisation will determine the keenness to take risks, make changes and evolve to create and capture value using data-driven initiatives.

• **Skills requirements:** This element pertains to the ability of the organisation, decision-makers, and key employees to understand, manage and align the value creation process to deliver the business needs of the organisation. Additionally, ability to create strategies that will co-ordinate and streamline business and
technical capabilities is pivotal for value creation and capture. It also requires managers to interpret and recognise the information presented in the sense-giving stage to make decisions.

- **Identifying relevant data sources:** This relates to identifying, capturing and storing real-time data obtained from social and physical sensors that will aid the organisation in creating value, which requires understanding of the data and business needs of the organisation. This element will require domain expertise (i.e. understanding the business needs to identify relevant sources) and knowledge about the analytics framework (not necessarily technical but conceptual).

- **Relevant Tools:** This represents the technological needs of the organisation to harvest relevant insights from the data, i.e. transform data into knowledge using suitable analytic tools, and infrastructure to support such techniques. It requires making decisions for purpose of the analytics to capture value, a strategy to identify and invest in the resources.

*Figure 2: Needs of the organisation to employ the proposed analytics framework*

**Value creation process**
Business organisations in a supply-chain need to understand the key elements involved in the value creation stage, to formulate suitable questions that will be posed to the analytics process. The quality of the output derived from the automated analytics process will depend upon the quality of the question (or the problem formulated by the managers). This section provides an overview of the key elements (*Figure 3*) that managers will need to consider in the value creation stage of the proposed framework taking into account an array of factors preceding this stage.
• **Purpose:** It is necessary for the organisations (key decision-makers) to use their domain knowledge, understanding of the business needs, and knowledge of the data sources to outline the purpose of the analytics, i.e. what is the question the automated process will aid in answering. This will streamline and eventually coordinate the business needs, data availability, analytics process and value creation (Sanders, 2016). The purpose will also determine which social media streams should be used depending on the nature of the query, quality and type of data available from the stream, and organisational trust in the data stream.

• **Question:** The question (i.e. definition of the problem) is a critical element to guide the aggregation and sense-making stages of the analytics framework (Shah et al., 2012). The relevance of the question should be critically assessed considering four key factors: (1) whether the question can be answered, or key insights can be gained by employing analytics; (2) whether the organisation has relevant access to the data streams that will aid in answering the question; (3) how answering the question/gaining insights will add value to the business needs of the organisation; (4) whether the question is relevant to the contemporary needs of the organisation, i.e. relevance and alignment to business needs, objectives and existing strategy.

![Figure 3: Key elements to consider in the value creation process](image)

• **Relevance:** It is key for the organisation to assess the relevance of data stream, i.e. how much the data source can be trusted after the pre-processing, given the veracity involved in the data collected from social sensors. It is critical to assess the key features of the data which will include capturing platform, times-stamp, location, author, motivation to create the data and event associated with the data. Additionally, relevance of technology, expertise to use the technology, and suitable tools need to be considered as well, which should again streamline with the purpose of the analytics and potential intended benefits.
• **Evolve**: This is a critical consideration for the organisation to the evolving needs pertaining to technology turbulence and the supply-chain (at all levels – both upstream and downstream). The whole analytics process is evolutionary both in terms of value creation requirements and needs of the organisations. Organisations need to be agile to manage and respond to market movements and make changes dynamically, which will involve taking risks and strategically tackle the uncertainty. Therefore, organisations will be required to revisit their strategy and reflect on it, instead of sticking to a one-stop solution, which is unlikely to reap benefit over a period of time.

**Conclusion**

This paper demonstrates the need to include a value creation stage in the existing social media analytics framework, so that organisations can streamline the technological and business needs in a suitable manner, which will aid in reaping the benefits from social media data. In this context, organisation will need to adopt an agile strategy that will respond to changes in market as well as the technological turbulence in this digital era.

The conceptual framework reported in this paper is yet to be validated in a practical business setting through a longitudinal study. In the future, we aim to conduct multiple case-studies with organisations (both small and large businesses) to validate the framework and identify the barriers stemming from the adoption of this framework.

Nonetheless, the value-creation stage in social media framework is non-trivial because in a real-life business setting, organisations often delve into analytics (both social media and IoT data), without having substantial knowledge of the process and randomly searching for patterns in the hope of capturing some insights (which eventually becomes a barrier due to uncertainties stemming from an non-focussed analysis).

Towards a seamless supply chain: A systematic literature review of influencing factors

Susana Bermudez Hidalgo (s.bermudez-hidalgo@warwick.ac.uk)
Warwick Manufacturing Group, University of Warwick, Coventry, CV4 7AL, UK

Janet Godsell
Warwick Manufacturing Group, University of Warwick, Coventry, CV4 7AL, UK

Abstract

The core rationale of supply chain management envisages an integrated supply chain as key to enhanced performance. However, this “end-to-end” approach has not been fully realized. The aim of this paper is to provide a comprehensive review and analysis of factors influencing integration in the supply chain. This is achieved through an exhaustive systematic literature review. From the analysis of 74 articles, a three-path influencing factors model is identified at internal, supplier and customer scopes. Subsequently, influencing factors are categorized into enablers, inhibitors, and dual according to behavioural patterns. The proposed framework provides an all-encompassing overview of factors influencing integration.

Keywords: supply chain integration, enablers, inhibitors

Introduction

Integration is the underlying perquisite to effective supply chain management (SCM). Hence, the study of supply chain integration (SCI) is central to SCM. Approaches to SCI suggest an emphasis in collaboration, coordination and integration in the flow of materials, services, processes and information through the entire SC with the ultimate objective of achieving an end-to-end supply chain (Chang et al. 2016; Childerhouse and Towill, 2003; Flynn et al. 2010). Despite the large number of publications exploring SCI, very few firms have yet materialized the seamless supply chain (Towill, 1997). In this view, the industrial challenge of planning integration processes among SC partners is still a major source of poor performance (Richey et al. 2009). Thus, there is a need to identify a novel approach for improving performance across the entire SC beyond the realm of the individual firm.

The present paper focus on the first part of this challenge. Accordingly, the purpose of this paper is to investigate and explain both, sources of poor integration and opportunities to enhance SCI. The aim of this paper is to identify the corresponding roles of different influencing factors in enabling and/or inhibiting SCI. This is achieved through an exhaustive and inclusive systematic literature review (SLR).

Methodology
This paper adopted a five-step improve methodology prescribed by Denyer and Tranfield (2009) to systematically reviewing papers in the field of SCI. This methodology encompasses the five-steps of question formulation, location of studies, selection and evaluation, analysis-synthesis, and report of results. The present research design aims to provide rigor and transparency while minimizing bias. In addition, it benefits from enabling replicability.

Formulation of over-arching research question followed a process of setting the scope of the study, identifying emerging literature and further discussions with members of the review panel. The review question is derived as:

- What are the factors that influence the performance of SCI?

The over-arching question suggested the following sub-research questions:

- What are the sources that lead to poor integration?
- What are the sources that provide an opportunity to improve integration?

Two types of keywords relating to the concept of supply chain and integration were used in developing search strings with Boolean operators. Construct search strings are shown in Table 1:

Table 1: Specification of key words used as search strings

<table>
<thead>
<tr>
<th>Supply Chain</th>
<th>Integration</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&quot;Supply chain&quot; OR &quot;Supply network&quot; OR &quot;Value chain&quot; OR &quot;Value network&quot; OR &quot;Logistics&quot; OR Logistic*)</td>
<td>(&quot;Integration&quot; OR Integrat* OR &quot;Alignment&quot; OR align*)</td>
</tr>
</tbody>
</table>

In order to allow access to all relevant literature search strings were applied across four databases: Emerald, ScienceDirect, Scopus and Web of Science. These were screened for title and abstract publications in English language, including academic journals, chapters of edited books, and reports published between 2000 and 2018. From initial search, 23,940 papers were retrieved. Following elimination of duplicates, title and abstract of remaining papers were screened against inclusion and exclusion criteria.

Subsequently, the remaining papers were read in full. In order to identify most relevant publications studies were evaluated against a set of specific quality criteria based on subject matter and quality assessment. These included papers providing a comprehensive understanding of the research area of SCI. Then, studies that contributed to the increasing knowledge of factors influencing the performance of SCI were selected. As a result, 66 papers from the original search were identified as relevant for this research. In addition, 8 publications were included from cross-referencing that were not originally identified in the primary search. In all, 74 papers were analyzed for descriptive and thematic findings. Full selection process is detailed in Figure 1:
**Descriptive Findings**

The 74 papers selected for review are descriptively analysed in this section in respect of year of publication, research methodology, journal, field of study and industry. The aim of the descriptive analysis is to identify the research trends in the field of SCI.

Figure 2 indicates a gradual interest over the years, with a dramatic increase between 2009 and 2017. During this time 55 papers were published, which amounts to 75% of papers included in this study. A surge in recent publications clearly indicates an increased interest of academics in SCI within the operations management field.

Accordingly, 88% of studies were empirical of which 57 (87%) employed survey and fewer 8 (12%) a case-study method. This confirms the advance mature stage of SCI field, emphasizing a high degree of theoretical development through validation.

The studies selected for this review were exclusively published in academic journals. Once again, this illustrates the mature stage of this area of research. Likewise, most papers were published in operations management and technology journals (82%), operations research & management science (7%), information management (7%), marketing (1%) and social sciences (1%). This indicates the predominance of studies in operations and technology with little interest from other fields of research.

Finally, the presence of industry sectors is fairly represented across SCI studies. Manufacturing/Machinery (23%), consumer products (19%) and electrical/electronic are predominantly the most discussed industries.

**Thematic Findings**

This section identify and explain a three-path influencing factors model at three different scopes including internal, supplier and customer.

*Types of influencing factors to SCI*

Factors are classified as inhibiting, enabling and dual. Inhibiting factors have an exclusive inhibiting influence to a particular scope. Enabling factors have an exclusive enabling influence to a given scope. In contrast, dual factors may act as both enablers and inhibitors at any scope.

At internal scope financial and risk are classified as inhibiting factors. Technology, human intervention, communication, alignment, culture, uncertainty, strategy and
organizational are dual factors, while commitment is a single inhibiting factor. At supplier scope, financial is classified as single inhibiting factor. Correspondingly, technology, human intervention, communication, alignment, culture, uncertainty, strategy, organizational, trust, commitment and risk are dual factors. Dependence and power are single enabling factors. In addition, financial and risk are inhibiting factors to customer integration. Technology, human intervention, communication, alignment, culture, uncertainty, strategy, organizational, trust and commitment are categorized as dual factors. In contrast, dependence and power are classified as enabling factors. The following section identifies influencing factors across different scopes. Figure 3 depicts SCI influencing factors model.

**Influencing factors: inhibiting forms**

*Common across all scopes (internal, supplier and customer)*

Influencing factors inhibiting integrative practices across all dimensions include lack of access to high-class technology (Leuschner et al. 2013); lack of a supporting platform/and or practices for technology (Cousins and Menguc 2006); management resistance to change (Bernon et al., 2013; Frohlich, 2002); lack of management support to assist SCI practices (Zhao et al., 2015); management minimizing sharing of sensible strategic information (Trkman et al. 2007; Wang et al., 2014); management lack of understanding of SCI; poor SCI- Issue fit Strategic Alignment (F Flynn et al. 2016); lack of communication (Forsslund and Jonsson, 2009; Pagell, 2004); low levels of environmental uncertainty (Wong et al., 2011); high levels of market, demand and supply uncertainty (Childerhouse and Towill, 2003; Lu et al. 2018); financial and supply risk (Leuschner et al. 2013; Zhao et al. 2013); independent functionality (Richey et al. 2009); lack of technical and business skills, and fragmented planning system (Frohlich, 2002); poor strategic alignment (Flynn et al. 2016); time constrains (Alfalla-Luque et al. 2013); lack of external perspective (Richey et al. 2009); and increased cost associated with acquisition of supporting infrastructure for SCI (Terjesen et al. 2012)

*Specific to external scope (supplier and customer)*

Influencing factors specific to the external scope include continued use of low performance logistic tools that are outdated and/or incompatible and management “know-best” decision-making (Forsslund and Jonsson, 2009); Management hindering integration practices to avoid personal risk (Villena et al., 2009); lack of trust (Revilla and Knoppen, 2015); absence/poor commitment (Yuen, 2016); partners lack of alignment (Das et al., 2006); deviation from the “optimum level” of integration (Swierczek, 2014); restricted share of knowledge or information sharing (Zhe et al., 2018); formal communication channels encouraging transmission but not proximity (Alfalla-Luque et al., 2013); SC partners organizational culture differences (Trkman et al., 2007); lack of governance structure to handle integration (Cousins and Menguc, 2006); centralised hierarchical structures that minimize employees involvement (Flynn et al., 2016); poor understanding of SCI (Leuschner et al., 2013); complexity of processes and materials requirements (Lockström et al., 2010); use of indiscriminate integration practices (Das et al., 2006; Gimenez et al., 2012); shared resources (Van Donk and Van Der Vaart, 2005); excessive intensity of SCI (Swierczek, 2014); and cost focused firms (Van Der Vaart and Van Donk, 2004)

*Specific to internal scope*

Influencing factors specific to the internal scope include employee use of soft skills to avoid undesirable jobs (Wang et al., 2014); poor functional, departmental and systems
alignment; poor quality of information hierarchical cultures that promote distance and
remove power (Pagell, 2004); internal politics that are not inclusive of SCM practices
(Zsidisin et al., 2015); and organizational resistance to change (Gimenez and Ventura,
2005).

Specific to supplier scope
Inhibiting forms include management cultural differences and a lack of cultural
understanding (Lockström et al., 2010); and poor quality of information (Alfalla-Luque
et al., 2013)

Specific to customer scope
Influencing factors specific to customer scope include instrumental commitment (Zhao et
al., 2008); hierarchical cultures (Cao et al., 2015); high levels of demand risk (Zhao et al.,
2013); and partners use of coercive power in the relationship (Zhao et al., 2008).

Influencing factors: enabling forms
Common across all scopes (internal, supplier and customer)
Influencing factors enabling integrative practices across all dimensions include logistic
tools (Alfalla-Luque et al., 2013); processes supporting its functioning (Arun et al., 2006);
top management support (Zhao et al, 2015); human capital (Huo et al., 2016a); high levels
of communication (Berna et al., 2013); supporting communication structure (Kim and
Narasimhan, 2002); information and knowledge sharing, and knowledge capability
supporting structure (Prajogo, and Olhager, 2012; Richey et al., 2009; Turkulainen et al.,
2017a; Zhu et al., 2018); commitment to the relationship and identification with the firms’
common norms and values (Huo et al., 2016a); alignment of SCI to the type of
performance indicator aimed to improve and alignment of enabler and degree of SCI
(Wong et al., 2011); development and group cultures (Cao et al., 2015); high
environmental uncertainty (Terjesen et al., 2012); an external strategic orientation (Yunus
and Tadisina, 2016); pursuit of both internal and external integration jointly as they
beneficially influence one another (Gimenez and Ventura, 2005); strategic processes and
practices that support SCI (Terjesen et al., 2012); closer location to the customer order
decoupling point (CODP) (Van Donk and Van Doorne, 2016); supporting management
and information processing infrastructure (Srinivasan and Swink, 2015); and use of
common platforms (Ralston et al., 2015).

Specific to external scope (supplier and customer)
Enabling forms of factors specific to the external scope include the use of inter-personal
relationships (Wang et al., 2016); information integration (Prajogo, and Olhager, 2012);
equal levels of dependence among SC partners (Zhang and Huo, 2013); trust (Chang et
al., 2016); a reliable and genuine interest in the relationship (Vijayasarthathy, 2010); desire
to move from traditional to strategic collaboration (Yuen, 2016); open-minded and
honesty (Zhang and Huo, 2013); appropriate use of power (Wang et al., 2016); partners
alignment (Li et al., 2009); externally focused culture (Yunus and Tadisina, 2016); high
Specification and volume uncertainty (Van Donk and Van Der Vaart, 2005); internal
integration approach as key to achieve further integration (Gu et al., 2017); an
evolutionary process approach to integration (II\rightarrow SI\rightarrow CI) (Chen, 2016); strategic
collaborative practices (Frohlich, 2002); information integration strategy (Prajogo, and
Olhager, 2012); pursuit of coordinative practices (Wiengarten and Longoni, 2015); a
simplification approach (Childerhouse and Towill, 2003); use of intangible/inimitable
resources (Xu et al., 2014); a low “proactive” strategic orientation (Stonebraker and Liao,
an “inside-out” removal of integration obstacles strategy (Frohlich, 2002); a socialization strategy (Cousins and Menguc, 2006); a continuous improvement approach to integration “not a one-time thing” (Trkman et al., 2007); joint influence of both interpersonal relationships and inter-organizational relationships (Wang et al., 2016); and a long-term relationship approach (Yuen, 2016).

Specific to internal scope
Enabling forms of factors at the internal scope include an open communication climate (Zsidisin et al., 2015); real time cross-functional communication that is informal (Arun et al., 2006); employee commitment (Alfalla-Luque et al., 2015); goal alignment (Turkulainen et al., 2017a); inter-departmental alignment (Alfalla-Luque et al., 2013); cultures that promote collaboration (Pagell, 2004); an innovative orientation (Li and Kuo, 2016); the “optimal timing” of Integration efforts must precede the practice intended to improve or being applied at a nascent stage (Narasimhan and Das, 2001); flatter/ decentralized organizational structures (Flynn et al., 2016); and inter-functional and Inter-departmental integration (Moyano-Fuentes et al., 2016).

Specific to supplier scope
Enabling forms specific at supplier scope include alignment of SCI efforts-environment (He et al., 2017); collectivism Culture (Chang et al., 2016); risk management practices (Villena et al., 2009); technological uncertainty (Huang et al., 2014); joint decision-making (He et al., 2017); and imitation of peers (Turkulainen et al., 2017b).

Specific to customer scope
Specific enabling forms at customer scope include high quality and consistent information (Chavez et al., 2015); and planning systems integration (Bernon et al., 2013).
Conclusion
This paper investigates factors that influence realization of SCI. From the analysis of 74 papers a three-path influencing factors model is identified at internal, supplier and customer scopes. Subsequently, influencing factors are classified as enabling, inhibiting, and dual according to behavioural patterns. The main outcome of this study is the establishment of a framework that explains the relationship between influencing factors and integration at specific scope levels. Hence, influencing factors to SCI act at scope level, with all three scopes influenced differently resulting in factors variation across scopes. This illustrates the complexity to understand SCI in practice and to achieve realization of the seamless SC. This framework should be used as a foundation to develop hypothesis and further empirical work.

Abstract

Industry 4.0 implies a future digitalized and interconnected industrial value creation and has the potential to transform buyer-supplier relationships. These relationships differ among industry sectors because of industry-specific circumstances. This paper sheds light on future buyer-supplier relationships in the context of Industry 4.0 focusing on industry differences. Qualitative semi-structured expert interviews with 65 experts from German industrial enterprises serve as empirical basis of the exploratory multiple case study. The results reveal how future buyer-supplier relationships differ among various industries. The paper contributes to the current state of research from a management perspective triggering further research in this area.

Keywords: Industry 4.0, Buyer-Supplier Relationships, Industry-comparison

Introduction

“Industry 4.0”, also known as the “Industrial Internet of Things”, indicates a de novo change in industrial value creation based on digitalization and interconnection (Kagermann et al., 2013). People, machines, objects, and information and communication technology systems get intelligently, horizontally, and vertically interconnected (Schneider, 2018). Given its far-reaching technological developments along with its revolutionary character for value creation, Industry 4.0 provides numerous opportunities and potentials, e.g., efficiency, quality, and flexibility improvements (Kagermann et al., 2013).

Industry 4.0 implies a digitized, real-time capable, and intelligent interconnection of value creation chains, networks, and ecosystems (Bienhaus and Haddud, 2018; Kiel et al., 2017; Tu, 2018; Wang et al., 2006). Technological developments enable collecting, processing, analyzing, and sharing data (Thun, 2010; Wang et al., 2006). In this context,
digital technologies may create new forms of collaboration, cooperation, and integration and change buyer-supplier relationships (Obal and Lancioni, 2013). A more intense collaboration, further integration of partners, usage of platforms, and cross-company systems transform the shape of future competition. Given substantial industry specific differences in terms of value creation, analyzing buyer-supplier relationships requires a separate consideration.

Buyer-supplier relationships in the context of Industry 4.0 have scarcely been analyzed so far and consequently little is known about particular differences in various industry sectors (Haddud et al., 2017). However, analyzing the interconnection of companies, cross-company cooperation, and shared value creation is relevant for several reasons. Firstly, analyzing these aspects is vital to unveil how to further develop and improve industrial value creation (Vanpoucke et al., 2013). Secondly, buyer-supplier relationships represent a great source of competitive advantage, e.g., reducing sourcing costs, especially against the backdrop of decreasing value creation depth (Tan et al., 2002; Wang et al., 2006). Thirdly, cross-company interconnection represents a central element of Industry 4.0 and thus asks for an investigation (Büyüközkan and Göçer, 2018).

Whereas it is expected that companies cooperate and interact more closely in the future (Vanpoucke et al., 2013; Wang et al., 2006), it is unknown how buyer-supplier relationships are characterized in the context of Industry 4.0. Both research and practice show great interest in discovering setting levers for future buyer-supplier relationships (Schneider, 2018; Tu, 2018).

For this reason, the study addresses the following research questions:

RQ 1. How are present buyer-supplier relationships characterized in various industry sectors?
RQ 2. What are the distinct characteristics of future buyer-supplier relationships in the context of Industry 4.0 dependent on companies’ industry sectors?
RQ 3. What drivers and causes can be identified why buyer-supplier relationships are transformed in the context of Industry 4.0?

The study sheds light on industry-specific differences in buyer-supplier relationships in the context of Industry 4.0 and indicates areas for future research. Aside from contributing to research, the derived recommendations and implications serve managers and corporate practice, which in turn ensures the study’s practical relevance.

**Theory**

*Industry 4.0*

Based on an ongoing digitalization and interconnection, Industry 4.0 implies a new paradigm shift of industrial value creation. Cyber-Physical Systems and the Internet of Things form its technical basis. Cyber-Physical Systems are characterized by physical objects being complimented with communication systems and technologies that exchange digital data and allow an autonomous and independent coordination (Blau, 2014; Kagermann et al., 2013; Lasi et al., 2014). By means of information and communication technologies, the Internet of Things interconnects physical and virtual objects and systems alike, and in so doing, enables comprehensive communication and vast interactions (Kagermann et al., 2013; Lasi et al., 2014). Applying these technologies paves the way to merge and interconnect the physical and virtual world in industrial value creation. The inclusion of Internet of Things solutions and applications in industrial value
creation is also referred to as Industrial Internet of Things, why this term can synonymously be used to Industry 4.0.

Given its far-reaching implications for industrial value creation, Industry 4.0 provides both strategical and operational potentials for individual companies. First, it paves the way for new, data-driven business models, e.g., platforms, and it may also transform existing business models (Kiel et al., 2017). Second, modular product designs and flexible production processes help to produce individual products nearly in a similar quantity and efficiency like mass production (“mass customization”) (Kiel et al., 2017). Third, value creation efficiency and productivity can be improved, for instance via optimizing capacity utilization and turnaround time. Fourth, Industry 4.0 can decrease overall risks by increasing transparency of the value creation process and fasten responsiveness to adapt to changes (Rong et al., 2015).

Aside from affecting individual companies, Industry 4.0 has the potential to reshape entire value creation processes forming integrated cross-company value creation chains and networks (Hofmann and Rüsch, 2017; Kiel et al., 2017; Vanpoucke et al., 2013). Against this backdrop, a broad and comprehensive horizontal and vertical interconnection represents a key to tap Industry 4.0’s full potential (Kagermann et al., 2013; Müller et al., 2018a).

*Industry 4.0 in Supply Chain Management*

Supply Chain Management aims at optimizing the performance of the value creation process, for instance improving quality, time, and cost, and building up competitive advantages (Tan et al., 2002; Vanpoucke et al., 2017). Supplier Management’s objective is to create, manage, and develop buyer-supplier relationships in order to efficiently organize and manage value creation (Choy and Lee, 2003). Being a central element, supplier integration represents a form of vertical cooperation. It is a set of strategies to design buyer-supplier relationships in a collaborative and cooperative manner, combining resources and capabilities to conduct common activities (Bienhaus and Haddud, 2018; Schoenherr and Swink, 2012; Tan et al., 2002; Thun, 2010; Vanpoucke et al., 2013).

Buyers and suppliers alike benefit from collaboration, cooperation and integration (Bienhaus and Haddud, 2018; Haddud et al., 2017; Tan et al., 2002; Vanpoucke et al., 2017). Intensifying cooperation allows conducting joint activities, for instance, carrying out common research and development projects (Bienhaus and Haddud, 2018; Tan et al., 2002; Vanpoucke et al., 2017). Integrating new or unrelated partners ensures access to further resources and expertise (Rong et al., 2015; Vanpoucke et al., 2013). On an operational level, closely working together reduces costs of value creation. First, it decreases process complexities and in turn increases process efficiency, e.g., via lower coordination efforts and less manual reworking. Second, it reduces inventory levels following greater information transparency. On an output level, it increases flexibility, agility, and responsiveness of value creation chains. Further, cooperation helps to address customers’ demand providing individual solutions and services (Bienhaus and Haddud, 2018; Dweekat et al., 2017; Vanpoucke et al., 2017; Wang et al., 2006).

Industry 4.0 affects Supply Chain Management and transforms buyer-supplier-relationships intensifying the interconnection of value creation chains. Technologies, such as the Internet of Things, Big Data, and Cloud Computing, enable real-time data analysis and data management across company boarders (Bienhaus and Haddud, 2018; Büyüközkkan and Göçer, 2018; Dweekat et al., 2017; Thun, 2010; Wang et al., 2006). Thus, Industry 4.0 increases information transparency improving efficiency of Supply Chain Management functions, decision-making, and overall business performance (Bienhaus and Haddud, 2018; Dweekat et al., 2017; Vanpoucke et al., 2017; Wang et al.,
2006). In addition, the supply chain is improved as for robustness, flexibility, responsiveness, and agility, for instance, using smart products that advance traceability and further automating processes (Wang et al., 2006). Furthermore, digital technologies pave the way to create new forms of collaboration, cooperation, and integration, for instance transferring value creation to digital platforms, and subsequently change buyer-supplier relationships (Obal and Lancioni, 2013). Intense vertical integration and ongoing collaboration does not only apply for first-tier suppliers, but includes suppliers of further value creation stages (Dweekat et al., 2017; Müller et al., 2017). Consequently, future competition will no longer be amongst individual companies, but between corporate network structures and ecosystems (Kiel et al., 2017).

**Methodology**

Using a qualitative explorative empirical research design and applying a multiple case study approach, the study analyses how buyer-supplier relationships differ in various industries in the context of Industry 4.0 (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007). Exploratory case studies are used to investigate complex, novel, and evolving phenomena (Yin, 2009). Multiple cases increase the results’ accuracy, reliability, generalizability, and robustness (Eisenhardt and Graebner, 2007; Yin, 2009).

The empirical data comprises semi-structured interviews with 65 experts from German and Austrian companies of heterogeneous firm sizes and different industry sectors conducted between August 2018 and March 2019 (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007). The companies’ characteristics vary in sales volume (av. = 29,200 million EUR) and number of employees (av. = 83,000). They were analyzed in their role as buyers and stem from the automotive (n = 8), automotive suppliers (n = 15), consumer goods (n = 4), electronic and electrical engineering (n = 13), mechanical engineering (n = 13), and raw materials processing (n = 12) industries. All experts hold management positions with an average company tenure of 8.55 years and they are involved in or responsible for Industry 4.0-projects. The experts’ names and companies are anonymized for confidentiality reasons. The sample’s heterogeneity enables generalizing results and counteracts potential negative effects of sample biases (Yin, 2009). Selecting competent and knowledgeable experts strengthens the findings’ reliability (Huber and Power, 1985).

The interview guideline was informed by literature but followed the principles of openness and flexibility. The first part deals with questions about personal facts and company contexts. The second part focuses on current buyer-supplier relationships and the third part deals with future buyer-supplier relationships. To concretize some aspects and to reveal further information, individual questions slightly deviated from the original guideline. All interviews were audio recorded and transcribed which reveals more than 820 pages of text material. Whenever possible, secondary data was used to verify the experts’ statements for triangulation purposes, which increases validity and reliability (Eisenhardt and Graebner, 2007; Yin, 2009).

In order to answer the research questions, a qualitative content analysis was used to identify pattern, themes, and categories in the empirical material (Miles and Huberman, 1994). The study follows an inductive coding procedure that facilitates theory building but the categories were partly informed by literature to allow new aspects to emerge (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007; Krippendorff, 2013). In a first step, first-order (informant-centric) categories were developed. Second, the categories were synthesized into second-order themes. Third, the themes were distilled into general dimensions. The process was conducted in a research team consisting of three authors to ensure validity and objectivity of the coding procedure (Weston et al., 2001).
Results
The results are divided into three subsections addressing the paper’s research questions in a buyer-to-supplier perspective: First, it is described how present buyer-supplier relationships are characterized in differing industry sectors. Second, we describe to what extend buyer-supplier relationships change in the context of Industry 4.0 and how future relationships vary in several industries. Third, drivers and causes are presented why buyer-supplier relationship are transformed. Given the limited space of the paper, the chapter does only present and discuss those categories that are predominantly named to be relevant for the industries regarded in the sample. Table 1 depicts the results differentiated by industry sectors:

<table>
<thead>

Present buyer-supplier relationships
Interviewees from the automotive industry state that automated data exchange is how they share data with suppliers. Interestingly, automotive suppliers predominantly use non-automated data exchange with their respective suppliers in contrast.

Automotive suppliers and companies from the consumer goods industry indicate that personal and direct contact to their suppliers is of utmost importance in the present. In the automotive supplier industry, however, the frequency of direct contact with their suppliers is largely dependent on the respective suppliers’ importance.

For mechanical engineering companies, in the present long-term relationships with their suppliers play a crucial role. Those relationships are of close nature, for instance integrating suppliers in innovation and product development processes from early on.

As far as level of trust is concerned, especially representatives from the automotive industry and from automotive suppliers perceive a rather low level of trust in their present buyer-supplier relationships. In contrast, representatives from mechanical engineering and electronic and electrical industries predominantly describe their current buyer-supplier relationships to be positive and well established.

Future buyer-supplier relationships
Automotive suppliers and raw materials processing companies name digital and automated data exchange to be part of their future buyer-supplier relationships. Foremost companies from electronic and electrical engineering state that the importance of platforms and cloud computing increases. In contrast, automotive suppliers indicate that direct and personal contact still remains important in the future, which is also true for the consumer goods industry. In the automotive industry, real-time data exchange is a central characteristic of future buyer-supplier relations. Representatives of raw materials processing enterprises name an enhanced traceability as crucial for future collaboration in their industry. In the electronic and electrical engineering and raw material processing industry major manual activities, e.g., procurement processes, are automated in the future.

Mechanical engineering enterprises predominantly focus on strategic suppliers and companies from consumer goods industry keep a smaller supplier base in the future. Mechanical engineering enterprises and companies from raw materials processing aim at further integrating external knowledge, especially IT-related expertise. Representatives from automotive suppliers as well as raw materials processing companies apply different selection criteria to choose suppliers in the future.

Companies from the automotive industry and automotive suppliers predominantly aim at intensifying buyer-supplier relationships in the future. In addition, automotive suppliers try to intensify and broaden cooperation with start-ups. Companies from raw materials processing intend to cooperate more closely with their suppliers when it comes to new product development. Representatives from the mechanical engineering industry state that they prospectively integrate their suppliers at an earlier stage compared to the present.

Drivers and causes for transformation
Industry 4.0 and accompanying technological developments play a central role in the transformation of buyer-supplier relationships according to all interviewees’ statements. Various interviewees express that well-established and smooth buyer-supplier relationships are required to successfully implement Industry 4.0 across companies and subsequently profit from its entire set of potentials.

Several drivers can be observed why buyer-supplier relationships are transformed that differ in various industry sectors. First, companies from mechanical engineering, electronic and electrical engineering, and automotive suppliers see potential for
optimization in reshaping buyer-supplier relationships. In addition, competitiveness, both on an individual and a supply chain level, is strengthened through enhanced buyer-supplier relationships foremost for companies from the automotive and consumer goods industry. Apart from this, representatives from the automotive industry and automotive suppliers indicate that demands from their customers, e.g., higher flexibility, reliability, and product availability, drives changes in their buyer-supplier relationships. Transforming future buyer-supplier relationships enables companies from those industries to create new forms of value offerings for their respective customers. Data exchange across the supply chain, for instance via platform solutions and horizontal and vertical data exchange, requires new relationships between buyers and suppliers. Especially interviewees from automotive suppliers and consumer goods industry state that the possibility to share information and to increase transparency drives the transformation of their future buyer-supplier relationships.

External causes why buyer-supplier relationships are transformed can be found manifold as well. Representatives of automotive, automotive suppliers and raw materials processing companies name an increased market dynamic and volatility as well as an increasing competition as influence factors for a transformation of buyer-supplier relationships. Especially companies from mechanical engineering face increasing cost pressure they address with transforming their buyer-supplier relationships. Technological changes, e.g., digital technologies for digital data exchange and analysis, pave the way for future transformations, mainly in the industries of mechanical engineering and electronic and electrical engineering.

Discussion
As far as present relationships are concerned, the study uncovers that significant industry differences in buyer-supplier relationships can be observed. Among others, the results show that present buyer-supplier relationships in the automotive industry and automotive suppliers are built upon rather low levels of trust. In contrast, buyer-supplier relationships in the mechanical engineering and electronic and electric engineering industries are characterized by higher levels of trust. For the majority of industry sectors, present buyer-supplier transactions and information sharing are mostly conducted via non-automated, analogue, and manual processes. In this context, personal and direct contact are frequently used and are very important in present buyer-supplier relationships.

Our study reveals that buyer-supplier relationships are transformed in the context of Industry 4.0, but the extent of transformation varies among industry sectors, given differing status quos and intensities of changes. The automotive industry and their suppliers prospectively aim for improving current rather mediocre relationships with suppliers, whereas other industries aim at deepening and intensifying already well-established relationships, for instance, further integrating suppliers. In this regard, the paper contributes to the current state of literature emphasizing that well-established relationships are a prerequisite for successful supplier integration. Further, the paper confirms that intense buyer-supplier relationships pave the way to streamline value creation and to provide a superior value proposition that is aligned on end customers’ demand which in turn serve to build up a competitive advantage (Schoenherr and Swink, 2012; Tan et al., 2002; Thun, 2010).

Extant research has shown that the automotive industry and its suppliers perceive Industry 4.0 rather from an operational, than from a strategic perspective, in contrast to, for instance, mechanical engineering and electrical and electronic engineering companies (Kiel et al., 2017; Müller et al., 2018b). Our paper partly confirms these results revealing that for instance, companies from mechanical engineering and raw materials processing
concentrate on strategical aspects of buyer-supplier relationships, e.g., integration of partners in product development.

The results show that prospectively information sharing will increasingly be conducted via digital and automated processes in all regarded industry sectors. However, the extent and the forms differ as indicated by the results. For instance, in the automotive and automotive supplier industry, especially real-time data plays a crucial role. Digital platforms become relevant predominantly in the electronic and electrical engineering and automotive supplier industry. Sharing information increases productivity and decreases inventory levels, maintenance efforts, and value creation costs (Vanpoucke et al., 2017; Wang et al., 2006). Whereas on an operational level, information sharing might increasingly be conducted digitally (Hofmann and Rüsch, 2017; Müller et al., 2018a), the results indicate that on a strategic level, personal communication remains important in the future. The paper extends literature in adding that direct personal contact will remain of high importance in buyer-supplier relationships in the context of Industry 4.0.

Responsible for a great proportion of value creation, small and medium sized firms keep on working with manual and semi-digitized solutions in many cases for technical and financial reasons. Subsequently, this requires a strategy that both strives for digital data exchange and develops buyer-supplier relationships on a personal level to unfold the entire potential (Dweekat et al., 2017; Müller et al., 2018a).

Changes in future buyer-supplier relationships can be referred back to several drivers and external causes. Literature has revealed that collaboration, cooperation and integration provide several benefits (Bienhaus and Haddud, 2018; Haddud et al., 2017; Tan et al., 2002; Vanpoucke et al., 2017). Our study adds to the current state of research differentiating between industries and providing an industry comparison.

Our paper extends studies that highlight the importance of buyer-supplier relationships for smooth supply chains in the digital era (Tu, 2018; Wang et al., 2006). Information and communication technologies and digital supplier integration efforts pave the way to establish digital value creation networks in the context of Industry 4.0 (Vanpoucke et al., 2017; Thun, 2010).

**Conclusion**

Industry 4.0 has the potential to transform future buyer-supplier relationships. Despite its importance for research and corporate practice, there is still little research about Industry 4.0 from a Supply Chain Management perspective. Using a unique sample of empirical data comprising interviews with 65 experts from German industrial companies, the study analyzes how buyer-supplier relationships in the context of Industry 4.0 differ in various industry sectors.

The study entails some limitations as for the data sample and its method that are worth to discuss. First, the data sample exclusively includes German companies that may limit the results’ generalizability. Second, the study focuses on selected industry sectors, which must be kept in mind when transferring its implications to other contexts. Third, the study does neither differentiate between different levels of value chain stages, e.g., first-tier versus second-tier suppliers, nor does it analyze differences that stem from various company sizes, e.g., small and medium sized versus large companies. Fourth, the study solely analyzes buyer-supplier-relationships from buyers’ perspectives. As far as methodical limitations are concerned, developing solid theoretical implications from explorative, qualitative research is rather difficult. However, the study consolidates empirical data from individual cases while keeping relevant content, and in so doing, is able to work out theoretical contributions. In addition, various biases, e.g., key informant
and retrospective bias, are addressed by our methodological approach and discussed along with measures to reduce their impact.

In the course of the analysis, the study uncovers space for future research. Given the study’s limitations and contributions, further research could shed light on the following aspects. Quantitative research may complement the study and, for instance, may quantify and statistically prove the discussed effects. Future research can add the supplier’s perspective to analyze buyer-supplier-relationships, focus on small and medium sized firms, and differentiate between levels of value chain stages. Going beyond the study’s scope, research could focus on the following further aspects. Research could investigate the incentives to integrate suppliers and incentives to intensify cooperation and collaboration. Future research studies are ought to analyze how supplier integration is to be conducted operatively, what efficiency gains and economical outputs can be expected, and which implications for future value creation can be derived. In addition, platforms possess the potential to revolutionize buyer-supplier-relationships and therefore call for special attention leaving great space for future investigations.

The study and its findings reveal several implications for management and corporate practice. First, well-established buyer-supplier relationships can be regarded as a prerequisite for close cooperation and supplier integration in the digital era, which is why establishing such relationships, is of utmost importance. Second, cooperating and collaborating is crucial in the context of Industry 4.0 to acquire knowledge about IT-processes, especially for traditional industry sectors, such as mechanical engineering. Third, companies are advised to consider present relationships with suppliers and to harmonize digital information sharing and transactions across the supply chain. Fourth, the role of digital data exchange across a supply chain, particularly by using digital platforms, must be supported in future buyer-supplier relationships, given their potential for value creation. Keeping these aspects in mind, may help to prepare companies for future challenges and unfold the potential Industry 4.0 poses for industrial value creation and Supply Chain Management.

Supply Network Design
The Configuration and Evolution of Korea Automotive Supply Network: An Empirical Study Based-on K-core Network Analysis

Ahrom Kang
Sookmyung Women's University

Joongsan Oh
Sookmyung Women's University

Abstract

The purpose of this study is to analyze the Korea automotive industry supply network based on the K-core method, not the traditional tier perspective. The analysis shows that the core structure is barrel-shaped and that even the same tier suppliers can belong to other core. From the analysis of network evolution from 2007 to 2017, most of the newly emerging nodes are entering 1-core, while nodes located in the 4-core are maintaining more than 80%. This study suggests theoretical and practical implications that a focal company should manage and care about nodes with high core on the network.

Keywords: Korea Automotive Industry, Supply Network, K-core method

Introduction

Traditionally, supply chain management has focused on vertical and linear relationships between buyers and suppliers. However, due to the development of industries and the globalization of enterprises, multi-tier supply networks have been formed, which does not explain the complexity of the supply chain from an existing perspective (Lamming, 2000; Borgatti and Li, 2009).

Recently, there have been a lot of studies on the supply network, but most of them are limited to theoretical and descriptive studies. Research to analyze the real supply network through social network analysis is still lacking. Because it is difficult to collect data for network analysis, and the theoretical basis for interpreting the various measurements used in social network analysis from the perspective of the supply chain is not clear (Harland et al., 2001; Kim et al., 2011).

The supply chain of the automotive industry consists of 1st, 2nd, and 3rd suppliers based on the automakers and the structure of the automotive industry was generally described as a tier structure (Nishiguchi, 1994). In reality, however, most suppliers do not belong to only one supply chain, so the automotive industry has a very complex network structure. Therefore, using social network analysis, the supply chain of the automotive industry can be understood at the entire network level.
The purpose of this study is to investigate the complicated multi-tier supply network of the Korean automotive industry, through $k$ -core network analysis. $K$-core is a beneficial way to find the core group in a complex network. Research questions are proposed as follows.

**RQ 1.** What is the configuration of the Korean automotive supply network when applying the K-core method?

**RQ 2.** How does the Korean automotive supply network configuration evolve?

**K-core analysis**

$K$-core, the primary analysis method of this study, can be defined as a maximal subgraph in which all nodes are connected to at least $k$ number of other nodes (Seidman, 1983; Scott, 2012). That is, all nodes in the $k$ -core have degree centrality greater than or equal to $k$ (Prell, 2012).

Small $k$ means the big size of the subgroup as it includes nodes having a low degree. On the other hand, the increased $k$ means a relatively small size of the subgroup as only the nodes having a high degree will be included. This is the way of forming a hierarchical structure according to the value of $k$, and nodes including a high-level $k$ -core are the vital node that makes the network cohesive (Tong, 2002).

$K$-core analysis has recently been applied to many real networks (Internet, WWW, a cellular network, etc.) and is used as an essential tool for visualizing and interpreting complex networks (Dorogovtsev et al., 2006).

![Figure 1 – Tier structure vs. k-core structure](image)

(a) Tier structure

(b) K-core structure

*Figure 1 – Tier structure vs. k-core structure*

(2) from Clark and Fujimoto, 1991, p. 139, (b) from Tixier et al., 2016

The Korea automotive supply network is a highly cohesive, forming a hierarchical distribution relationship with a small number of the automaker (e.g., Hyundai, Kia, and GM) in the center. Therefore, by using $k$ -core analysis, it is possible to find the core group by analyzing the cohesion structure of a complex network. It was common to explain the supply network of the automotive industry based on the tier structure. Tier was first introduced to describe the pyramid-shaped supply chain of Japanese automotive and electronics industry (Nishiguchi, 1994).

As Figure 1 (a) shows, the tier can be measured as the distance from the automaker to several steps away. However, in reality, the supply network looks rather close to Figure 1 (b). Suppliers' links forms complexed shapes, they are not just connected vertically
(from lower-tier supplier to higher tier supplier); connected within the same tier, or between the 1st and the 3rd tier.

As shown in Figure 1 (b), node ** is a 2nd tier supplier based on the distance from an automaker, but node **, differentiating itself from node *, is higher degree because it is also connected to other 2nd tier suppliers. In the tier structure, the node * and the node ** are the same tier, but the degree is different. Therefore, in the \( k \)-core structure, the node ** belongs to a higher core than the node * and more influential in the network (Kim et al., 2011).

For the analysis, supplier information is gathered using the "Automotive Industry Guide" issued by the Korea Automotive Industry Cooperative bi-annually. For the first research question, \( k \)-core analysis was conducted using the most recent 2017 supply network data, and the network structure was identified by measuring the geodesic distance to a specific supplier based on the automaker. For the second research question, from 2007 to 2017, we observed how the \( k \)-core of nodes in the supply network changes over two years. We classified all the nodes into three categories: a new entry into the network, same core compared to the previous period (two years ago), and core moving (rising or falling) and analyzed the drivers of change. UCINET6, a social network analysis tool, was used for data analysis.

**Tier structure vs. Core structure**

First, \( k \)-core analysis was conducted using data from 2017 to compare the tier structure and core structure of the Korean automotive industry network. As a result, the network is divided into four cores as shown in Figure 2. In 4-core, 55 firms including the automaker, 116 firms in 3-core, 71 firms in 2-core, and 113 firms in 1-core can be found.

![Figure 2 – Network visualization of the 2017 Korean automotive industry](#)
We also measured the 'geodesic distance' from the automaker to the specific supplier to identify the tier structure. The 'distance', which is commonly used in a network, means the shortest path among a plurality of paths between two nodes (Wasserman and Faust, 1998).

There are five automakers; Hyundai, Kia, GM, Renault Samsung and Ssangyong in the Korean automotive industry network. When we measured the geodesic distances to specific suppliers based on the five automakers, the tiers appeared mixed. For example, there are 2nd tier suppliers of Hyundai, Kia, and GM as well as 1st tier suppliers of Renault Samsung and Ssangyong. In this case, it was measured as a 2nd tier supplier, because it is the 2nd tier to more than half of the automakers in the network. As a result, we confirmed that there were third-tier suppliers in the network.

![Figure 3 – Tier distribution by core](image)

Figure 3 shows the distribution of tiers by the core. For the 4- core, which is the most central part of the network, 29 1st and 19 2nd tiers belong together. Unlike the hierarchical structure of the tier perspective, in a core-based network, different tier suppliers can be located in the same core.

Similar to the study by Kito et al. (2014), which revealed that the supply network of Toyota is a barrel-shape with a more significant number of 2nd tier suppliers than the 1st tier suppliers, it is confirmed that the core structure of the Korean automotive industry is also a barrel-shape. However, the difference is that the network is analyzed by the core structure and the tiers of the suppliers are mixed in each core.

**Evolution of Korea automotive supply network configuration**

Regarding the second research problem, Figure 4 visualizes the results of analyzing the supply network of the Korean automotive industry every two years from 2007 to 2017 using k-core. The network was divided into four cores in all periods. It can be seen that there is no dramatic change in the number of nodes and links in the entire network.
First, as shown in Table 1, most of the new nodes are entering at 1-core all the period. As expected, it can be confirmed that new entry into the lower core is relatively easy.

*Figure 4 – Evolution of Korea automotive supply network*
Second, we measured the percentage of nodes in each core that remained the same compared to the previous period and Table 2 shows that the remaining ratio of the nodes increases with the upper core. It is related to the supplier certification of the automotive industry.

For the automotive industry, most automakers have a supplier certification system because the quality of the parts directly affects the performance of the finished car (Cho et al., 2007). In the case of Hyundai-Kia Motors, only the 1st tier suppliers that have received the "5star" certification can participate in the bidding process, and the 2nd tier suppliers can also deal with the first tier suppliers only if they are certified as SQ (Supplier Quality) (Hyundai · Kia Motors 2012). These certified first and second suppliers are likely to maintain their existing high cores, and it is challenging for new suppliers to enter 3-core or 4-core.

Third, it is confirmed that the remaining ratio changes depending on the performance of major automakers. Compared to 2013, the remaining ratio was increasing in all cores in 2015. At this time, Hyundai Kia Motors, a major player in the Korean automotive industry, was in a period of growth and the supply network has also stabilized. On the other hand, it confirmed that the remaining ratio in all cores decreased in 2017, which is closely related to the poor sales performance of Hyundai Kia Motors due to a decline in sales volume in China.

Fourth, as shown in Table 3, for 14 suppliers in 4core for ten years, the production rate of auto parts is very high, and most of the production items; chassis, suspension spring, door frame, radiator grille, interior lamps, steering wheel, engine parts, drive axle,
modules and A/S parts are related to modules. Therefore, suppliers that produce critical components (or modules) are more likely to remain in 4-core.

Finally, we observed the rise and fall of the core for 196 suppliers in the network for ten years. Among them, we examined the sales of 30 suppliers whose core is steadily rising or maintaining core after ascending, which confirms the tendency of the sales increase. However, companies with core declines could not find a connection with sales.

Conclusion
The results of the study will be summarized as follows. Firstly, by measuring the geodesic distance from an automaker to a supplier, we confirmed that there are even 3rd tier suppliers in the network. Secondly, as a result of sub-group analysis with K-core, the network was divided into four sub-networks. The core structure is a barrel-shaped; the tiers of the suppliers are mixed in each core. Thirdly, as a result of analyzing the supply network evolution from the year 2007 to 2017, in most cases, new nodes in the network enter as 1-core.

On the other hand, more than 80% of the nodes located in the 4-core have remained the same core, and the remaining ratio changed significantly depending on the performance of major automakers. Fourthly, suppliers that specialize in auto parts and
produce major components such as modules are constantly in the 4-core. Lastly, suppliers whose cores have risen are continuing to increase their sales.

Unlike previous studies, which used behavioral analysis of dyadic relations or specific parts supply networks, this study is meaningful in that it empirically analyzes the entire supply network of the Korean automotive industry using actual transaction data. Also, this study complements tier structure-based studies by applying the K-core methodology for the first time in the supply network research.

This study suggests theoretical and practical implications that an automaker or a focal company should be careful about and manage nodes which have high K-core away from directly connected dyadic relations. In future research, it is necessary to examine the drivers of network evolution through the reinforcement of methodology.

Abstract

While there is substantial research about consequences of supply chain complexity on disruption risks, little research focused on the root causes of product recalls. Recall rates in the automotive industry have seen a severe increase in recent years. This research addresses the relations between supply chain design and product recalls in the automotive industry from a product-, process and location perspective. The results of this study suggest that higher supply chain complexity contributes to increasing recall rates. A mitigation approach consisting of multiple action fields is provided, tackling recalls arising from increasingly deep, broad and dispersed supply chains.

Keywords: Supply Chain Design, Decision-making, information processing

Introduction

Product recalls in the automotive industry have seen a severe increase within the last decades. This trend is observable for different markets. Analysis of data from the National Highway Traffic Safety Administration (NHTSA) and the Driver and Vehicle Standards Agency (DVSA) shows evidence that increasing recall incidents are not a national phenomenon, but an international development that affects the whole industry (DVSA, 2019; NHTSA, 2019).
The Takata airbag scandal further showed the reputational and financial damage that OEM and suppliers faced because of malfunctioning products. The malfunctioning airbags from the supplier Takata led to unintended ruptures, which caused at least 16 deaths and over 100 injuries (Bomey, 2017). Moreover, the product malfunction resulted in a recall of over 100 million inflators and over 42 million cars until the end of 2017 (“ADAC,” 2018). Although the effects of recalls are discussed in multiple facets, such as the effects on shareholder wealth or future product reliability, there is limited understanding of the underlying causes concerning the vulnerability of manufacturer’s supply networks (Kalaignanam et al., 2012; Ni et al., 2016).

Supply chain complexity
(Lyles et al., 2008) conceptualized the role of supply chains in China’s product recall problems and highlighted the challenges of supply chain depth and complexity in a globalized industrial environment. Deep supply chains are characterized by a large number of subsequent upstream tier stages. In this context, traceability refers to the obligation for a documentation that proves that the supplier has followed the instructions previously agreed upon throughout the entire process chain from origin to point of sale. In deep supply chains, it is often difficult to provide a sufficient traceability of the products (Maruchek et al., 2011; Tse & Tan, 2012). Reduced traceability can cause issues such as poor supplier material, product contamination or non-conformance incoming inspections that lead to compromised quality (Maruchek et al., 2011; Tse & Tan, 2012). Accordingly, among the most frequently mentioned risks in supply chain processes are more complex supply chains (Bode & Wagner, 2015; Lyles et al., 2008; Maruchek et al., 2011; Sheffi & Rice, 2005; Speier et al., 2011). Bode & Wagner conceptualized supply chain complexity as vertical, horizontal and spatial complexity, which refers to the number of upstream tier stages, the number of tiers on one stage, and the geographic dispersion of the supply chain. It was found that increased supply chain complexity increases the risk for disruptions. The causes of these disruptions in deep supply chains are rooted in an unforeseeable interaction of small failures in the upstream supply chain, which can cause disruptions downstream (Bode & Wagner, 2015). It was not further elaborated what causes these failures and more precisely, how product, process and location based attributes foster the complexity of supply chains. Furthermore, the relations between product modularity and the

Figure 1 – Number of recall campaigns in the USA and UK (normalized)
fragmentation of value adding processes are yet partly unexplored. (Novak & Eppinger, 2001) examined, how product complexity influences sourcing decisions, but made a major simplification for sourcing as being a binary variable (make or buy). Hence, it was not assessed how product architecture and complexity influence the supply chain depth and breadth. Therefore, this research bridges the gap between the findings of Wagner & Bode (2015) and Novak & Eppinger (2001) by examining how product architecture influences supply chain complexity and how this complexity relates to product recalls. Moreover, prior research identified proximity of first tier suppliers in production networks as essential to ensure design compatibility and avoid lack-of-fit risks by reinforcing inter-firm knowledge exchanges (Bode & Wagner, 2015; Frigant & Layan, 2009). Accordingly, following prior research about the geographic re-configuration of automotive supply networks, geographic supply chain dispersion is examined as a further contributor to recalls (Sturgeon et al., 2008).

The findings of this research were used to create a decision support framework for supply chain design to mitigate recall related risks. The research aims to answer the following research questions:

1. How do product-, process- and location related supply network design decisions of a firm affect its product recall rate?
2. How can product recall related vulnerabilities in these networks be effectively mitigated?

To systematically capture the characteristics relevant for supply chain decision-making, an academic framework was developed. The domains capture product, process and location related supply chain characteristics. These are defined by the characteristics of the component to be bought, the processes involved in producing this component, and the location where the component is to be bought as well as the location of the end product to be sold. The decision areas following from these characteristics are shown in the framework. The result of the supply chain decision-making process is the supply chain complexity. The complexity can relate to spatial complexity, which describes the spatial dispersion of the supply chain, and the vertical and horizontal complexity, representing the depth and breadth of the supply chain.

Figure 2 – Supply chain design framework
Method
This research relies on empirical data. This is due to the limited understanding of the relationship of supply network design decisions and resulting risks. A qualitative research approach was chosen, as the research questions to be investigated suggest an exploratory nature of the phenomenon (Yin, 2014). Hence, case study research was chosen to accommodate for the exploratory nature of the research questions.

Data collection
Semi-structured interviews were chosen to allow for enough flexibility during the interview process (Yin, 2014). The interviews were conducted with OEM and suppliers in the automotive sector. The questionnaire was handed to the interviewees prior to the interview to allow for preparation. In total 12 company representatives were interviewed. The units of analysis in this case study were supply chain design strategies. Multiple companies and accordingly multiple units were analysed, hence the case study design followed an “embedded” approach (Yin, 2014). Moreover, the focus in these companies was set on the Supply Chain, Purchasing and Quality Management departments in Europe and the USA in order to ensure that the data obtained in the case study was received from sources, which are familiar with the topic and relate to the markets of reference in the data analysis. Interviewing different departments involved in the supplier selection process allowed to identify differences in priorities with respect to selection criteria. Within the study, 24 purchased components used for the assembly in cars were analysed according to their product architecture, their supply chain breadth and supply chain depth. Information about supply chain design were matched with the framework to identify sources of network vulnerabilities that increase the recall risk. The list of participants is shown below:

Figure 4 – Interview feedback summarized

By analysing the feedback of the interview partners (“IP”) regarding supply chain design decisions and the depth and breadth of supply structures of the components, which were purchased for the assembly in cars, patterns regarding decision-making and supply chain complexity were identified. The results of this study show several facts:

- The depth and breadth of supply chains are determined largely by the product architecture and the integration concept.
- Cost pressure significantly extends supply chains towards deeper structures (IP 5…8,10)
- Sub-components for many products are negotiated, cost pressure affects the content of components (IP 5…8,10)
- Increased supply chain breadth and depth increases recall risks by worsening supply chain visibility, fragmenting value adding processes and increasing lack-of-fit risk
- The results suggest that geographic complexity is associated with stronger communication barriers and a higher lack-of-fit risk

Discussion

Prior studies have suggested increased supply chain complexity as a source of risk for disruptions (Bode & Wagner, 2015; Marucheck et al., 2011; Tse & Tan, 2012). The findings of the case study confirm that supply chain complexity increases disruptions and the scope is further narrowed down on automotive product recalls. In addition, a causal perspective on failures extends the predominantly logistical contemplation of
failure sources. During the case study, evidence for the relation between product architecture and supply chain complexity was collected.

Supply chain breadth & supply chain depth

Modular sub-systems such as oil or fuel pumps, electrical engines and electronics components have significantly broader and deeper supply chains than simpler, in most cases integral components. A great part of the integration efforts to create these subsystems is distributed among lower tiers (IP 2,5…8,10). Especially electronics components such as those for navigation systems, circuit boards and control units are so complex in nature, that most interviewees were not able to name the exact breadth and depth of the component, but indicated that it is very high (IP 2,6,7,10). It was found that supply chains become deeper and broader, the more electronic and electro-mechanical content is required, as confirmed by interview partners 2,5…8,10). This is due to a requirement for specialisation regarding development competences and technologies. Accordingly, requirements for competences in different technological fields lead to a fragmentation of supply structures. In contrast, supply chains become less complex when a large part of the value added can be generated with a single or several related technologies. This finding is somewhat contrary to the implications of (Novak & Eppinger, 2001) on product complexity and make-or-buy decisions. Whereas (Novak & Eppinger, 2001) found that increasing product complexity enhances in-house production, this research suggests that specialization of production and development capabilities lead to a more fragmented organization of supply and increases the breadth and depth of supply chains. Reasons for this discrepancy may be rooted in the change of product characteristics due to a higher degree of automation and electrification in cars and accordingly increased content of mechatronic, electronic and software units within the last two decades. Moreover, cost pressure was found to have an impact on the supply chain depth, but also on the content specification on lower tier levels (IP 5,7,8,10). More precisely, cost pressure encourages lower tiers to outsource their activities (IP 5…8) and determines the quality of sub components in the main component (IP 7,8). For components such as electronic control units, the sub-content is part of the negotiations and cost pressure reduces the quality of the end product (IP 7,8,10). The interviewees who were asked about the relation between supply chain complexity and recalls, confirmed that modular, often more complex products carry a higher inherent risk for malfunctions (IP 5,6,8,10). Reasons for higher failure probabilities for components with deep and broad supply chains were partly mentioned in prior literature. Worsened traceability in deep supply chain structures was identified as a source of risk for reduced quality (Marucheck et al., 2011; Tse & Tan, 2011). Multiple interview partners confirmed that traceability in general is guaranteed, but that informative value is lost when components cross firm boundaries (IP 2,5,7,10). Hence, supply chain depth is associated with worsened traceability. In addition, it was found that components that require particularly demanding manufacturing processes have a higher failure probability. For example, sub components that require particular manufacturing processes, like sintering, are more vulnerable for malfunctions, if the supplier is missing the know-how for specific steps, like the pressing or hardening of the part or if several difficult processing steps are done by different suppliers. This is why for certain components with high-tech production requirements, the failure probability is higher than for those with more basic requirements. More modular and complex components that have a high number of these critical parts are therefore more vulnerable for malfunctions.
**Geographic dispersion**

Multiple interview partners confirmed that product recalls in the automotive industry have its root causes mainly in design and layout failures (IP 5,8,10). Interview partner 10 is head of quality management and confirmed that approximately 80% of all recalls are due to design and layout flaws, whereas flaws in production and logistics cause the remaining 20% of the recalls. This implies that product design and development is the dominant contributor to product malfunctions and the identification and mitigation of root causes for lack-of-fit risks is highly relevant for product safety. (Marucheck et al., 2011) argued that increasing globalization in production networks reduces the traceability of components in the supply chain and therefore makes maintenance of product safety more difficult. The results of the case study confirm this argument. Multiple interview partners confirmed the importance of collaboration of design and development departments between OEM and first tier suppliers to ensure the compatibility of components (IP 5,7,8,10). The results of the case study confirm this argument. Multiple interview partners confirmed the importance of collaboration of design and development departments between OEM and first tier suppliers to ensure the compatibility of components (IP 5,7,8,10). This collaboration is compromised by spatial distance. Interview partners 8 and 10 highlighted problems with collaboration between OEM and FTS in cases where the FTS is located in rural areas, as direct communication for project based work is aggravated. Furthermore, language barriers in cases of collaboration with foreign partners make communication for joint development and design tasks more difficult (IP 6,8). This implies that more local collaboration in development may be a solution to reduce design flaws. However, an ongoing specialization process, technological constraints for production and strategic cost based considerations suggest that there is rather a trend towards more dispersed supply structures than towards local structures (IP 1,2,5…8,10). Multiple interview partners confirmed that competence for different key technologies are located in different regions of the world (IP 1,2,4,5…11). Therefore it seems unlikely that network structures will become less dispersed in the future.

**Mitigation strategies**

The case study revealed multiple action fields. Multiple research scholars highlighted the importance of traceability as an effective countermeasure to tackle issues such as poor supplier material, product contamination or non-conformance incoming inspections that lead to compromised quality (Lyles et al., 2008; Marucheck et al., 2011; Tse & Tan, 2012). As many interview partners pointed out, there is a trade-off between traceability costs and benefits, which determines the degree of the granularity of the data (IP5…8,10). RFID technology can improve data granularity, as it enables the traceability of the component within the production and assembly process. However, the associated costs for tracking and capturing field data from components that are used in cars in large numbers, which can easily reach several millions in case of car models that are sold in large quantities, imposes a significant cost factor for car manufacturers. It is questionable if a broad field data collection would be financially beneficial. Hence, an approach, which selectively collects data from a limited number of sold models would be more suitable (IP 7,10).

Production processes were identified as another field of high relevance for traceability (IP 1, 5…8,10). The interconnection of data flows across firm boundaries allows to capture important variables in all steps of the production process and to link the data of all steps to use it for the end product (IP 5,8,10). This interconnection enables the monitoring of process variables and a faster reaction in case of defective
production (IP 5…7,10). Moreover, root causes for product malfunctions can be detected more easily (IP 5,10). However, higher costs associated with the gathering and management of the data limits the applicability of production traceability. Accordingly, this requires an empirical evaluation of product categories and the scope of production traceability efforts should be focused on products and components with an empirically verified high failure probability (IP 6).

(MacDuffie & Fujimoto, 2010) anticipated the loss of control that automobile manufacturers will suffer due to products with a higher degree of digitization. However, they argued that older car manufacturers ("dinosaurs") will be able to manage greater product complexity in their supply chain due to their legacy better than younger companies. The results of this work suggest, however, that it is precisely this legacy that complicates the organizational learning of major manufacturers, thereby causing inertia in processes that compromise product safety. In order to establish minimum standards for software quality, legally binding conditions for tests should be defined for each safety relevant software component. In addition, several interviewees have argued that government authorities should consider a disclosure requirement for safety relevant software (IP 10,12).

Conclusion
As the first study to link product-, process and location characteristics with product recall rates, the findings of this study are highly relevant considering increasing product recall rates in the automotive industry. Prior literature identified trends towards a reconfiguration of supply networks in the automotive industry (Sturgeon et al., 2008). The results of this study suggest that the dispersion of supply networks is associated with higher recall rates as the compatibility of components is put at risks and collaboration is aggravated. The study further identified product complexity as a driver for product recall rates, as it fosters supply chain complexity and aggravates traceability. Cost pressure and capacity constraints exacerbate the supply chain complexity as outsourcing activities increase. In order to mitigate the consequences of increasing supply chain complexity, this research suggests the implementation of new technologies to increase the traceability of production and logistics processes. Data connectivity and production organization as well as new testing methods improve the product compliance and traceability along the supply chain. Moreover, the results reveal that the complexity of digital products require new ways of product testing and furthermore necessitate a reassessment of governmental regulations regarding the disclosure and testing procedures.

Implications and Contribution
By classifying supply chain design into three domains and matching the literature with empirical data, this study is the first to demonstrate how product-, process- and location based characteristics shape the complexity of supply chains. Furthermore, this study reveals new relations between product architecture and supply chain complexity that challenge findings of existing research regarding make-or-buy decisions. While prior research argued that product complexity fosters make-decisions, this research finds that higher product complexity leads to a fragmentation of value-adding processes and accordingly to deeper and broader supply chains. It was shown that the complexity of products has various effects on failure probabilities. Electronics, electro-mechanical components and software components are associated with a high number of sub-entities and functional interrelations within the components. At the same time, these components become increasingly important for modern cars. Hence, automobiles are expected to become more complex in the future.
To tackle problems associated with a higher product complexity, this research suggests a policy mix consisting of multiple fields of action for the implementation of mitigation strategies in practice. Accordingly, reducing recalls effectively is not straightforward, but requires actions in different fields regarding logistics, production and regulation. As technology in fields like autonomous driving is rapidly proceeding, the responsibility of car manufacturers to provide safe products despite increasing complexity gains an even greater importance. The results of this study show evidence that software related recalls are not an emerging issue for manufacturers, but already represent a significant fraction of recalls leading to potentially severe financial and human costs and are expected to increase further rapidly. This poses an urgent need for standardization of processes and regulations regarding the testing of new software. Inertia caused by the legacy of car companies has to be overcome quickly to cope with the transformation of the automobile from a purely mechanical to a highly digitized transport medium.

Limitations & further research
As with all studies, this research is subject to limitations and therefore provides possibilities for further research. Although several fields of actions have been identified by this study, further research should focus on implementation strategies with the aim to improve implementation strategies regarding data connectivity in supply chains and operations. Moreover, it should be specified, in which order the countermeasures should be implemented and if they should start upstream or downstream in the supply chain. Lastly, it should be mentioned that product recalls have only limited significance as a measure of product quality. Even though product recalls went up significantly within the last decades, there is little doubt that vehicles became significantly safer during this time. Hence, with new safety features there are more possibilities for malfunctions. This development certainly contributes to higher recall rates and puts the results in perspective. Nevertheless, we are convinced that this research provides valuable insights for theory and practice.

Abstract

The increasing emphasis on small series production in higher cost locations is particularly challenging in the textile/apparel industry due to global supply chain configurations. To support (re)configuration in this context, Total interpretive structural modelling (TISM) method is used to gain a deeper understanding of the inter-relationships among configuration/capability related aspects from the literature. TISM interviews were done with 24 industry practitioners producing/sourcing in the EU, or in the process of implementation. The findings validate extensive inter-relations, at the same time highlighting relational aspects, internal integration, and quality as significant drivers. Further in-depth research is required to understand these influences.

Keywords: Supply network configuration, Total interpretive structural model, textile and apparel industry

Introduction

Significant challenges to existing global supply chains include the need for faster development and delivery along with increasingly customised products. This demand for greater speed and responsiveness combined with rising wages offshore is leading to more reshoring or nearshoring production to higher-cost locations (Martínez-Mora and Merino, 2014, Benstead et al., 2017). These changes are especially relevant in the textile/apparel industry where demands for competitiveness and sustainability are leading to greater emphasis on agility, speed, and smaller-series/on-demand production (Andersson et al., 2018). However, in these industries, the current global structures and operations have resulted in decoupled supply chain stages due to locational separations (e.g. textiles in Ketokivi et al. (2017)), and thus are unable to deliver speed, quality and sustainability at the same time. For this reason, there is a need to re-design or configure these supply chains/networks in order to be able to deliver with respect to these demands. Therefore, context specific understandings are required regarding how the textile/apparel supply chain should be configured for competitive small series
production in high-cost locations, as there is no ‘one size fits all’ in supply chain design (Melnyk et al., 2014). Here, high-cost locations are defined in terms of GDP per capita (e.g. Ketokivi et al., 2017).

When designing and configuring the supply chain, there are many aspects that need to be considered related to configurations and capabilities. While several inter-relationships or associations between some of these aspects are touched upon in the literature, contributions focusing on these relationships are more limited. In particular, an emphasis on causality and understanding of how or why these associations exist is lacking. For example, literature has associated several aspects with high-cost production/sourcing locations such as product complexity and customisation (e.g. Grandinetti and Tabacco, 2015), quality, innovation and sustainability, and the need for fast delivery (Bryson and Taylor, 2010, Pal et al., 2018). However, the understanding of how these aspects individually, and in combination, influence products, production, relationships and the structure of the supply chain is lacking. This understanding is crucial for several reasons, as it may be necessary to focus on several aspects at the same time for competitiveness, as in the case of innovative, high quality and customised products (e.g. Bryson and Taylor, 2010). Additionally as competitiveness can require balancing these different aspects e.g. with respect to the level of product variety, customisation and speed required (e.g. Salvador et al., 2004). Further, the nature of these inter-relationships should be understood from the perspective of the decision-makers or practitioners, as their ‘factual premises’ are the basis for their decisions (e.g. Ketokivi et al., 2017), here regarding supply chain design. Crucially focusing on the textile/apparel industry as a relevant context to address for the reasons previously mentioned.

Thus, due to the numerous potential inter-relationships briefly discussed, there is a need for a deeper understanding of how these configurational and capability aspects (Table 1) relate to each other according to the practitioners within a particular context. Thus, the purpose of this paper is to examine the influences between supply network configurational aspects and associated capabilities with respect to small series textile/apparel production in high-cost locations.

**Conceptual model development**

As briefly discussed above, there are many potential inter-relationships suggested in the literature between aspects related to supply chain/network design and configuration. For brevity, the adopted view of configuration is mentioned, followed by the categorisation and presentation of the aspects from the literature that are included in the model. Thereafter, some inter-relationships between the categories are briefly touched upon.

The definition of supply network configuration (SNC) presented by Srai and Gregory (2008) is used here to categorise and understand the configuration and capability aspects generated from a review of the literature on small series production in a high-cost context (Table 1). According to the authors, SNC is composed of four elements: (1) network structures, (2) network relationships, (3) unit operations, and (4) the value structure. The value structure is encompassing the product related aspects, here including PS and PV. The unit operations including the type of operations- SK and how flexible- OF. The structure involving the shape and coordination of the network, here including LO, SF, II, SI, and CI. With network relationships relating to the governance and softer aspects of networks, including RE, CM, and TR. Further, Srai and Gregory (2008) address SNC in relation to capabilities and performance, with aspects such as customisation, quality and speed/responsiveness being included as strategic priorities, capabilities and performance. In line with this perspective, and due to the primary...
importance of defining these objectives when designing or configuring the supply chain (Melnyk et al., 2010, Melnyk et al., 2014, Calleja et al., 2018), these aspects (CU; IN; SU; QU; DE) are categorised as capabilities in this paper. These aspects being crucial for evaluating a supply chain (Calleja et al., 2018) as the configuration defines the capabilities that are possible to achieve (Srai and Gregory, 2008, Melnyk et al., 2014).

As discussed above, there are many inter-relationships between these categories of aspects suggested in the literature. For example, $PS$ and $PV$ can have implications on the level of $OF$ possible or required in relation to levels of $CU$ (e.g. Macchion et al., 2017a, Salvador et al., 2004), thus highlighting inter-relationships between value structure, unit operations, and capabilities. With increased levels of customisation necessitating greater employee knowledge-$SK$ and empowerment (e.g. Sandrin et al., 2018), as well as affecting or being related to the complexity and changeability of network structures-$SF$ and the characteristics of relationships in the network (Dedrick et al., 2008, Lyons et al., 2013). Additionally, with the structural aspect of customer integration/involvement being inter-related with operational production and supporting technologies (e.g. Piller et al., 2004, Salvador et al., 2015). Beyond these inter-relationships several others are potentially relevant e.g. the need for fast delivery or high quality influencing various aspects of the overall configuration. Thus, these interactions, which must be considered, necessitate interpretation and evaluation within a particular context.

**Methods**

In this paper, the purpose is to model the influence between relevant aspects of network configuration and capabilities for small series production textile/apparel production in high-cost contexts. Through this process identifying the drivers, dependent, and tightly inter-related aspects with respect to this particularly relevant industry context. This is done with the Total interpretive structural modelling (TISM) method undertaken through in-depth interviews, thus providing evaluation and interpretation.

**Interview process**

Total interpretive structural modelling (TISM) was employed with practitioners from the European textile/apparel industry to evaluate the influences between the configurational and capability aspects. Respondents were chosen from firms currently undertaking small series production in Europe, or that are strategically planning to (soon to start). Twenty-four responses were gathered from companies ranging from small retail brands to larger international companies, operating in various stages in the textile/apparel value chain (e.g. fabric and/or garment manufacturers, branded retailers, etc.). As studies employing ISM/TISM have been conducted with smaller sample sets (e.g. Lamba and Singh, 2018, Mangla et al., 2018), this number of respondents can be considered reasonable. Some relevant company characteristics are presented in Table 2.

**Total interpretive structural modelling approach**

The TISM process quality was ensured in line with Sushil (2017), with TISM going beyond the ISM process by interpreting the relationships and highlighting relevant transitive links (Sushil, 2012). In this case, the respondents were asked to evaluate whether an aspect ‘will influence’ or ‘influences’ another aspect and how strongly (0-4). With the following answers possible:

- V- Aspect $i$ influences aspect $j$;
- A- Aspect $j$ influences aspect $i$;
- X- Aspects $i$ and $j$ influence each other;
- O- Aspects $i$ and $j$ do not influence each other.

Further, any explanations were elicited to provide a deeper understanding and contribute to a knowledge-base. Thus, explanations and evaluations of strength of the relationships for insights regarding ‘how’ and ‘why’ this influence takes place (Sushil, 2012), and to emphasise the most important direct and indirect links between the structural levels in the resulting diagraph.

In addition to partitioning the aspects into levels to generate the diagraph structure, MICMAC analysis can be used with the same data to classify the aspects according to driving power and dependence (e.g. Lamba and Singh, 2018, Mangla et al., 2018). Specifically, classifying the aspects into four clusters: Autonomous–with low driving power and dependence, Dependent–high dependence with low driving power, Linkage–with high driving power and dependence, and Independent–high driving power with low dependence.

For the aggregate ISM diagraph and MICMAC analysis, an initial reachability matrix was generated by including each relationship between two aspects $i$ and $j$ that a majority of respondents marked as valid, regardless of the strength. Transitivity checks were done to generate the final reachability matrix and resulting diagraph structure. Thereafter the respondents’ interpretations regarding relationship strength were used to identify the most relevant inter-relationships for the TISM diagraph structure, with significant transitive relationships included. Thus, the final TISM structure highlighting the most significant drivers and dependent aspects by focusing on the strongest relationships.

**Results and discussion**

Following, the results are presented in aggregate, elaborated upon with some relevant explanations from individual respondents and discussed.

For the aggregate ISM results, relational aspects ($TR; RE; CM$), as well as $II$ and $SI$ are the strongest drivers, see the MICMAC and diagraph structure in Figure 1. There are many aspects that are classified as linkage with high levels of inter-dependence with each other, thus all being on the same level. The most dependent aspect is $CU$, which is influenced by all the other aspects.
The extensive inter-relationships with many aspects at level 2 necessitates highlighting the most relevant relationships. Here the respondent evaluations regarding the strength of the relationships are used to create the TISM structure (Figure 2). Thus, emphasising the most significant driving and dependent aspects with respect to both the direct and transitive relationships.
drivers (Melnyk et al., 2014) for high-cost textile/apparel. Specifically, the overall TISM process, interpreting the strength of the relationships with explanations has provided a deeper understanding of the configuration of supply chains/networks. Notably, there is a great deal of interdependence between the aspects, with many aspects classified as linkage and CU being driven by the other aspects (see Figure 1). Thus, many aspects must be taken into consideration when designing the network configuration individually as well as regarding how they inter-relate. Whereas relational aspects (RE; CM; TR) and II are drivers according to ISM, the TISM provides a more detailed picture of the strength and significance of these inter-relationships, with QU also found to be a driver in this context.

Some of these key drivers and their inter-relationships, according to the TISM/ISM structures, were explained by the respondents. Specifically related to TR and RE, one respondent said “...if you have good trust, the stability of the relation will be better... you know how to react or act, so you can plan for the future”. Additionally emphasizing that new activities are easier with stable and integrated customer relationships, validating the effect on agility as found by Um (2017). Further, another respondent stated that digital linkages support CM as people have greater trust in technology than they have in other people, thus emphasising the importance of internal and external information system integration (II;SI) for relationships in line with Gu et al. (2017). Another respondent described II as crucial although not easy, stating that “...you can be internally very well integrated and it all works very well internally but you are not integrated to the customer. Because that's outside your control.” Additionally that “...if you're not internally integrated then you cannot integrate with your suppliers”; further emphasising II and SI as crucial for OF. Thus, validating the primacy of internal integration efforts to support external integration, e.g. for flexibility, quality and customisation (e.g. Zhang et al., 2019). Further, regarding RE, the stability of relationships, especially with suppliers, was described as a focus for several respondents in particular to maintain the QU and DE that is required to satisfy the customers.

According to the TISM, the aspects with the greatest driving power were CM, TR and QU. Regarding QU, one respondent explained that, “Of course the speed is important but the quality and the environment is the most important.” Thus, highlighting the relationship between QU and SU. Along similar lines, another respondent stating that buying nearshore is about the speed and ability to order in-season and thus be responsive while maintaining their sustainability goals by not flying products. These motivations are in line with Pal et al. (2018), emphasizing the association between speed, quality and sustainability for competitiveness of textiles/clothing production in high-cost locations. Further regarding TR, one respondent noted that “...if we don't have the trust in what [suppliers] promised when it comes to delivery and production we can't guarantee to have 100 percent and customer satisfaction.” With another stating that without trust, it is not possible to share information; with an additional respondent highlighting the importance of information sharing between them and their customers to develop trust. In particular, several respondents described digital technologies and connections with suppliers for CM and SI as crucial for TR and CM with customers, in particular transferring detailed information about the product being produced on-demand. Thus, echoing the need for deeper information system integration with suppliers due to deeper integration with customers (e.g. Gu et al., 2017).

Additionally several respondents emphasised that they do not produce anything that is lower quality, in one case with no room for error due to the highly technical nature of the textile/apparel product. Thus, illuminating the relationship between QU focus and
the PS. While PS is one of the top three dependent aspects according to the TISM, PV and OF are the most dependent. Several respondents elaborated upon the relationships between these aspects, one describing the need to limit the variety of materials-PS for internal small series production, and another having limited fabric choices from external suppliers. Thus, using component commonality and some degree of modularity (e.g. Um, 2017) to offer sufficient PV while maintaining OF.

**Conclusion**

This paper has examined the influences between supply network configurational aspects and associated capabilities related to small series textile/apparel production in high-cost locations, in line with the need for context-sensitive supply chain design research (Melyn et al., 2014). The TISM method with MICMAC has enabled the identification of drivers, dependent, and linkage configurational and capability aspects. Overall, the findings show a great deal of inter-relationships with many linkage aspects. With these aspects requiring significant attention due to being impacted by and having impact on many other aspects, thus adding strength to inter-relationships suggested from the literature. Relational aspects including stability, trust and information sharing, structural internal integration, and quality capabilities were some of the most significant drivers. Thus, validating quality as a significant motivator for reshoring/reconfiguring the supply chain in this way (e.g. Gray et al., 2017, Martínez-Mora and Merino, 2014). Additionally, the product aspects and operational flexibility were some of the most dependent. Notably, the indicated impact of the relational aspects on capabilities, structures, operations and products should be further addressed, in line with the call to understand the influence of the supply chain on the product by Pashaei and Olhager (2015). Further, while the stability of relationships has been emphasised as enabling greater agility there is a need to understand the implications on the complexity and adaptability of the supply chain. Thus, potentially involving a tension between trust and stability, with the overall need to adapt to changing competitive landscapes.

The TISM presented here can serve as a multi-element/criterion decision-making tool to address the configuration of supply chains/networks. For the textile/apparel industry, these models show the most significant driving and driven aspects which can provide understanding and thus guidance regarding SC design/configuration. Notably, the analyses have highlighted the importance of communication and information sharing, trust and stability within supply chain relationships and internal integration. Thus, highlighting some key opportunities for development, especially related to integration, as many textile/apparel companies have limited IT and process integration within their own organisations, with even lower levels of integration with suppliers.

Supplier’s contractual embeddedness and sales performance in uncertain environments

Abstract

Literature offers limited knowledge on the online markets that consist of both open contractual and supply networks which are subject to environmental uncertainties. This study investigates how the environmental uncertainty dimensions and supplier’s contractual embeddedness (as informed by the degree and closeness centralities) impact the supplier’s sales probability in light of Complex Adaptive System theory, Social Network Analysis and the environmental uncertainty literature. Australian based Open Food Network data from 2012 to 2016 empirically validates that the supplier’s contractual embeddedness generally improves its sales probability and uncertainty dimensions moderate this relationship with the help of panel logit regression model.

Keywords: Contractual embeddedness, environmental uncertainty, sales performance

Introduction

Scholars increasingly conceptualise the supply network as a complex adaptive system (CAS) where a network topology emerges over time rather than a purposeful design by a single firm (Choi et al., 2001; Park et al., 2018). CAS view further explains the coevolution between the embedded firms of the supply network and the environment (Nair et al., 2016; Park et al., 2018). Yet, how an open contractual network that resembles a CAS leads the consumers to derive the supply network from the open contractual network in each order cycle offers very limited knowledge in the literature. In a broader view, how much effort a supplier needs to put into being central in the open contractual network to increase their sales probability in the supply network while adapting the environmental uncertainties remains mostly unexplored in the literature. The current CAS
validation of the supply network coevolution does not consider the dual networks are coexisting with each other that is present in Internet-enabled supply chain platforms.

There are two types of networks that freely emerge in these online platforms that resemble a CAS. These include the open contractual network where any supplier can register and connect to each other based on their mutual understanding and the supply network as a collection of consumer designed supply chains for each order cycle using the suppliers of the open contractual network. Suppliers’ contractual embeddedness (SCE), which is how they are linked with each other with open contracts, may influence their sales probability in online markets. The concept of SCE is vague because the current literature posits both linear and nonlinear effects of embeddedness on performance mostly based on subjective measures (Uzzi, 1996; Kim, 2014). Scholars popularly use perceptual measures to inform a supplier’s network embeddedness and ignore the objective measures due to the network data collection difficulties (Uzzi, 1996; Kim, 2014). Nevertheless, social network analysis (SNA) matrices are now widely available to inform the SCE in different aspects such as degree, eigenvector, betweenness and closeness centralities (Borgatti and Li, 2009; Kim et al., 2011).

Also, suppliers change their contractual relationships in an online market to adapt to environmental uncertainty dimensions of dynamism, munificence and complexity over time (Gligor 2018), but this remains poorly understood in the literature. To explore these gaps, this paper investigates the impact of environmental uncertainty and SCE dimensions on the supplier's sales probability in the supply network. In doing so, this study integrates the CAS theory, Social Network Analysis (SNA) and the literature of environmental uncertainty, supply chain and performance. This paper addresses the following research question:

- How do environmental uncertainty and supplier’s contractual embeddedness impact the supplier’s sales probability in the supply network, over time?

The open contractual network of the Australian based open food network (OFN), the research context consists of small to medium scale farmers and food hubs who register to the OFN with their product and shipping options and connect with each other. When a consumer makes an online order and designs its food supply chain by picking the preferred suppliers from the open contractual network for each item, the chosen food suppliers stand a chance of joining the supply network. It thus enabled the analyses of the impact of environmental uncertainties and the SCE on the supplier's sales probability in the supply network in a panel data setting involving food suppliers that registered to the OFN from 2012 to 2016.

This longitudinal study makes generous contributions to the literature. It elucidates how the supply network emerges in each order cycle as a derivative of the open contractual network that resembles a CAS that received less attention in the literature. This study relies on the objective measures using the SNA matrices to provide a network understanding of the SCE than the widely used perceptual measures. The results reveal that the SCE generally improves the supplier’s sales probability in the supply network context contradicting the beliefs that hold on to non-linear effects of the embeddedness on performance. This study graphically unveils the evolution of the open contractual and the supply networks from 2012 to 2016 using the SNA. This study further discloses that the environmental uncertainty dimensions have a moderating influence on the SCE and
the supplier’s sales probability relationship which remain largely unexplored in the literature.

**Hypotheses Development**

*Supplier’s Contractual Embeddedness and the Sales Probability*

The in-degree is the number of ties received by the supplier, and the out-degree is the number of ties initiated by the supplier (Borgatti and Li, 2009). In this study, the centrality calculations are based on the open contractual network where the value of a tie equals one for having a contract between two suppliers; otherwise, it is zero. When the supplier holds on to more ties, it can play a central role as a coordinator collecting the demand information from other suppliers and aligning the customer segments and innovative business strategies to achieve the greater supply network interests (Kim et al., 2011). The open contractual network exhibits complex multi-scale behaviour among the suppliers since a variety of food producers, restaurants and food hubs evolves and self-organises through a complex interplay of its structure and function (Choi et al., 2001; Pathak et al., 2007). Consumers prefer suppliers with high in-degree centrality who receive from many other suppliers and act as a food integrator (Kim et al., 2011). Those food hubs create vast opportunities for the consumers ordering a variety of food items ranging from meat, fish, egg, vegetables, winery, bakery and grain under one shelter and deciding the producers for each item from the available pool of suppliers that attached to the food hub. Hence, there is a high probability of consumers choosing them for their food supply chains. Accordingly, the suppliers with high out-degree centrality are the ones who promise to deliver food items to many other suppliers that act as a food allocator distributing its products across many suppliers, focusing on the economies of scale (Borgatti and Li, 2009; Kim et al. 2011). The food suppliers in the open contractual network also prefer to connect with such food producers/hubs who are readily available for the food supply to them and hence, there is a high probability of consumers picking them for the supply network.

*Hypothesis 1:* A supplier who holds a more significant number of contracts in the open contractual network has a high sales probability in the supply network over time.

The open contractual network consists of inter-supplier relationships that connect multiple food and beverages related industries in Australia. The consumers consider certain factors from multiple perspectives such as logistics cost, product costs, flexibility and quality in designing their food supply chains to fulfil their food requirements (Terjesen et al., 2011). The significant factors that a consumer might consider are the constraints of the open contractual network and the supplier’s adaptivity to the environmental uncertainties including the past customer experiences (Pathak et al., 2007). The OFN consists of geographically concentrated clusters to satisfy the regional consumers. Hence, the closeness centrality, which indicates how close a supplier to all the other suppliers in a network, is a significant factor that determines the supplier’s geographic and conceptual proximity (Borgatti and Li, 2009). The highest scores indicate more closeness. A supplier with high closeness centrality has more freedom from others’ influence and higher capacity for the independent actions (Kim et al., 2011). Such suppliers get the consumers’ attention in that region. Consumers might entertain less shipping and exchange fees by connecting original producers with the suppliers of high closeness to fulfil their orders. Since the high closeness suppliers hold on to shorter food
supply chains, they can optimally balance supply and demand with less inventory and lower operational costs (Borgatti and Li, 2009).

**Hypothesis 2:** A supplier who can quickly reach all the other suppliers in the open contractual network has a high sales probability in the supply network over time.

**Environmental Uncertainties as Moderators: Dynamism, Munificence and Complexity**

Dynamism refers to the level of environmental volatility or the unpredictable change within an industry that intensifies uncertainty (Gligor, 2018). The suppliers that possess more direct ties become more central and visible in the network, and they perceive a leadership role in coordinating the other suppliers due to its greater connectedness (Borgatti and Li, 2009; Kim et al., 2011). The dynamic rigour inlays unanticipated environmental fluctuations into the open contractual and supply networks which lead to the network transitions ensuring the embedded suppliers' survival. Hence, the suppliers with high in-degree centrality manage the incoming food supplies from the upstream suppliers by putting together or transforming different food items into a value-added product such as vegetable and fruit boxes, meat boxes and beverage cartons that ensure the product quality (Kim et al., 2011). Also, the suppliers with high out-degree centrality manage the demand flow by distributing consumer selected producer items focusing on the economies of scale. High degree centrality suppliers have a great impact on the operational decisions and the strategic behaviour of the other suppliers reconciling the differences in network members and aligning them with the OFN interests (Kim et al., 2011; OFN, 2018). The pressure on the high degree centrality suppliers is much higher during the dynamic events such as food surpluses and supermarket domination that prevent the regional farmers supplying beyond the restricted quotas (National Association of Retail Grocers of Australia, 2007).

**Hypothesis 3:** Higher dynamism leads to a stronger positive relationship between a supplier who holds a larger number of contracts in the open contractual network and its sales probability in the supply network over time.

Dynamism can bring adverse effects into the existing interrelationship structure thereby weakening the coordinated and shared supply chain strategies which may be obsolete in the face of emerging challenges. Nair and Vidal (2011) emphasise that long average path lengths between suppliers in a supply network are detrimental to its robustness against the disruptions while shorter average distances allow faster propagation of products and information. So, the closeness should enhance the responsiveness of the supply network in the event of environmental dynamics. Though the supplier's ability to remain in cliques by selectively connecting to the well-connected suppliers advances the regular supplier network operations, it is vulnerable to the environmental distractions due to the higher level of dependency on dominant suppliers (Borgatti and Li, 2009; Nair and Vidal, 2011). The consumers favour the suppliers that can quickly reach most of the other suppliers in a cluster in terms of logistics costs, but the product reliability and flexibility issues generated by the environmental disruptions may weaken customer loyalty. In adapting to dynamic situations, some ties and suppliers would disappear from the shortest paths, and new suppliers and ties enter the network and hence, the closeness centrality may decrease.

**Hypothesis 4:** Higher dynamism leads to a weaker positive relationship between a supplier who can quickly reach all the other suppliers in the open contractual network and its sales probability in the supply network over time.
Munificence refers to the resource abundance in the environment resulting in a higher capacity to support the sustained growth of a firm and thus focuses on an industry's sales trend (Terjesen et al., 2011). Network structure partially determines the opportunities and constraints to access valuable resources and information that would help the suppliers sustain competitive advantage (Burt, 1992). The suppliers with high degree centrality can influence their suppliers either to compete or corporate or both when developing value-added products by recognising, leveraging and deploying the market knowledge and demands (Kim et al., 2011; Bellamy et al., 2014). Since they experience high relational activity in the open contractual network that capture the potential transactional intensity or related risks, they can influence other connected suppliers' operational scope. High degree centrality suppliers are willing to absorb the opportunities generated by highly munificent environments to meet the diversified consumer requirements aligning with the anticipated actions of other connected suppliers.

**Hypothesis 5:** Higher munificence leads to a stronger positive relationship between a supplier who holds a larger number of contracts in the open contractual network and its sales probability in the supply network over time.

The environment interacts with the contractual relationships in ways that cause selective pressure and competition among the structural dimensions to create nonadditive effects on the supplier's survival (Gell-Mann, 1994). The OFN is more vital in munificent environments as its primary purpose is to become an alternative platform for the sustainable producers and hubs to sell their surplus produces to the consumers. Thus, the suppliers with high closeness centrality have the potential to deliver the produces promptly to consumers as they can quickly reach most of the other suppliers in the network (Borgatti and Li, 2009). The suppliers that are at a short distance from most other suppliers receive information and produces sooner than the suppliers that are far away from most others (Borgatti and Li, 2009). The other suppliers would like to join the short food supply chains to get more sales while consumers place orders assigning a pivotal role to the high closeness centrality suppliers to get the benefits of less operational and inventory costs (Lee et al., 2004).

**Hypothesis 6:** Higher munificence leads to a stronger positive relationship between a supplier who can quickly reach all the other suppliers in the open contractual network and its sales probability in the supply network over time.

An industry's complexity is implied by the number of firms and their composition in terms of size and perceived resources (Child, 1972). In a complex business environment, a supplier needs to satisfy the environmental expectations placed on it with the available resources, capabilities and products to remain operationally sustainable (Li et al., 2010). Having a higher number of direct contacts with other suppliers in the open contractual network enhances the supplier's ability to absorb the external knowledge in response to the increased information processing demands and open innovation. Also, suppliers that are unable to recognise and leverage the extensive information that can be accessed from other evolving suppliers are likely to face legal consequences and weak performances (Pathak et al., 2007). The new suppliers entering the open contractual network connects with high degree centrality suppliers than the isolated suppliers in a complex business environment to attract consumers. Further, consumers trust a high degree of centrality suppliers in a market spoiled by choice with a large number of physical establishments. Eventually, the OFN producers that start with fewer connections transform into high degree centrality food hubs over the years responding to the various market requirements.
Hypothesis 7: Higher complexity leads to a stronger positive relationship between a supplier who holds a larger number of contracts in the open contractual network and its sales probability in the supply network over time.

Food suppliers inescapably engage in a cycle of continuously changing inter-relationships to increase its internal fit to the supply chain and external fit to the environment (Choi et al., 2001; Park et al., 2018). It is even more critical in a CAS to find the strategic fit between the network structure and the collaboration patterns (functionality) (Li et al., 2010). Hence, the key interest of this study aligns with this interplay and the shorter food supply chains that cover a heterogeneous product range. Since the longer paths increase the operations costs and network disruptions, high closeness centrality suppliers are in relatively powerful positions in delivering a wide range of food items with shorter and flexible delivery times. Both the consumers and the embedded suppliers coevolving with the complex environment increasingly connect with the high closeness centrality suppliers that could reduce the logistics costs and improve on-time delivery.

Hypothesis 8: Higher complexity leads to a stronger positive relationship between a supplier who can quickly reach all the other suppliers in the open contractual network and its sales probability in the supply network over time.

Conceptual Model

![Conceptual Model](image_url)

Figure 1: Conceptual model

Research Methodology

OFN dataset was used for the analysis which started in 2012 with 34 food suppliers and grew to 96, 234, 1033 and 1876 in each consecutive year up until 2016. The corresponding supply network started with 30 food suppliers and evolved by 71, 234, 395 and 503 in each successive year along with the open contractual network’s evolution. The network deals with 52 main product categories. The IBISworld industry reports from 2008 to 2016 were used to measure the environmental uncertainty dimensions. SNA and panel logit regression modelling methods were used to test the proposed hypotheses.

In-degree centrality of a supplier is the number of ties received by the supplier and out-degree is the number of ties initiated by the supplier (Borgatti et al., 2002; Kim et al.,
2011). The log transformation of the sum of the in and out degree centralities of the supplier is used in this study for the degree centrality. Closeness centrality is the reciprocal of farness which is the sum of the lengths of the ties to every other supplier (Borgatti et al., 2002; Kim et al., 2011). As an alternative to taking the reciprocal after the summation, the reciprocals can be taken before. Since the data is directed, the average of both in and out closeness centralities was calculated after which the log transformation was obtained.

Munificence is measured as the five-year average growth in industry sales revenue and industry value added of the industries that the supplier is involved in (Keats and Hitt, 1988; Gligor, 2018). Measures were taken in $ millions. The basic equation followed is

\[ y_t = b_0 + b_1 t + a_t \]

where \( y = \) natural logarithms of sales/industry value added, \( t = \) year and \( a = \) residual. Growth measure is the average of the antilog transformations of the sales and industry value added regression coefficients. Dynamism is the five-year patterns of the instability of the environment (Keats and Hitt, 1988; Gligor, 2018). The measure is the average of the antilog transformations of the standard errors of each regression slopes (sales and income) measured for munificence (IBISworld, 2016; Gligor, 2018). Complexity is the breadth and variety of the industries' geographic markets that the supplier operates in (Child, 1972;). The five-year average growth of the number of physical establishments of the industries that the supplier operates in was used (Keats and Hitt, 1988; IBISworld, 2016). The basic equation followed is

\[ y_t = b_0 + b_1 t + a_t \]

where \( y = \) natural logarithms of the number of physical establishments, \( t = \) year and \( a = \) residual (Gligor, 2018). The growth measure is the antilog transformation of the regression coefficient. The probability of sales is a binary variable. If the supplier generates sales in the supply network it is 1; otherwise, it is 0 (Lanier et al., 2010).

**Results**

The analysis was conducted in two steps. SNA and the panel logit regression modelling procedures were used respectively. First, the SNA technique was applied using the UCINET software to visualise the network evolutions from 2012 to 2016 as shown in Figure 2 and to derive measures for our independent variables which are degree and closeness centralities. Second, the moderated panel logit regression modelling
methodology was used given the dichotomous nature of the dependent variable which is the supplier’s sales probability in the supply network and it is unbalanced due to the unequal number of suppliers presented by the regional food network evolutions. The control variables, product type and the state, do not significantly vary over time and the suppliers in the OFN are a small representation of the Australian food suppliers in each category. Hence, the random effects panel logit model was used. The odd ratio was used to infer the true nature of the relationship between the explanatory variable and the dependent variable (Wiersema and Bowen, 2009).

Results are shown in Table 2. These results show the support for six out of the proposed eight hypotheses. The first model includes the effect of the control variables on the supplier’s sales probability. The independent variables of centralities were added into the second model and the moderators of the environmental uncertainty variables into the third model. The fourth model includes the interaction terms, which are the product of each centrality variables with each of the mean centred environmental uncertainty variables. Since the odd ratios of the log transformations of degree and closeness centralities are greater than 1, they associate with higher sales probability supporting hypotheses 1 and 2.

In both highly dynamic and complex environments, the positive association between the supplier’s degree centrality and its sales probability are very high as their odd ratios are significantly greater than 1 supporting hypotheses 3 and 7. Though the munificent environments increase the positive association between the closeness centrality and the sales probability with an odd ratio greater than 1 supporting hypotheses 4, dynamic environment diminishes that positive slope with an odd ratio less than 1, thus confirming the hypothesis 6. The relationship between the degree centrality and the sales probability is not evident in the munificent environment, thereby contradicting the hypothesis 5. This may be due to when most of the food suppliers have product surpluses, and they get motivated to directly sell the products for lower prices rather than from selling through food hubs. Therefore, consumers may reach both the individual food producers and hubs to get price advantages in munificent environments. Also, the relationship between closeness centrality and sales probability is absent in the complex environment. Consumers that are spoiled by the choices with a heterogeneous product range chase after local brands without concerning the distance in a complex environment and hence it is possible to have hypothesis 8 not being supported.

### Discussion and Conclusion

This study primarily investigates how the open contractual network derives the supply network in each order cycle in response to the environmental uncertainties over five years by applying CAS theory. Results reveal that the SCE as informed by the SNA matrices of degree and closeness centralities generally improves the supplier’s sales probability in the supply network. This contradicts the belief about the non-linear effects of the embeddedness on performance. Further, the study elucidates how freely emerging open contractual network interacts with the environmental uncertainties without any global controller to increase the embedded supplier firm’s performance. This study discloses that environmental uncertainty dimensions moderate the relationship between SCE and the supplier’s sales probability which is mostly unexplored in the literature. Both the dynamic and complex dimensions improve the positive association between the degree centrality and the sales probability as per the odd ratios. Munificence increases the positive association between the closeness centrality and the sales probability nexus, but dynamism lowers this positive relationship.

This study graphically unveils the simultaneous coevolution of the open contractual and the supply networks embedded in a single system over five years to adapt the environmental uncertainties. The geographically remotes network clusters that connected through the structural holes in the networks evolve into different network patterns over time. These network transitions and the changes in the SCE centralities aim at catering the local interests than the global optimum, and hence these networks exhibit the characteristics of a locally sufficient CAS. This study offers a more rigorous and scientific analysis elucidating how to foster the CAS and SNA views of the open contractual
network to develop the supply network and increase the embedded suppliers' sales probability.

Abstract
Most companies include in their strategy, a commitment for sustainable growth which involves a switch towards a circular economy (CE). A CE transition is hindered by barriers that must be overcome to comply with sustainable growth. In this paper we identify barriers faced by industries, and we propose solutions for how to overcome these barriers. The main barriers were found to be complexities in supply chain, coordination problems, quality issues, little attention to CE in production and design, difficulties in disassembly of products and high start-up costs. To overcome these barriers, we present a model supporting life cycle information.

Keywords: Circular Economy, Sustainability, Barriers

Introduction
While globalisation gives both a larger market and an increased competition, the companies’ supply chains have become more complex and critical than before (Majta 2012, Sheffi 2018). The worldwide consumption has increased over the last decades and it is expected that the resource use globally would increase three times more by 2050 (Lucas 2014). The effect of population growth and the following increase in consumption raise challenges to the environment, the overall society, and the depletion of scarce resources (Ellen MacArthur Foundation 2015). The resource consumption of the linear model follows the take-make-consume-dispose pattern which is not sustainable as its over-use scarce resources and contribute to pollution of the environment. The cities are generating 1.3 billion tons of waste each year and it will surge to 2.2 billion tonnes by 2025 (Masi et al., 2017). Waste and trash have a negative impact, our oceans are accumulated with plastics, marine life in endangered, animal kingdom and wildlife are affected by too many pollutants, persistent chemicals are causing diseases, depletion of
the ozone layer, global warming and trash landfills which have led to serious actions against waste. The electronic waste is another kind of waste that is increasing fast. Businesses in need to satisfy their customers, must increase the prices of the materials due to the increasing scarcity of resources, which again might affect the progress and profitability of the companies in a negative way unless it is addressed. More pressure of environmental concern from customers are seen to result in more eco-friendly products. The CE model is based on the concept of changing the take-make-use-dispose pattern into closed-loops of material flows through processes such as maintenance, repair, reusing, refurbishing, remanufacturing and recycling (Masi et al., 2017). Supply chains are considered to be an important factor for implementation of the CE model because of the need for a joint effort of suppliers, manufacturers and customers. The co-operation and co-ordination between supply chain upstream and downstream partners are essential as upstream partners obtain eco-friendly inputs cooperating with downstream partners for environmental management practices such as product return, reuse and recycling (Zhu et al., 2010).

The transition to CE is not as easy as is evident from several studies that have identified many barriers. Due to these barriers, firms are slow to make a transition towards the CE (Masi et al., 2017; Preston, 2012). We claim that the transition to CE is only possible through the better management of information and the informational flow. We follow Rosén (2010) in defining the information needed for a product as “all the information required in making decisions and taking actions in the whole life cycle of a product”. Information technology is considered as a priority for managing the information flow across the supply chains, and standardization is helpful in providing rules and frameworks to support companies move towards the CE.

This study addresses the barriers to the CE in manufacturing industries and aim at shedding light on how these barriers can be overcome by applying information technology.

In this study, we refer to manufacturing industries as industries using highly equipped machines and digital instruments that are helpful in their production. Examples of such industries are construction industry, automotive industry, defence and arms, energy industry (electrical & petroleum), computer industry and aerospace industry. These industries work with tools such as massive machineries, heavy metals, digital and complex mechanical instruments, drills and cranes and other heavy transport equipment and appliances (GS1 2018). It is crucial for these industries to have a secure method to recycle or dispose of metal and electronics waste that can have hazardous effects on our environment. However, there have been challenges in recycling and disposing of these types of machinery and metals as elements and products that cannot be extracted easily.

**Manufacturing Industries**
The last couple of decades, we have seen an evolution from a traditional supply chain towards a green supply chain. Environmental-friendly production and consumption activities, reducing the negative effect on the environment, represents a major goal of green supply chains. The focus is not just on the reduction of negative consequences of production processes and residuals, but also on the repeated use of materials through such systems, where transformation is made through a relationship between ecological system and economic growth (Genovesea et al., 2017). In addition, the unique product identification is creating interesting opportunities for transparency in companies’ supply chains (Karkkainen & Holmstrom, 2002).

**Circular Economy (CE)**
Adoption of CE concepts have been the focus of the food industry for several decades. Irani and Sharif (2018) explored the role of sustainable food security with the closed loop business models. CE can be seen as consisting of two parts, where the first part focuses on reducing the impact on the environment, and the second part focuses on creating business models that implement the first part (Torstensson, 2016). Regarding the first part, which concerns reducing the impact on the environment, the Ellen MacArthur Foundation (2015) has given a model of circularity showing which activity-cycles that gives the highest positive environmental impact. The cycles focus on a material’s next use. The best next use i.e. most environmental-friendly, would be to close a cycle instead of going to a cycle with lower CE effect or end up in the waste-chain.

Figure 1 illustrates the CE cycles Maintaining, Reusing, Remanufacturing and Recycling (M+3R) and the waste-chain. Maintaining has highest CE-impact, followed by Reusing, Remanufacturing and Recycling respectively, and the waste-chain having the lowest CE-impact (Ellen MacArthur Foundation, 2015; Torstensson, 2016). The waist-chain consists of Waste collectors, Energy-from-waste operators, and Landfill operators.

According to Zhijun & Nailing (2007), shifting towards a CE model requires a deep focus on raw materials and energy. When producing a product, the focus should be on minimizing the entire product life cycles negative effects on the environment from the very early stage of material extraction towards the product disposal.

**Barriers to CE**

A shift to the CE model requires a dramatic change for the whole company involving all stakeholders. This shift is somewhat disruptive in nature because the current mode of working would be changed (Ritzéna & Sandström, 2017). In order to identify common barriers to CE, an exploratory review of existing literature was done using academic databases such as Google Scholar, ProQuest, ScienceDirect and Academia. Keywords such as “Circular Economy, Product Identification, Sustainability, and Barriers to Circular Economy” were used. In summary, the barriers found by (P) Preston, 2012; (LB) Liu & Bai, 2014; (E) Eijk, 2015; (T) Torstensson, 2016; and (BB) Berchicci and Bodewes, 2005) are, ordered by the authors: (P1): Resource-Intensive development models. Traditional models are highly resource intensive; less resource-intensive models
are lacking. (P2): High start-up costs. In the long run the CE model would show sustainable benefits and increase growth but in the short run, the start-up costs are high. (P3): Supply chain complexities. Multiple companies around the world are engaged to make a particular product for a global customer base. A challenge for the supply chain in the CE model is the alignment from the early design stage to consumption the durability and reparable of materials. (P4): Difficulty in coordinating companies. The coordination among companies is a barrier because it needs multiple companies to adjust their daily operations. (P5): Innovation diffusion challenge. It is critical that new breakthroughs rapidly find their way into the mass market, so that transition to the CE can contribute to tackling climate- and water-related goals in the necessary timeframe. (LB1): Structural. Innovation and flexibility are restricted by organizations’ hierarchical patterns. Lack of budget towards the CE model innovation. CE’s strategies are affected by the managers’ employment term restrictions. (LB2): Contextual. Competition in the market place restricts the movement towards CE. (LB3): Cultural. Managers are risk averse. (E1): Restricted supply chain. There is lack of enablers to improve cross cycle and cross-sector performance. Lack of exact knowledge of the composition and origin of materials used. (E2): Lack of industrial symbiosis. Industrial symbiosis is based on having good knowledge of material/energy flow within an industrial sector and geographical area. Thus, it requires exchange of information regarding inputs and output to optimize the processes, but this industrial symbiosis is a barrier towards CE because it’s costly or difficult to obtain. (E3): Logistics. Information exchange systems in logistics are limited. Cargo flows are handled by logistics, which also includes the reverse logistics and supply chain management. For the CE transition, existing network design is a barrier. The design should support switching between transportation modes. (E4): Product design and production. Removing of toxic material and separation of biological from technical substance is lacking. Shortage of information regarding green suppliers. Current product design is given less attention towards the end phase of products. (E5): Recovery. The products are becoming more complex; the recovery of such products is a big challenge. (E6): Recycling. Recycled materials are sometimes more expensive than the new raw materials. Investing in recycling is seen to be risky on a larger scale. (R1): Lack of technical skills. A barrier is the lack of skills in small and medium-size enterprises. They don’t realize the benefit of implementing more advanced technologies that reduce the negative impacts on the environment and would give them costs savings. (T1): Quality compromise. Companies’ reluctant attitude towards CE is their concern regarding the quality of materials. They fear materials would be chosen based on the environmental aspects instead of quality of performance. (T2): Disassembly of products is time consuming and expensive. A product is made of many different components which are attached in a way that their disassembly is hard and time consuming and it seems much better to produce a new product than to recirculate the materials, and also it would be very expensive to mould the components in a way they could be available to use again. (T3): No sure recycling, remanufacturing and reusing would help the environment and save money. There is no surety to the companies that this process of CE would definitely save money or protect scarce resources, and it might be the case that producing a new product is less costly than reusing the old one. (T4): Quality assurance. A barrier is that it is difficult to know what has exactly been done with the material and whether the recycled material is handled in a manner that is good with respect to quality, and all these things involve costs. (BB1): Design irrespective of CE. The products that are produced lack a circular design which is the reason the reusing, disassembly, remanufacturing etc. is hard. (BB2): Hygienic issues. Some perceive that recycled or reused materials are not safe and hygienic.
**Data Collection**

In order to explore how manufacturing companies look upon the CE concept, and what barriers they see, we carried out semi-structured interviews with three companies. Since semi-structured interviews are one of the most used methods of data collection within the social sciences (Bradford & Cullin, 2012). The interviews were conducted in three companies A, B and C, working with technical issues and who focus on the idea of green supply chain and sustainability. In the interviews, we aimed at gaining information about their internal capacities, challenges and barrier that they encounter each day by handling their products. Two interviews were carried out face-to-face, while one of the interviews was carried through by sending the interview guide via email since the person available for a face-to-face interview. Company A is a technology-based company that delivers competitive solutions to meet the power needs of its customers. The company works within the marine and automotive industry, and deliver products and services encompassing power systems, nuclear and many more. The company aims at having a reputable rule to minimize the risk of climate change, low carbon global economy, reduction of environmental impacts from production as well as improving the environmental performance of its products. Furthermore, the company are strongly committed to health, safety and environmental management. The respondent said that they do not exactly use the term CE, but we have all the focus on environmental protection:

> ‘We have the program called “Revert” which is about minimizing the demand for the new materials in which the metals are being recycled. This also helps in lowering the cost and reusing of finite resources i.e. rhenium, hafnium, nickel and titanium.”

Regarding the question about CE, the respondent said that almost 95% of the engine parts and equipment are recycled and have high quality but the main barrier is the cost of recycling. Through the “Revert” program tons of carbon dioxide are saved compared to using new materials. In addition to the cost of recycling, another barrier the respondent mentioned was the disassembly of the products.

Company B manufactures professional lighting solutions for global markets. Their goal towards a sustainable environment is:

> ‘Through obligations to comply with local, global government requirements and self-imposed requirements, we will contribute to a lower environmental impact. This implies objectives to reduce waste; increase reuse and; as far as possible, use environmentally efficient transport solutions; reduced energy consumption prevent emission’

The company complies the law that applies to follow the local and global standards and environmental policies, which is reflected in one of the answers of a former employee:

> ‘The company’s products also satisfy the WEEE Directives (Waste Electrical and Electronic Equipment), has ISO 14001 environmental certification and policy for Corporate Social Responsibility (CSR) to support a precautionary approach to environmental challenges, undertake an initiative to promote greater environmental responsibility and support the development of environmentally friendly technologies.’

Company C is Global Standards 1 (GS1 2018) who is a not-for-profit company that develops global standards for business to business communication. GS1 was established in February 2005, by the merger of EAN International (European Article Numbering) and
UCC (Uniform Code Council). GS1 is a leading global organisation dedicated to the design and implementation of global standards and solutions to improve the efficiency and visibility of supply and demand chains globally. The best known GS1 standards are the barcode and RFID standards. The identification of components and equipment enables efficient processes manufacturing industries. The procurement, storage, assembly, maintenance, repair and disposal of products and their components can be optimised based on GS1 identification standards. GS1 Norway has fifteen employees. This interview was conducted in the Department of Delivery Standards where we interviewed Terje Menkerud, a senior advisor at GS1. GS1 Norway has more than 6300 registered companies in Norway. In response to the question about challenges to the company with respect to sustainability the respondent said:

‘GS1 is not a logistics company, it came from the retail sector and not many companies see us as a logistics company. This is the biggest challenge to get the actors and the players in the field of logistics to know who we are and get aware our system and get to know how we could we help them in daily business by reducing the cost and solution towards environmentally friendly transportation.’

He further explained that since a lot of players in the market have their own systems, they don’t interact effectively. If you receive some material from another market you have to re-label it. To get the entire community into the same global standardized way of trace and track with unique identification is a big challenge in a way of sustainability. The reason is that if there are globally standardised system all the information about a particular product would be shared which is not the case in most of the countries. Further details of the questions and answers can be found in Naz and Rahim (2019).

**Barriers identified to the CE in technical industries**

Based on our findings, it seems that Norwegian companies in technical industries know the concept of “circular economy” and that they have a with a high focus on environmental sustainability. Even if they do not use exactly the word “Circular Economy”, all their efforts towards environmental protection have the base in this concept. The results indicate that large Norwegian technical companies have special attention towards regeneration of resources, and they have special programs to implement such thought as illustrated by the “Revert project”, the “sunshine program” etc. mentioned by the respondents. Company B’s move towards a sustainable environment is pushed added by charging their customers a small recycling fee that is transferred to the recycling funds to handle recycling. Company B has a membership in an association of recycling companies that make sure the electronic product waste is handled carefully and that products are reused instead of new raw materials. By doing this energy consumption is saved, and environmentally friendly products are produced by reducing the global waste. The company is also certified with ISO 14001:2004. This makes the company to comply with the rules and regulations of the environmental management system thereby reducing the negative effects on the environment. There are several barriers to CE adoption as identified by the literature review part.

The companies interviewed identified the six barriers: coordination problem, quality issue, disassembly of products, design and production, supply chain complexities and high start-up costs.

In end-of-life management, the disassembly of products is considered to be an important element. It is considered that almost every product has some amount of disassembly i.e. irreversible joints, maintenance and up gradation and degradation during
use. It is not actually the reverse process of assembly. If the instructions of disassembling are available with other relevant information such as design and life cycle information, it will ultimately help in product disassembly automation and decrease in disposal or components (Parlikad et al., 2003). All the respondents said that the disassembly of products is not easy and it expensive and time consuming because of complex nature of products and this fact is also supported by the literature (Torstensson, 2016). The complexity comes due to different aspects. The number of materials has increased, and many small materials are used with significant importance as well as the multiple components of different nature and connections assemble together and affect the transition towards a CE. If the resources contained in these materials and components are taken back through repair, upgrade or remanufacture can benefit the overall world (Peiró et al., 2017).

Another barrier which the companies have mentioned the technology sector is less attention towards the end-phase of product (Eijk, 2015). One of the problems is the production of cheaper goods, shorter-life expectancy and low cost and unsustainable products in today’s corporate culture. The culture of companies is, when they make a product, they don’t feel the need about how the product will end its life. Once the manufacturers produce the product and send it off for sale, they are not usually responsible for the end-phase of the products’ life. Furthermore, they report lack of information when recycling or reusing any product in their end phase of life, because product information is necessary to identify and know about the product parts. This has concerned governments and organizations to make strategies to pressurize companies and the corporate world to be more responsible while producing and have strict environmental considerations & policies (Hesselbach et al., 2001).

**Recommended model to overcome CE barriers**

We provide recommendations to the companies in technical industries for overcoming the CE-barriers based on an information model built on top of international product information standards by global Standards 1. The GS1 Standards being used by the retail sector for decades are currently being developed to fit the manufacturing industries. GS1 provides standards for identifying, capturing and sharing information about unique products, parts, components and assets, business locations, and documents that enable industries to achieve visibility and life cycle management including the maintenance and repair processes (GS1a 2019).

By uniquely identifying products and components companies can use the identifiers to look up information about the product in a database provided by the manufacturer. E.g. during the end-phase of product life dis-assembly can be eased by scanning the product identifier to use it for lookup of dis-assembly information provided by the manufacturer. The unique identifiers, therefore, needs to be attached in the initial design and engineering stage of components and products. To illustrate this, we use a crane as example. In the model, the crane has different components namely, trolley, hook, sewing bearing, cab, wedges and counter weight. Each component is given a different Serialized Global Trade Item Number (SGTIN) to be attached to the component. The unique identifier can be encoded in e.g. a UPC barcode or an RFID tag. When these components are assembled, the final product “crane” gets another unique SGTIN identifier linking the crane SGTIN to each SGTIN of its components. The SGTIN attached to each of components would help in the later stages of disassembly such as maintenance, reuse, remanufacturing and reuse. The SGTIN information related to a unique crane is stored in the company database. SGTIN will have information about manufacturing companies, the suppliers and material used e.g. master data and information about bill of materials. The sharing of
information is under the control of the manufacturer due to the security issue and threat from competitors. When the authors asked respondents, they argued that threat of copying of our components and material used inside the component is a big challenge they cannot share it publicly. In our model, we propose that the master data of company to be saved in the GS1 data base i.e. GS1 cloud and GDSN (Global data synchronization network). GDSN allows GS1 to be connected to different companies that want to exchange product data with their supplier or recycling companies. The information sharing of GS1 include data standards for master data, business transaction data, and physical event data, as well as communication standards for sharing this data between applications and trading partners (GS1 2018). Master data are valuable information about products of any company, it is stored in GDSN. In order to obtain information, the companies should register in the global register data pool by GS1. The GDSN can automatically share the business data with their trading partners (GS1 2018). This means that the required information regarding the product or its components will be shared and updated between the actors, i.e. the technical company and recycling company. In particular, to the company and GS1, GDSN will be a connecting network that will help the company to share and exchange their data in order to recycle and reuse its products and attain sustainability. For the sustainability of products, companies need to identify, measure, compare and transform the factors that improve production and consumption. Many of these factors inhabit the supply chain, as it is common having problems in complexity and problem in disassembling the parts. Using GS1 standards will help systematize supply chain data, ease its exchange and make efficient reporting against a sustainability profile (GS1 2018). In the GS1 Cloud, the data maintained in the GDSN database about brand-sourced data and the member organizations product catalogues are combined together with six new features about GTIN, Brand, label description, target market, product classification, company name. The data about crane components will be shared with the GS1, GDSN and GS1 cloud with permission from the producer and the information would only be given to the recycling companies i.e. Norsk Gjenvinning and Romerike Avfallsforedling IKS, by allowing access only by using the passwords and encryption of data. The recycling companies if get all the necessary data related to components and their material content. It would help companies in disassembling of components and recycle efficiently. For the privacy of information of manufacturing companies and their confidential data about product components there can be passwords, encryption that would be allowed to its users only. In a complete CE transition waste should be designing out always providing a next-use of materials. Products such as machines, electric equipment and other products with harmful substances, the substances should be extracted and reused. Hence, GS1 standards can help companies in extracting the harmful substances by giving company a specific identifier to each of their product and components. The lack of product information about product design and production is a barrier and this barrier can be removed by providing more accurate information. For this purpose, product information must be exchanged with product designers for later use in recycling, reusing and repairing. Consequently, another strategy to overcome this barrier can be, by formulating regulations for manufacturing industries to make them obliged to share product design information to the concerned recycling companies. The GS1 Global Data Synchronization Network (GDSN) concept can help in advancing the overall quality of the product information by automating exchange of master data information with trading partners. The GDSN concept has already been successfully deployed in health care by implementing unique device identification (UDI) in pharmaceutical companies. This implementation has increased the efficiency and flexibility, while also supporting regulatory requirements (GS1, 2018). We propose a
model for the technical industries based on the same principles applied in the health sector. See Figure 6.3 for the general concept. For details see (Naz and Rahim 2019).

![Figure 6.3: Recommended Model for shift towards circular economy](image)

Supply chain complexity and co-ordination problems depends on the information system used and differs from company to company. GS1 provide the standard EPCIS (Electronic Product Code Information Systems) for information systems that handle trace and track of products across their life cycle and across companies. Following the standard, companies can have a shared view of information related to each other’s businesses. This would reduce supply chain complexity, give more visibility and support coordination. In addition, sharing of information about products and components with following GS1 standards would help recycling companies to disassembly products for reuse and recycling. Hence, through identification standard with EPCIS code, sharing would be possible with all the recycling companies and other relevant partners to overcome the barriers of complexity and cooperation in supply chain, disassembly of products by the recycler and product design and production by the engineers and producers.

Conclusion
In this paper we have identified barriers to the CE transition of manufacturing companies by doing a literature review. By carrying out case studies of three Norwegian companies, we found that the major barriers for implementation of CE were a quality issue in recycled materials, supply chain complexities, coordination problem between companies, design and production of the product, disassembly of products and high start-up cost. These barriers are a sub-set of what we found in the literature on barriers. Our findings show that the companies are well aware of the challenges of moving towards the CE. To help companies to overcome the barriers we proposed a model for a product information management system to be used by companies.

Limitations
The main limitation is the limited amount of data collected due to companies’ confidentiality concern. Another limitation is that this study only focuses on one standard “identification” due to time constraint. Companies in this research have answered about CE and barriers in implementation but they, in reality, have only started on the CE adoption. Our proposed model should be tested to assess its applicability, and the use of GS1 standards should be contrasted with other standards.

Abstract

Circular economy (CE) has been proposed as a possible solution for the unsustainable take, make, dispose mentality of linear economy. Circular business model (CBM) is a company approach to CE. The purpose of this manuscript is to discuss CBM implementation on company, supply chain, and community levels. Triple bottom line with environmental, economic, and social aspects of sustainability is used to analyse sustainability on each level. Through multiple case study method implementation is analysed in six CBM firms from the clothing and textiles industry. The results may help other firms in their CBM designs, as well as authorities in policymaking.

Keywords: Circular economy, Circular business models, Implementation

Introduction

In the recent years, the circular economy (CE) has received attention from governments, NGOs, companies, and consumers to contribute to the fight against global warming. The CE, also called the ‘closed loop’ economy, is an economic model which aims for environmental, economic, and social gains through the underlying culture of zero-waste (De los Rios & Charnley, 2017; Murray et al., 2017). The potential of CE includes creation of new businesses and job opportunities, savings on materials costs, decreased risks in supply chains, and reduced negative impacts on the natural environment (Kalmykova et al., 2017). In Europe a CE could benefit resource productivity by 3% annually, therefore enabling annual benefits of €1.8 trillion by 2030 (MacArthur, 2015).

The circular business model (CBM) is a company approach to the CE by the strategies of slowing and closing materials loops in production and consumption (see e.g. Bocken et al., 2016). Several types of CBMs applying these aims have been identified (Bocken et al., 2016) and frameworks for CBM innovation and implementation have been provided (Antikainen & Valkokari, 2016; Lewandowski, 2016; Nußholz, 2017). However, there is no common knowledge of how CE has been applied to company operations (Murray et al., 2017; Merli et al., 2018), company’s supply chains (Masi et al., 2017; Geissendörfer et al., 2018) and in the society.

This study explores CBM implementation from the firm perspective through a three-level lens adopted to CE from industrial ecology (Murray et al., 2017); micro (company), meso (supply chain), and macro (community) levels. Triple Bottom line (TBL) model, which defines the three aspects of sustainability (environmental, economic, and social) is
used as a tool to gain holistic understanding of sustainability on each of the three levels. In-depth multiple case study approach including six firms from the clothing and textiles industry is chosen to generate insight on this unexplored angle on the CBM. Companies born to CE (natives) and companies transitioned/transitioning to CE from linear economy (adopters) are taken into account to comprehend whether a company’s foundation to the CBM influences its implementation. The research question is: How do companies implement CBM on company, supply chain, and community levels?

Theoretical background

Circular business model

The CBM is closely connected to the theories of sustainable business model, circular economy (CE), and industrial ecology. The CBM is considered to be one type of sustainable business model (Bocken et al., 2014). The origins of the CE are in economics and ecology, and industrial ecology is often seen as the closest antecedent of the concept (Murray et al., 2017). In the literature the terms circular economy business model and circular business model seems to be used interchangeably. This study employs the latter term. The CBM is also connected to the theory of business model. A business model is a description of the economic value creation, capture, and delivery logic of an organization (Osterwalder, 2004). A business model is further defined as a blueprint for strategy implementation through organizational structures, processes, and systems (Osterwalder & Pigneur, 2010).

Whereas the business model focuses only on economic value creation, the CBM considers value on a wider spectrum. Thus, value creation in the CBM connects to the aims of closing (Nußholz, 2017; Bocken et al., 2018) and slowing/extending resource loops (Nußholz, 2017; Bocken et al., 2018). The existing CBM studies focus on closing materials loops, whereas slowing materials loops has been given a marginal attention (Merli et al., 2018).

The CBM is typically based on environmental and economic sustainability. Social sustainability has been mentioned in several studies (e.g. Antikainen & Valkokari, 2016; Lewandowski, 2016; Rizos et al., 2016; Bocken et al., 2016; Merli et al., 2018; Geissendoerfer et al., 2018; Bocken et al., 2018), however, no study has taken it as an integral part of the definition of the CBM. Geissendoerfer et al. (2018) deploy a Triple Bottom Line (TBL) approach in the CBM, however, they do not seem to systematically utilize TBL in the analysis. In this study we define the CBM as: The logic by which an organization creates, delivers, and captures environmental, economic, and social value by slowing and/or closing materials loops. The CBM includes the key structures, processes, and systems which are involved in translating the strategy into value.

Theoretical background: circular business model implementation

One significant area of the literature on CBM implementation are frameworks for design and implementation. As a basis for frameworks, the business model canvas (Osterwalder & Pigneur, 2010) is typically used (Antikainen & Valkokari 2016; Lewandowski, 2016). To the original framework, some important elements added include: take-back systems and adoption factors (Lewandowski, 2016), as well as sustainability impact with environmental, social and economic requirements and benefits (Antikainen & Valkokari,
2016). However, it can be questioned whether adding CE elements to a canvas designed for a linear economy business model correctly reflects the CBM.

Another dominant area of the literature is challenges in the CBM implementation. Stål & Corvellec (2017) studied adaptation of take back systems, one type of a CMB, in linear economy companies within the apparel industry. They identified a horizontal decoupling between the take back system and the linear business model which still dominates the business. The contradiction between the linear BM and the CBM seems to be a hindrance in the CBM implementation.

A few case studies have identified challenges, enablers, and practices in the CBM implementation. In a study with 52 cases, Rizos et al. (2016) identified important challenges in SMEs’ transition to a CBM from a linear business model: “lack of support from supply and demand network” and “lack of capital”. Based on them, a successful CBM implementation depends on a “green” company culture, regional SME networks for raising awareness, and benefits of a “green” image (Rizos et al., 2016). Furthermore, Masi et al. (2018) identified challenges from the focal firm perspective in a survey with 77 cases: “major up-front investment costs”, “higher cost for making and planning”, “lack of clear, standardized, quantitative measurement and goals,” “lack of awareness and sense of urgency,” and “limited attention for end-of-life phase in current product”. The most common CBM practices were: “taking back products from consumers after the end of their functional life” and “taking back products from consumers after the end of their usage” (Masi et al., 2018). Therefore, the focus on challenges indicates a lack of knowledge of the CBM implementation.

In the CBM literature it is frequently acknowledged, that in CE, cooperation with other actors beyond company boundaries is important (see e.g. Antikainen & Valkokari, 2016; Nußholz, 2017; Masi et al., 2018). However, most of the CBM studies focus on the scope inside the company, an exception being Masi et al. (2017) who also take the firm’s supply chains into account. Furthermore, it is recognized that elements from macro (global trends and drivers), meso (ecosystem and value co-creation) and micro (company, customers, and consumers) levels should be integrated in the CBM innovation (Antikainen & Valkokari, 2016) and implementation (Lewandowski, 2016). However, only Geissendoerfer et al. (2018) have considered micro level influence on meso and macro levels. Each of their four Case firms had a proactive approach towards not only their shareholders but also internal and external stakeholders. They studied what value is captured by different stakeholders rather than how companies create, deliver, and capture value. As the micro, meso, and macro levels of the CBM implementation are not holistically studied in the CBM literature, a look on the CE implementation literature is taken to further comprehend the CBM implementation.

**Theoretical background: circular economy implementation**

In the CE implementation literature, the role of micro, meso, and macro levels is defined. CE implementation can be framed with three levels: micro (single firm or consumer), meso (eco-industrial parks, industrial symbiosis), and macro (city, province, region, nation) (Ghisellini et al., 2015; Merli et al., 2018). Firms, together with society, legislation, and policy, can be argued to have a central role in the CE implementation (Lieder & Rashid, 2016). This implies a concurrent top-down national effort and bottom-up company effort (Lieder & Rashid, 2016). A successful transition to CE requires collaboration and support from all the actors involved (Ghisellini et al., 2015). Therefore, CE implementation should include the micro, meso, and macro level initiatives with companies’ bottom-up effort and the national top-down effort.
Ghisellini et al. (2017) divide the literature on the three levels to themes. The micro level includes: “cleaner production”, “green production and green public procurement”, “product recycling and reuse, scavengers and decomposers,” and “policy”. The meso level consists of: “eco-industrial systems and industrial symbiosis districts and networks,” “waste trade markets,” and “policy.” The macro level has: “regional eco-industrial networks and productions, eco-cities, urban symbiosis”, “collaborative consumption”, “zero waste programs, innovative solid waste management systems,” and “policy.” They further write: “CE implies the adoption of cleaner production patterns at company level, an increase of producers and consumers responsibility and awareness, the use of renewable technologies and materials (wherever possible) as well as the adoption of suitable, clear and stable policies and tools.”

The literature on CE implementation has focused on identifying evidence of the environmental and economic benefits (Ghisellini et al., 2015). Alongside with environmental and economic sustainability, social and institutional implications of CE are marginally considered (Merli et al., 2018). However, social sustainability is increasingly acknowledged as an important part of CE (Ghisellini et al., 2016; Lieder & Rashid, 2016; Murray et al., 2017). It is yet to be researched how companies in the CE adopt this value creation logic with economic, environmental, and social sustainability principles in practice on micro, meso, and macro levels.

Method and data
Multiple case study method (see e.g. Voss et al., 2002) is used to analyse CBM implementation on micro, meso, and macro levels. The method helps to guard against observer bias, therefore enhancing reliability of the method, and augmenting external validity (Voss et al., 2002). The clothing and textiles sector is selected as the industry because it creates more pollution than international flights and maritime shipping combined (MacArthur, 2017). In the industry value of more than USD 500 billion is estimated to be lost yearly due to the lack of reutilization and recycling (MacArthur, 2017). The textile production has also significant negative effects for the natural (Fletcher, 2008) and human environments (Turker & Altuntas, 2014). Life-cycles of the products can be as short as two weeks (Niinimäki & Hassi, 2011), which greatly contradicts the principles of closing and slowing materials loops.

Firms with CBMs were selected from Finland. Finland was chosen as the Finnish government has set the target of Finland to become the forerunner in CE by 2025 (Ministry of the Environment, 2018). The case selection was based on the literature (Patton, 1990): each selected business model is employing slowing and/or closing the materials loop principles (Bocken et al., 2016). As an additional sampling criterion, the firms with frontline CE achievements were selected (third party awards, sustainability acknowledgements, and/or placements in sustainability rankings). The cases include mainly SMEs. Two types of firms were selected. A half of the firms were natives, i.e. firms which’ initial business models are based on the slowing and/or closing materials loops principles of the CBM. Another half of firms are adopters transitioning to CE i.e. those which have their origin in the linear economy (see Table 1). Semi-structured interviews were conducted with the founders of the companies or the persons officially or unofficially in charge of sustainability. Each interview protocol was formulated around the topics of drivers, values, and sustainable operations in the CE. Sustainability was discussed with the help of TBL model (Elkington, 1997). The interview questions were slightly modified during the data collection to take advantage of the emerging data (Spradley, 1979). The interviews were recorded and transcribed, and the accuracy of
information was verified by the company representatives (Voss et al., 2002). Validity of the interview data was enhanced by triangulating the data with information gathered from the companies’ websites, brochures, sustainability reports, and emails with the interviewees (Voss et al., 2002). In the analysis the study employs an inductive approach, combining within-case with cross-case method (Eisenhardt, 1989).

<tbody>
<tr>
<td>Case A</td>
<td>155/36.33</td>
<td>Case A is a B2C home textiles firm, which started its transition to CE in 2014. It has approached CE e.g. by launching products made from recycled materials and emphasizing quality and long lifecycles of products. Motivation for CBM implementation was to gain competitive advantage by differentiation from competitors and the eagerness to break the silence about sustainability issues in the industry. The company operates accordingly to its three values: “we are responsible,” “we are interested in the world,” and “we are brave.” It has had several campaigns on social issues; inequality of salaries between men and women.</td>
</tr>
<tr>
<td>Case B</td>
<td>3500/176.06</td>
<td>Case B provides interior, workwear and personal protective equipment solutions for companies (B2B) of different sizes (workwear rental model is the focus of this study). The textiles rental service was implemented in the 1950’s to gain competitive. In the firm’s workwear solution model, the ownership of products stays at Case B during the whole life cycle. The firm chooses the right kind of garment care for each cloth to lengthen product life-cycle. The products proceed through four-use categories based on their condition during their lifecycles. Company values are “profitable growth,” “long-term customer relationships,” “enthusiasm and the joy of learning,” and “responsibility.”</td>
</tr>
<tr>
<td>Case C</td>
<td>105/6.98</td>
<td>Case C is a B2C women’s garment manufacturer. In the company, responsibility has been important since founding of the company in 1983, but it has started the transition to CE in the recent years. Quality is essential in Case C’s products and emphasis is placed on consistent quality and materials rather than variability of the selection. The CE efforts of the company include for example a garment collection in which recycled blended cotton and wood fibres are used, product transportation bags for own use from unsold products, and the redesign of processes to eliminate waste. Values of the company include “openness,” “courage,” “trust,” and “responsibility.”</td>
</tr>
<tr>
<td>Case D</td>
<td>10/1.12</td>
<td>Case D (B2B/B2C) was founded in 2003 on its values of “ecology,” “ethics,” and “aesthetics” with the aim of making a difference into a more sustainable world. The firm aims at minimizing the negative environmental impact of its products throughout the supply chains for example by aiming to minimize geographical distances and therefore also the emissions from transportation in supply chains. In 2018 the company’s B2C product selection was revamped to consist of bags and accessories produced from recycled and left-over textiles materials and organic cosmetics. Case D also produces collections to B2B customers by commission from recycled materials, for example pack bags from the customers’ old ad banners.</td>
</tr>
<tr>
<td>Case E</td>
<td>3/0.77</td>
<td>A casual wear producer (B2B/B2C) Case E was founded in 2014. Some of the founders had experience of running a CBM in the past. The need for the business idea emerged due to the lack of as sustainable textile as possible. The company uses fabrics mainly from left-over materials of sewing factories and materials are 100% recycled. The company factory was designed to be as good place to work as possible, and the company</td>

Findings

Company level
It is evident the natives and the adopters have distinctive approaches to sustainability. Adopters emphasize long-term decision making in relation to financial stability. Two adopters, Case B and Case A, consider gaining competitive advantage from CBM implementation to be important. Case A also aims to find a “win-win situation” between the aspects of sustainability in its actions. Case C considers sustainability to be a part of everyone’s tasks in a sustainability-oriented company. The natives have sustainability as the basis for all decision making. Case F and Case E seek to develop their businesses and consider economic motivations to be important, however not on the cost of environmental and social sustainability. Case D sees economic sustainability as an enabler for ecology and ethics. To summarise, the setups for decision making greatly differ, particularly if the natives and the adopters are compared. Whether a company emphasizes economic or environmental and social standpoints in decision making affects all CBM activities in a firm. The economic and environmental aspects of sustainability are identified as the most prominent ones. All the cases also take social sustainability into account to some extent. The extent of environmental and social sustainability action seems to be vaster in the natives.

The CBM suggests alterations to the company operating logic. In particular, in the firms utilizing recycled materials, materials based design influences operations. Case F and Case D reutilize customers old textiles which is an integral part of their business models. Case E utilizes cutting waste from textile factories as its main material. In the adopters, Case A has had projects where recycled materials has been used. Common is that recycled materials flows are not standard in their form and timing compared to materials in the linear economy. In adopters these characteristics of materials based design are still somewhat viewed as a risk factor. However, the natives see handling uncertainty of unstandardized materials flows as a part of the business expertise.

Quality of products and materials is emphasized across the cases. Quality is seen as one of the key features to long life-cycles and environmental sustainability. In Case B’s workwear rental business model, quality is essential to keep the product in rental for a long time. Case A offers, for example, a 50-year guarantee for one linen sheet set and a five-year guarantee for duvet covers, pillow covers, and terry towels. At Case C, the emphasis is on consistent quality of materials and selection rather than on variability selection. The firms manufacturing from recycled materials also note that quality of materials needs to be good. For instance, Case D cannot use current consumer textiles as materials in its production due to poor quality. Additionally, functionality and design value of sustainable products were emphasized in several firms; they need to fulfil the customer needs in functionality and design. Case F mentions, that looking and feeling
good in a garment is important in workwear. Case D notes, the firm does not produce luxury, but aims to keep the prices in the reach of an average consumer. Several cases acknowledge that sustainable option is never the cheapest one. Particularly Case A and Case D feel their responsibility to educate customers about the price aspect.

Supply chain level
On supply chain level the companies are out to form requirements for sustainable operations. These include partners with shared values. Several firms mention that collaboration with companies with very different value bases would be difficult. Case B and Case A bring forth that they had to end collaboration with unethical partners. Based on the analysis, natives seem to have more partnership type of collaboration in their supply chains. The natives have chosen sustainable partners from the start, while the adopters are ensuring and improving their sustainability with their partners. The firms have formal and/or informal sustainability requirements for instance for working safety and waste management. Case B has a code of conduct which partners need to comply with. Case E only uses 100% recycled textiles, and this statement guides the criteria in their production; fulfilment is monitored by audits or visits to partners’ premises. Case A, Case B, and Case F monitor more actively the places with higher risk, e.g. human rights violations in distant locations. Case D and Case F visit their suppliers’ premises in Finland and Estonia, and Case E and Case C have their own factories. Values alignment in supply chains is seen as important for reaching the set sustainability targets.

Sustainability is present in the supply chain location decisions and transportation choices in some firms. Case D and Case F have a majority of their supply and manufacturing in the neighbouring areas. Based on them having geographically short supply chains decreases the negative environmental impacts of transportation. Case C has a large portion of the regular production at its subsidiary manufacturer in Estonia to ensure responsiveness and to minimize environmental impact of transportation. Case E found a sustainability-oriented shareholder in India and chose to locate its factory there in an area with expertise on fibre and textiles production, which for example Finland does not have.

The firms take into account sustainability of the product use period and end of life cycle. Garment care is a large part of the item’s environmental impact, and Case E, Case F, and Case C have created garment care instructions which are available for customers. Case B has its own laundries and choosing for example the right washing temperature and interval are important consideration. Optimizing garment care contributes to lengthening product life cycle. Case F also has a take-back-policy for their products. The ownership of Case B products stays within the firm, the company takes responsibility of reutilizing or disposing the products. Already in the product design phase Case E considers the recyclability of a product for example in their own collection as they use water-based prints instead of oil-based.

The importance of openness as a way to spread sustainability knowledge also came up in the analysis. Case D, Case E, and Case F proactively share information about supply chain sustainability to its stakeholders. In some products Case F has a QR code where origins of the product can be viewed. Case F has also had some customers to visit their production sites to ensure that, for example, working safety is in order. Case A is also mapping their supply chain networks as a part of adopting a CBM and sharing information about supplier locations on country level on their web site. Case B has its sustainability policy available for its stakeholders as the company believes that they are better taken to practice when they are brought visible. To Case A and Case B one reason for mapping
their vast supply chains is also risk control. Negative surprises in SCs are less likely to surface when more is known about the SCs.

To summarise, ensuring supply chain sustainability is seen as a responsibility in several of the firms, especially in natives. The firms which have strong environmental and social considerations on the company level also actively implement these aspects in SCs.

**Community level**

On community level all firms have sustainability efforts. Some of the firms have the efforts rooted in their ideologies and therefore integral parts of the CBM. Being a sustainable example, voicing out social and environmental issues, and participating in industry sustainability initiatives aim for change making in the respective community of each firm. Case A, Case D, Case E, and Case F aim by their actions to be sustainable examples to others. They aim to wide impact, for example, from their example large companies and consumers learn about sustainability. Case F also mentions that its large customers who openly talk about sustainability projects they have created together increases the company’s sustainability impact. Interestingly, the sustainability impact of these firms can potentially be much vaster compared to focusing on developing only operations. Particularly Case A and Case D have had campaigns and projects for voicing out environmental and social issues. Both of these companies have also had product lines to support these initiatives. Case D has been campaigning for example for transparency, human rights, fair trade, and lesser use of chemicals in manufacturing even before the legal and societal frameworks started to favour sustainability. Case A has had campaigns for social issues such as unequal salary for men and women, girls’ rights issues, and racism.

Case A, Case D, Case E, and Case F have participated or are participating in industry sustainability initiatives. The focus of a couple of projects initiated by the government together with companies has been to develop CE solutions for the clothing and textiles industry. In fact, several firms have worked together in these projects. Case A, Case D, and Case E are also part of the group of the organizations initiating corporate sustainability law change in Finland to obligate companies to attend human rights by United Nations guidelines (ykkösketju.fi). Hence, many CBMs seem to include efforts for a legal framework change for sustainability. Overall, community level change making seems to be an integral part of the CBMs of the natives. In adopters the extent differs by company. The natives’ objective to create social and environmental value can be seen to translate to community level in the actions described above.

**Discussion and conclusions**

The research question was: How do companies implement circular business models on company, supply chain, and community levels? The findings indicate that on company level standalone environmental and social value creation, competitive advantage, quality, design and functionality, producing for the need, materials based product and process design, recycling, and employee well-being were important CBM implementation practices. On supply chain level collaboration with partners with shared values, setting sustainability standards in supply chains, location choices, garment care, product end-of-life considerations, openness, responsible pricing, and risk control were identified as important CBM implementation practices. On community level being a sustainable example, voicing out social and environmental issues, charity, participation in industry sustainability issues, and rehabilitative working programs were important practises.
On company level the focus has been mainly on economic and environmental sustainability implementation, whereas on supply chain level social sustainability rose to more of an equal importance with the other two aspects. On community level social and environmental aspects were the most prominent ones; firms truly seem to aim for impacting behavioural change towards sustainability. The company level sustainability also reflects on the other two levels. In natives, sustainability has been integrated to all decision making from the day one, whereas adopters are implementing it piece by piece. CBM implementation focus and extent seem to differ based on whether a company is a native or an adopter. A lot could be learnt from natives of effective CBM implementation; they can be seen as vanguards. They are also eager to spread knowledge of sustainable values and operations. Adopters seem to expect a benefit from CBM implementation, but natives implement CBM because it has standalone value for them.

To conclude, neither CBM or CE implementation have been studied in the holistic context of three levels before, neither taking into account the three TBL aspects of sustainability. By increasing knowledge of more sustainable ways of implementing CE, the study contributes to acting against global issues such as global warming, overuse of natural resources, increasing pace of production and consumption, and social issues in the supply chains. The second contribution is that we study also natives in the CMB context; the current literature has focused on the CBM adopters. The results may provide guidance to other firms in their considerations of what to value in CE operationalization and what CE actions to implement. Also, findings can be helpful to authorities for policy making purposes by clarifying the incentives of CE companies. However, the CE operations discovered in this study are by no means an all-inclusive description of the key CE practices in firms. They rather provide some insights of the direction of CE implementation in CBM companies.

Abstract

This paper presents a methodological approach that combines circular economy perspectives with core industrial ecology concepts in order to specify a qualitative method to map food waste flows and the different industrial configurations across a food supply chain. The mapped waste flows and industrial linkages depict two time-related scenarios: 1. Current scenarios showing the status quo of existing food waste flows, and 2. Future scenarios pointing out circular economy alternatives along the supply chain. The framework provides a practical referential basis to inform benchmarking analysis and strategic alternatives for the reduction of waste in food supply chains.

Keywords: food supply chain; food waste mapping; circular economy

Introduction

The environmental sustainability of the food industry and its supply chain activities is a complex issue calling for sustainable practices that can be effectively achievable by the organisations operating in food value chains. In this context, food waste represents a major problem that remains to be addressed more effectively. The Food and Agriculture Organization (FAO) of the United Nations acknowledged that approximately a third of the global annual production of food ends up in landfill as waste (Mourad, 2016). An aggravating problem is that vital resources used in the production of food that is wasted are used in vain.

In order to improve its accountability and responsibility towards new expectations of customers and the society, the food sector needs to develop sustainable supply chains that minimise food waste across a wider spectrum of organisations from diverse sectors operating in different geographical contexts (Vermeulen, Campbell, and Ingram, 2012; Ghosh et al., 2016).
Many managerial concepts, frameworks and approaches are grounded on the notion of ‘waste’ as a valuable ‘resource’ and they consider the extended scope of supply chains when addressing sustainability issues concerning production and consumption systems (Pandey, Surjan, and Kapshe, 2016; Steeneck and Sarin, 2017). Yet, extant literature reveals some criticism on the practical implementation of the quantitative methods they involve, which present operational barriers in terms of cost, access to customised quantitative data, involvement of expert know-how and interpretation of outcomes by managers (Lake et al., 2015; Scheepens, Vogtlander, and Brezet, 2016).

This paper addresses these limitations by providing a qualitative methodological approach to mapping current scenarios of food waste in food supply chains, as well as identifying alternative circular scenarios that can potentially replace disposal flows. We report preliminary findings of a study where the framework was empirically tested. The paper brings circularity perspectives advocated by the circular economy into the framework, this way expanding the methodological basis to support initial analysis of food waste and recovery scenarios in circular economy based approaches. Key questions addressed in the paper are: 1. How can we capture industrial configurations and related food waste flows in a food supply chain without engaging with too complex and costly methodological approaches? 2. How can we identify circular industrial linkages that can minimise food waste disposal in a supply chain?

In the next section we highlight key aspects concerning the analysis of food waste and organisational synergies. This is followed by a presentation of the theoretical basis underlying the proposed methodological framework of analysis. In the sequence, we briefly discuss the methodology of the empirical study developed to test the framework. The main research findings and conclusive thoughts are discussed in the subsequent sections.

**Food waste and organisational synergies**

To derive food waste scenarios and potential organisational synergies from supply networks is not a straightforward task. Previous studies have pointed out that approaches to analyse and mitigate the environmental impact of food supply chains without proper consideration of the interconnections that exist between organisations and sectors in the chain are likely to fail (Cellura, Ardente, and Longo, 2012). To deal with the environmental complexity of food supply chains, it is necessary to have the support of analytical framework methods that take into account the array of industries involved as well as their geographical configurations and potential cross-industry linkages in different regions across the supply chain.

In general, food waste can be a valuable input material for organisations inside or outside the supply chain they were originally generated. Finding food supply chain gaps where such valuable resources are being wasted into disposal flows rather than being absorbed in further production processes is a core concern of this study. In essence, this represents a major concern of the circular economy, which advocates production systems that are restorative by purpose, shifting production value chains from linear (‘take-make-use-dispose’) to circular (‘take-make-use-recover’) cycles (Webster, 2015). The transition to a circular economy predicated on production systems that take into account opportunities for circular cycles and cascading of products, by-products and waste outputs calls for a more comprehensive consideration of the potential circularities linking different supply chain actors (Dervojetda et al., 2014; WEF, 2014; Nasir et al., 2017). This complexity posits methodological challenges to analyse food waste scenarios.

For instance, the implementation of circular flows comprising closed- and open-loops of food waste materials increases the complexity and expands the scope of supply chain
operations in the circular economy context. Following the call for more integrative approaches to designing sustainable supply chains (Bals and Tate, 2018), the design of supply chains for the circular economy should take into account more holistic perspectives integrating the different types of circular flows that maximise the recovery of materials. A wider perspective of industrial linkages is therefore a fundamental methodological approach adopted in this study.

**Methodological framework for qualitative food waste mapping**

In this section we introduce a methodological framework for the qualitative analysis of food waste and potential organisational synergies in food supply chains. The framework synthesises core concepts and approaches from previous studies and knowledge areas into a more practical and less complex analytical method. For this, we draw from a methodological approach developed by Ardente et al. (2009), combining the initial steps of their approach with a standardised classification of food waste proposed by Darlington, Staikos and Rahimifard (2009). Food waste synergy scenarios are considered with basis on the food recovery hierarchy model specified by the U.S. Environmental Protection Agency (EPA, 2014) and core industrial ecology/symbiosis concepts (Chertow, 2007; 2000) encouraged by the circular economy. Figure 1 shows the key supply chain stages from which waste synergy scenarios are derived from. The scenarios are the main outcomes of the analysis process and they ultimately describe potential food waste synergies not only within and between the industrial activities of the supply chain considered, but also potential industrial linkages with organisations outside the supply chain in focus.

![Figure 1 – Key industrial sectors from which food waste synergy scenarios are derived](image)

**Phase 1: Scope definition**

The initial phase of the analysis involves specification of ‘systems boundaries’. In this phase, we specify the unit of analysis and the systems-in-focus that are going to be investigated. The unit of analysis refers to the specific food supply chain in focus from which food waste and synergy scenarios are going to be drawn. The systems-in-focus refer to the organisations in each of the supply chain stages being analysed. As illustrated in Figure 1, the system-in-focus in each stage of the food supply chain that will be analysed are: 1. farming in the initial food production stage; 2. manufacturing in the food processing stage; and 3. retailing in the food gateway to consumption market stage. Organisations in the external environment of the systems-in-focus, i.e. outside the supply chain, will be taken into account regarding their potential to be involved in potential food waste synergies. With basis on Ardente et al. (2009), activities in this phase include: a. Specification of the unit of analysis, b. Definition of system boundaries and c. Identification of main industrial processes.

From an industrial ecology perspective, steps b. and c. above refer to the ‘industrial inventory’ process of the analysis, which in practice comprises the identification of local organisations in a specific region and their related resource flows. According to Chertow (2012), data concerning the inputs and outputs of relevant industrial processes are collected generically to form a base analysis from which further assessments can be developed.
Phase 2: Inventory of waste outputs
This phase of the analysis focuses particularly upon the identification and classification of the main waste outputs generated by the companies in the supply chain. For this, we apply the waste model for the food sector defined by Darlington, Staikos and Rahimifard (2009) as a basis to categorise, in a standardised way, the food waste and key by-product outputs identified in Phase 1. We adapt their model to specify a clearer differentiation among the five general types of waste in the food sector, namely: 1. Processing waste (material losses from the production process due to poor handling or processing failure); 2. Wastewater (water at the end of food processing or cleaning processes, which usually carries dirt or debris); 3. Packaging waste (materials disposed from packaging and re-packaging processes); 4. Nonconformity waste (edible food generated in the production process that have not achieved required market specifications); and 5. Overproduction waste (food that meets industry specifications but has to be scrapped because it no-longer has a consumer).

Phase 3: Scenarios specification
This phase involves the description of waste destination flows from each of the companies under study. The scenarios have two time-related perspectives, one portraying current waste destination flows and the other portraying future waste destination scenarios which involve industrial synergies that can potentially take place if circular economy practices are implemented. Ultimately, the future scenarios point out potential alternatives for supply chain transitions from linear to circular value chain ecosystems that divert valuable resources from disposal. Such initiatives are based on a fundamental principle of the circular economy, which advocates the implementation of sustainable production and supply chain systems that seek to prolong the lifespan of products, by-products and waste (Lovins and Braungart, 2014). This can be achieved through the purposeful design of restorative processes and supporting circular supply chains (De Angelis, Howard and Miemczyk, 2018).

The waste flows identified are classified according to the ‘food recovery hierarchy’ model of the U.S. Environmental Protection Agency (EPA, 2014), shown in Figure 2. The model provides a helpful referential basis to classify, in a standardised way, the current food waste destination flows and the future circular food waste destinations through which the environmental sustainability of the food supply chain can be improved.

![Figure 2 – Food recovery hierarchy model. Adapted from EPA (2014)](image)

The hierarchy model also indicates an order of preference for processes that should be targeted as better alternatives for food waste to landfill (disposal). Accordingly, the future waste destination scenarios identify potential industrial connections that move current
food waste flows up in the hierarchy pyramid, and most importantly out of landfill destinations. This is done by matching food waste streams from one organisation with inputs at other facilities inside or outside the supply chain in focus. From a circular economy perspective, this represents identification of industrial linkages through which supply chain transitions from linear to circular systems can be achieved.

The identified waste flow scenarios are classified according to the spatial scale typology of industrial symbiosis proposed by Chertow (2000). Industrial symbiosis is a specific stream of the industrial ecology area that is concerned with the flow of materials that may involve industrial linkages between organisations or institutions from diverse industries engaged in physical exchanges of waste, by-products, water and energy (Chertow, 2007). This classification provides helpful insights regarding the geographical distances concerning waste flows, as distinct geographical configurations demand different logistics operations for the materials exchanges/flows envisaged. Table 1 describes the general types of materials exchange through industrial connections from a spatial perspective.

Methodology
The methodological framework above specified was empirically tested in a case study of a food supply chain. Following recommended data collection methods and techniques adopted in qualitative approaches, besides field observation and analysis of documents, semi-structured interviews comprised the major activity for the collection of primary data conducted in the study (Bryman and Bell, 2015). The interviews were conducted with the founders or CEOs of the companies in the supply chain studied. The interviewees therefore had a comprehensive understanding of their respective suppliers, customers and key input/output materials necessary for their operations. The case study approach allowed a comprehensive understanding food waste flows and identification of potential food waste synergies in the food supply ecosystem considered.

The unit of analysis for the case study comprised a supply chain of vegetables, and related derived products, comprising local companies in the UK. The supply of vegetables was targeted due to the increased challenges that products with fast perishability and short ‘shelf life’ bring to supply chain operations. Their production is usually associated with intensive use of water and re-packaging processes across the supply chain that represent additional sustainability challenges.
Research findings

Phase 1: Scope Definition
The supply chain analysed involved three key agri-business players in the production and commercialisation of vegetables and derived products, namely: A food grower, a food manufacturer and a food retailer. These specific operations represent the systems-in-focus of the study and they are typical production and service ecosystems in food value chains, with systems boundaries clearly defined at the level of farming, food processing and food retail service respectively (Figure 1). Table 2 provides a qualitative industrial inventory (Chertow, 2012) of the organisations in terms of generic input-output mapping of the main production and service operations involved. The real names of the companies are not shown due to non-disclosure agreements.

Phase 2: Inventory of waste outputs
In this phase an inventory of waste materials was produced. The production waste created by each supply chain actor was identified and classified according to standard categories to facilitate qualitative analysis of the main types of waste generated across the supply chain. The results are presented in Table 3. The table shows that ‘processing waste’ is by far the predominant type of food waste across the supply chain analysed. It is particularly critical at manufacturing level. This might be explained by the higher degree of complexity involved in the input transformation processes that take place in the food manufacturing context considered. ‘Overproduction waste’ is an evident issue at farming and retail levels, suggesting difficulty of growers and retailers to match volume capacity with demand. While ‘packaging waste’ is present across all stages in the supply chain, ‘wastewater’ is more localised at farming and manufacturing levels. Indeed, vegetable washing processes are much more substantial in these two operational instances
when compared to retail operations. Finally, ‘nonconformity waste’ is an issue of more concern for growers, which in fact have more difficulty to produce on a regular basis vegetables with the aesthetic specifications required by retailers due to varying climate circumstances that are out of their control.

</tbody>
</table>

Phase 3: Scenarios specification

Current destination flow scenarios for the main types of waste identified above are presented in Table 4. They are classified according to the EPA food recovery hierarchy model (Figure 2) and the spatial scale typology related to the organisations involved.

Most of the waste generated at the farming level (company A - grower) is destined to further industrial processes. More specifically, nonconformity waste A1 (vegetables that do not fulfil aesthetic requirements specified by retailers or present labelling/packaging errors after going through packaging processes) are currently sent to commercialisation in the wholesale market. This is the same destination of overproduction waste A3 (surplus vegetable produce), which is not under exclusive contracts with customers. Packaging waste (A4) go to recycling organisations located within the farmer’s region area (type 4 spatial scale) and wastewater (A5) is treated within the farm (type 2 spatial scale) and used to reinforce its irrigation systems. From a circular economy perspective, waste A2 (processing waste resulted from vegetable cutting/trimming processes) represents a major concern, as it currently goes to landfill. The grower disposes A2 for collection by government contractors that provide waste collection services (Type 1 spatial scale).

At manufacturing level (company B), waste B3 presents highly recommendable flows in circular economy terms, as they are donated to NGO organisations running food banks and shelters in the region. The spatial linkage through which B3 flows is Type 4. However, the manufacturing company is not performing well in implementing sustainable waste flows for wastes B1, B4 and B5, which are currently destined to landfill.
Used vegetable oil (waste B2) is currently taken by a recycling operations in the region which refines cooking oil into biofuel for power generation and heating.

The current waste flow scenario at retail level presents good circularity capability, as there is no waste flow to landfill. While food not sold by the expiry date (wastes C1 and C3) is sent to local recycling operations that produce compost, food not sold due to packaging damage (wastes C2 and C4) is removed from the shelves and made available to local small farmers for animal feed purpose mainly. Finally, packaging waste (C5) is sent to local recyclers.

The current scenario analysis pointed out areas in the food supply chain where linear open flows of waste to landfill represent sustainability main issues of concern. The specification of future waste destination scenarios allowed identification of alternative industrial linkages that can potentially promote the shift of waste flows from open (linear flows to landfill) to circular (more sustainable) processes. Further improvements of waste flows can also be done through the identification of industrial linkages that bring food waste flows up the food recovery hierarchy. Figure 3 points out the areas in the supply chain where such improvements could occur. For example, the figure shows that circularity improvements at farming level could be achieved through the implementation of alternative flows for A1, A2 and A3 wastes. For instance, to improve social sustainability part of the A1 vegetables that are currently going to wholesale markets could be destined to feed people through NGOs running food banks or shelters. Vegetable cuttings and trimmings (waste A2) could be made available to local farmers for animal
feed purposes. Improvements on farming techniques and better demand forecasting would allow reduction of overproduction waste (A3). Further improvements are shown at manufacturing and retailing levels.

**Figure 3 – Potential food recovery improvements in the supply chain**

**Conclusions**

This paper introduces the theoretical and methodological basis of a qualitative framework of analysis that brings circular economy perspectives into the core of key knowledge areas supporting analytical tools applied in research concerned with the environmental sustainability of food supply chains. In the paper, our main intention is to put forward a qualitative methodological framework of analysis that is, in practice, realistically straightforward and simple to apply without being simplistic in terms of its conceptual basis and supporting antecedent frameworks.

We encourage future research that involves complementary quantitative data in mixed method approaches that expand the analytical contributions of the framework here developed. For example, the different contexts of waste hierarchy processes, categories of food waste, and spatial scale of industrial linkages can all be numerically scored. Depending on the availability and access to data from the organisations being analysed, this can be combined with figures related to cost reduction and revenue enhancement enabled by potential exchanges of food waste materials that can take place in the future. Such quantitative perspective can be applied to facilitate comparative analysis and to support simulation applications showing how emergent industrial ecosystems influence the potential costs and revenues of the organisations involved.

Abstract

The sustainable manufacturing literature informs how to technically change but is weak on how an organisation should facilitate the change. We know that organisations learn quickly from external sources, especially peers, but that technical practices and tools alone are insufficient to replicate and sustain improvements. Communities of practice could frame how organisations make use of sustainable manufacturing knowledge and how learning is shared within and beyond manufacturing sites through peer-to-peer support. This research seeks to capture how organisations share knowledge beyond site boundaries and how sustainability leaders in companies, often without dedicated teams, engage in sharing for mutual benefit.

Keywords: Sustainability, peer-to-peer support, communities

Introduction

The sustainable manufacturing literature can inform how to technically change but is weak on how an organisation should facilitate the change, especially when working across site boundaries. Lean manufacturing (Womack & Jones, 2005) shows us that technical practices and tools alone are insufficient to replicate and sustain improvements (Drew et al., 2004). Advancing sustainability (Mejías et al., 2016) demands tacit knowledge that will be impacted by the willingness to share and receive (Dudley, 2006). We know that organisations learn quickly from external sources (Cummings, 2004) and adopt new organisational routines (Argote & Ingram, 2000) through organisational learning theory. Additionally, communities of practice (Bodrožić & Adler, 2018) allows us to frame how organisations make use of sustainable manufacturing knowledge and how learning is shared within and beyond manufacturing sites. Whilst these theories have the potential to address peer-to-peer support, there is little work in sustainable manufacturing (e.g. Davies, 2012) and knowledge on the barriers focus on the individual and neglect the organisation (Ball & Lunt, 2018).

The purpose of this research was to conceptualise how organisations share and receive knowledge beyond site boundaries and how sustainability leaders in companies (who often operate without dedicated teams) engage in sharing for mutual benefit. Whilst it is known that companies of the same type, in similar supply chain positions and potential competing in the same market may share (MacBryde & Ball, 2018) little is known about how different companies share and support, especially through community and peer-to-peer exchange. The motivation for better understanding is driven by the urgency to
address the impact of manufacturing on global resources. Through better understanding of sharing it could be possible to support manufacturers in faster and more extensive change for their own and global benefit.

This paper first considers the literature on sustainable manufacturing and how knowledge sharing and communities of practice could influence the adoption of better practice. The methodology followed by the findings detail how two different industrial networks shared knowledge between peers and the analysis to derive a conceptual framework that is underpinned by a community for sharing. The ongoing work is briefly presented before the contribution is restated.

**Literature**

Manufacturing operations need to reduce their environmental impact by considering input cost, waste cost, regulation and ‘doing the right thing’ (Giunipero et al., 2014). One way forward is to adopt lean thinking. The links between lean and green have been well documented with, in general, those implementing lean having better green performance (King and Lenox, 2001). Whilst Martínez-Jurado & Moyano-Fuentes (2014) see the link between lean and sustainability as the “new frontier”, Yang et al. (2011) working on practice bundles argue that lean is insufficient to improve environmental performance.

Claro et al. (2013) assert that leadership is key for implementing practices and this leadership must be an organisational commitment to properly motivate those designing products and services (Pagell & Wu, 2009). It is likely that the skills learnt for lean achievements help with the skills for environmental achievements (Hajmohammad et al., 2013). Mollenkopf et al. (2010) argued for collaboration to share knowledge and build capability by working across the supply chain.

The willingness to share knowledge and the willingness to receive knowledge are two key aspects of how knowledge within and across supply chains can propagate. Dudley (2006) recognised the importance of relationships for smooth knowledge transfer. For sharing, a sense of identity (Bresman et al., 1999) is important for knowledge exchange, so too is physical interaction, e.g. through meetings and visits (Kohlbacher & Krähe, 2007). For receiving, motivation is important for absorption (Minbaeva et al, 2014) as well as similar understanding and language (Cohen & Levinthal, 1990). Underpinning this transfer, especially for tacit knowledge, is trust (Dyer & Nobeoka, 2000). In summary, knowledge, especially tacit knowledge, sharing is enhanced through physical interaction of individuals who identify with one another through common language, common understanding and a shared sense of identity. Peer-to-peer sharing therefore offers an effective conduit for the dissemination of sustainable manufacturing practices.

Knowledge exchange between companies in pursuit of sustainable operations is emphasised by Gavronski et al. (2012) for organisational learning. Apart from a few works (e.g. Davies, 2012), there is an absence in the sustainable manufacturing literature. The relevance here is that organisational learning theory (Argote, 2011) can be used to understand routines which include rules and procedures (Levitt & March, 1988). Davies (2012) presents a conceptual framework detailing the flow of learning from a trigger to change through to people learning that improves understanding and in turn new methods that results in improved eco-performance. The focus on routines is important to distinguish between the knowledge of an individual and the knowledge embedded within an organisation independently of the individuals. Inter-organisational learning (Gieskes et al., 2002) offers a conduit to move expertise and practices from one organisation to elsewhere in the community.

Communities to support this could endorse knowledge to encourage others to adopt practices and promote the ‘stickiness’ of those practices (Brown & Duguid, 1998).
focus on the socially embedded knowledge that allows both the ‘what’ as well as the ‘how’ of the practice to be transferred. Cox (2005) see the theory of community of practice as defining the facilitation of a group (virtual or informal) to share with one another and learn from one another. The evolution of technology revolutions has seen the transition from strategic integration to one of networks (Bodrožić & Adler, 2018) that emphasise knowledge management in which we “cultivate the communities of practices needed to sustain innovation in … dispersed value-chain activities”. The knowledge of a practice and the actual practice itself is different (Gherardi, 2009) and so communities of practice to foster the exchange of tacit knowledge aids communication of practices beyond accessing practice repositories, literature on practice types, etc.

Whilst a focus on people and their communities would be advantageous, barriers may occur. A barrier hinders the achievement of improved efficiency (Jaffe & Stavins, 1994) and may describe fear of change, lack of urgency, lack of tools, lack of knowledge, absence of vision, etc (Lunt et al., 2014). Overcoming these barriers through ‘remedies’ or enablers will permit advance. Overcoming the barriers in the context of communities that share practices and support one another offers a means to advance sustainable manufacturing using existing practices.

The sustainable manufacturing literature has significant work what practices companies are using and in turn what they are achieving as a result. With the organisational learning and communities of practice literature there is significant work on how knowledge is embedded with organisations and how communities are able to share that knowledge within and between organisations. What is absent is how sustainable manufacturing practices are shared. The literature tells us what has been shared but not the underlying mechanisms of exchange and what helps and what hinders that exchange. In particular there is an absence of work conceptualising the exchange between peers. A better understanding of such peer-to-peer exchange through communities, especially beyond the boundaries of individual companies, could inform how to facilitate wider and faster spread of practice to reduce the impact of manufacturing operations.

The research objective is therefore to understand how communities of practice can capture exchange and be used to foster sustainable manufacturing advance. In particular, what motivates peer-to-peer sharing and how it can be supported.

Methodology

The research sought to understand how sustainable manufacturing practices are shared across operations. We know what practices can be adopted and the corresponding typical performance improvement. What is less well understood is how those practices are shared across networks, whether within the same enterprise or across multiple enterprises. This research was therefore exploratory to inductively characterise how manufacturing organisations share knowledge.

The research draws empirically from UK manufacturers. The work reported here sought to understand how they adopted sustainable manufacturing practices with the support of networks and communities. Data was gathered from companies within two UK manufacturing sectors. The unit of analysis was a company including its sustainability lead and local improvement team. Whilst supply chain interactions beyond the company boundary were acknowledged they were not investigated.

Firstly, a single company with a formal sharing network operating across its 11 sites that formed an internal supply chain was examined (Network 1). Secondly, 26 companies from the same tier of a distinct sector who interacted in an informal collegiate way was considered (Network 2). Companies approached were those motivated to improve their sustainability work and were self-selecting for inclusion. A grounded approach was used
to capture the enablers for sharing, apparent barriers and actions to remove those barriers to aid further sharing. Of interest was how sharing took place from transactional information transfer to learning through joint activity.

A process thinking mindset in line with lean manufacturing thinking was used to capture and structure interactions. Data analysis was by coding and clustering to capture characteristics. Codes (e.g. a type of barrier or practice) were refined into final codes which are shown as the barriers, practices, etc. Clusters were formed around how the sharing took place. Two separate networks were investigated so further consolidation of results was carried out as a second phase.

**Findings**

**Industrial networks**

Two industrial networks are used to characterise the practice sharing in pursuit of sustainable manufacturing advance. The first is a formal network that was created across a multi-site, multi-country enterprise. The second is an informal network that exists within a specific industrial sector that grew out of shared passion for the products produced and sold.

The first network (Network 1) was a European aerospace manufacturer that initiated an industrial energy efficiency network to engage multiple sites in energy and other resource reduction. The programme of reduction consisted of a lead (or champion) in each site responsible for reducing consumption against agreed targets and connected together by a network lead. The network lead did not have line management responsibility for the site leads and the site team members were not necessarily line managed by the site leads. Each site used a common improvement method that had been incorporated within the enterprise lean production system. Site leads and their teams were trained on the methods to deploy and would maintain regular contact with the network lead and in turn the other network teams. The contact between the teams consisted of day-to-day informal direct contact, formal virtual sharing on a monthly basis and regular, less frequent assembly at a given site. The teams were also virtually and physically supported by the network lead. The achievement against target was reported formally in the site management reporting and collated by the network lead. Through observation, document analysis and interview, data was collected on performance achievement, practices implemented, enablers to success and barriers hindering or preventing success.

The second network (Network 2) was a UK beer brewing network that had grown from years of mutual support. Breweries have multiple strong brewery-to-brewery links, often within a locality as well as openness new links from any brewery. The community had formed out of smaller brewery shared interest in production of high quality ‘craft ale’ and selling in competition to the ‘goliath’ multinationals (although no significant barriers to exchange were overt for such parties in workshops). The improvement lead for a brewery tended to be the head brewer reflecting production knowledge and the small size of most breweries. Brewers tended to come from within the brewing industry or business outside of manufacturing. So, whilst brewers would use language, descriptions and motivations that could be recognised by a manufacturing engineer, the language was not typical of manufacturing hence lean thinking and sustainable manufacturing were not cited explicitly. Sharing could be by email, messaging apps, etc. but was more typically combined with mutual interest for the product within a brewery. Such sharing could therefore arise from scheduled workshops or site tours or more ad-hoc meetings resulting from a challenge a particularly brewery was seeking help on. Through observation, workshop output and interview, data was collected on the typical metrics used, the practices implemented, enablers to success and barriers hindering or preventing success.
Barriers
A barrier is used to describe a condition that may hinder or prevent an improvement process taking place. It could refer to something related to process (the first six lines in table 1) such as absence of supporting techniques, to people (the next five lines in table 1) such as a lack of knowledge or to tools (the last three lines in table 1) such as insufficient metering to gather data. Such tools (inc. hardware), processes and people categorisation draws on the technology, management and people categorisation used by Sarkis (2001). Using Lunt et al. (2014) as the reference point for barriers to progress in energy efficiency projects in manufacturing, evidence for the presence of barriers was sought in the two industrial networks.

In Network 1 numerous barriers were evidenced from observation of difficulties in progress on projects in the enterprise manufacturing sites and from project documentation (meeting minutes and final reports). Checks for the barriers revealed many existed that hindered the progress of the improvement projects. During the period of data capture some barriers remained throughout, some were removed, and some grew stronger. Key barriers captured in Network 1 are displayed in Table 1 against the bands of process, people and tools. For the process barriers, accountability was referred to disconnect between the local improvement objectives and corporate strategy. This disconnect with strategy was tolerated for a while as site managers site emphasised the priority of the resource reduction projects. Some projects could have been easier to manage had the team making the improvement seen benefit of the cost savings realised as well as them, rather than others, being the beneficiaries. For the people barriers, two key problems were identified. Firstly, insufficient staff were allocated to some projects and, in a few cases, staff were later redeployed on unrelated projects. Secondly, it took time for staff to have confidence in their decision making because of the training. For the tool barriers, initially there were problems access funds for capital acquisition and that the information needed for decision making was either not in a suitable form or data needed to be collected first with portable metering.

</table>

In Network 2 similar barriers were reported and also appear in Table 1. For process barriers, priority was highlighted due to the lack of pressure from consumers or regulators to improve. In a few cases saving water or separating wastes did not benefit the brewery
due to tenancy or municipal arrangements. Additionally, the lack of methods and techniques available were low, in part resulting from a view by some that resources such as water were cheap. For people barriers, the small size of many breweries meant time, additional resource and competence hindered sustainability improvements. This was amplified by a caution towards product quality and the difficulty in judging where to spend funds most effectively. Finally, for tool barriers, the lack of data for decision making was further hampered by small cash reserves to fund decisions.

In Network 1, the site leads each experienced many of barriers cited. Through the guidance of the network lead, these barriers were shared to make each other aware of what may cause problems for future projects as well as trigger actions to mitigate these barriers through ‘remedies’ or enablers. In Network 2, the leads detailed the barriers they faced, many of which were people related. The people related challenges could explain why the network was openly helpful to each other which leads onto how the companies enabled their improvement work.

**Enablers**

An enabler is used to describe a positive condition supports improvement activity. It could refer to something related to process (the first three lines in table 2) such as a clearly articulated vision, to people (the next four lines in table 2) such as a mutually supportive community or to tools (the last two lines in table 2) such as enough equipment to gather necessary data.

Network 1 was a formal network in a multi-national hence guided by a distinct vision and strategy. Through incentives and accountability, the company was able to align activities to objectives and create a sense of urgency. Training was developed and delivered early in the network life and was built around a standard methodology (adapted from one developed by a previous project collaborator in another industrial sector) that had been piloted in the same site as the network lead. Through brokerage with site managers, a site lead and associated teams were formed from competent members of different site functions. The network lead fostered the interaction between the network lead and the site leads and encourage site to site interaction. Using standard company reporting the teams evidenced their activities and used the mechanism to share knowledge within and across the sites. Finally, by improving the metering and the subsequent software reporting of the data captured the site teams were able to utilise the standard methodology to make decisions more quickly and more confidently. The sharing that took place across the network of how to use the methodology, how to overcome problems, how to rationalise sometimes conflicting requirements enabled the teams to overcome barriers and achieve significant improvements in resource utilisation. It was observed that collegiate team members would help those in other sites unprompted out of a shared imperative without direct benefit to themselves. These enablers are summarised in column one of Table 2.

Network 2 was an informal community of like companies in the same sector and same supply chain position as each other. The vision therefore was not a formal corporate one but based on core company values and development of their individual brands. The small size of many of the companies meant that improvement activities to reduce resource use or increase production intensity had a meaningful direct link to profit. Many of the individuals had not received formal training but informally mentored one another through mutual support and direct knowledge sharing. It was observed that sharing was more detailed than would be acceptable practice in other industry sectors, illustrating the level of trust and shared endeavour that exists here. Interestingly, within brewing the level of cooperation goes well beyond knowledge sharing and with many formal and informal
practices from sharing facilities to cask swapping (for selling each other’s beer) and from short term help on raw materials to co-developing products. Whilst Network 1 was data driven, Network 2 company leaders had line of sight and intimate knowledge of their entire process and therefore would readily connect own operational metrics and own visual observations with the practices of other companies to support decision making. Standard metrics reported across the sector allowed ease of interpretation as well as benchmarking. All companies used site level metrics and those that used more localised metrics reported immediate behaviour changes that in larger companies would typically need analysis prior to process change. Demonstration and endorsement of practice strongly influenced knowledge transfer and practice acceptance. Communities formed out of physical visits to breweries and continued virtually (e.g. WhatsApp groups). These enablers are summarised in column two of Table 2.

The Network 1 and Network 2 enablers show strong similarities in what guided motivation to change, how performance was captured, how people shared knowledge and where part of virtual and physical community interaction. The enablers from both networks are aligned within Table 2 and common generic descriptors are used to capture the generic enablers of: Vision, Operational responsibility, Objectives and Targets, Training, Methods, People, Community, Data provision and Equipment.

Conceptual framework

Drawing from the network barriers and enablers findings, a conceptual framework to capture the overall behaviours has been derived and is presented in Figure 1. The enablers and barriers are drawn from Table 1 and Table 2 respectively and categorised into process, people and tools as before. The linkages are drawn from the work of Davies (2012) work on organisational learning for sustainable manufacturing cited earlier. The associations between the barriers and the enablers are derived from the network data on what actions leaders and teams took to mitigate against the barriers they are faced with. The flow from left to right exists to illustrate the journey from having the justification to make changes, the people and process to approach change and the practices changed leading to improvements captured by the site and process metrics.
Figure 1. Enablers and barriers for advancing sustainable manufacturing

The community aspect was a prominent conduit for the sharing of knowledge, sharing of specific practices and, in some cases, providing help to others. It is significant that this sharing takes place across boundaries for which there is no command and control structure. Individuals did not have to share but saw mutual benefit in meeting (physically and virtually) to help one another. The practices being shared were not new to the field but can be considered new to each individual site. The community of practice therefore offers a means to explain and foster the advance of sustainable manufacturing practices across the companies.

The research captures how clusters of companies engaged in sharing sustainability knowledge with others on a mutual basis. The work differs from existing forms of digital exchange (through knowledge portals), verbal presentations and ‘industrial tourism’ as it engaged those in the cluster to actively help one another beyond simply exchange of information. Whilst good practice was revealed through presentations and tours, the communities are not just sharing high level knowledge but willing to trust in peers and assist one another.

There is little peer-to-peer learning and communities of practice literature focused on manufacturing operations and in particular sustainability programmes within them. Whilst there are different interpretations of how a community is defined (Cox, 2005), there is commonality in the language of collective learning, informal groups, membership cutting across boundaries and improvisation/unstructured pathways. Whilst some works see the community as one of equals others cite a more master-apprentice type relationship. In the research here, all were willing to learn from others who have particular knowledge but the exchanges identified were between equals in terms of general expertise and standing. The research outcome here provides context for the community specific to manufacturing operations. In particular it links the behaviour of the community with the activities of the community.

Ongoing work

The learning as led to the set up of two formal peer-to-peer networks involving non-competitive companies. The first from sub-sectors of food and drink for sustainable manufacturing, second looking at sharing new product introduction good practice with a geographic region. Acknowledging the barriers and enablers, the network addresses a shared ambition to seek further advance in improvement beyond individual company
current trajectories. The networks are made up of peers who are responsible for leadership of sustainability and design respectively, driven by their own company strategies. They have similar levels of achievement and target improvements and have a similar level of (advanced) competence. They are able to marshal teams within their companies and have experienced community and network sharing previously. Importantly, the interactions are at each site in turn with the visits split between the sharing of achievements and the presentation of challenges. The mix of “give and take” provides immediate gain for all, especially the host, prior to rotation to the next company in the network. The visits seek to provide consultancy-like input into each company in turn. This draws on the advantages of the formal single enterprise Network 1 and the informal multi-company community of Network 2.

Conclusion
The research has revealed the common barriers and enablers for sustainable manufacturing improvement for multiple sites of a single enterprise and multiple similar enterprises within a single industrial sub-sector. The community support and sharing of knowledge and specific practices reveals the willingness to help peers and others in the absence of immediate reward or fulfilment of line management expectation.

The research therefore contributes to the communities of practice literature by characterising how sustainability practice is shared from a manufacturing operations perspective. What motivates individuals to participate in peer-to-peer exchange and how it is justified to colleagues has been absent from the sustainable operations field. Capturing how tacit and explicit information is transmitted and received between organisations that may not have a formal relationship provides new insights to how sustainable manufacturing can be advanced. The characterisation focuses on how peer-to-peer sharing can foster advance through a community perspective on barriers and enablers.

From a practice perspective, such decentralised sharing offers an opportunity to enable organisationally ‘lean’ companies to advance through learning with trusted peers without incurring significant cost. From a policy perspective, this could have potential for facilitating rapid, cost effective change in manufacturing.

Abstract

Remanufacturing is one of the processes to extend products’ life cycle in closed-loop supply chain. The process runs by OEMs, certified firms or third parties and flows as receiving used products, making them function at least the same as brand new one and selling them again with warranty. Despite highlighted economic and environmental benefits, the remanufacturing industry is still underdeveloped with great opportunities. Due to the nature of the process, understanding customers’ perception and purchase intention are vital for further and faster development of the industry. This paper reviews 26 journal articles.

Keywords: Remanufactured product, purchase intention, systematic literature review
Introduction

Remanufacturing is a closed-loop supply chain (CLSC) strategy that aims to recover the residual value of returned products (Wang et al., 2013; Bittar, 2018; S. Wang et al., 2018). It is a process that brings used-products to like new condition with warranty and at least the same quality, functionality, and performance as brand new ones (Jiménez-Parra et al., 2014; Bittar, 2018; Vafadarnikjoo et al., 2018). The process involves stages of product acquisition, disassembling returned products, cleaning, repairing or replacing worn-out parts, quality testing, reassembling and remarketing (Wang et al., 2013; Bittar, 2018; Vafadarnikjoo et al., 2018) that is an industrial process (Wang and Kuah, 2018). Remanufacturing is fundamentally different from repair, recycle, and reuse due to the requirement of converting the product to like a new one (Xu et al., 2017; Matsumoto et al., 2018a; Vafadarnikjoo et al., 2018). The difference between these is not well understood in the market (Wang and Kuah, 2018). Therefore, these terms cannot be used interchangeably. On the other hand, the term refurbished means the same as remanufactured (McKie et al., 2018).

Due to global sustainability issues, many countries took legal actions to promote sustainable actions (Qu et al., 2018) and reduce carbon footprint such as the Paris Agreement. Also, customers become more sustainability-conscious and sustainability measures influence their purchase decisions (Vafadarnikjoo et al., 2018). These players put pressure on organisations to take action towards becoming more sustainable and even they can gain competitive advantage by becoming greener. The benefits of remanufacturing mentioned in the literature are minimising landfill and waste, reduction of energy usage, increase sustainability consciousness, reducing manufacturing costs (Qu et al., 2018; Wang and Kuah, 2018).

The success of remanufactured products in the market is dependent on customer acceptance (Wang and Hazen, 2016; Y. Wang et al., 2018) which is mentioned as one of the main obstacles for remanufacturing industry (Vafadarnikjoo et al., 2018). This is also a reason why organizations do not challenge themselves in terms of sustainability because the profitability of remanufacturing activities is dependent on sufficient demand for these products (Wang et al., 2013) which is not high enough yet. Hence, understanding the potential customer and their perception has critical importance to have a place in the market and improve CLSC performance (Xu et al., 2017; Qu et al., 2018; Y. Wang et al., 2018). One of the ways to improve customer acceptance level suggested is that highlighting and promoting potential benefits of purchasing remanufactured products to convince customers to consider them as an option (van Weelden et al., 2016). The research focusing on marketing, and customer acceptance of remanufactured products is limited (Bittar, 2018; Matsumoto et al., 2018a, 2018b; McKie et al., 2018; Wang and Kuah, 2018).

Accordingly, the overall purpose of this literature review is drawing an overall picture of customers’ perception of remanufactured products and influencing factors by reviewing the journal articles. The outcome will be helpful to form future researches with the aim of establishing better remanufacturing strategy to reach more customers. This paper will try to answer the following review questions with the findings from the literature.

Review question:

- What are the factors influence potential customers’ purchase intention towards remanufactured products?

Sub-questions to be able to construct the subject on a better ground are:

- RQ1-What characteristics of products were considered as influencing factors?
- RQ2-What makes people avoid purchasing remanufactured products?
• RQ3-What encourages people to purchase remanufactured products instead of brand new?

The paper is organized as follows: methodology, descriptive analysis, findings, conclusion and a reference list.

Methodology

In order to increase the validity of results and not to miss any related article while reviewing the literature, the systematic literature review is chosen as an appropriate method to apply. The methodology used in this paper was influenced by the works of Denyer and Tranfield (2009), Durach et al., (2017), and (Larsen et al., 2018). Five steps of the systematic literature review were formed which is called 5S, see figure 1.

Figure 1: 5S’s of systematic literature review process (adapted from Denyer and Tranfield, 2009; Durach et al., 2017; Larsen et al., 2018)

Set of keywords defined for each customer and remanufacturing focused. As mentioned before, terms remanufacturing and refurbishing are used interchangeably in the literature. Hence, these were selected as keywords for remanufacturing focus and customer and purchase intention for customer focus. Articles located in 3 different databases which are Scopus, ProQuest, and Web of Science. Initial research located 1720 articles and after duplicates removed there were 725 articles left for quality check by considering the journal ranking which left 292 articles for titles and abstracts screening, see figure 2.

Figure 2: Selection of articles

Duplicates were eliminated by using a referencing software (Mendeley). This review includes the articles published in 2, 3, 4, and 4* ranked journals by Academic Journal Guide (AJG). A data extraction sheet was created to gather data for all included articles which include information of title, author(s), year published, journal, AJG ranking, data
sources, researched product or industry and location. This information was used for descriptive analysis. For coding, a qualitative data analysis software which is NVivo 12 Pro was used.

71 articles were included in the full-text review and 26 final articles selected for the final review. This review has three inclusion criteria, see table below: first, the article has to be written in English due to language barriers. Second, the article has to be published in a 2, 3, 4, or 4* journal according to AJG to make sure the publication quality. The last and most importantly, remanufacturing and customers have to be the main constructs of the articles. The articles do not meet these criteria were excluded. The paper

**Descriptive Analysis**

This section will try to answer RQ4 which is focusing on research methodologies applied for the selected 26 articles. Information about the following point will be extracted: data source, data analysis method, researched product(s), and year of publication, journal ranking.

![Figure 3: Descriptive analysis of 26 papers according to the year of publication and AJG journal ranking](image)

The most common method of collecting data is questionnaire which is used by 18 out of 26 articles (69%), eBay transactions by 4, 2 experiments and lastly 1 review article and interview. Structural equation modelling and regression (ordinary/ partial least square, hierarchical) were the data analysis method used by 22 articles. Only one study considered three different product categories (technology, household and personal care) to compare the results. Three studies do not focus on any specific product or industry. Seven articles were about the automotive industry mostly about spare parts and more than half of the articles were about electronics such as phone, laptop, etc. Figure 3 demonstrates that researches published in 2, 3 or 4 AJG ranked journal were increased from maximum 3 to 7 and 9 in 2017 and 2018. Even there is a recent increase, still, there
is not a lot of examples of publications in top journals within the field. Furthermore, 35% of the papers were published in the Journal of Cleaner Production, and 12% in Business Strategy and the Environment, International Journal of Production Economics, and Production and Operations Management.

Findings
The following model was created to illustrate influencing factors of customers’ perception or purchase intention towards remanufactured products by affecting perceived value or benefit and perceived risk of customer through different variables about product, personal and other attributes (van Weelden et al., 2016; Wang and Hazen, 2016; Matsumoto et al., 2018a; Y. Wang et al., 2018), see figure below. This study will handle attributes separately to be able to purely focus on a single item. But, this does not mean that the study assumes the items do not have an impact on each other or together the impact is stronger or weaker.

Figure 4: Conceptual model

Influencing factors extracted from the literature will be summarised by starting with availability.

Availability
Some authors claim that availability is one of the main obstacles to reach potential customers, especially, because of not being included in their purchase channels (Abbey, Meloy, Blackburn, et al., 2015; van Weelden, et al., 2016). Some studies show that some customers do not know where to access remanufactured products (Wang et al., 2013; van Weelden et al., 2016; Qu et al., 2018). Wang et al. (2013) suggested to government and remanufacturers take initiative to form a sales network to increase accessibility. Additionally, country and region might affect this (Matsumoto et al., 2017).

Brand Equity
High brand reputation means that customers trust the brand in terms of quality and performance. Original equipment manufacturers’ brand reputation is a factor that can help to reduce the perceived risk of remanufactured products (Matsumoto et al., 2018b; Vafadarnikjoo et al., 2018). Furthermore, involved organisations’ reputation also plays an important role to reduce perceived risk (Pang et al., 2015; Vafadarnikjoo et al., 2018).

Negative Associations
Even the definition of the term suggests that the condition is like new, some customers consider them as undesirable, second graded (Abbey, Meloy, Blackburn, et al., 2015;
Khor and Hazen, 2017). These negative associations found stronger for personal care products than technology and household products (Abbey, Meloy, Guide, et al., 2015). Furthermore, this disgust and repulsion directly affect the purchase intention towards and interest in remanufactured products (Abbey, Meloy, Blackburn, et al., 2015).

**Only New**
Some consumers associate remanufactured products with negative terms such as dirty, garbage, trash, disgusting, etc. (Abbey, Meloy, Blackburn, et al., 2015) and consider as undesirable (Khor and Hazen, 2017). It is expected that this customer segment which is 20-40% would never consider purchasing remanufactured products. Therefore, there is a potential of 60-80% of the customers would consider purchasing remanufactured products. On the other hand, unwanted innovative features might be a motivating factor to look for remanufactured products (van Weelden et al., 2016).

**Price – Discount**
Provided price advantage for remanufactured products reduces perceived risk and increases perceived value (Wang and Hazen, 2016). Therefore, one of the main drivers of demand for remanufactured products is lower price (Michaud and Llerena, 2011; Wang et al., 2013; Jiménez-Parra et al., 2014; Abbey, Meloy, Blackburn, et al., 2015; van Weelden et al., 2016; Xu et al., 2017; McKie et al., 2018; Vafadarnikjoo et al., 2018). Lower price also provides an opportunity for OEMs to access new customers who couldn’t afford the brand new product (Xu et al., 2017) even further, price is one of the most important factors that have a positive impact on convincing customer to switch from purchasing brand new products to remanufactured ones (Hazen, Mollenkopf, et al., 2017). Impact of discounting might be different in different regions (Matsumoto et al., 2017).

There is not a consensus about a standard ratio of discount (Bittar, 2018). This ratio is usually between 20 and 40% (Wang and Kuah, 2018). As a demand driver, discounting up to 60 is suggested due to quality concerns of products that over discounted (van Weelden et al., 2016; Bittar, 2018), it could even lead to distrust of the overall brand and damage brand reputation (Abbey, Meloy, Blackburn, et al., 2015). Additionally, customers are willing to pay more for products remanufactured by OEMs or authorised organisations than third-party firms (Subramanian and Subramanyam, 2012). Surprisingly, Mugge, Jockin and Bocken, (2017) found that financial benefit don’t have a direct impact on purchase intention which is widely seen in the literature and practice. The reason behind this might be that participants could have seen the lower price as an already provided benefit.

**Product – Technology, Warranty**
Consumers interested in remanufactured products prioritise functionality over newness or appearance, and also performance is another important point to convince customers to purchase remanufactured (van Weelden et al., 2016). Available return option and length of warranty increases the attractiveness level of remanufactured product (Pang et al., 2015) by providing after sales services. Technology not mentioned much as an influencing factor. It might be because most of the researches focus on a specific product instead of a variety of choices where technology could be considered as a factor.

**Product Usage and Treatment History**
Knowledge about the product and treatment during remanufactured process is an important issue highlighted as information gap (Wang et al., 2013; van Weelden et al.,
2016; Bittar, 2018) such as how remanufacturing been conducted, product usage history (S. Wang et al., 2018; Wang and Kuah, 2018; Y. Wang et al., 2018). These negatively impact remanufactured products’ attractiveness (S. Wang et al., 2018) by increasing ambiguity level (S. Wang et al., 2018) and risk perception (Wang et al., 2013). Therefore, reducing ambiguity level would be beneficial to attract more customer (Xu et al., 2017; Vafadarnikjoo et al., 2018) by making the steps of remanufacturing more transparent (S. Wang et al., 2018). On the other hand, reducing the information gap might have a negative impact on purchase behaviour (Wang et al., 2013). Additionally, some customers have the intention to purchase remanufactured products they do not, due to lack of information which is called as intention-action gap (S. Wang et al., 2018). To handle this issue, (Wang et al., 2013) suggest governments and remanufacturers to take action to improve the image of remanufactured products by setting some standards.

**Quality**

Quality perception of remanufactured products is one of the factors that affect the purchase intention most (Abby, Meloy, Blackburn, et al., 2015; Abby, Meloy, Guide, et al., 2015; Wang and Hazen, 2016; Hazen, Boone, et al., 2017; Vafadarnikjoo et al., 2018). Customers do not a chance to test the product quality before making the purchase decision, therefore they require some signals to trust the like new condition as the definition of remanufacturing promises (Michaud and Llerena, 2011). Warranty, certification, and brand image could be used to increase perceived quality and reduce associated risk (Matsumoto et al., 2018a). It is safe to say that if a remanufactured product is certified by a trustworthy organisation this will be seen as a symbol of quality (Matsumoto et al., 2018a). Furthermore, as mention in the previous sub-section, sharing information about product usage history and remanufacturing processes could be used to increase perceived quality instead of leaving these uncertain and ambiguous. Additionally, country of origin is a factor that affects the perceived quality, such as Matsumoto et al., (2018a) found that customers willing to purchase more remanufactured products from developed countries than developing.

**Risk**

There are six types of risk associated with remanufacturing; performance (malfunctioning), time (effort and time spent to repair in case of any problem), physical (safety risk), financial (repair or return cost and required new purchases), social (being laughed because of purchasing remanufactured products) and resource (dishonest parties) (Wang et al., 2013; van Weelden et al., 2016). All these have a negative relationship with customers’ purchase intention (Matsumoto et al., 2018a).

Providing information about products’ usage and treatment history (Hazen et al., 2012; Wang and Hazen, 2016; Abbey et al., 2017), quality certification (Michaud and Llerena, 2011; Matsumoto et al., 2018a), and warranty (Pang et al., 2015; van Weelden et al., 2016) would be beneficial to reduce associated risks.

**Subjective Norm**

Most scholars expect that remanufactured products would attract more environmentally friendly customers than others (Wang et al., 2013). Surprisingly, there are studies claiming that environmental friendliness does not always reflect on the action of individuals (Khor and Hazen, 2017; Bittar, 2018; Qu et al., 2018; Wang and Kuah, 2018). One of the main reasons why this gap exists is lack of information available about product, processes and environmental benefits (Wang and Kuah, 2018) but the challenge
to build the link between intention and action is greater than informing (Abbey, Meloy, Blackburn, et al., 2015). Furthermore, approval or encouragement of purchasing remanufactured product by important people to customers (family, friend) would increase the chance of purchase happening (Jiménez-Parra et al., 2014; Qu et al., 2018; S. Wang et al., 2018) also culture and country might make difference (Matsumoto et al., 2017).

Being familiar with the concept of remanufacturing and previous purchase of remanufactured products are found to be an important factor to purchase them instead of new ones by reduced risk due to familiarity (Hazen et al., 2012; van Weelden et al., 2016; S. Wang et al., 2018). Also, ambiguity tolerance limit of individuals positively relates with purchase intention of remanufactured products (Hazen et al., 2012; S. Wang et al., 2018). A study found that remanufactured products are more attractive to younger people (Abbey, Meloy, Guide, et al., 2015).

Being sustainability conscious consumer started to become a status symbol (Wang and Kuah, 2018). Surprisingly, when people make green purchases they tend to display and when there is not a viable way of displaying the action or product they tend to prefer non-green option (Abbey, Meloy, Blackburn, et al., 2015; Wang and Kuah, 2018).

**Sustainability**

Being environmentally friendly product is considered as a factor that influences customers willingness to purchase remanufactured products (Michaud and Llerena, 2011; Jiménez-Parra et al., 2014; Hazen, Mollenkopf, et al., 2017). On the other hand, there are researches claim that environmental benefits of remanufactured products do not play a major role to convince more customers (Abbey, Meloy, Guide, et al., 2015; van Weelden et al., 2016; Vafadarnikjoo et al., 2018). The reason behind this behaviour would be that customers do not know enough about the environmental benefits of remanufactured products (Michaud and Llerena, 2011; Khor and Hazen, 2017; Mugge et al., 2017). Furthermore, even customers receive information about the benefits, they are not willing to pay extra for remanufactured products just because of their green characteristics (Michaud and Llerena, 2011).

**True Understanding of Remanufacturing Concept**

Studies reveal that, surprisingly, consumers do not see remanufactured products as green (Abbey, Meloy, Blackburn, et al., 2015; Khor and Hazen, 2017) even some see them as second hand, unusable (S. Wang et al., 2018). Also, customers do not trust remanufactured products in terms of quality and performance (Abbey, Meloy, Blackburn, et al., 2015; van Weelden et al., 2016; Wang and Kuah, 2018) even the definition of the term says that their condition is like new. This misconception of remanufacturing is one of the main barriers to overcome (van Weelden et al., 2016; Matsumoto et al., 2018b). Because, awareness of remanufacturing have a positive impact on purchase intention (Mugge et al., 2017) and if customers know more about the similarities between remanufactured and new products their chance of purchase increases (Jiménez-Parra et al., 2014). Governments and enterprises should take action to overcome this issue and increase awareness (Qu et al., 2018), also reducing ambiguity in remanufacturing activities is another recommended step to reduce perceived risk (Wang and Kuah, 2018).

**Conclusion**

Attributes that potentially influence customer’s purchase intention are extracted from the academic articles and explained separately in the findings section which tries to answer the review questions.
RQ1: Selected 26 article mainly focus on a single product. Quality, price/discount, reputation, environmental benefits, warranty and being able to display were mentioned. If researches look for more than one product or product family the outcome would be different due to the availability of options. Also, this will make the studies closer to reality, especially in these days it is possible to find quite a few replacement products for the same purposes.

RQ2: Risks associated with remanufacturing products are the main reason why customers avoid purchasing or even do not consider as an option. The other potential reasons are the thrill of newness, misconception of remanufacturing, unavailability, social pressure and unawareness of ways to access remanufactured products.

RQ3: Being able to have access to a product with a lower price seems to be the main driver of demand for remanufactured products. In addition to price, approval of close individuals, culture, familiarity, and ambiguity tolerance are important. Surprisingly, being sustainability conscious was not found as a one of the main factors to look for remanufactured products. The reason might be the misconception or not seeing them as green products. One of the suggested solutions to this issue was taking actions to increase awareness. Also, previous experience of individuals is important.

The main contribution of the paper is providing a comprehensive overview to guide researchers for further studies in the field. A conceptual model is delivered with the aim of demonstrating the overall picture. This systematic literature review will be functioning as the ground for future empirical work. Future work will be testing the potential influence of different attributes by hypothesises to develop a better understanding of customers’ perception to promote greener behaviour.

Abstract

Manufacturing organizations face intertemporal choice problem, i.e., falling victim to pursuing short-term financial objectives or pursuing long-term environmental protection and social equity objective. Despite of the need to balance the present with the future, most sustainability research is centred on the tension between business and society, irrespective of time. We argue in this research that principles of Industry 4.0 could contribute to mitigating this intertemporal tension in sustainable manufacturing, moving towards a more sustainable society as well as world-class sustainable manufacturing.

Keywords: Sustainable Manufacturing, Industry 4.0, Intertemporal Tensions.

Introduction

Much of the literature on corporate sustainability is centred around the tension between organizations and society, regardless of time (Smith and Lewis, 2011; Slawinski and Bansal, 2015). However, it is unclear how manufacturing organizations balance the short term and the long term sustainability objectives without restricting manufacturing organizations growth and freedom. Sarkis and Zhu (2018) posit that advances in manufacturing technology in the pursuit of manufacturing sustainability assumes achievement of organizational growth besides bringing about better cleaner production and rationalization of the use of resources that has a positive impact on environment and social welfare. In this realm, an emphasis is placed on the offerings of Industry 4.0 technologies, also known as smart manufacturing (de Sousa Jabbour, Jabbour, Foropon, et al., 2018). Industry 4.0 is based on the establishment of smart factories, smart products and smart services embedded in an internet of things and of services (Lasi et al., 2014, Stock and Seliger, 2016). It facilitates providing real time information on production, machines, and flow of components; integrating this information to help managers to make cost-effective decisions, monitor performance, and track parts and products (de Sousa Jabbour et al., 2018). It is argued by Gouvea et al. (2017) that technological developments, such as those brought by Industry 4.0, is related to the sustainability of countries, and that technical advancements of manufacturers can
significantly enhance progress towards improvements in environmental quality (Song and Wang, 2016). For instance, de Sousa Jabbour et al. (2018) explained that using real-time data from manufacturing systems and suppliers can achieve high levels of efficient and economical use of resources such as materials, water, energy and products; as this leads to more sustainable manufacturing decision-making. Also, connecting machines, tools, devices, components, products, customers and logistics by means of internet, sensors, and RFID technologies would enable reconfiguration of these production system parts (Wang et al., 2016) based on customers’ requirements, production parameters, and environmental performance (de Sousa Jabbour et al., 2018). In addition to these advantages, Industry 4.0 offers different sustainable approaches to cope with the social challenges of sustainability. Stock and Seliger (2016) asserted that Industry 4.0 adoption, first, increases the training efficiency of workers by combining new ICT technologies. Second, it increases intrinsic motivation and fosters creativity by establishing new cyber-physical based approaches of work organization and design, and, third, it increases extrinsic motivation by implementing individual incentive systems for the workers. Furthermore, the principles of Industry 4.0 enable instant data collection on customer requirements, usage and consumption patterns, thus allowing enhancement of service aspects of products, which will, in turn, improve customer satisfaction and well-being (de Sousa Jabbour et al., 2018). Based on this, it is argued in this paper that practices of Industry 4.0 support diverse temporal perspectives which encourage manufacturing organizations to juxtapose the short and long-term dimensions of sustainable manufacturing. Therefore, the following research question has been driving this research: RQ. How does Industry 4.0 principles and practices impact intertemporal tensions in sustainable manufacturing?

This paper is of a theoretical nature that is based on literature reviews of tensions of corporate sustainability, sustainable manufacturing, and Industry 4.0 topics. First, a literature review was conducted without focusing on one particular example or industry that was later followed by a more focused systematic review. Google Scholar was used to locate previous literature reviews conducted within the domain of Industry 4.0, tensions of sustainability, and sustainable manufacturing. Second, possible dimensions were inductively identified for analyzing relationships between the three main keywords used in this literature review process. This resulted in the identification of five different Industry 4.0 mechanisms to assist with mitigation of intertemporal tensions. However, this paper is further organized as follows. The next section presents the literature review conceptualizing intertemporal tensions in corporate sustainability. Next, principles of Industry 4.0 are characterized. This is followed by an attempt to link offerings of Industry 4.0 with intertemporal tensions of sustainable manufacturing. Finally, Industry 4.0 mechanisms for mitigating intertemporal tensions are explained and conclusions presented.

**Intertemporal tensions in corporate sustainability**

According to der Byl and Slawinski (2015), intertemporal tensions in organizations is understood through prioritizing short term economic dimension of sustainability over the two other long term dimensions. According to authors, this has been detrimental to our understanding of corporate sustainability. This is due to the fact that instrumental logic neglects intertemporal tensions where social and environmental goals cannot be aligned with profit maximization targets (Smith and Lewis, 2011). Slawinski and Bansal (2015) uniquely defined corporate sustainability as “the ability of firms to respond to
their short-term financial needs without compromising their (or others’) ability to meet future needs”. Arising from this, Marginson and Mcaulay (2008) revealed that short-termism cannot be understood through organizational economic causes only; short-termism must be approached through a lens that includes individual and organizational level to advance organizational ability to mitigate its detrimental consequences for the long-term performance. Similarly, Hahn et al. (2015) make the case that short-termism, in corporate sustainability context, is caused by a mismatch between information available for managers to make sustainability decisions and information needed for those decisions. In other words, lack of complete information that lowers uncertainty about the future force managers to focus on sustainability aspects that are relevant in the short term. This would firmly suggest that mitigating intertemporal choice problem is possible through cutting-edge technologies that facilitate real-time information on all aspect of the business (Marginson and Mcaulay, 2008; Hahn et al., 2015). However, in response to this need, Similarly, Slawinski and Bansal (2015) suggest three mechanisms for temporal ambidexterity. The first mechanism is the collection of broad range of qualitative and quantitative data. The combination of such data provides information that is useful for decision-making processes and widens dialogue with organizational members on possibilities to juxtapose short-term objectives with long-term targets. The second mechanism is stakeholder engagement; starting an open dialogue with stakeholders allows organizations to intake different perspectives on sustainable issues and helps them learn about how best to attend these issues. The third mechanism occurs when organizations collaborate with each other. It is through this collaboration that organizations approach short and long-term business issues more holistically, therefore, providing better quality solutions for environment and society.

**Principles of Industry 4.0**

Stock and Seliger (2016) explain that the concept of Industry 4.0 is centred around three main dimensions of the manufacturing paradigm. First, the horizontal integration between organizations and organization-internal intelligent cross-linking and digitalization of value creation modules. This takes place throughout the entire value chain of a product life cycle and other related product life cycles. Second, smart digitalization and cross-linking of all phases of product life cycle from raw materials acquisitions to product end of life (i.e. end-to-end engineering). Third, vertical integration of cross-linking and digitalization of different hierarchical levels of value creation modules; from manufacturing cells, production lines, factories, and other associated value creation functions such as marketing and sales. According to de Sousa Jabbour, Jabbour, Foropon, et al. (2018), Industry 4.0 has four fundamental components through which it can be understood. These technological components are explained below.

*The internet of things technology* refers to a system where the physical devices (things) are equipped with embedded electronics such as software, sensors, RFID, tags, and controllers and connected to the internet to collect and exchange data (Burritt and Christ, 2016). In this sense, the internet of things constitutes an information technology infrastructure providing real-time connection of people, machines, devices, and information technology systems to solve complex business problems (Kiel et al., 2017). As a result, large quantity of data, also known as big data (Zhong et al., 2017), is generated and exchanged along the entire manufacturing value chains which can be
subsequently analysed to support and improve decision-making processes of organizations.

Cyber-physical production systems are defined by Deloitte (2015) as physical systems monitored and controlled by computer-based algorithms using virtual networks. They are operating in a self-organized (non-human) manner through means of artificial intelligence to continuously interchange data in real-time. Sensors, data processing units, and actuators are main components of cyber-physical production systems enabling real-time data transfer (de Sousa Jabbour, Jabbour, Filho, et al., 2018).

Cloud manufacturing is an advanced manufacturing model using cloud computing technologies for enabling virtual on-demand network access to a shared pool of configurable manufacturing resources with minimal interaction with resources provider (Xu, 2012; Liu and Xu, 2016). In other words, it enables transformation of manufacturing resources into digitalised services that can be shared seamlessly through the support of virtualization and internet of things technologies (Zhong et al., 2017).

Additive manufacturing is considered as an essential ingredient that is expected to increasingly be deployed in the Industry 4.0 movement (Stock and Seliger, 2016). It is a technology through which manufacturing of different components of products is possible without the need for a specialised manufacturing tools (de Sousa Jabbour, Jabbour, Filho, et al., 2018). The virtue of additive manufacturing lies in the fact that it is able to produce physical parts based on digital information “piece-by-piece, line-by-line, surface-by-surface, or layer-by-layer” (Thompson et al., 2016), thus, allowing the determination of components’ materials properties (Dilberoglu et al., 2017).

Linking Industry 4.0 and intertemporal tensions of sustainable manufacturing
From an environmental perspective, smart digitalization and cross-linking of the entire product life cycle (i.e. from raw materials acquisitions to product end of life) provide broad range of data with an immense opportunity for manufacturing organizations to understand patterns of usage and consumption (i.e. qualitative and quantitative information), which in turn can help organizations plan for the short-term (e.g. prioritising raw materials acquisitions processes and maintenance schedules) and long-term (e.g. improving product end-of-life reuse, remanufacturing, recycling, recovery and disposal). Also, cleaner production of products without generating waste or consuming unnecessary resources inherent in Industry 4.0 (de Sousa Jabbour, Jabbour, Foropon, et al., 2018) create cost saving opportunities (i.e. short-term), enhance possibility of protecting environment with reduced depletion of resources (i.e. long-term), and improve intergenerational equity due to protecting interests of future generations (i.e. long-term) (Hahn et al., 2018). Additionally, by analysing real-time data on energy consumption behaviour at production lines and machine level, energy data can be integrated in production management practices to improve energy efficiency of the factory (Shrouf, Ordieres and Miragliotta, 2014). This has a short-term objective of reducing energy consumption costs and contributes to long term reduced generation of GHG emissions. Manufacturing organizations, this way, can mitigate intertemporal tensions of corporate sustainability by creating the possibility to juxtapose short-term and long-term sustainability aspects. Furthermore, Industry 4.0 technologies seem to help juxtaposing the short and long-term issues of corporate sustainability by means of integrating value chains through real-time data analysis and sharing (de Sousa Jabbour,
Jabbour, Filho, et al., 2018), thus, providing optimised solutions (Stock and Seliger, 2016). This virtue of Industry 4.0 is also matching Hahn's et al. (2015) acceptance strategy of dealing with temporal tensions, explained earlier, of adopting practices that are beneficial for short-term financial outcomes while also not detrimental to environmental and social issues. In this context, it is evident that Industry 4.0 offerings are beneficial in terms of short-term financial winnings and are fraught with practices that benefit environmental and social outcomes in the long run (Burritt and Christ, 2016; de Sousa Jabbour, Jabbour, Filho, et al., 2018).

In fact, engagement of different stakeholders in Industry 4.0 such as customers, employees, suppliers, distributors, manufacturing equipment, and other organizations along value chain of products can play an essential role in achieving temporal ambidexterity. According to Slawinski and Bansal (2015), stakeholder engagement contributes to temporal ambidexterity by means of exposing an organization to plethora of information on diverse sustainability perspectives. Many of these stakeholders have strong ties with community representatives and other activists’ groups who make their views listened to on different social and environmental impacts of businesses (Rivera, Muñoz and Moneva, 2017). This enables organizations to see broader range of timeframes of sustainability issues that help formulate better responses (Marginson and McAulay, 2008; Slawinski and Bansal, 2015). Another aspect that has been stressed in Industry 4.0 is the intelligent automation and cross-linking of organizational levels (Herrmann et al., 2014; Schuh et al., 2014; Stock and Seliger, 2016). Thus, the manufacturing jobs will entail more knowledge work and hard-to-plan tasks that require decentralised decision making processes (KIEL et al., 2017). This is particularly important, since the establishment of Industry 4.0 technologies will bring about agility and connectivity to daily decision-making (de Sousa Jabbour, Jabbour, Foropon, et al., 2018). This manufacturing organization’s structural change would redefine traditional role of lower level employees to be responsible for achieving short-term operational aspects of the work and are not expected to deal with long-term strategic issues. Thus, the achievement of long-term objectives of sustainability is the responsibility of top management. This traditional notion of role separation is in line with Hahn's et al. (2015) “spatial separation strategy” of dealing with temporal tensions. However, we argue that cross-linking of organizational levels offered by Industry 4.0 technologies allow “spatial integration strategy”. In this context, empowered lower level employees will be focused on monitoring and sense-making of the automated equipment (Schuh et al., 2014; KIEL et al., 2017). Different organizational levels, including top management, take part in the sense-making process through interpreting shared information to understand complex situations, and to assess the short-term and long-term consequences. This cooperative sense-making produce new knowledge on how to rapidly attend to short and long-term issues of corporate sustainability (Hofmann and Rüsch, 2017; Zhong et al., 2017). In addition, through increased digitised connectivity lower level employees, sustainability managers, accountants, and other senior managers would have access to real-time environmental management data where they could work together, in collaborative manner, on environmentally sound eco-efficient action for the long term (Burritt and Christ, 2016). Such offerings of Industry 4.0 broadened the solution space of issues of sustainable manufacturing, such that several simultaneous short-term and long-term considerations are achievable, thus juxtaposing present and future. Contributions of Industry 4.0 to mitigation of intertemporal tensions in corporate sustainability are depicted in Table 1.

**Conclusions**

This work shed the light on the unique potential of Industry 4.0 technologies to unlock juxtaposition of the short and long-term dimensions of sustainable manufacturing without restricting manufacturing organizations growth potential. To date, studies that explore the contributions of Industry 4.0 to sustainable manufacturing have been very limited. This paper is the first of its kind to analyze the role of Industry 4.0 in mitigating intertemporal tensions by enabling five different mechanisms of cross-linking of entire product life cycle, cleaner production, real-time data sharing and analysis, stakeholder engagement, and cross-linking of organizational level “spatial integration”.

Although this study points to Industry 4.0 as a significant savior for manufacturing sustainability (Sarkis and Zhu, 2018), it has some limitations which may pave the way for further research in the future. This paper is of a theoretical nature that is based on literature reviews of tensions of corporate sustainability, sustainable manufacturing, and Industry 4.0 topics. Therefore, the set of identified mechanisms might not be fully comprehensive. A question for future studies would be, therefore, under which conditions each one of these mechanisms would be more effective in tackling intertemporal issues of sustainable manufacturing. For this, it is strongly recommended that in-depth case studies be conducted using different methodological tools to further explore these mechanisms and their underlying aspects. Further, it would be relevant to include other domains in the analysis of the role of Industry 4.0 in mitigating intertemporal tensions of sustainable manufacturing. For example, exploring the role of green human resources management practices (Renwick, Redman and Maguire, 2013) in efficient application of different mitigation mechanisms of Industry 4.0. Another topical area is the investigation of impacts of information linkages and flow in Industry 4.0 on management of environmentally focused supply chains, and how this relates to intertemporal mitigation in manufacturing context. Overall, it is
evident in this paper that there is optimism that Industry 4.0-associated technologies hold numerous social and environmental sustainability benefits; beside those of financial benefits. Our suggested mitigation mechanisms thus help to provide substantive contributions to embracing intertemporal tensions of sustainable manufacturing.

Abstract
Sustainability concepts inform business considerations of production and procurement in order to satisfy consumer demands for ethical products. Drawing on the Deception Impact Model, the aim is to understand the severity of deception, implementation of socially sustainable practices, and impact on consumers by examining a case in the Indigenous art Australian souvenir industry. It found where a firm decouples from socially sustainable practices the result, a form of deception, negatively impacts ethically motivated consumers. The paper highlights where Indigenous people should be involved in the development chain to avoid infringing on human rights as it relates to commodification of culture.

Keywords: Social Sustainability, Ethical Practice, Deception, Indigenous Art

Introduction
The growing consumer desire to make ethical purchases necessitates firms to become more transparent in their production and procurement processes. Sustainability concepts, which include social, environmental, and economic dimensions, are ways in which business can consider the production and procurement in order to satisfy
consumer demands for ethical products. Likewise, the sustainability dimensions are a lens in which to examine operational processes to understand where practices decouple from what is legally and socially accepted in the provision of goods and services.

Sustainability issues transform the competitive environment for business (Longoni and Cagliano, 2015). There are various reasons for the private sector to demonstrate sustainability practices in their operations and behaviour. For example, the recent shift within the sustainable development paradigm has seen the private sector take a more prominent role alongside civil society and governments in addressing issues facing inclusive global growth and development (Scheyvens et al., 2016). Beyond contributing to global aspirations for sustainable development, economies can be achieved through environmentally sustainable operational practices, such as waste reduction and energy conservation. These savings can be amplified across a supply chain through coordination with upstream and downstream partners (Gupta and Benson, 2011) and assist in achieving a positive long-term performance of individual companies and their supply chain (Ahi and Searcy, 2015).

When considering sustainability within a supply chain context financial returns are not the only benefits for a network of firms working together to compete in the industry. Supply chain partners also have an interest in understanding each other’s processes in order to ensure they are satisfying the needs of stakeholders in both legal and social aspects. The reason is to uphold legal obligations and avoid broader scrutiny by society.

Despite the benefits of practising sustainability in business processes, there are many instances of firms decoupling from strategic sustainability goals during implementation at the operational level. This paper uses the case of the Australian souvenir industry to illustrate where a firm decouples from socially sustainable practices in the production and procurement of low-cost souvenirs featuring stylised designs representative of the culture of Indigenous people. The result of the decoupling, a form of deception, negatively impacts consumers who are motivated to make ethical purchases. In addition to upholding the rights of Aboriginal and Torres Strait Islander people to protect and commodify their culture as a fundamental concept of Indigenous human rights.

This case has been chosen to illustrate deceptive practices as it has been recently highlighted within a Federal Government Inquiry (the Inquiry) and subsequent report (the Report) and legal proceedings brought before the Australian courts prosecuting a well-known souvenir distributor (the Distributor) mislabeling products to deceive consumers who are concerned with making ethical souvenir purchases. Further, this case highlights the role of social sustainability in business to protect human rights as it relates to the cultural dimension. Reasons for this will be outlined.

To understand deception in this context and understand where operational processes decouple from sustainability objectives happen, the Deception Impact Model (DIM) by (Hammadi et al., 2018) is utilised. The DIM connects three dimensions to provide an understanding and positioning of a firm’s practices and impacts regarding severity of deception, implementation of sustainability practices and, impact on customers and other stakeholders.
There are differing attitudes and values towards the commodification of culture to produce souvenir product influencing what is classified as ‘authentic’ or ‘fake’ product. It is not the aim of this paper to classify or debate authenticity concepts, rather demonstrate the implementation (or lack) of social sustainability concepts in the production and sale of souvenir products featuring designs representative of Indigenous culture, and their subsequent impacts on operations management, supply chains, consumers and stakeholders. The term inauthentic will be used in reference to objects or products that do not engage Indigenous people in the design for the purpose of providing clarity and consistency.

The aim of this paper is to highlight where operations management and supply chain concepts can add value to society - particularly with respect to developing Indigenous Australian enterprises which are a valuable mode of sustainable development in remote regions. The paper provides a background to unsustainable practices, then discusses the concept of culture within a human rights framework and how it relates to the social sustainability in the Australian souvenir industry. The legal proceedings brought before the Distributor are examined using the DIM framework to understand the severity of the Distributor’s deception. The Distributor’s development chain is then examined to understand the degree to which the firms are implementing socially sustainable practices from an operations management and supply chain perspective. Finally, the impact of consumers and other stakeholders is considered to position the Distributor in relation to the implementation of social sustainability practices.

**Background**

Historical factors also demonstrate a lack of internal culture towards social sustainability among distributors and retailers with the issue of deception relating to inauthentic products within the Australian souvenir supply chain having been addressed in 2003 prior to the Distributor case in 2018. The Australian Competition and Consumer Commission, brought action against Australian Icon Products Pty Ltd (AIP) for engaging “in conduct likely to mislead or deceive consumers” due to making claims that souvenirs were hand-painted by Indigenous Australians (NSW Government, 2007). Under Australian consumer law, “consumers are entitled to receive goods that match their description”. The ACCC alleged Australian Aboriginal Art Pty Ltd (AAA) mislabelled products claiming they were ‘Australian Aboriginal Art’, ‘Aboriginal Art’ and/or ‘Authentic, made by Aboriginal artists or artists of Aboriginal descent’ despite not employing Indigenous people in the production process (NSW Government, 2007). The 2003 and 2004 cases demonstrate broader public awareness of deceptive practices by souvenir wholesalers in the form of mislabelling products. Despite this awareness, the production and sale of goods to retailers with misleading labels continued.

Recently in Australia, the Arts Law Centre of Australia revealed the widespread use of deception in the souvenir industry through an advocacy campaign. The campaign, known as *Fake Art Harms Culture*, highlighted the pervasiveness of merchandise available at tourism retailers, which presented as Indigenous cultural souvenirs appeared
ambiguous in provenance (Indigenous Art Code, 2019). One of the aims of the Fake Art Harms Culture campaign was to draw awareness to products whereby culture is commodified, often with inappropriate designs and materials, to create a product for a specific market. The advocacy campaign led to the Federal Australian Government undertaking an official Inquiry into the growing presence of inauthentic Aboriginal and Torres Strait Islander 'style' art and craft products and merchandise for sale across Australia (Inquiry) and a final report (Report) into the findings was published in 2018 (Australian Government, 2018).

Additionally, in 2018, the Australian Competition and Consumer Commission (ACCC) launched legal proceedings against a souvenir distributor finding the firm in breach of labelling laws (Australian Competition and Consumer Commission, 2018). The ACCC case demonstrates a legal mechanism (i.e. consumer law) in which incorrectly labelled souvenirs representing Indigenous culture assist in protecting consumers from making unethical purchases.

Despite consumer law providing protections for consumers in this context, Australian law does not extend to the “underlying idea or information that is put into a work” or a “style or method of art” such as dot painting techniques synonymous with Indigenous culture. Therefore, there are limited legal mechanisms in place to prevent a product being produced that references an Indigenous story or artistic style associated with a culture or specific nation (Artists in the Black, 2019). The commodification of Indigenous cultures to produce and sell souvenirs, without having an overt connection to an Indigenous person is not legally prohibited, and are termed ‘inauthentic’ for the purposes of clarity. Thus, as evidenced by the 2018 Distributor case, producers, wholesaler, and retailers of souvenirs continue to engage in deception.

Social sustainability: Culture as an aspect of human rights
While social sustainability is becoming an increasing concern of business (Mani and Gunasekaran, 2018), there is ambiguity regarding the social sustainability dimension and what it encapsulates (Ajmal et al., 2018). Cultural and ethical issues have been overlooked compared to factors related to legislative compliance, and the hierarchy of factors enabling social sustainability has not been clearly established (Mani et al., 2014).

A dimension of social sustainability is the rights of Indigenous people. The United Nations Declaration on the Rights of Indigenous Peoples protects Indigenous people's “right to maintain, control, protect and develop their cultural heritage” and “to maintain, control, protect and develop their intellectual property over such cultural heritage”; the “right to the dignity and diversity of their cultures”; further advance their economic and social conditions including employment (Australian Human Rights Commission, 2012).

Supply chain management research has been limited in considering the interrelationships between sustainability issues (Gimenez et al., 2012). The three sustainability pillars are ubiquitous in our understanding of sustainability, however, their distinction as separate dimensions is conceptually fuzzy (Kuhlman and Farrington, 2010). There has been a stronger focus on addressing economic and environmental
dimensions of sustainability in business, while the social aspect has not been well
developed (Ajmal et al., 2018). As a concept of social sustainability, upholding the
rights of Indigenous people demonstrates the convergence of positive social and
economic development outcomes.

The *Declaration* highlights the role of culture, cultural heritage, and intellectual
property as fundamental to the rights of Indigenous people. A successful example of
Indigenous Australians engaging in enterprise and using culture as a means of
advancing economic and social conditions is Indigenous art centres. Art centres have
become important institutions in remote Australia as they provide people with access to
the mainstream art market where only a limited opportunity for economic inclusion
exists, and in some instances, represent the only non-welfare form of income available
to Indigenous people (Seet et al., 2018). Art centres are also linked to the overall
wellbeing of Indigenous people and broader communities by generating positive
psychological and emotional impacts (Allain, 2011).

Despite the success of art centres in facilitating cultural production for the art market,
commercialisation of culture can lead to conflicting priorities between producers and
consumers within the souvenir industry. Indigenous artisans producing handcrafted
goods according to cultural protocols (e.g. use of a specific material or production
technique) for tourist markets may not be able to price a product to fit the requirements
of consumers seeking a low-cost travel memento (Guttentag, 2009). Thus, non-Indigenous firms with capabilities to produce low-cost products, and without legal
obligations to follow cultural protocols, are free to appropriate elements or styles of
Indigenous culture to meet consumer demands (Guttentag, 2009). In this instance, the
non-Indigenous producers are able to exploit the legal environment and take away
opportunities for Indigenous people to advance their economic and social conditions
through the commodification of culture and intellectual property. The example of
non-Indigenous firms participating in the market under these conditions illustrates how
firms can engage in socially unsustainable practices in the production of inauthentic
goods within the souvenir industry.

**Severity of the Distributor’s deception**

The relationship between social sustainability and the production of authentic
souvenirs has been established as an aspect of human rights. Examining levels of
deception is one of the three interrelated factors proposed by DIM to determine the
degree to which a business is delivering on sustainability objectives from a supply chain
perspective. In the case of the Distributor who was prosecuted by the ACCC, the DIM
framework provides a basis for understanding the severity of deception. In a supply
chain context, deception can occur between buyer-supplier or organisation-consumer.
Deception is the gap between actual claims, practices and outcomes of those practices.

The development of nomenclature for deception relating to sustainability within
supply chain literature demonstrates its prevalent in contemporary business.
Green-washing and blue-washing (Dadush, 2018) describes the practice of misleading
consumers by misrepresenting the degree to which a product or service is environmentally (green) or socially (blue) sustainable.

The Australian Federal Court found the Distributor in breach of Australian Consumer Law over misrepresenting souvenirs featuring Indigenous style designs as being hand painted by Indigenous people (Australian Competition and Consumer Commission, 2018). The products at the centre of the case were represented to be ‘associated with Australian Aboriginal Art’ and using words in the labels including ‘Aboriginal Art, ‘genuine’, and ‘Australia’ (Australian Competition and Consumer Commission, 2018). Several products were featured in the case including loose boomerangs, boxed boomerangs, bullroarers, didgeridoos and message stones. Some of the products featured designs licenced by an Indigenous artist. However, the products examined in this case that were in breach of labelling laws were manufactured in Indonesia with designs the firm procured from Internet sources (Federal Court of Australia, 2018).

Blue-washing is applicable to this case as the Distributor made claims on particular products to infer a connection to Indigenous people and local products that do not exist in that form. The deception not only impacts consumers but also the buyers (retailers). When using the DIM model (Figure 1) to investigate the deception, consider the inauthentic supply chain in the Donald Trump quadrant as the supplier deceives with low sustainable impact yet are liked for the low price. The change to the authentic responsible supply chain can risk failure as consumers may not like the increased price despite having an authentic product and thus have made an ethical purchase. However, it is most likely that it shifts to influencer with an outcome being the partial loss of consumers, triggering a new concept/idea being marketed for its sustainability, with a final shift towards maturity. Note though, Robin Hood is a possibility if both supply chains collaborate and find a solution to be authentic and to keep the price in an acceptable price range.

Figure 1: Deception Impact Model (DIM). See also Hammadi et al. (2018)
Implementation of sustainability practices

The sustainability orientation of an organisation is significant and is based on sustainability practices to achieve sustainability goals. The DIM proposes a firm’s sustainability orientation on a spectrum between compliance with standards or legal obligations through to internal firm culture. The spectrum has been developed through Goldsmith and Samson’s (2005) four categories of sustainability practices: compliance, conformance, performance, and transformation. Compliance and conformance are on one end of the spectrum, considered a reactive approach to sustainability implementation, and are demonstrated by firms who will only do what is necessary within a particular industry (Goldsmith and Samson, 2005). The DIM proposes the impact of this reactive orientation as an indicator of low implementation of sustainability.

To operationalise this impact in the context of the Australian souvenir market, the Distributor's development chain was examined. A strategic business activity is new product development (Hilletofth and Ericsson, 2010), with the intersection of product development with the supply chain known as the development chain (Primus, 2017). Attributes of products and the supply chain process can be aligned by firms to increase competitiveness (Morita et al., 2018) and thus, influence operations processes.

Two key elements of the development chain are ‘planning and design’ and ‘sourcing’ activities, with product architecture (planning and design phase) connected to the attributes of products. Within souvenir purchasing Revilla and Dodd (2003) found “appearance/utility, traditional characteristics and certification, rarity, local production and low cost” as factors impacting purchases. The Distributor sourced Indigenous symbols from the internet to be incorporated into souvenir products to give the products a particular appearance that would be attractive to customers (e.g. traditional characteristics). Labelling and packaging also inferred local production.

Design sourcing is the primary activity in which the Distributor decouples from human rights within the social sustainability dimension. This represents a key stage during the development chain where a firm can go beyond legal requirements, and ethically source a cultural element which will return positive benefits to Indigenous people, while satisfying product architecture requirements, thus supporting the human rights of Indigenous people to protect, maintain, and control their cultural heritage.

Make or buy decisions is another dimension of the planning and design phase, and supplier selection falls under sourcing activities. A factor influencing souvenir purchases is price. Research has found that price-orientated operations strategy models are less likely to compliment social and environmental sustainability aims (Longoni and Cagliano, 2015). The products considered in this case are at the lower end of the market and there is evidence that the Distributor outsourced production of souvenirs to Indonesia (Federal Court of Australia, 2018). Offshoring production of Indigenous style souvenirs may not result in decoupling from social sustainability as a discrete activity. However, combined with a decision to not include Indigenous people in the design of
the product combined with mislabeling statements on the product’s packaging demonstrates a low commitment to social sustainability.

Consumers and other stakeholders

Within souvenir purchasing there are a variety of customer motivations “including workmanship, sensuous appreciation, cultural linkage and ease of handling” (Hu and Hong, 2007, p. 123). As consumers become more aware of products and manufacturing processes, firms are driven to address sustainability concerns (Mani et al., 2014). Despite customer trends, retailers need to consider balancing the demands of customers who are interested in sustainability, while also guarding against potential loss of market share and sales resulting from sustainable practices (Wilson, 2015).

Within the DIM, organisations able to accomplish positive impacts on consumers, despite relying on deception, are considered to be at the high end a deception severity spectrum. Retailers who knowingly procure products such as those discussed in the Distributors development chain, that disregard the cultural aspect of human rights, and are also priced at the lower end of the market, can satisfy price conscious consumers who are not motivated by ethical purchases. Due to the nature of competitive environments, buyers and suppliers on the supply chain may be motivated to align competitive priorities and have a low commitment to social sustainability. A challenge for business in the operationalisation of sustainable practices is reconciling traditional operations management models that focus on price, markets, and capability, to fit sustainability aims (Longoni and Cagliano, 2015). An internal ‘reactive’ culture towards social sustainability, which relies on maintaining minimum compliance with regulatory requirements, demonstrates the low commitment of those Australian souvenir supply chains to address human rights issues.

Conversely, authenticity is also a dimension motivating souvenir purchasing. Authenticity is considered a social construct, and consumer perceptions of authenticity is shaped by the “social and cultural conditions under which the product was produced” (Littrell et al., 1993, p. 200). It is not the aim to classify which product attributes constitute an authentic Indigenous souvenir product. However, this concept is important when souvenir producers mislabel products and engage in blue-washing as consumers seeking authenticity are at a disadvantage when making an ethical purchasing decision. This is also relevant in a buyer-supplier context as retailers may also be deceived if they are seeking to supply ethical products.

Conclusion ideas

Applying the DIM, this paper contributes to the understanding of product development and supply chain decisions within the Australian souvenir industry with regards to Indigenous art. When examining the Distributors development chain it was revealed that a critical stage in which a firm decoupled from social sustainability practices occurred in the procurement decision supporting a product’s architecture. The paper highlights where Indigenous people should be involved in the development chain for
other non-Indigenous firms selling like-for-like products so as to avoid infringing on human rights as it relates to commodification of culture.

For Indigenous organisations and individual artists, seeking to enter the souvenir industry as a means of economic participation and inclusion, the paper provides an understanding of why specific techniques (such as offshoring) are used to satisfy customer purchase requirements, conversely impacting social sustainability. Additionally, for existing firms within the souvenir industry seeking to satisfy the market for ethical products, the research highlights where deception and decoupling from social sustainability relating to human rights and the cultural paradigm can occur from a production perspective.

Here, we addressed the gap in supply chain and operations management knowledge Indigenous producers face when participating in souvenir markets as established in the Report. Finally, the research contributes to the understanding of cultural paradigms within commodification contexts, as they relate to social sustainability as a concept.

Acknowledgments
The authors acknowledge Aboriginal and Torres Strait Islander peoples as the traditional owners of Australia, and pay respects to elders past, present, and emerging. The term Indigenous is used in reference to the cultures of both Aboriginal and Torres Strait Islander people throughout this paper.

Can lean management practices in the operations of the universities lead to sustainability?

Dr. Niladri Palit (Niladri.Palit@gcu.ac.uk)  
Glasgow School of Business and Society, Glasgow Caledonian University, UK

Abstract

Sustainability in the educational curriculum of the higher education providers like universities has received considerable attention due to its importance in practice in most of the industry sectors. However, when it comes to having a sustainable operation in universities, limited evidence is found in both theory and practice. The few research papers that addressed the issue, did not quite address the underlying barriers by proposing effective solutions. This research aims to propose solutions to this problem by examining if lean practices would be able to facilitate environmental sustainability in the universities’ operation in the UK.

Key Words: Sustainable University, Lean Management, Barriers to Sustainability

Introduction

Sustainability has been a buzzword in practice for the last couple of decades. It has also been a matter of academic interest to most of the universities in modern times. There has been a considerable shift in sustainable development in the last two three decades due to the increasing importance of policies to promote sustainability (Jorge et al., 2015). Yet, the universities often struggle to manage their sustainability targets in their own operations especially in the case of environmental sustainability. This has been documented in several studies from different parts of the world including studies in Portugal (Aleixo et al., 2018), in the UK (Robinson et al., 2018), in Poland (Kogcielniak, 2013), in Lithuania (Dagiliute and Liobikiene, 2015). The present study focuses on the UK higher education providers and to the issues on the environmental sustainability of the triple bottom line framework. The rational for this is the documented concerns regarding the performance of many of the university’s environmental sustainability issues based on People and Planet League table. Following the Data Energy Certificate release in 2017, a study was followed to identify the potential savings opportunities in the UK higher education sector. A potential £15.6 million savings opportunity was identified (Hawkins, 2017). In a report published in the Guardian (2016), only 25% of the UK based university campuses are on course to meet the carbon reduction targets by 2020 (Lightfoot, 2016). The author further mentioned- “UK universities are helping lead the world on environmental research – but when it comes to their own back yard they appear to be falling behind.”
This leads to the question of why the higher education sector falls behind their environmental performance. This has been mentioned in the literature including Disterheft et al. (2012), Netaji and Netaji (2013), Kogcielniak (2014), Berchin et al. (2017), and Akins et al. (2019) where the authors highlighted the presence of certain challenges/barriers to sustainable approaches in the form some case studies. These studies highlighted the importance of cultural change, but these studies did not highlight the type of change required and the stages involved in operational improvements to achieve those changes. Some authors tried some assessment tools to offer some practical insight regarding assessment and reporting of sustainability performances, but these have limitations in terms of addressing some of the basic barriers including awareness (Lauder et al., 2015). Moreover, there has been limited evidence on how to address those challenges against achieving those sustainability targets in the university set up by improving the universities’ operations. Adoption of some of the continuous improvement techniques from operations management such as lean management has been found to be improving the sustainable operations in practice in many sectors including manufacturing (Piercy and Rich, 2015). Yet, limited evidence is available when it comes to operations in universities. On this backdrop, “this research aims at exploring and examination” if lean management principles can be implemented in universities operations to facilitate the sustainability targets to be achieved by addressing the barriers. This research will focus on the operations of the universities in Scotland in the first phase with an extension to the UK wide research in the subsequent phase. The objectives are

**Objective 1.** To examine the barriers to achieving sustainability goals in universities operations in the UK.

**Objective 2.** To examine if the lean management principles can be applied to address those barriers and improve performance.

**Literature review/Research backdrop**

There is a growing body of literature on sustainability in the universities and other higher education institutions. This section presents an appraisal of extant literature considered relevant to this study, highlighting key themes and theoretical propositions for this research. A conceptual framework is also presented.

**Sustainability Tools**

A literature review shows some of the themes in the research involving sustainability issues such as tools used for sustainability measures (Li et al., 2018; Marrone et al., 2018; Algamdi et al., 2017; Berzosa 2017; Jorge et al., 2015; Lozano, 2011; Lozano, 2006), application of environmental management system (EMS) (Disterheft et al., 2012; Clarke and Kouri, 2009). Research in presenting the tools used for sustainability performance reporting has been considerably popular in the last 10-15 years. Lauder et al. (2015) presented a review of the Green Metric of the university ranking that is used for sustainability reporting in the university. In early research, Lozano (2006) presented a comparative study among the different tools used to assess and report the sustainability efforts by the universities along with some proposed modification in some of the tools such as Global Reporting Initiative (GRI), and Graphical Assessment of Sustainability in Universities (GASU). The author further extended the study to incorporate the GASU to compare the performance of the 12 universities’ sustainability performance (Lozano, 2011). Townsend and Barrett (2015) used Environmentally Extended Input Output Analysis (EEIOA) in their empirical study based on the University of Leeds. The authors found this tool to be allowing the performance
Jorge et al. (2015) proposed a multi-item quantitative tool which can be used for cross-university comparison. Alghamdi et al. (2017) examined 12 tools in sustainability in universities. Berzosa et al. (2017) conducted a comparative study with the application and application of multiple tools of sustainability applied for universities. Li et al. (2018) used the Analytical Hierarchy Process approach to propose prioritisation of the sustainability indicators in an Australian University. Marone et al. (2018) analysed and investigated the strengths and weaknesses of one of the popularly used index, the green metric index. Leon (2018) used Neighbourhood Evaluation for Sustainable Territories (NEST) tools for the environmental assessments of the University of the Basque County. Alshuwaikhat et al. (2018) proposed a model using the application of Geographical Information (GIS) tools to evaluate the sustainability related performance at the King Fahd University of Petroleum and Mineral. Alba-Hidalgo et al. (2018) proposed the definition/scope of environmental sustainability in the context of universities. The authors highlighted some of the characteristics of the tools that are used for this purpose such as STARS, SAQ (ULSF), AISHE, GASU, Green Report card, CSAF, AUA, STAUNCH, UI Green Metrics, CRUE, and USAT (MESA).

Alongside the sustainability performance reporting, the research on the application of Environmental Management System (EMS) has also been the topic of discussion in the literature. Clarke and Kouri (2009) discussed different campus EMS frameworks, their characteristics, and the drivers of implementation. Disterheft et al. (2012) conducted an empirical study on EMS development and implementation in universities across Europe. Velazquez et al. (2013) conducted a study on Sustainability Management System (SMS) implementation at the University of Sonora in Mexico to reduce the waste of water. Lo-Iacono-Ferreira et al. (2016) emphasized the importance of having an EMS for Ecological Footprint Assessment using Life Cycle Assessment. In a recent work by Omrecen et al. (2018), the authors presented a case study based on the implementation of climate strategy at the University of Gothenburg by the effective use of EMS. However, a limited insight was offered in these studies on the perceptions of the staffs and students. A study by Sammalisto et al. (2015) addressed this issue in a case study of a Swedish university. The authors addressed the perceptions of the staff members of the university on ISO14001 implementation. Other tools found such as Sustainability Management System.

Perception of Sustainability
Sammalisto et al. (2013) addressed the perceptions of the staff members by proposing a conceptual model. The author concluded with some insightful findings including variety in staff perceptions, and the importance of top management’s encouragement. The importance of top management support was also highlighted in the studies of Wright (2010), Wright and Horst (2013). Nejati and Nejati (2013) proposed a scale for capturing the student perception on sustainability in the universities. Sylvestre et al. (2014) conducted an empirical study to address the perceptions of the professors of Dalhousie University by the implementation of Q-method.

Barriers to Sustainability
Despite a considerable amount of research in sustainability reporting and the tools used for sustainability in the universities, the efforts to achieve sustainability in the universities often fall short. This is mainly due to the existence of some of the barriers. This has been highlighted in few studies including Wright (2009), Wright and Horst (2013), Kogcielniak (2014), Robinson et al. (2015), Disterheft et al. (2015), Dagiliute
and Liobikiene (2015), Leal Filho et al. (2017), Alexio et al. (2018), and Akins et al. (2019). The issues identified as barriers includes financial predicament (Wright, 2009; Wright and Horst, 2013; Aleixo et al., 2018), lack of awareness/weak acknowledgement (Wright, 2009; Dagiliute and Liobikiene, 2015; Leal Filho et al., 2017; Alba-Hidalgo et al., 2018; Akins et al, 2019), resistance to change (Wright, 2009), lack of leadership/management support (Wright and Horst, 2013; Kogcielniak, 2014; Leal Filho et al, 2017 ), type of approach adopted by policy makers/lack of support from policy makers (including Government) (Kogcielniak, 2014; Dagiliute and Liobikiene, 2015; Robinson et al., 2015; Leal Filho et al., 2017; Aleixo et al., 2018). In addition, authors including Vieira et al. (2018) discussed barriers to the EMS implementementation in the university set up. Vieira et al. (2018) conducted the study in the Brazilian higher education sector.

One of the key internal issues has been identified as the barrier was the lack of top management support in some of the above studies in the last paragraph. A top-down approach to entail the goals and objectives of the sustainability has been recommended as a proposed requirement in the studies including Wright and Horst (2009), and Kogcielniak (2014). However, some counterintuitive evidence has also been documented such as Dagiliute and Liobikiene (2015) the existence of a top-down approach in their study in the Lituanian universities. The authors extended this as a possibly due to external barriers including government support and frequent policy changes. This has been highlighted in some other studies such as well to be having a significant impact on the clarity on the sustainability goals at the workplace among the higher education providers (Kogcielniak, 2014; Robinson et al., 2015; Leal Filho et al., 2017; Aleixo et al., 2018). In fact in the study by Robinson et al. (2015), the authors identified a need for setting a realistic and achievable carbon reduction target to be set in place.

There are certain limitations are in existence in the above studies such as

- Many of the studies were conducted in specific geographic locations such as Canadian universities (Wright, 2009), Portugese universities (Aleixo et al., 2018), Polish universities (Kogcielniak, 2014), Lithuanian universities (Dagiliute and Liobikiene, 2015), Brazilian universities (Vieira et al., 2018). Li et al. (2018) highlighted the geographical differences may have implications on the results to be changing form case to case.
- A need for a more exploratory investigation with a different group of stakeholders (Wright and horst, 2013; Disterheft et al., 2015; Leal Filho et al., 2017);
- A need for identifying solutions/ways to overcome the barriers (Filho et al., 2018).

Earlier, this research highlighted the importance of the problems of poor environmental performance and related flak being drawn towards the universities in the UK. This has motivated the present research to aim at conducting an exploratory study and identifying if any proposed solution can be offered to address some of the barriers.

Problems of environmental sustainability can be improved by improoving the practices of operations within the organisation. Some well known continuous improvement practices such as Lean operational practices have been identified as one of the key facilitators towards environmental sustainability in manufacturing sector in some early researches by Florida, (1996), and Corbett and Klassen (2005): “lean is green”. In fact, this mantra was the theme of a literature review of Garza-Reyes (2015). Authors including Hughes et al. (2012) highlighted the importance of lean practice with the focus on “doing more with less being used/spent”. Simpson and Power (2005) found the similarity between the practices that support lean manufacturing and environmental performance. This type of overlap between lean and sustainable practices has been
identified in the study of Cabral et al. (2012) where the author found the environmental waste reduction from lean tool implementation. According to Piercy and Rich (2015), one of the key limitations of the majority of these previous research topics was the focus on the relationship between lean practice and environmental sustainability only. In their research, the authors showed far stretching benefits that could be derived from lean practice towards sustainability in the UK based manufacturing sector. In recent research by Halldosson et al. (2018) reiterated the potential for integrating the principles of lean management and sustainability initiatives. The authors further supported the findings of Piercy and Rich (2015) on the need for exploring the potential benefits of lean practices beyond environmental sustainability to other forms of sustainability that can be derived from the triple bottom line.

Despite its proven success in many other sectors including manufacturing, the application of lean management practice in higher education’s own operation has been quite limited. Thomas et al. (2015) argued that higher education institutions (HEI) in the UK are quite slower to adopt the lean practice and derive the necessary benefits. Balzer et al. (2014) highlighted some of the factors as a facilitator including institutional readiness, leadership, awareness, understanding, support, and a favourable culture or the associated changes towards it. Similar was the finding by Anthony et al. (2012) where the authors highlighted some additional critical success factors of successful implementation of lean six-sigma such as support from top management, effective communication, strategic and visionary leadership, and a favourable culture. This research has identified some of the similar key facilitators/success factors in the case of achieving sustainability by the universities. In fact, Balzer et al. (2014) highlighted based on some previous research by Balzer (2010), the amount of paper cost reduction up to 92% in facilities and management work orders in University of Central Oklahoma. Based on these observations and the growing concern in terms of league table performance and the follow up implications, our research focuses on the aim highlighted in the introduction section.

Design/Methodology/Approach
The objectives of this research aimed to understand the barriers of sustainability in the operations of the higher education sector in the UK. This was followed with the exploration and examination of some of the solutions using the concepts of continuous improvement such as lean management techniques. According to Creswell (1998), when the phenomenon of interest is its early stage with a lack of understanding around the theories, qualitative exploration is more appropriate. On the contrary, the well defined phenomenon may render a need for the quantitative investigation. The research methods adopted in similar research are quite diverse including qualitative methods such as in-depth interviews (Wright, 2009; Wright and Horst, 2013), semi-structured interviews (Disterheft et al. 2015; Aleixo et al., 2018), and qualitative case study (Akins et al., 2019). In the study of Leal Filho et al. (2017) used survey methods to gather qualitative and quantitative data in respective phases to conduct a mixed method research study. Secondaruy data based research was also found in some literature including Robinson et al. (2015). To select an effective methodology for this study, a set of literature on methodological discussion in operations management and related fields such as supply chain management were referred including merediuth et al. (1989), Craighead et al. (2007), Boyer and Swink (2008), and Golicic and Davies (2012). The framework proposed by Meredith et al. (1989) (Please see fig 1.) was found to be the appropriate starting point for this research as it allowed the current research to cater the three elements of research paradigm: Ontology, Epistemology, and Methodology.
(Denzina and Lincon, 1994, Frankel et al., 2005). The vertical dimension of the framework represents the epistemological elements where as the other dimension explains how the reality exists (Meredith et al., 1989). Although, the concepts of sustainability are not new, given the present research context, the concepts are relatively in its earlyy days (Jorge et al, 2015). The objectives of this research require an understanding of the way people perceive, behave and react to the changes that are brought about by the incorporation of the principles/strategies required to achieve sustainable goals. Thus, this research adopted qualitative methods. The intension of the researcher of the present research is to interpret people’s perception. Considering these elements, this research adopted semi-structured interviews with the university academics/non-academic staff members and the policy makers including the top management. In phase 1 of this study, the interviews will be conducted with the above mentioned participants from Scottish Universities. Then a preliminary analysis will be conducted. This is expected to be followed by the UK wide sampling.

![Figure 1 – Framework for research method (Source: Meredith et al. (1989))](image-url)

**Relevance/Contribution**
The literature review section of this research highlighted how the research about sustainability and lean management in the operation of the higher education sector is in
their early stage. Similar is the case in practice as well as highlighted in the form of documented problems with certain league table performance in the UK higher education sector. On this backdrop, the present research is expected to contribute to the theoretical knowledge especially identifying the barriers of achieving environmental sustainability and proposing some conceptual solutions with the help of lean management principles. Recent trends including plastic free society, requirements of less energy consumption in public sector premises, and less consumption of paper are some of the modern day challenges modern day universities face including the Scottish universities. Moreover, wider issues including challenges including a change in geopolitical changes, tighter budget, societal changes including poverty, and increasing tuition fee are also posing challenges in terms of the sustainable performance of the universities in the UK. However, often the universities do struggle to set out an optimal policy with respect to sustainability performance. Hence, the present research is expected to contribute to the generation of ideas to have an effective policy by having a more efficient operation in the universities for Scotland with a further expectation to generate future research ideas for UK wide.

**Discussions and Conclusions**

This research is expecting to find a similar set of barriers including lack of awareness, financial constraints, lack of stakeholder engagement, and resistance to changes. It is expected to be found that the lean management principles to be having a positive impact on achieving the sustainability targets of the university by addressing the barriers. There are some counter-intuitive resultst were shown in an earlier study by Rothenberg et al. (2001) in manufacturing set up where the authors found some negative relation between the lean practices and sustainability in certain particular cases. However, this research ahhs shown a great deal of literature has found a positive relation between the implementation of lean practices and achieving sustainability in manufacturing. In fact, the authors including Anthony et al. (2012) even argued that the non-applicability of lean practices in a non-manufacturing sector like higher education is a misconception. Thus, this research is expecting to generate new ideas as a solution to overcome some of the barriers toward achieving environmental sustainability in the higher education sector in the UK.

A possible limitation would be some of the barriers of sustainability would be quite external in nature and proposing a solution would either require a longitudinal study over time. Another possible limitation that would emerge would be the applicability within the specific geographical situation. This problem has been highlighted in some of the research papers cited in the literature review. This study is expected to set the basic foundation solution approaches/concepts which could be extended in future research to offer more generalisable solutions. In addition, future research could also take into consideration the other dimensions triple bottom line i.e. social and economical sustainability.

**Acknowledgments**

The author would like to thank the two anonymous EUROMA reviewers of this article. They contributed with valuable feedbacks that are incorporated in this manuscript improving the quality of the final version of this paper. The author would like to thank Glasgow Caledonian University for awarding a research excellence grant which helped conducting this research.

**Abstract**
This paper aims to propose a set of practices that can be used across firms to perform sustainability practices and enhance sustainability performance for the SC members. For this end, after a bibliometric review, the extracted papers were analyzed to derive a classification of practices for supply chain sustainability based on the framework of Campos (2015, p.21) on integrated sustainable supply chain practices. Findings demonstrate a total of 55 practices that represent what companies can do to perform better sustainability. The contribution involves the development of this set of practices in order to support scholars and practitioners in advancing on sustainability.

**Keywords:** Supply chain sustainability, Sustainability practice, Practice-based view.

**Introduction**
There are several challenges for the supply chain sustainability (SCS) theory regarding the effective definition of how it is possible to manage sustainability through firms and spread it throughout the supply chain (SC). One possibility is by using the practice-based view (PBV) approach and going beyond the focus on performance and resources (Carter et al., 2017; Silva et al., 2018). This is still an underexplored theoretical lens, which demonstrate a interesting contribution from this paper. More than advance by proposing a new framework, this paper focus on demonstrate that the current knowledge and comprehension may be reorganized to reach supply chain sustainability.

This paper aims to propose a set of practices that can be used across firms to perform sustainability practices and enhance sustainability performance for the SC members, including the economic, environmental, social and governance dimensions of
sustainability of sustainability. In practice, all these dimensions need to be considered for sustainability assessment via, e.g., the ISO 26000 or the Global Reporting Initiative. In academia, research is still focused on performance as the main target; however, to have a comprehension on what and how to do things in SCs, it is necessary to combine sustainability performance and practices due to contextual factors that influence SCS such as local culture or working conditions (Fritz and Silva, 2018).

**Bringing Practice Based View to debate Supply Chain Sustainability**

The current proposal focus on to debate about the topic several strategic management approaches may emerge, and here the debate around practice based view that is timely and contributively for the purpose. In this context, Bromiley and Rau (2014) pointed out that in contrast with the resource-based view (RBV) which emphasize that firms cannot imitate each other, PBV could be used to focus on firms interactions. Corroborating that argument, for Carter et al. (2017), ‘PBV focuses on differences in performance among firms across the entire range of performance ... [and] the explanatory variables in the PBV are practices that are imitable and amenable to transfer across firms, as opposed to ... RBV’.

According to Bromiley and Rau (2014), 'focusing on practices will help us to create specific, actionable advice for managers and other practitioners while continuing to advance our ability to explain firm behavior and the influence of firm behavior on performance.' As indicated by Bromiley and Rau (2016) 'performance is not only a more tangible construct than competitive advantage, it has the advantage of being more readily measurable.' Related to supply chain strategy the debate should consider the organisational level of analysis as well. Hence, more than consider only the firm resources, capacities or practices, it is necessary to observe interactions.

This recent approach need to have more discussion once there is a critical perspective beyond the debate. For Jarzabkowski et al. (2016), PBV is not presenting the total debate about practice that is necessary. According to the authors instead of to analyse only what to do, the practice related to strategy (i.e. strategy as a practice) should also analyse how and who is involved in all the process. Therefore, as argued by Carter et al. (2017), PBV is a new and unexplored theory, which stimulate the use, refine and advance of the approach, mostly the debate of supply chain practice view. PBV has been applied by Silva et al. (2018) to understand sustainability practices facing natural disaster in Brazil. The research demonstrate that the use of PBV in SC studies is timely and possible to advance towards sustainability.

In order to better map and analyze SCS practices, Campos (2015) developed a holistic framework consisted of seven clusters of initiatives: Supplier Relationship, Governance, Procurement, Production, Distribution, Waste and Customer Relationship (Figure 1). According to this model Customer Relationship practices can be divided into Demands and Engagement. The first subgroup includes one-way initiatives from companies to study and forecast customer demands and offer more sustainable
products/services/processes that fits to their demands. The second subgroup, which includes double-way initiatives, intends to engage customers in actions where they can change their daily purchasing and usage habits towards a more sustainable behavior.

Figure 1: Framework for managing supply chain sustainability practices
Source: Campos (2015)

This framework can support scholars to understand how to perform sustainability in both internally and externally way by considering its supply chains. For the current paper, we use the seven categories presented by Campos (2015) and advance identifying in the literature which practices can be used to introduce sustainability. It is important to highlight that these practices need to be shared among the supply chain members in order to have a more consistent practice from the sector. Also it is important to highlight that there are several contingency factors that influence the practice (cf. Silva et al., 2018), which sometimes is forgotten from the studies on supply chain sustainability.

Research Method

To develop theory on sustainability management in SCs, a multi-disciplinary approach is necessary, such as using a social science theory, the branch the PBV belongs to. To develop a set of practices for a PBV to SCS management, two steps were followed. First, a bibliometric analysis with the R program (an open and free software) was used, which is an appropriate method to analyse a large body of literature. This bibliometric analysis was undertaken based on 11 databases chosen for their clear links with management and operations. For instance, ABI/INFORM Collection, ProQuest, Business Source Ultimate (EBSCOHost), Sage Journals, Taylor & Francis e-Journals, and Wiley Online Library Journals, were analysed. No timespan was defined since there is no consensus in literature on when research in this field started. To extract the papers from these databases, the following keywords were used: "sustainable" AND “supply chain practices”, and “sustainably AND supply chain practices” and searched in the
whole article. This led to a total of 71 research papers. Out of these 71 papers, 48 were retained after reading and examining the summary and conclusions of each paper.

Second, the extracted papers were analyzed to derive a classification of practices for SCS that is presented in the finding section based on the framework of Campos (2015, p.21) on integrated sustainable supply chain practices. This framework is meant to support companies in developing their SCS strategies and was chosen for its comprehensiveness on categories of practices: supplier relationship management, internal supply chain management, and customer relationship management. However, there is no clear recommendations on which are these practices that can support the integration of sustainability in SC. Through this proposal a focus was set on finding out which are these practices.

**Findings**

Data was collected from 2009 and 2018. Developing the analysis was found that the largest years in the publication of papers in the field is the year of 2018 with a total of 204 papers, and the lowest is in 2011 with only 33 papers. The last three years represent more than half of the total papers published in the last 10 years, accounting for 52.5% of the total published in 10 years. This confirms that the concerns of researchers and practitioners are directed towards sustainability methodology and sustainable supply chain practices. The most published periodicals on the sustainability practices of supply chains were: (1) Journal of Cleaner Production - 75; (2) Supply Chain Management - 54; (3) Sustainability - 27; (4) Resources Conservation And Recycling - 23; and (5) Business Strategy And The Environment - 23.

The framework of Campos (2015), is formed by three dimensions, namely: 1) supplier relationship management, 2) internal supply chain management, and 3) customer relationship management. These dimensions are composed by seven categories (e.g., procurement, customer relationship) and twenty sub-categories (e.g., supplier selection, customer engagement). When selecting the practices, groups of practices were found for each sub-category of this framework (Table 1). For instance, supplier collaboration has six practices (e.g. cooperation with supplier for sustainability), solutions development has seven practices (e.g. design of products for easy disassembly), and customer relationship has ten practices (e.g. collection of feedback).

By considering this set of practice, the purpose is to develop an empirical research in order to understand how this happen in the market. We purpose to advance in the comprehension of practice of sustainability, since so far there is no clear theoretical debate around the topic. In addition, we purpose to understand elements that go beyond the Triple Bottom Line perspective. This idea is aligned with some recent research on, e.g., determining how sustainability is managed in different contexts since it highlights that practices such as routines or culture are to be considered to enhance SCS (e.g., Fritz and Silva, 2018). This first step is important to demonstrate how we can develop research and advance in the comprehension of sustainability in supply chains.
Conclusions

This paper demonstrate via a bibliometric review, how is possible to group a set of practice that facilitate a better performance in a supply chain. By using an under-explored debate regarding practices toward sustainability in supply chains following the practice-based view approach, this paper advances theory in the field of sustainability management in supply chain. The use of PBV is still incipient in the literature which ratify our contribution. Furthermore, this paper provides a first set of sustainability practices that firms can use to implement their sustainability goals within their supply chains. It is necessary to understand that several other practices can be found; however for our proposal, there are some criteria that could be used and influence companies.

Abstract
Survey data from multiple respondents in 295 plants in 15 countries are used to explore how the configuration of stakeholder relations can influence the effects of both internal and external environmental practices, in terms of their contributions to environmental as well as manufacturing performance. We find that the implementation of environmental practices can be beneficial for both environmental and manufacturing performance, when the manufacturers have developed close relations with all three main groups of stakeholders: suppliers, employees, and customers. Otherwise, implementation of environmental practices can only improve environmental performance, but cannot improve manufacturing performance.

Keywords: environmental practices, manufacturing performance, stakeholder relations

Introduction
Customers, suppliers, and the general public are increasingly demanding businesses in general, and manufacturing plants in particular, to minimize any negative impact of their products and operations processes on the natural environment. Moreover, as manufacturers move toward environmental sustainability, it is an imperative to improve environmental practices across their supply chains (SCs) (Vachon & Klassen, 2008). While it is relatively easy for manufacturers to implement certain environmental practices, including pollution prevention and pollution control, and to achieve some quick benefits, such as water/energy saving (Klassen & Whybark, 1999), the real challenge is to effectively implement environmental practices across SCs to go beyond low-hanging fruits and reap substantial benefits from environment investments. In other words, how can environmental practices contribute to environmental as well as manufacturing performance in terms of cost, quality, delivery, and flexibility?

To identify contingencies that can make environmental practices more effective, researchers on sustainable supply chain management (SSCM) have explored various factors related to industrial context, market environment, product specifications, manufacturing processes, and firm specifications. However, researchers have yet to clarify how stakeholders can impact on the performance implications of environmental practices, although multiple groups of stakeholders including customers, employees, regulatory agencies, and NGOs have been identified as important drivers of implementing environmental practices. We see this as a
A major gap, considering that effective implementation of environmental practices entails active participation of multiple groups of stakeholders. In this study, we conjecture that the focal manufacturers’ relationship quality with three main groups of stakeholders – namely suppliers, customers, and employees – can influence the effectiveness of environmental practices implemented at the focal manufacturers’ SCs.

A survey methodology was used to examine the complex relationships among bundles of environmental practices (internal and external) and stakeholder relations to improve environmental and manufacturing performance. The fourth round of data collection for the High Performance Manufacturing (HPM) project serves as the empirical setting for our study. Structural equation modeling (SEM) approach was used to test our hypotheses. For what concerns stakeholder relations, cluster analysis was used to identify configurations of three dimensions of stakeholder relations, i.e., supplier relations, employee relations, and customer relations, following a configuration approach (Meyer et al., 1993). Then, we used multi-group analysis to examine possible significant differences in the performance implications of internal as well as external environmental practices among different configurations of stakeholder relations.

Theoretical Foundations and Hypotheses Development

Environmental practices and manufacturing performance

Industrial activities of the past half century have created serious environmental problems, including global warming, ozone depletion, loss of biodiversity, resource depletion, and pollutions (Shrivastava, 1995). Against this backdrop, environmental management has emerged as a core issue of manufacturing strategy, as manufacturing plants have to reduce their impact on the natural environment. In the early 1990s, practitioners and academics alike were generally critical about the strategic value of environmental management, and the shared concern was that allocating resources to reduce environmental impact can harm the core competitiveness of manufacturers. As Friedman put it: “there is one and only one social responsibility of business – to use its resources and engage in activities designed to increase its profits as long as it stays within the rules of the game, which is to say, engages in open and free competition without deception or fraud” (Friedman, 2007). One common argument used by environmental skeptics such as Milton Friedman was traditional economic trade-off, in which any environmental improvement made by a manufacturing firm transfers costs previously incurred by society back to the firm. As a result, manufacturing performance, traditionally defined in terms of cost, quality, speed, and flexibility, worsens (Klassen & Whybark, 1999).

Growing empirical evidence (Orlitzky et al., 2003; Margolis et al., 2007; Horváthová, 2010; Golicic & Smith, 2013) and theoretical development (Hart, 1995) show that improved environmental performance does not necessarily come at the cost of worsened manufacturing and/or financial performance. Several scholars (Hart, 1995; Porter & Van der Linde, 1995; Shrivastava, 1995; Russo & Fouts, 1997) have developed converging arguments that can justify the strategic value of environmental management: proactive investments for improving environmental performance can enable the manufacturers to develop product, process, and managerial resources and capabilities that generate competitive advantage. For example, pollution prevention can drive manufacturers to critically evaluate and improve the product and/or process design, so as to achieve a higher level of resource productivity (Porter, 2008). Essentially, all forms of pollution and wastes represent resources that are misplaced. As such, pollution prevention calls for continuous improvement, through which the managers and engineers within the manufacturer can develop in-depth knowledge about the products and processes. Arguably, these in-depth understanding, knowledge, and capabilities are rare, difficult to imitate, and have few substitutes. More importantly, the development of such capabilities is largely path dependent, and they are not readily available in the market. Likewise,
several other internal environmental practices, including design for disassembly, manufacturing for the environment, and total quality environmental management (Shrivastava, 1995), are found to contribute positively toward manufacturing performance, which forms the baseline the first hypothesis of this study.

As operations management (OM) has moved beyond the four walls of the manufacturers, environmental management has already been extended to include upstream as well as downstream SC activities, in order to mitigate the environmental impact of these activities (Golicic & Smith, 2013; Lund-Thomsen & Lindgreen, 2014). These practices are here referred as external environmental practices. Typical environmental practices in this category include green purchasing (Green et al., 1998), supplier assessment and development for sustainability (Gimenez & Tachizawa, 2012), and green logistics (Lai & Wong, 2012). Implementation of external environmental practices can also affect a plant’s manufacturing performance. Although past research has not always provided consistent empirical evidence of the effect of external environmental practices, a prominent argument is that the joint effort of a manufacturer and its suppliers and customers can enable knowledge sharing and the development of relation-specific and capabilities that are socially complex and not easily tradable, and therefore can result in competitive advantage (Pagell et al., 2007; Paulraj, 2011). For example, environmental collaboration between a manufacturer and its suppliers and customers, such as joint decisions about ways to reduce environmental impact of products and/or processes, promotes exchange of technical information and mutual learning, which can lead to innovative solutions for environmental management and in turn improvements in both environmental and operational performance (Vachon & Klassen, 2008). In line with this reasoning, we also hypothesize a positive relationship between external environmental practices and a manufacturer’s performance.

**Hypothesis 1:** Implementation of environmental practices positively relates to manufacturing performance.

**Hypothesis 1a:** Implementation of internal environmental practices positively relates to manufacturing performance.

**Hypothesis 1b:** Implementation of external environmental practices positively relates to manufacturing performance.

Many (environmental) sustainability programs started as isolated efforts by a manufacturer. However, over the years, more and more companies have recognized the need to extend such programs beyond the firms’ boundary, thus engaging in (environmental) sustainability practices with their supply chain partners (Kytle & Ruggie, 2005). It can be expected that, in this process, knowledge and capabilities developed in sustainability management at plant level could act as an enabler for the implementation of external practices (Graham, 2018). In line with this, some recent research suggest that bundles of (environmental) sustainability practices may be related to each other, with some studies also highlighting significant implications for performance (Zhu et al., 2012; Green et al., 2012; Gualandris & Kalchschmidt, 2016; Graham, 2018). We therefore hypothesize:

**Hypothesis 2:** Implementation of internal environmental practices positively relates to implementation of external environmental practices.

**Stakeholder relations and environmental management**

Various groups of stakeholders, including customers, local community, and NGOs, have been the driving force for manufacturers’ implementation of internal as well as external environmental practices (Kassini & Vafeas, 2006). While prior studies have thoroughly investigated the “driving” effect of stakeholder pressures on the manufacturers’ environmental management, rather limited attentions have been paid to explore how and to what extent these
stakeholders enable the effective implementation of internal and/or external environmental practices. We see this as an important omission, considering that several seminal papers on the strategic value of environmental management (Hart, 1995; Porter & Van der Linde, 1995; Shrivastava, 1995; Russo & Fouts, 1997) consistently highlight stakeholder engagement as a key to the effective implementation of environmental practices. For example, several studies on SSCM (Santha et al., 2016; Gualandris & Kalchschmidt, 2016) show that good buyer-supplier relations can significantly enable the effective implementation of supplier sustainability practices. This study aims to advance this stream of studies by exploring the performance implications of internal as well as external environmental practices while explicitly taking into account the contingency role of the manufacturer’s relation quality with three main groups of stakeholders: suppliers, customers, and employees.

We adopted a configuration approach (Meyer et al., 1993) when investigating the impact of stakeholder relations on the effectiveness of environmental practices. Configuration approach is deemed appropriate for handling complex relationships, such as the relationships between patterns or “arcs” of SC integration and manufacturing performance (Frohlich & Westbrook, 2001; Flynn et al., 2010). Instead of analyzing the impact of specific contingencies separately, a configuration approach explores configurations of various elements and their interactions (Drazin et al., 1985). Therefore, a configuration approach allows us to not treat stakeholders as separated entities one from the others. Many advanced projects for improving environmental performance entail engaging suppliers, customers, as well as employees. Cooperation and interactions among different groups of stakeholders can facilitate knowledge sharing and creation, which can foster the effective implementation of environmental practices. However, the quality of relations a company has with its employees, suppliers, and customers can differ across organizations. For this reason, we acknowledged the existence of different configurations of stakeholder relations, and posit that in different configurations of stakeholder relations, environmental practices will have different performance implications.

**Hypothesis 3**: In different configurations of stakeholder relations, environmental practices will have different performance implications.

**Methods**

Data from the HPM survey was used to explore the research question (see for example Schroeder & Flynn, 2001). The HPM is an international network of researchers that have collaborated for many years with each other and with manufacturing plants all over the world to develop a common survey. The primary aim of the survey is to explore the relationship between OM and SCM and the success (i.e., high performance) of manufacturing plants. However, the dataset can be used to examine many other research questions in the OM field. This study uses data from the fourth round of HPM, which includes plants located in 15 countries (Brazil, China, Finland, Germany, Israel, Italy, Japan, Korea, Spain, Sweden, Switzerland, Taiwan, UK, US, and Vietnam) and operating in 3 industries (machinery, electronics, and automotive).

Data collection was performed in a similar way across countries, thanks to the use of shared guidelines. In all countries, a team of researchers was in charge of selecting the plants, contacting them, administering the questionnaires, and providing assistance to the respondents to ensure that the information gathered was correct and complete. Selection was on a random basis, from a master list of manufacturing plants in the country. All plants received a set of 13 different questionnaires (translated as needed). Each questionnaire (except the accounting one, not used in our study) was administered to two respondents within the plant, selected by the CEOs considering who were the best informed about the topic of each questionnaire. This choice was made to minimize the risk of common method bias, which is higher in case of a single compared to multiple respondents. The final sample includes 331 plants, with a response.
rate of approximately 65% in each country (Danese et al., 2018). However, we deleted thirty-six plants due to missing data.

Results

Baseline Model: Environmental Practices and Manufacturing Performance

We checked that the fit indices of our baseline model were indicative of a well-fitting model. The results of path analysis for our baseline model are reported in Tables 1. The results of direct paths from internal environmental practices show a strong and positive relationship with environmental performance, a strong but negative relationship with cost, and no significant relationship with both quality and responsiveness (Table 1). For what concern external environmental practices, we found strong positive relationships with both environmental performance and cost, weak positive relationship with quality, and no significant relationship with responsiveness. We also tested the total effects, which show strong positive relationships with environmental performance and quality, a positive but weak relationship with cost, and no significant relationship with responsiveness. Overall, these results provide partial support for hypothesis 1.

Table 1 also shows a strong positive relationship between internal environmental practices and external environmental practices, which provides support for hypothesis 2.

Cluster Analysis Results: configurations of stakeholder relations

Hypothesis 3 posits that configurations of stakeholder relations can be developed based on the quality of the relations of firms with their employees, suppliers, and customers and calls for a differential effect on the pattern of linkages in Table 1 according to the configurations of stakeholder relations. Hair et al.’s (2010) two-step cluster analysis procedure was used to classify plants into configurations of stakeholder relations. That is, we first applied a
hierarchical clustering procedure to determine the number of clusters, and then a non-
hierarchical procedure to produce the final clusters.

Figure 1 shows results of the analysis of the agglomeration coefficient, which was used
to determine the number of the clusters. Four clusters were judged as sufficient, as the
percentage of change in the agglomeration coefficient was the highest when the number of
groups changed from four to three (Flynn et al., 2010). A four-cluster solution was also
preferred over a five cluster solution due to a better interpretability of the data (Hair et al.,
2010), having the five cluster solution a cluster of only 29 plants. In the second step, the K-
means algorithm was used to assign observations to the four clusters. We then used ANOVA
and a Scheffé post-hoc test of mean differences to examine the quality (or strength) of relations
with employees, suppliers, and customers across the four clusters. The final clusters and their
centroids are reported in Table 2.

<td>47</td>
</tr>
</tbody>
</table>

Note: \(^1\)Higher, Medium-Higher, Medium, Medium-Lower, and Lower based on Scheffé post Hoc tests of mean differences.
In interpreting the results of Table 2, we first examined the balance of the relations with each stakeholder. Cluster 1 developed good relations with employees, suppliers, as well as customers. We labelled it “comprehensive orientation”. Instead, the other three clusters have unbalanced patterns, with relation with one stakeholder scoring lower than the other clusters, and the relations with the other two stakeholders scoring medium (medium-lower, medium, or medium-higher). For this reason, we referred to a “selective orientation”. In order to better categorize clusters with a selective orientation, we also analyzed the quality (or strength) of relation with each stakeholder. We labelled cluster 3 as “external orientation”, as it scored medium in relations with suppliers and customers, but has a lower score in the internal relations. Clusters 2 and 4 have symmetrical patterns. Cluster 2 has a lower score in the customer dimension and was therefore labelled as “upstream orientation”, while cluster 4 has a low score in the supplier dimension and was therefore labelled as “downstream orientation”.

**Multi-group Analysis: Moderating Role of Stakeholder Relations**

The aim of Hypothesis 3 was to see whether the configurations of stakeholder relations can moderate the relationships among environmental practices and manufacturing performance. We ran an iterative process assessing the presence of significant differences in χ² values (∆χ²) between pairs of nested models. As for the path analysis in the overall dataset, we verified both the direct and the total effects. The results of our multi-group analysis are reported in Table 3.

**p < 0.01**

**p < 0.05**

**p < 0.1**

Firstly, the results of direct paths from internal environmental practices show a strong positive relationship with environmental performance, a strong but negative relationship with cost, as well as no significant relationship with both quality and responsiveness across the four clusters. For what concern external environmental practices, we found strong positive
relationships with environmental performance and cost, while relationships with quality and responsiveness were not significant. In addition, the impact of external environmental practices on environmental performance in cluster 3 was significantly higher than in the other three clusters.

Secondly, the analysis of the relationship between internal and external environmental practices showed a strong positive relationship in all the clusters. However, internal environmental practices has a higher impact on external environmental practices in cluster 1 than in the other three clusters, there was a similar impact in cluster 2 and 3, and a lower impact in cluster 4.

Finally, the test of the total effects revealed additional differences in the performance levels across the four clusters. While environmental performance was positively affected in all the clusters, cost and quality were positively affected only in cluster 1. The effect on quality was positive but weak in clusters 2 and 3. Cost was negatively affected in cluster 4, although the impact was not statistically significant.

Overall, the multi-group analysis results suggest that differences in configurations of stakeholder relations can result in different performance, providing support for hypothesis 3. In addition, they suggest that such differences can be due to (1) a different impact of the internal environmental practices on external environmental practices and (2) a different impact of external practices on performance.

Conclusions
This study contributes to SSCM literature by providing a better understanding of the complex relationships between specific bundles of environmental practices and their interaction with stakeholder relations to improve manufacturing performance. Our results have also important implications for practitioners. Firstly, managers should acknowledge the importance of both internal and external environmental practices. While the implementation of external practices is particularly important to overcome trade-offs between environmental and operational performance, internal practices not only contribute to environmental performance, but are also an important enabler for external environmental practices. Therefore, manufacturers should invest in both internal and external environmental practices to make the most out of their environmental programs.

Secondly, managers should carefully assess their general relations with employees, suppliers, and customers, as they affect the effectiveness of their environmental programs. Only when good relations with all of these stakeholders are present, manufacturers can expect to achieve the full benefits of their environmental programs. A selective orientation, excluding one of these groups, it is likely to result on environmental improvements only, thus precluding improvements on operational performance. However, good relations with multiple stakeholders can require significant resources to be developed or even maintained. Our results can also guide manufacturers that do not have good relations in place, on which group(s) of stakeholders target their limited resources. Indeed, we found that a downstream orientation (cluster 4) can be more detrimental than other selective orientations for operational performance. This suggests to not exclude suppliers, as it is likely they have important as well as unique knowledge and capabilities that can booster effectiveness of environmental programs.

It is important to note some limitations of our study, which suggest an interesting agenda for future research in this area. First, for what concern the research setting, manufacturing plants in our sample operate in machinery, electronic, and transportation components industries, and this can limit the generalizability of our findings. It might be that other sectors may show different results. Therefore, future research should replicate and extend our model to samples drawn from other industries.
Second, our study examined environmental practice effectiveness considering manufacturing performance of focal manufacturers. However, it could be interesting to also include the performance of suppliers as well as customers in order to provide a better understanding of possible trade-offs in performance at a SC level.

Third, we analyzed the role of stakeholder relations by including three groups of stakeholder, i.e. employees, suppliers, and customers. Although these may arguably be the stakeholders with a more direct impact on effectiveness of environmental practices, literature suggested other groups, including regulatory agencies and NGOs, as important drivers of environmental programs. Therefore, we call for future research that analyzes the role of various groups of stakeholders for environmental program effectiveness.

Finally, our study focused on environmental sustainability and impacts of environmental practices on two dimensions of the so-called triple-bottom-line (Elkington, 1998). As manufactures are nowadays required to also improve their social performance, an interesting venue for future research is to also include the social dimension in the investigation of the effectiveness of sustainability programs.

Abstract

Global sourcing has dominated in industrial sourcing understating operational impacts as key objective. Low unit price has been pivotal: This paper investigates buyers’ and influencers’ decision-making on local versus global industrial sourcing, from a qualitative perspective, by contrasting between intentional and actual drivers related to operational fundamentals. Our study indicates that the prioritization in sourcing are: 1) unit costs; 2) quality and lead time; 3) flexibility of sourcing; 4) transportation/logistics, dependability, inventory level. Simpler drivers (unit costs) are favoured over “complex” drivers such as flexibility. This paper calls for closer reviews of sourcing decisions to streamline sourcing and operations better.

Keywords: Local Sourcing, Global Sourcing, Operations Management

Introduction

The choice between local and global sourcing has presented an ongoing challenge for decision makers over the last three decades (Bailey and De Propris, 2014; Bals et al., 2016; Johansson and Olhager, 2017; Monczka et al., 2016). The location of sourcing influences the geographical dispersion of business activities, and thus creates consequences throughout the company. Managerial issues relating to the geographical dispersion of sourcing and product development activities have been extensively studied (Echtelt et al., 2007; Gray et al., 2017), and this has improved our understanding of the drivers influencing the location of sourcing (McIvor, 2013), the involvement of suppliers (Dain and Merminod, 2014), cross-border collaboration and knowledge sharing (Revilla and Knoppen, 2015). However, decisions on the location of sourcing are mostly disconnected from operations (Dekkers, 2011), mainly due to a lack of understanding from sourcing management about the practical consequences of their decisions on operations (Brown, 2013). Indeed, Ketokivi et al. (2017) point out that senior managers
often have a perfunctory understanding of operations, and this results in decision making that does not reflect the short- and long-term opportunities and consequences.

Accordingly, by exploring the drivers influencing the decision on local versus global sourcing and analyse these drivers in the light of the impact on operations the purpose of this paper is to provide analytical means for qualifying and improving decision making in the relationship between sourcing and operations management. To do so, this paper draws on Argyris’ and Schön’s (1974) classical work highlighting a gap between “espoused theory” (a practitioner’ intentional action) and “theory in use” (a practitioner’s actual action). This understanding is used to distinguish between intentional drivers and actual drivers, and to guide the research as a research question we ask “to which extent are the local versus global decision-making based on intentional- or actual drivers”.

The empirical setting for this qualitative study is a global company with business activities around the globe. We focus on the sourcing of strategic materials for manufacturing plants located in Denmark.

Theoretical background

Definition of terms

Weele (2014) focuses on activities related to sourcing, and thus regards sourcing as a process of identifying, selecting and managing an optimal source of supply around the globe. Drawing on Weele’s viewpoint and Webster and Wind’s (1972) “Buy Grid” model, sourcing is understood here as a phased process involving activities related to the creation of specifications, supplier selection, negotiation and contracting, ordering, expediting and follow-up. The first three phases involve strategic sourcing, and thus mainly entail collaboration with product development, while the last three phases deal with operational sourcing in collaboration with operations (manufacturing). Thus, this paper defines operational sourcing as the ordering of materials, ongoing follow-up on these orders and activities related to the final evaluation of the sourced materials.

The globalisation of business activities has turned global sourcing commonplace (Kotabe and Murray, 2004). Weele (2014) regards global sourcing as the accomplishment of sourcing activities in globalised settings, often as sourcing from low-cost countries. Wagner and Bode (2006) describe global sourcing as an extension of the sourcing network in geographical terms. Local sourcing is understood by Wagner and Bode (2006) to be the activity of sourcing from geographic and socio-economic vicinity (Contractor et al., 2010). Accordingly, this paper understands local sourcing to take place within the domestic setting, while global sourcing refers distance and complexity.

Kraljic (1983) and Bensaous (1999) focus on the existing products being produced, meaning that these two well-known approaches to categorising the sourced materials draw on an operational perspective. According to Kraljic (1983), strategic materials are characterised as having high financial impact and high supply risk, while Bensaou (1999) defines strategic materials as requiring high levels of investment in the relationship by both the buyer and supplier. Since its publication, Kraljic’s approach has been widely adopted by practitioners in various business areas (Rezaei et al., 2015) and in academia. For instance, Gelderman and Weele (2003) call into question the sensitivity to measurement drivers, while Gelderman and Semeijn (2006) emphasise that in the case of strategic material, companies often have to accept the dominance of a supplier. Pagell et al. (2010) and Hesping and Schiele (2016) have further developed Kraljic’s model, and emphasise that not only the profit impact but also the long-term strategic importance of materials should be considered relevant when identifying portfolio groups.
Based on the above, *strategic materials* are defined here as having high strategic importance, including high profit impact, high supply risk, and deviations will have high impact on the operational performance.

**Identification of drivers**

Sourcing decisions must be analysed from its impact of general business functions such as sales and marketing (Ketokivi et al., 2017), logistics (Wagner and Bode, 2006), quality (Stanczyk et al., 2017), and warehousing and levels of inventory (Slack et al., 2016).

A study of 373 manufacturing companies (Johansson and Olhager, 2017) illustrates that although low labour cost is the determining driver in the globalisation of sourcing, the consequences of this decision are often disappointing in terms of quality, lead time and flexibility of performance, thus prompting a reconsideration of the chosen sourcing location. Stanczyk et al. (2017) present a comprehensive literature review of drivers influencing the globalisation of companies’ sourcing activities; the drivers are divide into those relating to operational performance and financial performance, respectively. The former includes drivers such as lead time, inventories, quality and complexity, while the latter consists of costs related to materials, transportation, inventories and overhead.

According to the sourcing process model presented above, the selection of suppliers (i.e. the sourcing location) is one of the first decisions to be taken (Webster and Wind, 1972; Weele, 2014), meaning that the decision on sourcing location is decoupled from operational issues (Dekkers, 2011). Accordingly, the review of influencing drivers in this study focuses only on the performance-related consequences of sourcing location decisions; in other words, the aim of this review is to reveal the drivers of location decisions taken by practitioners in operational areas.

Slack et al. (2016) suggest that performance-related consequences include quality, time of delivery, lead time, dependability, flexibility (to cope with fluctuations in demand) and costs. Bozarth and Handfield (2016) agree, but omit dependability. Schönsleben (2004) identifies quality, costs, delivery and flexibility, while Chae (2009) emphasises inventory days of raw material supply and the dependability of upstream actors. Leonczuk’s (2016) finds that quality, dependability of delivery, lead time, flexibility, inventory levels and costs are key performance drivers.

Drawing on the above, it seems that researchers agree upon the following performance-related consequences: costs, quality, dependability (supplier reliability), lead time, inventory levels and flexibility. In the following, these performance-related consequences are used to structure a review of articles examining the drivers influencing the choice between local and global sourcing.

Costs are considered to be an influencing driver by Fagan (1991), Bozarth et al. (1998), and several others; Table 1 gives a comprehensive listing. These costs involve both unit costs and indirect costs, for instance transportation/logistics costs (Fagan, 1991). Trent and Monczka (2003) find that direct costs (unit costs) are the most important influencing driver. According to Kotabe and Murray (2004), although opportunities for reductions in unit costs were previously a crucial influencing driver, unit cost currently ranks alongside quality and dependability drivers. Zhai et al. (2016) echo this viewpoint, and mention unit costs alongside quality as the primary drivers. Joubioux and Vanpoucke (2016), Stentoft et al. (2016) and several others (see Table 1) consider quality to be an influencing driver. Except for Kotabe and Murray (2004) and Wagner and Bode (2006), these authors also find that lead time is a driver influencing decision making. Trent and Monczka (2003), Bailey and De Propris (2014) and others (see Table 1) suggest that dependability influences this decision. Inventory level, including the volume of the sourced material, is considered to be an influencing driver by Kotabe and Murray (2004), Ashby (2016) and
Finally, according to Bailey and De Propris (2014), Fratocchi et al. (2016), and several others (see Table 1) flexibility is a determinant of the choice between local and global sourcing.

In summary, based on the above review of 16 articles, the seven drivers are as follows: unit costs (identified in 14 articles); transportation/logistics costs and quality (identified in 13 articles); lead time (identified in 12 articles); flexibility of sourcing (identified in 10 articles); dependability (supply reliability; identified in nine articles); and finally inventory level (identified in seven articles).

Methodology
This research is exploratory, and a qualitative research approach is applied here (Creswell, 2014). Boer et al. (2015) suggest that a review in an explorative study should be short, rather than comprehensive as for theoretical tests. Narrative literature review in this paper is to gain an overview of the influencing drivers (Hammersley, 2001). A literature review reveals seven identified drivers. These seven drivers feed into and structure the empirical analysis. Thus, although the research commences with a literature review, the line of inquiry is not a purely deductive approach; as Bertilsson (2004) states, “Deduction does not really ‘see’ anything at all as it serves a control office”.

The empirical context for this paper is a large global company producing complex products with both mechanical components and hardware with embedded software. The company has operated with both local and global sourcing methods for 10 - 15 years. While the company has several facilities globally, the focus in this research is on sourcing strategic materials for its manufacturing plants located in Denmark. Thus, the distinction between local and global sourcing is based on the geographical location of suppliers in relation to the Danish facilities. The study of this company constitutes a case-based research approach (Woodside and Wilson, 2003; Yin, 2009).

Product variants are often made on engineer-to-order basis. There is also a certain degree of customisation or configurability of each system with respect to a range of customer or local requirements. Most parts are manufactured by suppliers, but critical
parts are assembled within the company. The planning horizon for assembly and shipping systems to customers is typically very long – measured in years.

The data collection carried out here involves observations and semi-structured interviews with practitioners in a range of different organisational functions. Seven semi-structured interviews were conducted. A gatekeeper (Bryman and Bell, 2007) supported the identification of each of the practitioners interviewed. Informants were identified with a range of different organisational functions, who were either involved in or directly influenced by the local or global decision making, for example operational procurement, engineers involved in engineering changes to existing products, quality, planning, warehousing and production. Extensive action research was also used to underpin the results, consisting of a presence in the company for approximately one year, shadowing meetings, decision-making and daily data processing.

Our analysis draws on the above interviews and observations, which were coded into a matrix with the identified drivers as one dimension, and the informants and observations making up the other dimension. Focal point of this analysis is the influencing role of the drivers, rather than the different functional areas. Through our approach, a pattern gradually emerges from the collected data, enabling an understanding of the current approach to the decision on local versus global sourcing followed by clarification of the practitioners’ suggestions for an ideal approach to determine the location of sourcing.

Empirical findings and analysis
With the aim of providing analytical means for qualifying and improving decision making in the relationship between sourcing and operations management the analysis in this section explores the drivers influencing the decision on local versus global sourcing. To guide the analysis we focus on “to which extent are the local versus global decision-making based on intentional- or actual drivers”.

Although the seven influencing drivers are presented and analysed separately below, the majority of practitioners emphasised that the decision between local and global sourcing location should not be based on a single driver. Instead, proper decision-making should take into consideration several of these seven drivers. Intentional driver for the local/global decision-making is to apply a trade-off approach among all drivers.

The majority of practitioners ranked unit costs (direct material costs) as a pivotal driver affecting the decision between local and global sourcing. Few practitioners ranked it in second place, who considered dependability as the most crucial driver. Even though placing unit costs as their first priority driver, the practitioners acknowledged that the total cost of sourcing strategic materials would be more appropriate, emphasising that although global sourcing has lower unit costs, the total cost of global sourcing will in some situations be higher than for local sourcing.

Although the practitioners noted the benefits of applying a total cost analysis in this decision, the weighting of transportation/logistics costs was surprisingly low. All practitioners stated that this driver had only a minor influence on the decision-making process; issues being highlighted by the practitioners are costs consideration based on INCOTERMS agreements (Weele, 2014). The viewpoint in the company is that since the supplier is responsible for carrying all risk and transportation/logistics costs, the unit cost is the pivotal driver. Thus, costs related to increasing the safety stock (inventory level) due to longer lead times and potential quality issues are neglected. This indicates that the actual driver for the decision-making is unit costs.

All practitioners highlighted that dependability was not a matter that greatly influenced the decision-making process. The only dependability issues that influenced decision-making were audits of the suppliers’ financial positions; dependability in terms of timely
deliveries and the right quality had no influence. Practitioners pointed out that dependability influenced the selection process of suppliers, but did not have any influence on whether local or global sourcing was selected. The practitioners acknowledged that dependability in regard to on-time deliveries and quality should have a higher degree of influence on the selection process of suppliers, as it could be a means of reducing the risks of sourcing. It seems the actual influence of the dependability driver is minimal.

Responses regarding the influence of lead time are diverse. Practitioners who were involved in engineering change management, quality and planning stated that lead time was among the most important influencing drivers. Their argument was that sourcing with a short lead time (from suppliers) was more capable of handling fluctuations in production plans than sourcing operating with long lead times. Practitioners working in production and operational procurement considered lead time to have a degree of influence on decision making, and ranked lead time as having a medium degree of importance. As long as a supplier’s dependability in terms of timeliness and quality was acceptable, lead time considerations should only have a minor influence on the decision-making process.

All practitioners agreed that quality influenced the selection of local or global sourcing location. In the past, quality issues had been frequently encountered when receiving materials from global sourcing locations; however, practitioners stated that the level of quality from foreign locations ranked alongside domestic sourcing locations at the time of response. Indeed, quality was not regarded as a main influencing driver when distinguishing between local and global sourcing locations. Rather, quality was considered to be a generic driver in the choice of suppliers, and some practitioners ranked the influencing role of quality as lower than unit costs, while others suggested that quality was less important than both unit costs and lead time. Nevertheless, all practitioners felt that quality should be the pivotal driver in all sourcing decisions, as it could ensure the lowest total cost in the long term; as stated above, differences in quality performance are not generally caused by the location of sourcing, meaning that quality should remain a generic selection intentional driver.

All practitioners responded that inventory level did not influence the selection process of suppliers in any way. Practitioners pointed out that issues related to inventory level were handled by operations totally decoupled from the sourcing location. Practitioners apparently faced the consequences of this neglect, and they emphasised that inventory level considerations should be taken into account in the choice of local and global sourcing location. Practitioners from warehousing and procurement suggested that either local sourcing locations should be used or that global sourcing locations (suppliers) should establish local warehouses.

In regard to the last driver, the majority of practitioners considered flexibility of sourcing to be a driver of some importance. All practitioners underlined two aspects of flexibility: the availability of technology and the availability of free capacity. Both aspects were rated as being highly important when selecting local or global sourcing methods. In terms of the availability of technology, the practitioners did not identify any issues associated with local sourcing; however, in terms of the availability of free capacity, they emphasised that it was often necessary to use or supplement local sourcing with global sourcing, via a dual-sourcing scheme. Compared with the present situation, the practitioners did not see any need to change the priority of the flexibility of sourcing driver, highlighting that the total costs should be the pivotal influencing driver in the choice between local and global sourcing.

In summary, a huge gap between intentional and actual drivers for the local/global decision-making is revealed. The practitioners highlight the importance of using a trade-off approach in an attempt to reduce the total cost, but at the end of the day, the actual
driver having pivotal influence on the location decision is unit cost. Following unit cost, quality and lead time have also high priority, while flexibility of sourcing (capacity-wise) has a certain level of influence. Transportation/logistics costs, dependability and inventory level have only a minor influence. To close the gap between intentional and actual driver, the analysis indicates that practitioners should pay more attention to flexibility, dependability, inventory level and transportation/logistics costs.

Discussion

The consequences of an excessively one-sided focus on unit costs have been examined by researchers. For instance, due to issues relating to quality, lead time and flexibility performances, local versus global sourcing decision making based on reducing unit costs are often reversed (Johansson and Olhager, 2017), meaning that production is backshored (Ashby, 2016). Practitioners in the operations department were “held hostage” by the sourcing decisions, as they had to find a way to cope with inadequate quality, long lead times, a lack of flexibility, high transportation/logistics costs, low dependability and high inventory levels. According to the practitioners in the operations it was often necessary to carry out rescheduling of the productions and produced rush-orders/deliveries, which were resource demanding and costly for the company. Accordingly, it seems that the drawbacks of decisions made in the early phases of the sourcing process model (Webster and Wind, 1972; Weele, 2014) are difficult to overcome.

In contrast to the prevailing theoretical viewpoint regarding decisions on local versus global sourcing, which suggests a trade-off in terms of costs (Monczka et al., 2016), the findings in this paper illustrate that the practical realities of sourcing decisions favour unit costs at the expense of considering the total costs. The question thus arises as to why practitioners favour a total costs approach while at the same time acknowledging that since the suppliers carry both the risk and costs of delivering the materials, transportation/logistics costs should not have any influence. Likewise, although the influence of dependability is regarded as being small, a low degree of dependability makes it necessary to increase the level of safety stock, handle rush deliveries and increase the awareness of inventory management. Hence, we echo Stentoft et al.’s (2016) viewpoint that it is important for practitioners to have knowledge about the rationales of both local and global sourcing to carry out a balanced decision-making process. Our findings suggest that practitioners need to use a simple overall benchmark, unit cost, in the verbal expression of decision-making, but can analyse and verbalise complexity in depth when necessary due to their professional background and experience.

Researchers suggest using a total cost approach in the local-global sourcing decision-making (Bailey and De Propris, 2014; Johansson and Olhager, 2017; Kotabe and Murray, 2004; Zhai et al. 2016). Practitioners have accepted this viewpoint, but the practical realities revealed in this study illustrate that the decision makers struggle in applying such a method. Basically, it can be argued that the empirical findings in this study challenge the distinction between local vs. global sourcing. For instance, these practitioners suggest that quality, logistics and transportation costs, dependability and inventory level should be seen as generic drivers for selecting suppliers, and that these drivers are therefore not directly linked to the local and global sourcing decision. This implies that unit costs, lead time, and to a certain extent flexibility requirements due to fluctuations are the determining drivers in the location of sourcing; trade-off exists between a reduction in unit cost and coping with the consequences of increased lead time.
Figure 1. Local/global sourcing decision-making

Figure 1 illustrates a framework for qualifying and improving the relationship between sourcing and operations management in terms of local/global sourcing decision-making. As it appears from the analysis, the practitioners have acknowledge that it is crucial to prioritise short lead time if they should be capable of coping with high fluctuation. In contrast if the fluctuation is low, it is just a matter of drawing up a good plan. Having a laser like focus on fluctuation as the determinant for handling operations issues is well-evidenced (Christopher, 2016; Slack et al. 2016;). These researcher suggest addressing the level of fluctuations in downstream activities, in the internal value creating activities and final in the upstream activities. Acceptance of the viewpoint depicted in figure 1 reduces the distinction between local versus global sourcing, making it a matter of simply balancing unit costs and lead time issues.

This study has certain limitations. Findings are based on one company study with data collected from an inside-out perspective, and our empirical understanding does not draw on the network of the enterprise. The company examined here is sourcing high-end industrial products in low quantities, with a high level of engineer-to-order, but is making sourcing decisions partly with a “grocery shopping” philosophy, based on individual attitudes, perceptions and behavioural traits. Finally, we address the local versus global sourcing issues from an operational perspective, and thus deliberately neglect the decision-making processes in relation to product development. Future research should therefore extend the number of companies examined, and should also include both local and global suppliers, meaning that both an inside-out and outside-in perspective should be used. A comparison of the differences between the working practices of different companies and carrying out more interviews in each organisational department may pave the way for further learning points and increase the reliability of the research.

As a reflection upon the practical realities of sourcing decisions recalls Argyris’ and Schön’s (1974) classical work presented in the introduction of this paper. The practitioners are aware of the benefits of applying a total costs approach, and in general, the level of education in the company is very high. In other words, the espoused theory suggests that a total costs approach should be used, while the theory in use demonstrates that the practitioners limit themselves to a direct unit costs approach. Hence, by addressing the gap between the espoused theory and the theory in use, future research could study the extent to which social and/or technical drivers allow the practitioners to ignore decision-making based on total cost considerations.

Conclusions
This study focuses on operations, with the dual aims of improving the current understanding of the drivers influencing the motives of individual decision makers, and thereby influencing decisions on local and global sourcing.
A literature review identifies seven drivers, which shows that the drivers of unit costs, transportation/logistics costs, lead time, quality, dependability, inventory level and flexibility influence the location of sourcing. Although unit costs are mentioned most often in existing articles, a review does not provide us with the knowledge necessary to rank the influence of the drivers identified here. These seven drivers are studied empirically. The practitioners interviewed in this study had various functional affiliations. Our empirical study indicates that the prioritisation of these drivers is as follows: 1) unit costs; 2) quality and lead time; 3) flexibility of sourcing; and 4) transportation/logistics costs, dependability and inventory level. Although unit costs constitute the most important driver, practitioners are aware that a total cost approach may be more appropriate; however, this is largely left at an intentional level. Global sourcing enables a reduction in unit costs, but the total costs of global sourcing often surpass those of local sourcing. A better approach to local and global decision making would pay more attention to quality, lead time, dependability, inventory level and transportation/logistics costs.

Finally, this study aims to understand the drivers driving practitioners. “Simple” drivers such as unit costs are favoured over “complex” drivers such as flexibility. We call for careful reviews of sourcing decisions in order to ensure the overall optimisation of costs, and for continuous lessons learned activities.

Abstract

As the sustainability debate gained momentum, the idea that firms should simultaneously pursue social, economic, and environmental goals (Elkington, 1997) was progressively incorporated. In face of difficulties or even the impossibility to equally serve all stakeholders at the same time (Jensen, 2010), further investigation on sustainability trade-offs (i.e. prioritizing one dimension in sacrifice of others) and on the insurance effect (i.e. the meeting of one sustainability goal possibly attenuating effects of poor performance in others) is urgent. Through the analysis of 20 variation vignette-based scenarios, the present study investigates these issues within a typical supply chain of the food industry.

Keywords: Sustainable supply chain management, sustainability trade-offs, insurance effect

Introduction

As the sustainability debate became mainstream (Lyon et al., 2018), the idea that firms hold responsibilities to society gained momentum. Tensions between profit-orientation perspectives (Friedman, 1970) and those of the stakeholder theory (Freeman, 1984), for example, seem to have influenced the expectations of consumers, pushing companies to stretch their focus beyond financial performance. Assorted and complex issues such as climate change (e.g. Procter and Gamble, 2015), preservation of wildlife (e.g. Kingfisher, 2018), the promotion of child education (e.g. Henkel, 2018), and social equality (e.g. Tata, 2016), among others, were progressively incorporated into corporate strategy. The meeting of these demands led organizations to (re)shape business models, in a way that their images among stakeholders could be enhanced, or at least preserved as they operated in a responsible manner. Just like a short blanket, however, the pursuit of one goal may lead to the sacrifice of others, even if an alignment is argued to be possible (Porter and Van der Linde, 1995).

Along with the perception that the objectives of companies should be reconsidered not to privilege the interests of specific groups (e.g. investors, customers) over others (e.g. local communities), real sustainability in business has been often pointed as unlikely (Wells, 2013), utopian (Lyon et al., 2018), or even impossible (Garrido, 2009). Despite noble, the idea that the needs of disparate parties could be concurrently fulfilled would be non-realistic. In analyzing the relationship between corporate productivity, social welfare and the accountability of managers within the corporate objective function, Jensen
(2010), for instance, claims that the maximization of more than one dimension would be logically impossible. Accordingly, the stakeholder theory would not allow purposeful decision making, once, at the same time its proponents claim that “managers should attempt to balance the interests of all corporate stakeholders”, they “refuse to specify how to make the necessary trade-offs among these competing interests” (pp. 32). With responsibilities extending beyond organizational borders (Bowen et al., 2001) and companies jointly responding for the negative social or environmental conducts of their partners (Fracarolli Nunes, 2019), the interaction between sustainability dimensions within supply chain contexts becomes particularly critic.

While the skepticism over corporate sustainability is not a novelty, the interaction between its dimensions indeed calls for further investigation. It is not clear, for example, the extent to which sustainability trade-offs (i.e. prioritizing one dimension in sacrifice of the others) are accepted by stakeholders. Likewise, the insurance effect (i.e. the meeting of one sustainability goal possibly attenuating the effects of poor performance in others) remains cloudy. In search to offer empirical evidence on that direction, the present study investigates the impact of these matters on distinct players of a typical multi-tier supply chain of the food and beverage industry (i.e. pesticide producer, farmers, companies from the food and beverage industry, and retail chains). Through the application of 20 variation scenario-based experiments, the impact of both sustainability trade-offs and the insurance effect on the perception of consumers is measured. More specifically, we analyze the power of social and economic performance to justify, excuse, or, attenuate severe environmental damage in terms of corporate credibility – trustworthiness and on the corporate credibility – expertise within supply chains. The objectives of the study are then framed into the following research questions: (1) Do stakeholders accept poor environmental performance if they are necessary for social and economic ones in supply chains (sustainability trade-offs)?; and (2) Does the meeting of social and economic goals grant supply chain partners with an insurance effect for poor environmental performance?

Along with adding to the understanding of sustainability issues in general, the investigation stretches the sustainable supply chain management debate to dimensions which, despite relevant to business practice, are often neglected in the field. Also, the joint analysis of the effects of sustainability trade-offs and the insurance effect on the corporate credibility of different tiers contributes to the research over the dynamics of intangible resources within supply chain contexts.

**Method**

**Experimental study design**

In search to test for the impact of the trade-off and the insurance effects on corporate credibility, we conducted a vignette-based experiment situated on a multi-tier food and beverage industry supply chain. Scenarios portrayed four different supply chain tiers (i.e. pesticide producer, farmers, companies from the food and beverage industry, and retail chains), within five distinct conditions – the first one featuring a neutral situation, and the other four referring to the social trade-off, the economic trade-off, the social insurance, and the economic insurance effects. Participants were randomly asked to focus on one supply chain player, and assigned with a variation scenario, generating 20 possible combinations. The base vignette featured the description of the fictitious US-headquartered Martin-Losano, profiled as one of the largest agricultural biotechnology companies in the world, present in 69 countries with over 20,000 employees, with annual sales yielding above USD 14 billion, and supplying farmers with products such as seeds, crop protection products, and data analysis. It was also stated to be a leading player in

2

3605
technology and innovation development, having intensively contributed to enhance productivity in food production.

Next, accusations for unsustainable practices were introduced, linking the company’s products to water contamination with heavy metals and pernicious chemicals in decades of litigation processes. Culminating in an international citizen court case represented by environmentalists, activists, academics, and jurists, the company was vindicated to have acted in violation of human rights, crime against mankind, and ecocide. Farmers, four large companies from the food and beverage industry, and three retail chains were also pointed as accomplices in the scandal, widely reported by the media.

Manipulations were then described in the text, giving rise to the five possible scenarios. In the first one, the chief executive officers from the accused companies and farmers’ representatives came forward to publicly admit the damage caused by the use of the products, configuring thus a base scenario with no variation. The second and third manipulations referred to the social and the economic insurance effects, respectively. While admitting to the environmental harm caused, they claimed that the company was also responsible for significant social and economic development through the enhancement of farmers’ productivity, reinforced by an extensive report. Examples of such would be a wider access to food, insuring minimum amounts of nourishment to less favoured populations, and the development of small farmers working in poor regions for the social contributions, and the proper remuneration of shareholders and employees, along with significant customer price reduction for the economic ones. Finally, the fourth and fifth manipulations concerned the social and the economic trade-off effects. In these scenarios, the same social and economic benefits were presented, but as having had the environmental harm pointed at the scandal as consciously triggered and, furthermore, as a necessary outcome that permitted the company to achieve such contributions.

Data collection, manipulation and realism checks
An initial pool of 698 participants from the US was recruited through a research-specialized crowdsourcing platform (Prolific Academic, www.prolific.ac). 51 respondents were removed from the experiment after failing attention gauge points, and 44 did not complete their participation, leaving a final sample of 603 respondents. Additional manipulation check points were provided after the main questionnaire, asking participants if the company was stated to have contributed to social or economic development, and if the mentioned environmental harm was caused in order to do so, and 83 responses were further removed from the sample as not having had correctly identified their respectively assigned variation scenario, thus configuring 520 valid responses, being 45.96% female, with average and median ages of 34.80 and 32 years old, and 78.46% Caucasian.

Scenarios were clearly classified by respondents as realistic (M = 6.048 against the mid-score 4, standard deviation = .043, t = 47.216, p-value = .000), believable (M = 6.028, standard deviation = .044, t = 45.672, p-value = .000), and likely (M = 5.984, standard deviation = .047, t = 41.955, p-value = .000). Furthermore, scenario check questions were inserted to test if respondents coherently captured the described vignette, regarding the company’s global presence (M = 6.571, standard deviation = .042, t = 60.135, p-value = .000), its annual revenue (M = 6.575, standard deviation = .041, t = 61.374, p-value = .000), and if it has been accused of severe environmental and social damage (M = 6.551, standard deviation = .040, t = 63.593, p-value = .000), to which participants’ means were significantly higher than the neutral point.
**Measurement instruments validation**

Corporate credibility was measured through the composition of expertise and trustworthiness (Newell and Goldsmith, 2001). Seven-point Likert scales were drawn from the literature, and Confirmatory Factor Analysis (CFA) validated the constructs, having both remained integrally with their original items scored above .80. Although $\chi^2$ and the $\chi^2$ per degrees of freedom ratio ($\chi^2/DF$) did not yield in favorable values, incremental indexes (comparative fit index – CFI, normed fit index – NFI, and incremental fit index – IFI) above the recommended .95 threshold demonstrated good model fit for both constructs, along with strong reliability in Cronbach’s alpha values higher than .90. Composite reliability also denotes the measurement models’ internal consistency and average variance extracted indicates that the larger portion of the constructs’ variance is being captured by the instruments, and not by measurement errors. Table 1 displays validation, unidimensionality, and reliability analyses, and the items for each operationalized construct.

**Results**

Hypotheses were tested through a series of ANOVAs, analyzing the differences in corporate credibility – expertise and trustworthiness for the distinct supply chain tiers when a social / economic insurance or trade-off effect takes place following an unsustainability scandal (Table 2), and for such effects given each supply chain link (Table 3).

| The numbers in parentheses are sample standard deviations. The numbers in brackets indicate the group means from which this group is significantly different at the 0.10 significance level, as indicated by Tukey and Games-Howell pairwise comparison tests. Results suggest that social insurance, economic insurance, and social trade-off effects have a significant impact in corporate credibility when it comes to perceived expertise and trustworthiness, yet with different repercussions for distinct tiers of the supply chain. The industry-level, for instance, was the one that benefited the less from the social insurance effect in terms of perceived expertise, but was also perceived as the most trustworthy link in comparison with the other players within the same situation. Farmers were also considered more trustworthy than the retail-level when the social insurance effect were drawn, and than the pesticide producer when the economic insurance effect was in place. On the other hand, the social trade-off effect seems to benefit the corporate credibility of the upper supply chain tiers – while the pesticide producer was granted with higher expertise scores than the retail-level companies, respondents seem to place higher trustworthiness in farmers than in the downstream supply chain players.
Discussion and Conclusion
As discussed throughout the text, with the popularization of the triple bottom line in business (Elkington, 1997), managers have struggled to simultaneously meet social, environmental, and economic performance. Within the perspectives of corporate social (Carroll, 1999) and environmental (DesJardins, 1998) responsibilities, industrial operations came to the center stage of public debate, being not only closely monitored by scientists, governments, and NGOs, but also openly debated in traditional and social media. Not restricted to single companies, these calls typically spread across whole supply chains, increasing the intricacy of the task. This “green revolution” in business was vigorous, to the point that “corporate sustainability – once viewed as utopian, irrelevant, or even subversive – has gone mainstream” (Lyon et al., 2018).

In that direction, by exploring the dynamics of sustainability trade-offs and the insurance effect within supply chain contexts, our investigation adds to the literature on sustainable supply chain management. Beyond contributing to the further understanding of the consequences of sustainability fails and misconducts, our results offer empirical evidence that supply chain partners may jointly absorb the consequences of such issues, at least in the eyes of consumers.

Abstract
The importance of supply chain sustainability has been recently receiving growing attention from practitioners, academics and policy-makers. Although there is a consensus that sustainability cannot be narrowly viewed as an issue within the organizational boundaries, most of the existing research tackle the issue by using an organizational perspective, instead of a more holistic and broad approach pertinent to the supply chain perspective. However, research on how supply chains learn, adapt and evolve on their sustainability trajectory is still scarce. This research aims to fill this gap and draws from the contingency theory and evolutionary theory to explore how the development of ordinary and dynamic capabilities affect the supply chain sustainability trajectory and supply chain sustainability performance. Methodologically, it employs a multi-method approach encompassing a large-scale survey, exemplary case studies and archival data. Contributions of this research extend existing supply chain sustainability theory and inform practitioners, academics and policy-makers on how supply chains actually learn and evolve on their sustainability trajectories.

Keywords: Supply chain sustainability trajectories, Contingency theory, Evolutionary theory
Introduction

Although supply chain (SC) sustainability has been receiving growing attention recently, details on how SC sustainability trajectories evolve overtime are still unclear. The literature converges to the fact that SCs do not become sustainable overnight, but go through a complex and dynamic learning process behind the evolution of their sustainability performance. This research aims to uncover key nuances of and empirically test how SCs learn and improve their sustainability practices. The construct of SC sustainability trajectories (Silvestre, 2015a) highlights that SCs go through learning loops to enhance the practice of sustainability. SC learning requires players within the SC who deliberately learn and incorporate sustainability knowledge into their daily business processes (López et al., 2004). The next section describes the concept of supply chain trajectories. The structural model relating SC trajectories to performance and research hypothesis ensue, followed by a section on research methods. The conclusion outlines key expected results and future practical, research and policy implications.

Supply Chain Sustainability Trajectories

This paper adopts a learning approach to SC sustainability (Spekman et al., 2002) to develop the theoretical framework. Through the lenses of the evolutionary theory, SCs are similar to organizations: they are initially immature, but they learn and accumulate knowledge and capabilities overtime (Nelson and Winter, 2002; Silvestre, 2015a). This SC dynamic evolution strongly connects to those type of capabilities SCs deliberately try to acquire or develop. SCs can focus their efforts on the acquisition/development of exploitation or exploration capabilities (Benner and Tushman, 2003). Yalcinkaya et al (2007: 66) defines exploration capabilities as the “ability to adopt new processes, products, and services that are unique from those used in the past” and exploitation capabilities as the “ability to improve continuously its existing resources and processes”. This evolutionary perspective relates to the elements of contingency theory, which suggests there is no single approach that can be applicable to all situations (Lawrence and Lorsch, 1967).

Contingency theory argues the environment within which a SC operates shapes its structures and processes (Flynn et al., 2010), and the way they behave and change. The four basic postulates of the structural contingency theory provides a powerful lens to analyze SCM trajectories. First, contingencies have an impact on the organizational structure, which has an impact on performance. Second, there must be some level of adjustment between the structural variable and each contingency level, where high levels of adjustment produce efficiency and low "fit" causes inefficiency. Third, there is no universal type of more efficient organization. Fourth, the impact of organizational structure on performance is empirically analysable (Donaldson, 2001). This contingent perspective highlights the notion of path dependence (Pierson, 2000), where decisions managers will make in the future depend on the decisions they have previously made.
Although very few studies combine path dependence with SC management, the literature argues that path dependence is a key construct to understand SC evolution toward sustainability (Holweg and Pil, 2008; Silvestre, 2015b). This dependence from the past can be positive as it represents the accumulation of critical knowledge, competences and experiences, but can also be negative by offering significant resistance to learning and implementing new sustainability practices. This harmful phenomenon is what the literature calls lock-in. In this context, this research aims to answer the following research question (RQ): How do ordinary and dynamic capabilities affect the SC sustainability trajectory and sustainability performance?

Through the lenses of the contingency and evolutionary theory, this empirical paper develops an innovative theoretical framework to analyze such issues and proposes a typology of SC sustainability trajectories and performance. This typology will be tested based on large-scale survey in four major supply chains in Brazil: automobile, oil and gas, agriculture and tourism. Survey instruments will be developed and employed to focal companies and 1st and 2nd tier suppliers/buyers. The survey will also serve to identify four case studies within each of those supply chains to be explored further.

**Structural model and hypothesis**

Very few studies combine path dependence with SC management, the literature argues that path dependence is a key construct to understand SC evolution toward sustainability (Holweg and Pil, 2008; Silvestre, 2015b). This dependence from the past can be positive as it represents the accumulation of critical knowledge, competences and experiences, but can also be negative by offering significant resistance to learning and implementing new sustainability practices. This harmful phenomenon is what the literature calls lock-in. Through the lenses of the contingency and evolutionary theory, this empirical paper develops an innovative theoretical framework to analyze such issues and proposes a typology of SC sustainability trajectories and performance. The theoretical approach led to the identification of two critical dimensions for the evolution of SC sustainability trajectories and performance (Figure 1). The construct of path dependence/lock-in is the dimension representing the contingent perspective of SCs. SCs can be classified as low or high path dependence/lock-in. Low path dependence/lock-in is associated with SCs that currently possess resources (e.g., knowledge, skills, workforce, and machinery) that are broad and flexible enough to change the course of action without an overwhelming resistance from the current state.
On the contrary, high path dependence/lock-in is associated with SCs that currently possess resources that are too narrow and specialized that resistance to change can be overwhelmingly high. The construct of capabilities is the second key dimension, representing the evolutionary perspective of SCs. SCs can be either classified as investing in exploitation capabilities, i.e., predominantly making efforts (e.g., learning, investments and innovation) that are directed towards improving existing sustainability capabilities, or exploration capabilities, i.e. predominantly making efforts that are directed towards acquiring new sustainability capabilities. Figure 2 depicts the structural research model.

<table>

</tr>
</tbody>
</table>

**Figure 1: Current state and efforts for future supply chain sustainability positioning**
Based on the extant literature, the model of Figure 2 offers the following hypothesis.

**H1:** Companies with higher level of organizational capabilities will have higher SC sustainability performance

- **H1a:** Companies that invest primarily in exploitation/ordinary capabilities will have lower SC sustainability performance than companies that invest primarily in exploration/dynamic capabilities
- **H1b:** Companies that invest in ambidextrous approaches will have higher SC sustainability performance than companies that invest primarily in exploitation/ordinary
- **H1c:** Companies that invest in ambidextrous approaches will have higher SC sustainability performance than companies that invest primarily in exploration/dynamic capabilities

**H2:** Path dependence mediates the relationship between organizational capabilities and SC sustainability performance

- **H2a:** The higher is the company’s focus on exploitation/ordinary capabilities, the higher the path dependence will be
- **H2b:** The higher is the company’s focus on exploration/dynamic capabilities, the lower the path dependence will be

**H3:** Environmental turbulence moderates the relationship between organizational capabilities and SC sustainability performance

- **H3a:** The higher is the environmental turbulence, the higher is the path dependence
Research methods

The research adopts a multi-method design for data collection and analysis, combining survey data with case study and archival data.

A random sample for the survey will be drawn from the 276 organizations affiliated to the Brazilian National Foundation for Quality, which were enrolled in the 2019 Brazilian National Innovation Award (BNA). The respondent’s organisation is the unit of analysis. For monadic constructs, the sole best respondent will be the plant manager or a high-ranked and experienced manager in services operations. To reduce the risks of common-method and single respondent bias in polyadic constructs, multiple respondents will be assessed in the focal firm and in the paired firms in the supply chain (either suppliers or buyers). This rigorous design corresponds to SCM type 4 design in Flynn et al. (2018). Perceptual scales will be validated using Anderson and Gerbing (1988) two-step approach to structural equation modelling. Confirmatory factor analysis will be used to validate unidimensionality, validity and reliability of the scales. Multi group measurement invariance will be tested for companies exhibiting high and low levels of environmental turbulence. Conditional process analysis (Hayes, 2017) of the moderated mediation model will run on SPSS and structural equation modelling will use the M-Plus software (Muthén and Muthén, 2017).

The four case study research will focus on firms representing high and low path dependence segments among those improving existing sustainability capabilities (exploitation) and those acquiring new sustainability capabilities (exploration). GRI, OECD and São Paulo Stock Exchange (BOVESPA) reports on sustainability will be used to validate survey and case study research whenever feasible.

Conclusions

This research contributes a new perspective to the analysis of SC sustainability. It offers a novel and rigorous multi-method research triangulating survey data with case study research and archival data on sustainability. It explores sustainability performance mediators and moderators through the powerful lenses of operations management practices contingency research (Sousa and Voss, 2008). By employing an innovative theoretical framework, that combines elements from the evolutionary and contingency theory, this paper aims to contribute to the discussion on how SCs actually learn and evolve on their sustainability trajectories. This research extends the literature of SC sustainability management and opens up several new practical, research and policy avenues. Practitioners can learn how to evolve in their sustainability practices to enhance sustainability performance. Policy-makers can gain insights about the contextual variables that would be more conducive to the economic, social and environmental gains of sustainability trajectories. Researchers will benefit from a novel approach to multi-method research that could be applied in different sets.

Enhancing the environmental performance of last mile logistics in e-commerce

Valeria Belvedere (valeria.belvedere@unicatt.it)
Catholic University of the Sacred Heart, Milan - ITALY

Abstract

This paper addresses the problem of sustainability in last mile logistics, trying to understand how consumers can be led toward the adoption of more eco-friendly delivery solutions. Building on the technology adoption literature and on extant studies on consumers’ sensitivity to environmental issues, this paper tests the hypothesis according to which, if consumers are properly informed about the superior environmental performance of parcel lockers, they become more willing to consider their adoption as an alternative to the traditional home delivery. Empirical data collected through a survey among 290 consumers supports this hypothesis.

Keywords: Last mile logistics, E-commerce, Sustainability

Introduction

This paper aims at understanding the conditions under which consumers become willing to choose delivery options for the last mile logistics that are more sustainable from the environmental viewpoint. The remarkable increase of the e-commerce and the widespread adoption of omnichannel strategies by “brick and mortar” companies are resulting in a huge diffusion of the home delivery as the best-preferred delivery option by the consumers. Although home delivery can bring about positive effects in terms of service level to the client, it also results in a higher traffic congestion in urban areas, as well as in a relevant increase of CO₂ emissions due to the low level of efficiency peculiar to home delivery (Belvedere and Grando, 2017; Brown & Guiffrida, 2014; McKinnon et al., 2012; Edwards and McKinnon, 2010). In this setting the adoption of alternative delivery solutions, namely parcel lockers, could be beneficial from the environmental viewpoint since it would increase the efficiency of the delivery process. On the other hand, such a choice could negatively affect the logistic service perceived by the client. This paper tests the hypothesis according to which if consumers are properly informed about the superior environmental performance of an alternative delivery option (namely parcel lockers), they would be more willing to consider its adoption.

In the remainder of this paper a brief literature review on last mile logistics and on its environmental effects is proposed. Then, the empirical evidence stemming from a survey conducted among 290 consumers is presented and conclusions and managerial implications are drawn.
Literature Background
The rise of the e-commerce phenomenon and more recently the widespread adoption of the omnichannel strategy are leading to a new interest toward logistics and supply chain management solutions suitable for supporting companies in this new scenario.

Indeed, the successful implementation of omnichannel strategies relies very much on the ability of the company to manage the tradeoffs between several performance attributes, providing customers with a good logistic service at reasonable logistic costs (Lim et al., 2016). In the early stages of the e-commerce, nearly two decades ago, several e-tailers started offering a limited variety of items provided to customers with a high speed and most of them failed in their attempt to gain reasonable market shares due to the high delivery costs. Nowadays, these trade-offs are becoming even more challenging and complex to manage since e-tailers are offering a much wider product variety, coupled with fast and flexible deliveries at competitive prices, while delivery costs continue to be a critical success factor, driven by labor costs, product’s value density, and average order size (Lim et al., 2018). Due to the relevance of the logistic process and namely of the last mile logistics for the success of any initiative of digital selling, several studies have tried to identify the main factors affecting the delivery costs, as well as the organizational solutions suitable for properly managing the trade-off between logistic service and transportation cost. According to Gevaers et al. (2014), the main drivers of the latter rely on the service level promised to the customer, the delivery security, the geographical features of the market in terms of people density, and the technological level of the fleet. Boyer et al. (2009) focused on the customer density and the delivery window as conditions that sharply affect the efficiency of the delivery in the context of e-commerce. Wollenburg et al. (2018) have highlighted the relevance of the nature of the product in the design of the last mile logistics. On top of these operational features that act as driving factors of the key design decisions of the delivery process, several proposals have been made concerning the distribution network design (Marchet et al., 2018; Melacini et al., 2018; Gevaers et al., 2011; Boyer et al., 2005).

This discussion is leading scholars and managers to think about the kind of logistic service that can be offered under reasonable conditions of efficiency, still providing the client with good levels of speed, dependability and availability of the products for digital purchases. This is leading companies to offer such services as click and collect or technological solutions as parcel lockers (Melacini et al., 2018).

Another area of concern associated with the delivery process in the context of e-commerce and omnichannel strategies is the environmental sustainability of e-fulfilment. Indeed, several studies have tried to understand whether and to what extent the wide adoption of home delivery (as a result of the rise of e-commerce) can result in a higher production of CO₂ emissions. In this regard, while some researchers claim that the overall effect can be even positive, due to the fact that consumers will not visit traditional shops anymore (Brown and Guiffrida, 2014), thus reducing the use of cars or other vehicles, other contributions seem to demonstrate the opposite. As matter of fact, in an omnichannel environment, consumers frequently visit shops in order to see and choose the product, then they place the order on-line, asking for home delivery in most cases. This choice results in the fact that the delivery process takes place in a way which is highly inefficient, due to the use of smaller vehicles to support the last mile logistics and to their low level of saturation (McKinnon et al., 2012; Goodman, 2005; Sarkis et al., 2004). The widespread phenomenon of returns of goods sold online further worsen the environmental performance of e-commerce.
Edwards and McKinnon (2010) claim that comparative analyses between the two scenarios (pick-up at the traditional shop vs. home delivery) can result in a wide range of different (and conflicting) results due to the complexity of the shopping activity, which can be carried out in many different ways and through the adoption of several vehicles that support the flows of goods and people.

In order to cope with the increasing complexity (and the related lower efficiency) of home delivery, some new technologies are now emerging, which try to involve the customer into the fulfillment process. This is the case of parcel lockers, which can be adopted to combine a good enough service level to the client with an improved efficiency and eco-friendliness of the last mile logistics (Vakulenko et al., 2017). Such new technological alternatives are leading to the development of new types of organization of the order fulfillment process (Ranieri et al., 2018), which aim at achieving three main objectives: providing the client with the best possible shopping experience in the context of e-commerce; improving the efficiency of the delivery process; improving the environmental performance of last mile logistics.

**Research question and methodology**

Building on the above mentioned literature review, the following research questions are proposed:

- What drives the willingness of the client to use parcel lockers instead of home delivery solutions?
- If a client is properly informed about the higher environmental sustainability of the parcel lockers, would he/she become more willing to use them?

To answer these research questions, a survey was conducted among consumers. To design the questionnaire, the second UTAUT model proposed by Venkatesh et al. (2012) was leveraged, which describes the drivers of acceptance and use of technology. According to this model, the factors that influence the willingness (“behavioral intention”) to adopt a technology are: performance expectancy; effort expectancy; social influence; facilitating conditions; hedonic motivation; price value; habit. Although this model was considered a sound interpretative framework suitable for understanding the levers behind the customers’ willingness to use a technology (namely parcel lockers to collect products bought through an e-commerce system), some modifications have been made in order to make it more consistent with the context of e-commerce and parcel lockers as delivery option. In particular, as it can be seen in Figure 1, the “Habit” construct has been removed since the use of parcel lockers is still at its beginning, so it can be excluded that consumers have already developed any sort of repetitiveness in its use. Three new constructs have been added to the second UTAUT model. In particular, “Technology anxiety” has been included (as it has been already done in other extensions of the second UTAUT model) since the technology under analysis is new and is a self-serving one.

On top of these drivers, the questionnaire used for this research encompassed also two more constructs. One refers to the “Environmental knowledge” of the customer, the other concerns his/her “environmental sensitivity”. The former construct is understood as the ability of individuals to recognize symbols, concepts and behavior patterns related to environmental protection (Laroche et al., 2001) and has been operationalized through questions aimed at understanding how the customer reacts to information concerning the higher level of sustainability of parcel lockers in the context of e-commerce. The latter has been operationalized through questions aimed at testing the environmental sensitivity of the respondents (Markle, 2013). We assume that
“Environmental knowledge” can have a positive direct effect on “Behavioral intention” (on top of all other drivers previously highlighted by Venkatesh et al., 2012). We also formulate the hypothesis that “Environmental sensitivity” can have a moderating role in the relationship between “Environmental knowledge” and “Behavioral intention”.

Questions related to the second UTAUT model (and its extensions) required answers on a 1-7 Likert scale. Although all of them were based on extant studies, their wording has been adapted to make them consistent with an e-commerce context and to clearly highlight that the technology under analysis was the parcel locker. Totally, 290 usable questionnaires have been collected insofar.

![Theoretical framework](image)

**Figure 1 – Theoretical framework**

**Empirical evidence**

A confirmatory factor analysis (CFA) was initially carried out to check that all the constructs encompassed in the model are properly described by the related questions. The results show that all constructs, but “Facilitating conditions”, enjoy a Cronbach’s Alpha higher than 0.6 and a Variance Explained above 0.5. Thus, “Facilitating conditions” was excluded from the subsequent analyses.

Then, a regression analysis was conducted in order to understand whether and to what extent the drivers of our model can explain the willingness of the client to use parcel lockers instead of traditional home delivery, and if “environmental sensitivity” is a moderating variable. Our evidence shows that the adjusted R-square on the overall model (including also the moderating variable) is 0.706, which witnesses the robustness of the model. Furthermore, it is also demonstrated that, among all predictors of...
“Behavioral intention”, only “technology anxiety” does not show a statistically significant regression coefficient. Furthermore, the driver with the highest regression coefficient is “Environmental knowledge”. Finally, “Environmental sensitivity” is not confirmed as a moderating variable.

Conclusions and managerial implications
This paper addresses a topic of increasing relevance, i.e. the sustainability of the delivery process in the context of e-commerce. The empirical evidence reported in this study demonstrates that a customer properly informed on the higher level of environmental sustainability of alternative delivery options (namely parcel lockers) becomes much more willing to use them. This positive effect is not moderated by client’s sensitivity to environmental issues, which means that even customers who are not strongly concerned about this topic can change their delivery preferences if properly informed on the related environmental performance.

Identifying the Formula of Success for Bike-Sharing Operations: Evidence from Sweden and Greece

Dr Alexandros Nikitas (a.nikitas@hud.ac.uk)
Huddersfield Business School, University of Huddersfield

Abstract

A new mobility ethos is needed to overcome the problems that have been accumulated by a transport paradigm prioritising automobiles over people. Bike-sharing, a measure promoting travel behaviour change, could be part of a refined mobility provision toolbox. Despite a rapid emergence during the last decade, as evidenced by 1963 operating local schemes globally, bike-sharing is attracting negative attention. Numerous schemes closed down as huge financial or operational failures stigmatising bike-sharing’s brand. This paper identifies the formula of success for bike-sharing operations based on evidence from two survey-based studies in Sweden and Greece and from a state-of-the-art case study analysis.

Keywords: Bike-sharing, Shared Use Mobility, Sustainable Transport Operations

Introduction

A predominately car-oriented transportation has been the cornerstone of urban development for decades now; a cornerstone associated with adverse effects on social, economic and environmental sustainability. The problems of the reign of the conventional, fossil-fuelled, human-led privately-owned car include increased traffic congestion, climate change, local air and noise pollution, road injuries or casualties, obesity and decline in physical activity, chronic diseases and loss of social engagement (Nikitas et al., 2016; Thomopoulos and Nikitas, 2019). A new urban mobility ethos is needed for cities looking to effectively address these challenges, which among others will require from policy-makers and mobility suppliers to promote voluntary travel behaviour change via powerful shared transport initiatives. Bike-sharing, the greenest form of shared use mobility interventions, can be defined as a system that provides affordable short-term access to a fleet of locally customised bicycles on an “as-needed” basis (Nikitas, 2018).

Bike-sharing, typically framed as an ideal first- and last-mile travel solution for congested metropolitan environments (DeMaio, 2009) and less often tested for the context of smaller and medium cities (Caulfield et al., 2017) is now with the recent game-changing introduction of station-less, free-floating, GPS-equipped schemes more relevant than ever before. It has emerged rapidly across the globe, with 1963 operating schemes and approximately 14,850,000 self-service public bicycles and pedelecs in use (Meddin and DeMaio, 2019), as an easily implementable modal shift mechanism that is iconic for the host city’s commitment to sustainable transport and logistics operations (Nikitas, 2018).
But at the same time bike-sharing, especially with the somewhat reckless and under-designed implementation of numerous dockless systems, is attracting negative attention with tens of schemes closing as huge financial or operational failures putting major public bicycle companies in jeopardy. The withdrawal of Mobike from Manchester and Ofo from London in the UK, who represent the two global bike-sharing colossuses that have invested in Europe, and the closure of Bluegogo, China’s third-biggest bike-sharing company with 20m users and £226m in deposits at its zenith, underline the need to revisit what makes bike-sharing services efficient in an operational level and how local schemes can transform to valuable smart city ingredients and flourish long-term.

This paper aims to identify and re-write the formula of success for bike-sharing operations by developing policy and business lessons that will help policy-makers and transport providers in establishing and managing successful micromobility schemes. This paper supports that the concept of bike-sharing is not a failing one that will be dismissed in the near future but a resourceful one that is simply “tested” because of bad operational thinking and decision-making.

Hereafter, the paper provides a description of the chosen methodology, a concise analysis of the key results, a discussion that will identify lessons learnt and suitable policy and industrial recommendations and a conclusion section that will epitomise the genuine contribution of this work to academia, policy and practice.

Methodology

This work adopts a dual methodological approach for providing validated and triangulated findings that could be widely representative and generalisable. It is a systematic effort designed to collect and analyse results that will allow the author to understand how bike-sharing can re-establish its reputation as a pragmatic long-term transport alternative and how local systems can develop better operations strategies that fit the needs of the cities hosting them.

On the one hand, it is based on quantitative evidence from two survey-based studies held in Gothenburg, Sweden (mid-sized city ~520,000 residents) and in Drama, Greece (small city ~ 60,000 residents) looking at acceptability and usage determinants. The two surveys captured road user attitudes for Gothenburg’s 1000-bike station-based scheme Styr&Ställ that was established in 2010 and for a hypothetical small-scale forthcoming city-centre scheme in Drama. The combined sample refers to 1175 respondents that could be users, future users or non-users of the local scheme(s); 535 respondents in Sweden and 640 respondents in Greece.

On the other hand, this paper will present the key findings of a state-of-the-art analysis of the latest developments in bike-sharing operations using exemplary bike-sharing case studies from across the world. Some of these case studies refer to successful implementation and service delivery stories and others to systems that failed to establish commercially viable operations capable of adding value to the image of the city hosts.

This versatile mixed method approach ultimately creates a synthesis of well-supported arguments that may allow the delivery of some important lessons, valuable to transport academics, urban policy-makers and mobility providers that could be applicable to a wider context at least for similar urban environments and schemes with the ones discussed in this paper.
Results and analysis

Survey results
This part of the research work provides evidence that if bike-sharing is introduced, operated and promoted adequately could be acceptable in small and medium sized cities (including those that have yet to establish a pro-cycling culture) even from people not intending to ever use them. Acceptability could be therefore regarded as equally, if not more, important than strict usage-related criteria for success because it means that people would be willing to see more investment going towards bike-sharing because of its ability to add to their city’s smart and eco-friendly image. These are valuable lessons proving that bike-sharing is not a fundamentally flawed concept that somehow emerged because of a rush to push forward relatively inexpensive sustainability-centric mechanisms; it is a sound shared use mobility initiative that in some case suffers from bad operational management and is doomed from unrealistic profit expectations.

Gothenburg study
Gothenburg’s dock-based Styr&Ställ is highly supported by more than 90% of the city’s residents despite usage rates reflecting some level of participation to the scheme by only a quarter of the study’s sample (Nikitas et al., 2016; Nikitas and Sochor, 2018).

More specifically, the vast majority of the respondents believed that Styr&Ställ is an affordable travel mode with the capacity to promote healthy living, improve road traffic conditions, make cycling more popular, complement the city’s other public transport services and help the city becoming more liveable. Also 85.3% of them recognised bike-sharing’s potential for making people’s travel behaviour increasingly less car dependent. Most importantly though, the survey participants acknowledged the significance of bike-sharing for their city; 92.4% agreed or strongly agreed that the scheme is good for Gothenburg and 93.5% disagreed or strongly disagreed with the notion that Styr & Ställ is a sub-standard transport initiative. Even the respondents that have never used it before or self-reported no (or little) intention to bike-share in the future were positive towards the scheme. Many respondents were also supportive of the scheme’s further expansion through more bike-sharing investments and considered that the scheme is a viable public service for the city; 86.5% and 96.1% agreed or strongly agreed with these notions respectively. Also, only 6.5% of the people that had actually used the scheme considered that there is something fundamentally flawed with it. It is almost a unanimous decision for Gothenburg respondents that the local scheme is a good addition to their city’s transport provision that needs to continue its operations and even expand.

Despite these high acceptability rates, it was found that the majority of the respondents rarely used the scheme even as a secondary travel option; 76.8% of the respondents stated that they never use the scheme while only 2.8% use it as their main mode choice. Nonetheless, longitudinal data collected for the first four full operating years of Styr&Ställ (based on respondents’ self-reporting capacity) indicate a small but distinct annual increase in the number of participants that used the scheme especially for those using it as a main or a secondary travel alternative to their typical modal choice. This underuse indicates that there is, in theory, a massive untapped potential for utilising, in real usage terms, the scheme’s wide acceptance.

The reasons for which the respondents of Gothenburg did not use the bike-sharing scheme that often have also been captured (each respondent was limited to give only two reasons when filling in the survey). Only 14.9% of the respondents answered that limited road safety could act as an obstacle for them in using bike-sharing, while 30.9% felt that lack of good bike-sharing related infrastructure was an issue. Another 16.9% of
the respondents thought that cycling was not ideal for the city and 11.5% that bike-sharing was not convenient for all purposes. Nevertheless, the most popular answer by far (i.e. 41.1%) was that people had their own bike so they did not need to bike-share. Figure 1 presents the full set of these results.

![Figure 1 – Reasons for not using bike-sharing more regularly or at all (Sweden)](image)

**Drama study**

The second survey results were in some regards very similar to the Gothenburg’s key findings. Close to 90% of Drama’s respondents thought that bike-sharing could be a good scheme for their city despite significantly lower usage intention rates (that could have been exaggerated due to unintended optimism bias).

Overall, Drama’s respondents recognised that bike-sharing could be beneficial for their city. The vast majority of them considered that bike-sharing is a sustainable modal option that could improve road traffic conditions, compliment other means of public transport, offer an inexpensive transport option for the society, promote wellbeing, make cycling a more popular travel choice and reduce people’s reliance on automobiles. However, perhaps the strongest finding, directly referring to the public acceptance of an eventual scheme, was people’s disagreement to the notion that “public bicycles constitute an investment that they would not like to see being materialised”. In absolute numbers, 86.5% of the respondents disagreed or strongly disagreed with this notion; only 5.1% agreed or strongly agreed and 8.4% were neutral respectively. The respondents self-reported relatively high levels of potential usage with expected usage in a somewhat frequent basis being 46.9% and “rarely or never” being 31.5%. Still these rates were considerably smaller than the reported acceptance rates.

The main reasons according to the respondents of Drama for being reluctant to cycle and potentially to use public bicycles are principally associated with the lack of cycling-oriented or bike-friendly urban infrastructure and the feeling that currently there is only
limited road safety for cyclists. Almost one in every two respondents made the case for each of these two specific answers making clear that physical and cognitive barriers associated with the way a cyclist is hosted in one’s respective urban environment constitute the key in giving up the ideas of cycling and bike-sharing. It is true that only recently the construction of bike lanes, bike roads and bicycle racks has been initiated in the city of Drama; thus these specific attitudes are well justified (Nikitas, 2018). Dislike of physical effort was chosen by 12.5% of the respondents, lack of time by 13.8% and cycling and bike-sharing not being suitable for the city for 21.9%. Figure 2 presents the full set of these results.

![Figure 1 - Reasons for not cycling and not being willing to eventually bike-share (Greece)](image)

**Case study analysis:**
Perhaps the most critical problem for conventional bike-sharing schemes is the renting and returning station-based operations that do not allow door-to-door convenience; traditional bike-sharing assumes that users can rent a bike from one of the existing bike-sharing stations and return it either to the original station or another station in a different location after using them. Schemes like Seattle’s (U.S.) Pronto paid (among other reasons including local politics, hilly topography and mismanagement) its poorly and sparsely placed docking stations and the lack of having a systematic and incremental expansion strategy by ceasing its operations (Small, 2017).

Over the last five years, many operators are actively trying to solve this problem by providing station-less, maintenance-free, intelligent bicycles that lock and unlock through the use of mobile applications. This transition is led mainly by a few Chinese bike-sharing start-ups including Mobike and Ofo, a pair with a combined valuation likely to have exceeded in 2018 the £3bn threshold since they have been supported by two of the biggest internet giants Tencent and Alibaba,

Mobike has now bike-sharing operations in 200 cities and 16 countries around the world and is responsible for as many as 30 million daily trips with a fleet of 8 million bikes including electric options. As of July 2018, Ofo claimed to have around 15 million
bikes in operation in more than 300 cities across 22 countries, as well as 250 million
global users but since then it has considerably scaled down its operations outside China.
Introducing with an unprecedented speed, hundreds of schemes of this new breed of‘door-to-door’ bike-sharing systems, in China, the wider Asia and finally over the last
two to three years in North America, Australia and Europe, the homeland of
conventional public bicycle programmes, has the power, in theory, to transform the
world of cycle hire, in a similar fashion with the one that saw Uber and other
ridesourcing initiatives conquering carpooling and taxi-related services. Nevertheless,
this monumental, and in many cases somewhat rushed, “embracement” is neither
unproblematic nor without a fair share of early fiascos and overwhelming questionmarks
that have recently disrupted the rise and stigmatised the public image of bike-sharing.

Stories of failure
In November 2017, China’s third biggest bike-sharing company and the first dockless
bike-share system to launch in the U.S. Bluegogo, went bankrupt, creating for the first
time a dark cloud over the future of dockless bikes. The bankruptcy of a company that
grew at an incredible pace to compete Mobike and Ofo, peaking at 350,000 bicycles in
China alone and poised to conquer San Francisco, raised concerns that there are simply
too many bikes at very low prices on offer and insufficient demand. Bluegogo collapsed
leaving vast bike-share graveyards that challenged the ‘sustainability’ and ‘eco-friendly’
value of the dockless bike-sharing concept after falling according to Gillin (2018) $30
million in debt and struggling to repay customer deposits with the surviving bikes being
sold as low as $5 per piece. Bluegogo’s chief executive apologised for this collapse
saying that he had been “filled with arrogance” (Haas, 2017) that practically meant that
the company had unrealistic expectations, expanded too soon in an unsustainably big
scale and was mismanaged.

Wukong Bicycle, a minor Chinese start-up of 1200 bikes in the notoriously hilly
Chinese city of Chongqing went out of business after only six months of operations in
July 2017, since 90% of its bikes were lost presumed either missing or stolen. This was
the direct consequence of the operators’ fatal mistake to not install GPS devices in their
fleet. Beijing-based bike-sharing firm 3Vbike also bankrupted in June 2017 after losing
more than 1,000 of its bikes in just four months of operations; not having its own mobile
app to track the bikes and having to depend on a cycle location tracking function on its
WeChat page was the key reason for this downfall. This scheme also failed to get traction
due to limited fundraising; the owner had to purchase the bikes himself in lack of other
investors (Nikitas, 2017).

The operations of the Mobike Manchester scheme, the first of its kind in the UK,
launched in June 2017 is another story of misfortune for the concept of dockless bike-
sharing. In a span of 15 months, Mobike had to cease its operations in Manchester
because of “unsustainable” losses from theft and vandalism making this the first time
the Chinese firm has abandoned a city because of antisocial behaviour. Stationless
mobikes have been found dumped in canals and bins, vandalised, and others have been
stolen making the company representatives to suggest that the system has been
“misunderstood” and that “the learning is already being put to good use for creating a
more suitable scheme in the not too distant future”.

Ofo in an even more dramatic fashion was forced to withdraw from most of its UK
market including the cities of Norwich, Sheffield and Oxford and as of January 2019
from London that was home of 3,000 Ofo bicycles. The company admitted that its UK
business was loss-making and had to move to a different direction.
Similarly, Hong Kong-based bike-sharing operator Gobee shut down its operations in France in February 2018 after suffering what the company called “mass destruction” of its fleet. Gobee, which had 2,000 bikes in Paris and claimed around 150,000 users across the country, reported that 3,400 of the company’s bikes have been damaged and more than 1,000 have been stolen (Agence France-Presse, 2018). Gobee pulled out of Belgium for similar reasons meaning that this was not an isolated country-specific issue.

OBike, another start-up with international reach, also exited from some of its key markets with most important the ones in Singapore and Melbourne during 2018. These cities having a long track record of supporting environmentally friendly urban growth are now trying to ensure responsible bike-sharing use, introducing stricter licensing regulations that prevent visual pollution and unsustainable public space intrusion. Complying with these regulations and in other cases with the helmet rules that govern bicycle use in Australia, can be expensive, as it requires investments in technology, security, and management. Operators, like OBike, sometimes decide that this extra investment is excessive, so they concentrate on other cities with softer regulations.

These examples have generated concerns about the long-term viability of bike-sharing and mainstream allegations that there is now a body of evidence proving that bike-sharing has been opportunistic or even failing as a concept. de Chardon (2019) concludes that most schemes typically benefit the privileged, help little to increase mass cycling transport and are used as easily deployable technological (false) solutions to contemporary problems while advancing unjust tendencies to privatise public space and services.

Stories of success:
Nonetheless, as the primary data research has indicated there is much more than failure and misfortune associated with bike-sharing operations; there is also hope and genuine potential for improvement that could help restoring the image of bike-sharing.

The government of the city of Hangzhou in China launched Hangzhou Public Bicycle in January 2008 starting with 2,800 bicycles, 30 fixed stations, and 30 mobile stations (stations which can be moved to meet demand). This scheme went on to become the world’s largest bike-sharing system with 100,000 bicycles and 4,100 stations as of December 2018. This scheme has been successful in acting as a complement to existing public transit and as a tool for modal shift; members exhibited a higher rate of auto ownership than non-members meaning that bike-sharing was attractive to car owners (Shaheen et al., 2011). Some of the key success factors are: the low subscription fee, the availability of bicycles throughout the city, the subsidies from the local authorities, the fact that this was an initiative that the local transport agency created and is still a not-for-profit scheme (i.e. the riding is free for the first 60 min), its complete integration with the other public transport services, its good real-time information system, the upgrade of the bike hardware and the existence of a ‘green corridor’ that promotes cycling in general. Hangzhou, a city with a registered population exceeding 9 million, widely considered as an emerging technology hub (home to the e-commerce giant Alibaba) also hosts some dockless bike-sharing fleets from Mobike, Ofo, Hello Bike and Qibeji. Chen et al. (2018) argue that Hangzhou Public Bicycle has already become rooted in the city as one of the public transportation modes and because its stable performance and the city’s features fit for cycling, the habit of riding bikes has been awakened in Hangzhou, which has in turn provided an ideal environment for free-floating bikes to come into use.
Introduced in 2011, originally as Barclays Cycle Hire, London’s bike-sharing scheme, Santander Cycles is a station-based system that can be accessed by anyone with a credit or debit card, with daily usage charged at £2 for unlimited journeys of up to 30 min. There is the option of annual membership charged at £90 (~25p per day). The scheme after incremental strategic expansions, now spreads across 100 km² of London and is the largest cycle hire scheme in Europe with 11,500 bicycles available across 750 docking stations (Transport for London, 2019). It has approximately 240,000 active members making over 10 million annual bicycle hires and its continued expansion is viewed as a central component of the Mayor’s policy to transform London’s transport system into one which is based on sustainable modes (Morton, 2018). Therefore, the scheme is subsidised and promoted heavily by Transport for London and is well linked with all the public transport modes of the city. Santander Cycles have demonstrated the capacity to normalise the practice of cycling in city life; its users are not solely representatives of particular social cohorts like sporty people (Goodman et al., 2014). Also, the scheme has become more equitable over time, encouraging women to use it, and with the eastern extension increasing the share of trips made by residents in poorer areas features that have been partly offset by increased prices (Goodman and Cheshire, 2014). As a whole, this is an award-winning intervention recognised not just for its impact on transport in England’s capital city and its sustainability value but also for its innovative design, the public relations exercise and the challenging delivery timescales.

Dublinbikes is a public bicycle rental scheme which has operated in Dublin, Ireland since June 2009. At its launch, the scheme, which is sponsored by JCDecaux in exchange for 72 free advertising spaces around Dublin, used 450 bicycles organised in 40 stations. Now the scheme has 114 stations and 42,000 active annual subscribers and is one of the cheapest schemes in Europe with a €25 annual fee. Dublinbikes was the 17th bike-sharing scheme ever and has been considered one of the most successful local applications in the world as reported regularly in media (e.g. Duly, 2011; Collison, 2017), however occasionally there were reports suggesting that progress has stalled making the scheme loss-making. Synergies with industry have been notable for the Dublin scheme. Coca-Cola Zero was a commercial partner with Dublinbikes for three years (June 2014 to June 2017) with Just Eat taking over on July 2017 for the next three years with plans to invest €2.25 million in the scheme over its tenure; in both cases the name of the scheme was rebranded accordingly.

Discussion: Lessons to be learnt
The primary data analysis provides strong statistical evidence that bike-sharing is still a timely and meaningful proposition for urban policy-makers that is widely accepted even from those citizens not expected to be scheme subscribers or occasional users; the survey respondents coming from two very different urban environments would support their respective cities if they decided to invest on the schemes in both occasions.

The case study analysis identifies that inflexible standardised business models and operation strategies lacking an ability to tailor their offering to different areas, largely adopted from China, are not suitable for all urban environments. Dock-based systems despite their inability to provide door-to-door services seem to do better than dockless schemes for now. Expansion tactics that have been over-aggressive, defied established competition, did not actively seek the collaboration and support of the local hosts and were not adequately justified by travel demand data have failed. Schemes that were tailored to the city needs, were integrated or complemented the public transport provision, had a clear incremental expansion strategy, kept relatively inexpensive prices, secured the support of the local authorities, forged synergies with commercial partners
and embraced technology have been successful and set the bar for the industry. Some recommendations that this work can provide primarily to operators but also to cities looking to host sustainable and long-lived bike-sharing schemes that will add value to their image suggest that they should:

- Make unique city-specific plans for delivering each scheme. The ability to tailor an offering to reflect the character of a city and the norms of its citizens is critical.
- Prioritise the scheme’s long-term success over easy profit and unrealistic revenue return expectations; bike-sharing should be user-centric and not profit-centric.
- Realise that the bulk of benefits that a scheme can deliver refer to avoiding the negative externalities of excessive car usage. This is a profit worth paying so operators should actively seek the support of the cities when possible in subsidies and supporting infrastructure.
- Work together (operators and cities) so the latter will be incentivised to support their local schemes. Private-public partnerships can work.
- Seek strategic commercial collaborations like the London and Dublin schemes. Extra financial support and brand adding value is always helpful.
- Acknowledge that an oversaturated bike-sharing market can be lethal, especially for smaller providers, although bigger operators could be also be in jeopardy as evidenced by the examples of Bluegogo primarily and Ofo to a smaller extent.
- Invest more efforts in regulating the responsible usage of bikes. Protection mechanisms and penalties for vandalism and theft should be in place from day one. Cities should support these efforts with better policing.
- Employ joint market and education campaigns to promote bike-sharing culture and encourage people to adopt a positive attitude towards these bikes. Cultural engagement from the outset is a prerequisite for success.
- Focus on providing fair fares, member subscriptions, and “ways out”.
- Finance better business planning and bike management; companies need to constantly innovate to stay on top of this very dynamic market. The option for docking stations and enough people on the ground to ensure schemes are reliable and serve their purpose should be provided.
- Technology is not always a panacea; it is only one of the several tools in the toolbox of successful bike-sharing provision. However, mobile apps, rental machines, GPS tracking should be modern, user-friendly and functional.
- Manage the distribution of bikes more effectively and responsibly. Operators need to be more accountable about visual pollution. In exchange cities could be more flexible with their regulations (e.g. easing helmet use regulations or help supplying shared use helmets).
- Recognise in line with Zhang (2015) that bike-sharing systems need to be carefully developed to appreciate the quality and timely interplay between the physical design of the system and the provision of services being offered.

**Conclusion**

This work provides an evidence-based roadmap for helping a still growing, but somewhat jeopardised and stigmatised, mobility innovation to avoid an unforgiving path that leads to an unsustainable and ill-fated future. This paper disengages “scheme success” from a strict usage rate perspective and informs policy-makers and scheme suppliers that citizens, want to see systems that deliver sustainability benefits to be supported by city funds. More importantly though it generates policy and business lessons from current practice forming a unique survival guide for running micromobility schemes.

Do relationships matter?
Linking the advancement of shipper-logistics service provider relationships with green logistics implementation

Amer Jazairy (amrjai@hig.se)
University of Gävle

Robin von Haartman
University of Gävle

Abstract

The contract logistics literature implicitly suggests that establishing advanced relationships between shippers (logistics buyers) and logistics service providers (LSPs) plays a role in facilitating green logistics practices. We systematically test this claim through surveying 335 companies (170 shippers; 165 LSPs) in Sweden. Using factor- and multiple regression analyses, we confirm that implementing green logistics practices is influenced by advanced relationships settings, but not all practices adhere to this. Also, a distinction is made on whether relationship advancement is expressed by the contract design or the degree of integration between the partners; the former better explains the implementation of the practices.

Keywords: LSPs, environmental sustainability, logistics relationships

Introduction

The destructions caused by the logistics industry on the environment have placed logistics service providers (LSPs) under the spotlight when logistics activities are scrutinised (Grant et al., 2017). The transport industry alone is accountable for 23% of total greenhouse gas emissions in Europe (ESLMM, 2016), and such figures are expected to rise in parallel to the growing world economies (Grant et al., 2017). Despite increased LSPs’ adoption of green practices over the last decade (Centobelli et al., 2017), there is still a lot to be done; LSPs still possess little control over the emissions released by their operations (Nilsson et al., 2017). However, a substantial share of responsibility lies on the shoulders of shippers (i.e. logistics buyers) as well, since they are the ones choosing the LSPs to work with and the solutions to be deployed (Wolf and Seuring, 2010). Consequently, there is a growing scholarly demand for investigating shipper-LSP dyads to conceptualise how their relationships design and settings could influence the facilitation of green logistics practices (Centobelli et al., 2017; Evangelista et al., 2018).

In parallel to this, the concept of outsourcing logistics activities by using LSPs has surpassed a state where shippers simply exploit the competencies of LSPs, towards a more advanced competence development state that cultivates mutual benefits for both actors alongside advancing their dyadic relationships (Andersson and Norrman, 2002; Bask, 2001; Halldórsson and Skjøtt-Larsen, 2004; Sharma and Choudhury, 2014). Halldórsson and Skjøtt-Larsen (2004) deployed a resource- and competence-based view, together with
a transaction cost economics (TCE) one, to reconceptualise a typology of shipper-LSP relationships, arguing that such relationships advance alongside a triaxial development of competence, degree of integration and asset specificity between the partners. Recent studies on green logistics within the contract logistics domain signal a higher likelihood of conducting green logistics solutions within advanced shipper-LSP relationships (Eng-Larsson and Kohn 2012; Jazairy, 2018; Monios and Bergvist, 2016; Sallnäs, 2016). According to these studies, jointly-commenced green logistics practices (particularly those requiring up-front investments) seem more detectible in relationships that are beyond arm’s-length arrangements, based on the reasoning that such practices demand: a willingness of shippers and LSPs to share risks/rewards, long-term contracts to enable LSPs’ green investments, mutual development of green performance measures, and a sufficient level of trust and transparency between the partners. However, studies making such claims are mainly based on inductive and exploratory methods, where insufficient generalisability forms a clear limitation. Besides, there is a need to distinguish which green practice necessitates such advanced relationship settings for its facilitation, as some practices seem rather cheap and easy to implement with no prerequisite for shippers’ substantial involvement (Nilsson et al., 2017; Sallnäs, 2016).

Given the rationale above, and to our best knowledge, no survey study has been conducted to test the linkages between shipper-LSP relationship advancement and the implementation of different green logistics practices, which forms the purpose of this paper. A research question is formulated to serve the purpose:

RQ. How can the advancement of shipper-LSP relationships explain the implementation of green logistics practices in such relationships?

The survey utilised in this study is based on a large sample of shippers and LSPs operating in Sweden. In line with Halldórsson and Skjott-Larsen (2004), two theoretical lenses are used to describe the advancement of shipper-LSP relationships: resource- and-competence-based view, and TCE. Findings of this paper enable understanding whether the way shipper-LSP relationships are established has an influence on the facilitation of green logistics practices. Understanding this linkage can aid practitioners in shipper/LSP firms in deciding whether or not they should strive for forming advanced relationships with their logistics partners when certain green logistics practices are pursued.

The remainder of this paper is structured as follows: the next section covers a literature review on shipper-LSP relationship advancement, green practices in the logistics industry, and possible linkages between the two. The succeeding section describes the survey used and the data collection/analysis techniques. This is followed by the findings and discussion sections. The last section draws the main conclusions of this study, together with its limitations and directions for further research.

Literature review
Shipper-LSP relationship advancement
Grounded on a TCE standpoint, Cox (1996) guides firms to shape their contractual relationships with their suppliers by considering the competencies needed to provide the goods/services in question and the degree of asset specificity associated with such competencies. Firms should form arm’s length alliances when asset specificity is low, and move towards more strategic alliances as asset specificity increases—in conjunction with the strategic importance of the skills needed for creating these goods/services. When the skills are associated with a very high degree of asset specificity, they become the core competencies of the firm, favouring means of internal contracting such as merger
acquisitions or vertical integration. Supplemented with a resource- and competence-based view, Halldórsson and Skjótt-Larsen (2004) apply Cox’s typology onto the contract logistics context as a basis to identify three stages of shipper-LSP relationships: (i) market exchange (i.e. short-term relationships with standard LSP skills and low asset specificity), (ii) customised logistics solutions (a broad range of standardised services is offered over a limited contract period, where LSPs’ skills complement those of the shippers with low/medium asset specificity), and (iii) joint logistics solutions (a unique solution is jointly developed by both parties to create mutual advantages and facilitate innovation via assets and information sharing, in which the competencies of both parties complement each other over a long-term contract). As shipper-LSP relationships move towards a more advanced scheme, learning from the other party as well as joint-learning materialise further (Håkansson et al., 1999), together with higher degrees of personnel exchange between the partners and higher potentials for integrating their IT systems (Halldórsson and Skjótt-Larsen, 2004). It is important to note that companies should not view advanced partnerships as the ‘best way’ to form an outsourcing relationship, rather, they should consider the right (‘fit-for-purpose’) alliance based on the competencies and skills at hand (Cox, 1996). Other notable works can be found on shipper-LSP relationship advancement (e.g. Bask 2001; Sharma and Choudhury, 2014), yet we mainly build on Halldórsson and Skjótt-Larsen’s (2004) typology due to its robust theoretical grounding.

Green logistics practices
The contract logistics literature has comprehensively identified the green logistics practices commenced by LSPs (e.g. Colicchia et al., 2013; Martinsen and Huge-Brodin, 2014; Perotti et al., 2012). We build upon Martinsen and Huge-Brodin (2014), since they inclusively grouped the offerings of environmental practices in the logistics market under ten items (Table 1). We will also add the practice ‘green packaging’, due to the evident influence of packaging on the environmental performance of logistics; i.e. packaging affects transport efficiency (by increased weight/space of transported goods) and the amount of waste along supply chains (Molina-Besch and Pålsson, 2014).

Linking relationship advancement with green logistics implementation
The underlying assumption of this paper is that implementing green logistics practices within a contract logistics context requires some sort of coordination and risk/reward sharing between shippers and LSPs, which can be translated in (i) high degree of customisation and asset specificity (Jazairy, 2018; Monios and Bergvist, 2016), (ii) shippers’ long-term commitment (Eng-Larsson and Kohn 2012; Jazairy, 2018; Monios and Bergvist, 2016), (iii) systems and IT integration (Isaakson and Huge-Brodin, 2013), and (iv) knowledge and personnel exchange (Monios and Bergvist, 2016; Rogerson and
Santén, 2017). Taking investing in a fleet of biofuel trucks for example, Jazairy (2018) remarks instances where LSPs were able to invest in such fleets only after securing five year contracts with shippers—and these were attainable only when customised transport services were offered (e.g. shipping heavy goods with special handling). Jazairy relates this to the oversupply of standardised transport services (i.e. shipping palletised goods), which drove the competition high in this segment, making investing in new trucks unfeasible due to shippers’ aversion of long-term commitments (to allow continuous benchmarking among LSPs and lowering costs). Another example is provided by Monios and Bergvist (2016), who studied four intermodal platforms in Europe and found that the common denominator for success in all these platforms is expressed in inter-organisational ‘trust, learning, knowledge sharing, coordination and complementarity’ (p. 548)—where risks of owning locomotives was shared between shippers, LSPs and other stakeholders over long-term agreements. However, not all green logistics practices should adhere to this; a distinction should be made on which green practice requires advanced settings, and why is this the case. That is, there is a need to understand the contextual factors associated with a respective practice that necessitate advanced relational settings, since one could argue that not all practices need upfront investments for instance (Nilsson et al., 2017). Moreover, all the above mentioned studies are based on exploratory and inductive case studies, calling for large-scale surveys to further generalise their claims.

Figure 1 shows our main theoretical model. Elements of relationship advancement are extracted from Halldórsson and Skjøtt-Larsen (2004), whereas green logistics practices are adapted from Martinsen and Huge-Brodin (2014). As our study takes dyadic views into account, we control for the role to find whether operating as a shipper/LSP influences the outcomes. We also control for size (in terms of number of employees) due to the commonality of treating it as a control variable in operations management studies. The third control variable is green strategy (in a relationship-specific context), since green strategies are likely to influence green logistics practices but also to be associated with relationship advancement.

### Methods

**Survey design**

This study is based on a web-based survey on green logistics implementation within shipper-LSP antecedents. To include shippers and LSPs, two ‘mirrored’ versions (one for each) were designed using the web application Qualtrics XM. Questions were asked in a relationship-specific context. First, respondents were requested to identify an ongoing business relationship with an environmentally conscious buyer/provider. This was followed by a question on the importance of green strategy in such relationship (based on a Likert scale that ranges from 1: ‘not important’ to 5: ‘very important’). Then, six questions were asked to describe this particular relationship, one question for each element under ‘relationship advancement’ (Figure 1). We used 5-point bipolar scales for
these question, with one end reflecting arm’s length arrangements, opposed by another that reflects advanced partnerships. Last, respondents were requested to estimate (on a scale from 1: ‘very low’ to 5: ‘very high’) the extent of implementing each of the 11 green logistics practices in this particular relationship. An option ‘inapplicable’ was provided for each question, and questions could be left unanswered. We pre-tested the survey with 3 logistics experts to ensure a proper understanding, and modified our survey accordingly.

**Data collection**

As clarified above, we targeted two different groups of firms: shippers and LSPs. Finding these was achieved using the database ‘Retriever’—a list was extracted for each group operating in Sweden. For shippers, we selected the industries that are likely to purchase logistics services (those who have goods to transport and store, e.g. manufacturing, forestry). Shippers with revenues under 100 MSEK (~10 M€) were excluded, as it is mainly large ones who address environmental concerns in their purchasing (Björklund, 2011). This yielded 1,231 shippers. For LSPs, the main selection criterion was providing logistics services. Unlike shippers, we did not exclude the small ones (unless below 1 MSEK), since even those offer green services, and their customer portfolios often include large shippers (Jazairy, 2018). 873 LSPs were found. To give large firms, which are fewer but have more impact on the environment, a higher chance of being included in the sample, we used a stratifying logic to cluster firms into categories based on their revenues, followed by a random selection on each strata (see Table 2)—yielding 1000 firms (500 each). These firms were contacted by phone with an attempt to reach respondents responsible for purchasing/selling logistics services, preferably on a managerial level. We succeeded in sending our survey to 183 shippers and 290 LSPs, whereas the rest did not show interest in participating or could not be reached. After two rounds of reminders, a total of 335 companies (170 shippers; 165 LSPs) have answered our survey, representing a well-balanced sample of logistics buyers and providers in the Swedish logistics market. Data collection took place between mid-November, 2018 and mid-February, 2019.

**Data analysis**

We tested the data for skewness and kurtosis to assess normality: all values fall below the critical value of ±1.96 as suggested by Hair et al. (2010). Data analysis took two main steps using SPSS: exploratory factor analysis (EFA), and multiple regression analysis (MRA). EFA was used to discover possible groupings for the 6 items under relationship advancement—as basis for MRA. Performing EFA with Varimax rotation (chosen because the extracted components are not correlated) revealed the presence of 2 components with eigenvalues exceeding 1.0, explaining 30.914% and 26.393% of the variance, respectively. The choice to retain these 2 components was supported by running a parallel analysis using Monte Carlo PCA, which reported only 2 components with eigenvalues exceeding the randomly generated corresponding values with the same size (6 variables, n: 335)—confirming retaining both. To include an item under a certain factor, it must report a factor loading of 0.4 or above on this factor only (Hair et al., 2010). With no co-
loading problems, 3 distinct items loaded above 0.4 on each factor (Table 4). In line with previous studies (Andersson and Norman, 2002; Halldorsson and Skjott-Larsen, 2004), factor 1 represents contractual issues (henceforth ‘contract’), whereas factor 2 is about ‘integration’. Cronbach’s α was checked to test internal consistency for the new scales (Table 4). Hair et al. (2010) recommend accepting values of 0.7 and above, or 0.6 and above for new scales, whilst rejecting values under 0.5. Factor 1 adequately passes this test, whereas factor 2 is below the recommended value—yet not to the level of rejection. Also, low values are common for scales with a few number of items (less than 10) (Briggs and Cheek, 1986). Hence, we retained factor 2. MRA was performed to detect causal relationships between the 2 relationship advancement factors (independent variables—IVs) and the identified 11 practices (dependent variables—DVIs). We performed MRA hierarchically, with model 1 including the control variables: role (shipper/LSP), size (logarithmic value for no. of employees), and green strategy (GrStrategy), proceeded by models 2 and 3 where the 2 new factors (IVs) were added (one at a time). All VIF values for the IVs are considerably lower than 10, and all tolerance values are largely above 0.10, indicating that no multicollinearity problem is present in our MRA (Olague et al., 2007). However, we noticed slightly skewed residuals when regressing ‘transport management’ and ‘EMS’—albeit their normality was accepted based on Hair et al. (2010).

Findings
Table 3 shows descriptives for all variables used in our analysis. Note that we combined datasets of shippers and LSPs to report both actors’ views. Table 4 reports the performed EFA (see Methods), and Table 5 reports MRA with 3 regression models that treat each green logistics practice as a DV, and the factors ‘contract’ and ‘integration’ as IVs.

</table>
We only comment on the third models in Table 5 due to text limitations. These models explain the total variance in each DV as follows: 19% (mode choice), 17% (transport management), 22% (logistics system design), 41% (vehicle technology), 44% (eco-driving), 36% (alternative fuels), 12% (EMS), 35% (choice of partners), 27% (emissions data), 22% (green and efficient warehouses), and 15% (green packaging). From Table 5 we can see that ‘contract’ significantly explains the variance in 7 out of 11 practices, with the strongest influence reported on choice of partners, vehicle technology and alternative fuels, respectively. With slightly lower β values, ‘integration’ significantly explains the variance in 5 practices, with the strongest influence reported on green and efficient warehouses, logistics system design and transport management, respectively.

Discussion

Linking relationship advancement with green logistics implementation

Our findings generally indicate that establishing advanced shipper-LSP relationships has an influence on facilitating the majority of green logistics practices in such relationships (Figure 2); only two practices (emissions data, green packaging) do not adhere to this. Also, a distinction is made on whether relationship advancement is expressed by the contract design or the degree of integration between the partners; the former better explains the implementation of the practices, noting that some (green and efficient warehouses, choice of partners, EMS) are influenced by both.

The combined influence of contractual and integration elements on facilitating green and efficient warehouses (and coherently acquiring EMS certificates such as ISO 14001) indicates that green solutions in warehouses (e.g. harnessing renewable energy sources, motion sensors to control lighting) do not only require shippers’ long-term commitments to secure payback on LSPs’ investments in these solutions, but also high levels of IT integration and knowledge/personnel exchange between the two—compatibly with the nation asserting that warehousing services generally fall under complex contractual agreements that differ from routine freight exchanges (Andersson and Norman, 2002). We find that such advanced partnerships also affect LSPs’ choice of partners based on their green performance, which could be seen as a result of environmentally conscious shippers’ emphasis on greening logistics functions over the entire downstream chain due to the high strategic importance of such functions—if viewed through a TCE lens.

For the practices vehicle technology and alternative fuels, our findings confirm Jazairy’s (2018) assertion that ‘modern’ eco-fleets are rather relationship-specific assets, and investing in them is particularly feasible for LSPs when long-term contracts are secured, which are typically found when customised transport services are offered. This challenges the idea that investing in eco-fleets is easier in the standardised logistics market (where long-term contracts are rare) due to LSPs’ utilisation of economies of scale (Liedtke and Friedrich, 2012). LSPs’ acquisition of these fleets appear more problematic in this market due to shippers’ (i) diversified demands and (ii) desire to form short-term agreements to lower costs through LSPs’ competition.

We notice an influence only from ‘integration’ on logistics system design (e.g. improving distribution networks, reducing haul length) and transport management (e.g. increasing fill-rates, route optimisation). This might relate to the complex nature of these practices that is associated with advanced levels of cooperation between the partners (Rogerson and Santén, 2017), regardless of the type of contract that is agreed upon.

As mentioned earlier, emissions data and green packaging do not require advanced relationship settings, which may indicate that these practices are becoming fixed and imbedded within LSPs’ business models irrespective of the type of relationship established with their partners.

**significant at p<0.01; *significant at p<0.05
°values for role: 1: shipper; 0: LSP
The influence of role, size, and green strategy

Whether a company operates as a shipper or an LSP does influence the linkages between relationship advancement and green logistics implementation in 5 practices (where $\beta$ values for *role* are negative and significant — Table 5); LSPs appear to engage more than shippers in these practices (in line with Wolf and Seuring, 2010). Noteworthy, firm size (in terms of number of employees) does not have a significant impact on the findings, whereas having a relationship-specific green strategy significantly ($p<0.01$) impacts the results in all the 11 practices—which is not surprising, since firms with green strategies are obviously more likely to implement green practices (as discussed earlier).

Conclusions

By conducting a large scale survey on shippers and LSPs, we systematically verify an implicit claim within the contract logistics literature: establishing advanced shipper-LSP relationships plays a role in facilitating green logistics practices. Relationship advancement was described through two theoretical lenses: resource- and competence-base, and TCE. Our findings differentiate whether such advancement is expressed by contractual elements (customisation, contract length, asset specificity) or integrational ones (IT integration, knowledge exchange, personnel exchange); the former better explains the implementation of the practices—though some practices are influenced by both, whilst others are influenced by neither (Figure 2). This research connects shipper-LSP relationship advancement studies with green logistics applications ones, laying the foundation to investigate further the contextual factors associated with the practices that require advanced settings for their facilitation. For practitioners, insights are offered for managers in shipper/LSP firms to formulate the right (‘fit-for purpose’) agreement with their logistics partners with respect to the desired green practice (together with other considerations such as level of competence, of course). As our survey covered actors in Sweden only, we recommend replicating our analysis in other countries.

Abstract

In a time where stakeholders increasingly demand social, environmental, and economic sustainability, mismanaging suppliers can harm a corporations’ reputation and business severely. By means of a case study, our research explores the challenges and the coping mechanisms in supplier relationships of multinational enterprises from an agency theory perspective. Based on the findings, we propose a framework that can support multinational enterprises in developing corporate sustainability strategies and in implementing them in the supplier network. Our contribution to the literature lies in the integrated approach of combining sustainable strategy implementation within multinational enterprises as well as across their supplier networks.

Keywords: sustainability, supplier management, MNEs, agency relationships

Introduction

In view of the recent corporate scandals and growing societal and environmental challenges around the world, corporations face growing pressure from stakeholders, such as customers, governments, local communities and NGOs, to manage and contribute to the triple bottom line (TBL) of social, environmental, and economic sustainability (people, planet, profits) (cf. Elkington, 1998). Companies tend to promote their sustainability initiatives through sustainability reports, homepages, corporate communications, advertising campaigns, logos, and trademarks, aiming to build global “social brands” (Huber et al., 2011). Recent studies provide evidence that investment in
corporate sustainability may enhance the bottom line (e.g. Fosfuri et al., 2015; Kaul and Luo, 2018). In order to reap the potential benefits, Bettencourt et al. (2013) emphasise the need to move from “intent” to “action”, thereby stressing the role of effective implementation. Similarly, Melé and Guillén (2006) propose to integrate sustainability development with strategic management. Strategic decisions tend to have drawbacks in the operationalisation and implementation of sustainability, possibly due to conflicts between the individual and organisation. Understanding the drivers and inhibitors of effective sustainability strategy implementation is particularly challenging in multinational enterprises (MNEs), since it involves subsidiary units that are separated geographically, legally, culturally and politically. Not surprisingly, a growing body of literature acknowledges the potential disconnect between what HQ wants and how subsidiary units actually act in the realm of sustainability (e.g. Asmussen and Fosfuri, 2019). Kostova et al. (2017) propose an agency model for headquarters-subsidiary relationships in multinational organizations with headquarters as the principal and the subsidiary unit as the agent. Agency relationships occur when one partner in a contract-based transaction (the principal) delegates authority to another (the agent) and the welfare of the principal is affected by the choices of the agents (Alchian and Demsetz, 1972). Kostava et al. (2017) suggest that tensions between HQs and subsidiaries are particularly endemic to organizations such as MNEs, which are characterized by significant decentralization and delegation of decision-making authority (Jensen and Meckling, 1976). Distribution of authority and responsibilities creates a level of uncertainty as to whether the subsidiaries will work towards the achievement of corporate sustainability goals or, alternatively, would use the delegated power to engage in undesirable behaviours for their own benefits.

From a supply chain perspective, investigating sustainable strategy implementation from an internal agency relationship perspective appears to be a good starting point but is not sufficient. Instead, companies have realised the necessity to develop sustainability strategies which extend their traditional corporate governance processes beyond the firm’s boundary to their suppliers. Mismanaging suppliers in the realm of sustainability can harm a corporation’s reputation and business severely. For example, Amazon has been exposed to immense negative headlines due to the unethical and illegal labour standards of its supplier, Foxconn. Adidas and Nike have been criticised for working with a Chinese textile supplier charged for discharging toxins into a river. These cases exemplify supplier sustainability risks, i.e. the harmful impact on a buyer from a supplier’s social and environmental misconduct (Hajmohammad and Vachon, 2016). Simultaneously, they reveal that sustainability management in the external buyer supplier relationships share the same assumptions underlying agency theory: between the buyer (principal) and supplier (agent) exist potential goal conflicts, each party acts in its own self-interest and there is information asymmetry between principal and agent (Eisenhardt, 1989; Zu and Kaynak, 2012). Within MNEs, the role of the buyer is assigned to subsidiary managers who hold the direct supplier contact. This said, the subsidiary managers act as agents in the relationships with the HQ and as principal in the supplier relationships. Overall, our paper builds on two bodies of knowledge, which so far, have not been integrated. On the one hand, studies investigating sustainability development in MNE’s from a strategy implementation perspective and on the other hand the integration of corporate sustainability in supplier relationship management (Neumüller et al., 2016). This focus comprises two integrated relationships: firstly, between HQ and subsidiary units and secondly, between subsidiary units and suppliers. Our goal is firstly, to explore the challenges and the coping mechanisms in the two overlapping agency relationships. Secondly, from the findings, we aim at developing a framework that can support MNEs
in developing corporate sustainability strategies and in implementing them in the supplier network. The remainder of the paper is structured as follows. Next, we review the literature and derive the empirical research questions and conceptual foundation. The third part describes the methodology of our case study, which is followed by a fourth part summarizing the key findings. In the last part of the paper, our implications propose a framework for sustainable supplier relationship strategy development and implementation in MNEs.

Literature Review
To provide a conceptual foundation for our research, we review the literatures on strategy implementation in MNEs, corporate sustainable strategy implementation and sustainable supplier relationship management (SSRM).

The strategic management literature tends to agree that strategy implementation is often harder than strategy content development (e.g. Hrebiniak, 2006). In the implementation, selected corporate strategy options are translated into various concrete managerial activities (de Wit and Meyer, 2010). According to Roth and O’Donnell (1996), the specific issues identified in the sustainability implementation in MNEs, stem from the geographical and cultural disconnection between corporate HQ and regional subsidiaries. This may lead to an overreliance on financial performance as the most important and easily manageable control mechanism. Additionally, the HQ and the subsidiaries may differ on the level of sustainability engagement they consider appropriate. For instance, Durand and Jacqueminet (2015) demonstrate that when subsidiaries face strong demands from their external constituents, they pay less attention to the internal sustainability norms given by the HQ. Hence, when subsidiary managers take decisions within daily operations, they may be tempted to pinch pennies to increase their subsidiary's profits, increase the output, win contracts, or simply adapt to idiosyncratic competitive circumstances – even if such choices conflict with the social brand of the MNE (e.g. Aguilera et al., 2007; Lyon and Montgomery, 2015). These findings are particularly valuable in the light of the two root causes of the agency problems in the relationships between the HQ and its subsidiaries, i.e. self-interest and bounded rationality (cf. Hendry, 2002; Jensen and Meckling, 1976). For example, subsidiaries may prioritise their own interests over those of the whole organization represented by corporate HQ managers (Mudambi and Navarra, 2004). They may overstate performance results to HQs, misrepresent the subsidiary’s capabilities to access resources, or violate the corporate code of conduct for unit level benefits even if such actions are detrimental to the whole organisation (Kostova et al., 2017).

Concerning the mechanisms to overcome the implementation barriers, Kim and Mauborgne (1993) found that the typical mechanisms – incentive compensation, monitoring systems, and rewards and punishments – are not sufficient in MNEs but that other factors which they summarise under the term “due process” are even more crucial: (1) that the headquarter (HQ) is familiar with subsidiaries’ local situations; (2) that two-way communication exists in the global strategy process; (3) that the HQ is relatively consistent in making decisions across subsidiary units; (4) that subsidiary units can legitimately challenge the HQ’s strategic views and decisions; and (5) that subsidiary units receive an explanation for final strategic decisions.

In SSRM, the boundary of responsibility extends beyond the reach of a firms ownership and control to suppliers (Gimenez and Tachizawa, 2012). Although SSRM covers the three pillars of the TBL, apart from the traditional economic focus, the majority of the SSRM literature has focused on the environmental pillar (Bastas and Liyanage, 2018; Gimenez and Tachizawa, 2012). The literature features some obstacles to SSRM
adoption. For instance, Seuring and Müller (2008) find that SSRCM implementation can trigger significant resistance in organisations, stemming from additional cost implications, inherent complexity and interorganisational communication difficulties. Further complexity challenges have been associated with the multi-dimensional (economic, ecological, social) view which comes with multiple objectives and agendas and the potential risk of inter-and intra-organisational conflicts (de Brito and Van der Laan, 2010).

In their pursuit of SSRM implementation, many companies draw on mechanism such as control through supplier assessment tools, codes of conduct a.s.o. and/or collaboration with suppliers (Andersen and Skjoett-Larsen, 2009; Keating et al., 2008). On the control side, the implementation of ISO14001 environmental management system and use of certified suppliers were identified as influential factors for green SRM implementation (Agi and Nishant, 2017). In their literature review, Bastas and Liyanage (2018) find that several authors emphasise the importance of key performance indicators (KPIs) for supplier sustainability performance in the implementation of SSRM practices, but at the same time highlight the current absence of guidelines, metrics and standards for measurement, monitoring, reporting and improvement of supplier triple bottom line performance. De Brito (2016) state that measurable indicators would allow companies to evaluate the advancement and impact of their strategies, establish priorities, facilitate continuous improvement and thus, contribute to effectiveness of SSRM activities. Still, Gimenez and Tachizawa (2012) question the overreliance on control mechanism and highlight that supplier assessment may be the initial step to identify what actions are needed; yet, companies need to engage in collaborative practices with their suppliers to improve sustainability.

![Figure 1: Literature-based conceptual framework](image)

While these existing studies shed some light on SSRM implementation, there is no study which has explicitly investigated SSRM strategy implementation with the combined focus of people, planet, profit in a complex, interorganisational company
context. Our research aims to do this, taking an agency theory perspective (Alchian and Demsetz, 1972; Jensen and Meckling, 1976). We propose that sustainable supplier relationship strategy implementation takes place in two overlapping principal agency relationships. Based on our literature review, we propose the following challenges in the two agency relationships as well as mechanisms to overcome them. In line with the literature (Göbel, 2002), the coping mechanisms can be structured into three categories: building trust, ensuring goal congruence and lowering information asymmetry (see Figure 1).

**Method**

We conducted a case study (Ellram, 1996). Through purposeful sampling, an information rich case was selected (Patton, 2002). A single case is justified by the context specificity of a strategy implementation process and the demanding sampling requirements, i.e. a MNE with a corporate sustainable strategy in place and substantial preparedness for cooperation with access to data in multiple countries. The selected MNE is a provider of leading mobility solutions in the realm of escalators, moving walkways and elevators. It does business in more than 100 countries including production sites and research and development facilities in the US, Brazil, Europe, China, and India. We broke down our research objectives, i.e. to identify the challenges of a SSRM strategy implementation and to develop a managerial framework for implementing SSRM in complex, interorganisational company contexts, into the following empirical case research questions:

*Agency relationship between HQ and regional subsidiary units:*

1) Which challenges do HQ managers perceive in their relationships with the regional subsidiary unit managers concerning the countries’ contribution to implementing the corporate sustainable supplier strategy and to meeting the sustainability targets?

2) Which measures does HQ apply in order to ensure that the corporate sustainable supplier strategy is implemented by the regional subsidiary unit managers?

3) Which challenges do the regional subsidiary unit managers perceive in their relationships with HQ concerning their role and responsibility to implement the corporate sustainable supplier strategy?

*Agency relationship between regional subsidiary units and suppliers:*

4) Which challenges do the regional subsidiary unit managers perceive in their relationships with suppliers concerning their role and responsibility to ensure that the suppliers meet the sustainability targets?

5) Which measures do the regional subsidiary unit managers apply in the supplier relationships?

We collected data from multiple sources of evidence: strategy documents, a focus group with five members of corporate purchasing and 11 semi-structured interviews, one with a corporate purchasing manager and 10 with regional sourcing managers. The interviews were selected based on a purposeful sampling approach designed to represent the following structural characteristics of the company’s global purchasing organisation: 1) four functional responsibilities within the purchasing function, 2) HQ and four regions (Europe, North America, South America and Asia) and 3) two hierarchical levels (strategic and operational). Data analysis followed a template coding approach (King, 2012). The initial template consisted of: challenges for HQ and zone managers and mechanisms for overcoming agency problems derived from the literature (see figure 1 above). During the coding process, the initial template evolved further through the addition of a number of sub-codes.
Findings

Agency relationships between HQ and regional subsidiary units

Our data confirmed the challenges HQ managers perceive in their relationships with the regional subsidiary unit managers concerning the countries’ contribution to implementing the corporate sustainable supplier strategy. Most importantly, the question of how to implement a balanced TBL approach is a key concern. The HQ managers agreed that it is easier to enforce “profit” than the remaining pillars of the TBL because more KPIs exist, which can more readily be measured. They also admitted that they struggle in determining which requirements can and should be set that can also be measured in line with the philosophy of “what cannot be measured cannot be managed”. Subsidiary units supported this view by stating that the corporate guidelines, support tools and systems do not cover all aspects of the SSRM implementation. Specifically, hardly any guidelines existed on how to formulate ecological and social requirements in calls of bids for regionally selected suppliers. Interestingly, subsidiary managers expressed a clear desire for more information and education on ecological and social issues. The lack of ecological and social performance targets gives rise to the perception of a perceived lack of a sense of urgency for these pillars from the HQ as well as a perceived lack of incentive provision to implement these pillars regionally. This in turn, triggers uncertainty on behalf of the regional subsidiary units and, consequently, the risk of an overreliance on financial KPIs with the neglect of corporate ecological and social codes of conduct.

Furthermore, the inconsistent implementation of the corporate sustainability requirements across regions was another challenge confirmed by the case study data. HQ managers explained this through the geographical and contextual distance in conjunction with their own limited regional reach. They see that continuous learning across the regional subsidiaries and motivating the subsidiary managers to enter a constructive competition on sustainability performance would be helpful in balancing performance between the regions but struggle with their resource and capacity constraints. At the same time, the HQ managers stressed that equal performance was not feasible, given the differences in the regional markets. Hence, how to manage the trade-off between compulsory HQ requirements and regional context specificities was seen as a further challenge. In the interviews with the regional managers, differences in the mindset, understanding and level of implementation of sustainability were confirmed. The gap appeared to be dependent on the geographical distance between subsidiary unit and HQ as well as the differences between the regional and home market contexts (e.g. developing versus developed economy). While some regional managers seemed to have a lack of awareness and blamed poor communication, others emphasised the special characteristics of their regional supplier market context, which impedes the implementation of the SSRM strategy. For example, a regional sourcing manager pointed out that corporate guidelines to source locally with an emphasis on customised parts are relatively difficult to implement in the Brazilian market where suppliers are more specialised on mass production.

Further challenges raised in the case study interviews which have not been identified in the literature concern the challenge of prioritising between the high number of 45,000 suppliers and the related difficulties in balancing between two potential trade-offs. Firstly, between efficiency and risk and secondly, between volume and resilience. Pursuing efficiency targets is important from an economic sustainability perspective and, according to the HQ managers, a necessity when dealing with such a large number of suppliers. From this perspective, relationships with small suppliers for low value items can have massive saving potential if transparency was provided across the regions. Instead, high risk suppliers are crucial from a social or ecological sustainability perspective. Similarly,
an emphasis on volume suppliers is essential from an economic perspective but since even small supplier glitches can cause media outbreaks or operational disruptions, resilience is not only bound to high volume suppliers. Interestingly, one regional subsidiary manager pointed out that the priorities may or may not be applicable from a local perspective. For example, gaps may exist between corporate und local SRM since the spend and dependency on suppliers is lower. Hence, they have a risk-based assessment of how exact HQ guidelines for supplier qualification are adapted at the regional level.

The measures the HQ managers apply to ensure that the corporate sustainable supplier strategy is implemented across regions relate to all three mechanisms to overcome agency problems from the literature (cf. Göbel, 2002). With the aim to lower information asymmetry, the HQ currently has a project underway to improve transparency and planning. An IT-based supplier relationship system is being introduced providing visibility across the 45,000 suppliers to enforce global standards and focus attention on top 45 suppliers globally. Measures to build trust are e.g. listening to the subsidiary managers and working with external agencies (Ecovadis) for compliance monitoring. This also reinforces credibility of the compliance reports. Finally, an exemplary measure to safeguard goal congruence concerns the HQ approach to KPI definition. Corporate HQ managers first carefully evaluate which KPIs are used how by subsidiary units. From this assessment, KPIs which cannot be consistently measured across regions due to context specificities are excluded and only globally applicable performance indicators remain.

Agency relationships between regional subsidiary units and suppliers
In their role as principals, regional subsidiary unit managers reported the challenges they have when ensuring that the suppliers meet the corporate sustainability standards. Most of the challenges identified from the literature were also reported in the interviews. For example, financial and other resource constraints were frequently stressed by the regional subsidiary units. They feel that they do not have enough resources and capacity to implement corporate guidelines concerning the SSRM strategy in their supplier relationships. For instance, a manager pointed out that her subsidiary is not able to spend enough time with suppliers at their premises to really get them to improve their processes in a more ecological friendly manner. Likewise, resource constraints render it difficult to anticipate supplier deviation from defined standards and KPIs. According to the subsidiary managers, these issues are even more pronounced in relationships with smaller, local suppliers. Here, the supplier’s own resource constraints make operational buyer-solicited adaptations almost impossible. Since economic sustainability is operationalized through financial KPIs that are easier to control, well known and established, regional managers emphasised that the ecological and social dimensions of the sustainability strategy suffer. This in turn, highlights the challenge of maintaining a balanced triple bottom line approach in the supplier relationships. Concerning the challenges related to interorganisational communication and inter- as well as intraorganisational conflicts, subsidiary managers referred to the many different contact points. Supplier relationships are managed through a complex network involving contacts between different regional and in some cases also corporate managers and the supplier organisations. Suppliers may use the complex and often inconsistent communication to their advantage. A challenge that was not identified in the literature was an imbalance of guidelines not only across the TBL dimensions but also across the supplier relationship phases. One subsidiary unit manager pointed out that while there are good measures in the early stages of new supplier qualification and selection, once they are in operation, he struggles to detect if the supplier requires additional support in the
development stages or, alternatively, if phasing out a supplier may become a sustainability risk.

The regional subsidiary unit managers also apply a number of measures in the supplier relationships that can be categorised into the three mechanisms to overcome agency problems (cf. Göbel, 2002). To lower information asymmetry, various measures are in place: Firstly, the subsidiaries have a very structured process of selecting new suppliers. The subsidiaries conduct a series of audits regarding supplier compliance with selected aspects of the three dimensions of the TBL. Secondly, subsidiaries engage in continuous monitoring of supplier compliance to their specifications by tracking supplier performance with KPIs. Thirdly, the subsidiaries maintain ongoing communication with suppliers including e.g. order forecast update and supply performance feedback. To ensure goal congruence, subsidiaries use a variety of incentives for supplier. For instance, led by the purchasing or specialist division, they provide active support to smaller suppliers to develop their business. This may be in the form of training, education or support to achieve conformity to new legal requirements. Also, financial incentives are provided, e.g. for supplier endeavours to acquire certain certificates. To build trust and ensure goal congruence, senior subsidiary management meets suppliers on a regular basis. For example, a supplier conference is held on a bi-annual to annual basis where suppliers are informed on the MNE’s long-term strategy and how suppliers are expected to contribute to its implementation. Suppliers also have the opportunity to raise questions and discuss pressing issues. Another measure to ensure goal congruence is supplier industrialisation. As part of this process, the subsidiary’s supplier development industrialisation teams support the supplier in improving their systems, processes and products to comply with the corporation’s standards. Moreover, the team exposes suppliers to new competitive opportunities in this respect which may ultimately also result in a business advantage for the subsidiary due to e.g. cost saving. If necessary, subsidiary management also involves third parties to make the supplier “fit” to stay in business with them which supports trust building.

**Contribution and Implications**

Overall, our contribution to the literature is the integrated approach we take by investigating sustainable strategy implementation within MNEs and across their supplier networks. By combining both topics through our conceptualisation of two overlapping agency relationships, we identify challenges and mechanisms to overcome potential agency problems in both relationships. This in turn, is the basis for our proposed framework for SSRM strategy development and implementation (see figure 2). The core of the strategy is a balanced TPL sustainability improvement approach. The case study has highlighted the particular challenges of an equal representation of the three dimensions. Future research should support MNEs through further insights into social and ecological KPIs as well as supportive organisational processes and structures. The external layer of our framework reflects the fact that SSRM strategies are relationship strategies. Furthermore, due to the potential agency problems both within and across the company boundaries, specific attention must be devoted to the crucial role that regional subsidiary units play. Further research should address the potential conflicts between their role as agents and principals in greater depth and provide insights into how the agency problems can be overcome. The mid circle of our framework represents a cyclical five-phase process which can be applied in both relationships: those between HQ and subsidiary units and between subsidiary units and their suppliers. Transparency is a key element to foster standard practices and, at the same time, minimise information asymmetry. Our case study suggests that IT plays a growing role in ensuring transparency.
about sustainability practices in MNEs which has yet to be researched. In addition, transparency enables a bottom-up-top-down process of setting the sustainability requirements. Next, compliance with the requirements across suppliers and regions is monitored. This in turn represents the baseline from which sustainability improvement targets and appropriate KPIs can be derived. The fact that performance targets are followed by trust stresses one again relationship character of the strategy. Trust is the linking pin between both, taking actions to improve the sustainability performance and the willingness to share this information within and across the organisation.

Abstract

Various qualitative and quantitative research approaches are driving research on sustainable supply chain management (SSCM). The ongoing Delphi study attempts to map the theories, methods, and fields of application in SSCM research in order to outline possible integration avenues needed to advance SSCM research on environmental and social aspects in developing, emerging, and industrialized economies. The findings of the second survey round indicate that the circular economy and industrial symbioses as well as reverse and closed-loop supply chains are deemed most relevant for future SSCM research on multi-tier supply chains, particularly in emerging and industrialized economies, to support environmental sustainability.

Keywords: Sustainable supply chain management research, Theories, Methods, Delphi study

Introduction

Research approaches to sustainable supply chain management (SSCM) avail of conceptual frameworks and formal models from Operations Management (OM) and Operations Research (OR) to extend the scope of analysis toward environmental and social aspects relevant for managing operations and supply chains (SCs). However, qualitative and quantitative research streams in SSCM still appear disconnected with regard to a common literature background, which is indicated by low citation numbers between conceptual, empirical, and formal modeling publications that consider
stakeholders and risks in SSCM (Rebs et al., 2018). This observation of rare interactions points to the potential of benefits gained from integrating qualitative and quantitative research approaches for SSCM.

Different research approaches in SSCM have been reviewed thoroughly by recent publications (Reefke and Sundaram, 2017; Rajeev et al., 2017). However, an overarching investigation into the use of different theories, methods, and application contexts in SSCM research is not available, but strongly needed to unveil potentials of considering both qualitative and quantitative approaches.

The Delphi study, as a survey research design, enables a structured debate on the issue by engaging the researchers in the field (Linstone and Turoff, 1975), i.e., the very nucleus of the current split of approaches. This is a crucial step towards the identification of synergies between different research approaches as well as enhanced cooperation opportunities that eventually lead to an overall higher impact of SSCM research. To this end, we pose the following research questions (RQs) to be answered by this survey study:

RQ1: What are the theories, methods, and application contexts that are deemed highly relevant for future SSCM-related research?

RQ2: How is the current maturity and future potential of the use of economic, environmental, and social dimensions of sustainability as well as for different multi-tier SC levels of analysis in SSCM perceived by the SSCM experts?

RQ3: How could qualitative and quantitative approaches be linked to reap the benefits from integrating and extending theories, methods, and application contexts for future SSCM-related research?

**Literature background**

Delphi studies have proven to be appropriate to capture the scope of complex problems or the structure of emerging research fields like SSCM (see, e.g., Seuring and Müller, 2008a). Reefke and Sundaram (2017) enquired into the key themes for SSCM research using the SC planning matrix as a conceptual basis. While the past use of theories, methods, and applications can be discerned by systematic literature reviews, which typically suffer from the time lag produced by peer-review and publication procedures of up to or even more than one year. The current use and future potential of theories, methods, and applications or other items of interest can only be identified at a current given point in time by a survey research approach so that no considerable gap exists between the research endeavors and their publication.

A range of theories and formal models has been applied in SSCM research. Sarkis et al. (2011) reflect the role of organizational theories in green supply chain management (GSCM) research and identify promising theories for future GSCM research. Touboulic and Walker (2015) provide a systematic literature review to examine the theoretical lenses used in SSCM and find that efforts to build theory in SSCM still remain limited to a few mostly imported theories. Apart from qualitative- and quantitative-empirical research designs, e.g., case studies or surveys, the use of quantitative-theoretical formal models in SSCM-related research articles was reviewed (see, e.g., Brandenburg et al., 2014). In effect, it was evident that the field of SSCM is divided in two streams which can be divided based on their prevailing ontological, i.e., constructivist and objectivist stances, which reflect the use of different qualitative and quantitative research methods in SSCM (see, e.g., Rebs et al., 2018). While the constructivist stance that lends itself to the social sciences is hard to assign to a particular group of SSCM researchers, the objectivist stance with its tendency towards the assumptions and methods from the natural sciences can be assigned to the OR community (see Bryman and Bell, 2011, for the ontology). Despite
this ontological and methodological split, the research foci of both streams overlap and might thus benefit from an integrated evaluation.

Central to the discourse on sustainable management is the role of the economic, environmental, and social dimensions of sustainability, i.e., the so-called triple bottom line (TBL) of sustainability (Elkington, 1998; Carter and Rogers, 2008). Their interplay is of constant interest, particularly with regard to their operationalization by formal models. Finally, multi-tier supply chain management (multi-tier SCM) appears to receive increasing attention for managing sub-suppliers and enhanced SC transparency (e.g., Mena et al., 2013; Grimm et al., 2014; Sauer and Seuring, 2018a,b).

When reflecting qualitative and quantitative approaches in SSCM with regard to a generic “normal research cycle” (Meredith et al., 1993: 4), theoretical frameworks and formal models are involved in an iterative process of describing and explaining certain phenomena to build theory, which is subsequently tested, e.g., by quantitative models. In this context, Rebs et al. (2018), recommend to strengthen the nexus between conceptual, empirical, and formal modeling research for SSCM in order to close the cycle and drive SSCM research further.

**Methodology**

The study at hand represents a Delphi study, i.e., “a structured group communication […] to deal with a complex problem” (Linstone and Turoff, 1975, p. 3). The method is particularly suitable for exploratory theory building on under-researched, complex, and interdisciplinary topics (Akkermans et al., 2003) such as the outlined interaction between qualitative and quantitative research streams in SSCM. Adopting methodological suggestions by Linstone and Turoff (1975) as well as Okoli and Pawlowski (2004), individual panels are built to gather the opinion and expertise of authors of research articles in SSCM. Delphi studies feature a high construct validity as the participants comment on their previous answers (Okoli and Pawlowski, 2004). Reliability is ensured by rigorous study design and documentation as well as pre-testing the single questionnaires (Okoli and Pawlowski, 2004). These drivers of validity and reliability are part of our study design and conduction to ensure high quality results.

Adopting a typical three-round structure, the Delphi study encompasses:

- **Round 1** (finished; 104 answers): Open questions to comprehensively identify theories, methods, and application contexts as well as the most relevant academic discussions for quantitative and qualitative researchers in SSCM.
- **Round 2** (ongoing; 96 answers): Closed questions on (a) which of the academic discussions are perceived as relevant in the single panels and (b) the potential of the selected discussions to induce theoretical advancements of SSCM regarding the (b1) TBL dimensions, (b2) SC levels of analysis, and (b3) industrial, emerging, and developing countries.
- **Round 3** (in preparation): Investigation of the differences and integration potentials among the panels. To craft the integrated research agenda, we will also investigate which theoretical and methodological approaches the single panels see in relation to the highly relevant discussions in SSCM research for achieving theoretical advancements.

The addressees of the study were systematically identified according to the selection criteria defined in the following. Authors of research articles in SSCM had to be listed as a first author in the paper samples of at least 2 of 22 analyzed literature review papers on SSCM published between 2008 and 2017. The consideration of only the first author of a
sample papers ensures that the identified person is familiar with the topic. Moreover, in this way, both researchers and practitioners, who once published a research article but are now inactive researchers, are considered as source of expert knowledge with regard to their opinion on and perception of the current use and future potential of theories, methods, and application contexts in SSCM research. Finally, further experts that were recommended by the identified experts could be included. This is a valid approach to populate the panel (Okoli and Pawlowski, 2004), as deeming that the answers given by the initially identified experts are valid, then it is valid to trust their recommendations for further experts. Based on feedback we received on previous conferences, we decided to extend the initial list of identified experts by including further recognized SSCM researchers, particularly young scholars and PhD candidates that currently conduct SSCM-related research, as addressees in the second round.

Results
In this section, we present general information about the panel, briefly summarize the findings from the first round and, subsequently, we concentrate on analyzing the interim results from the ongoing second round.

Information about participants
In total, 104 participants completed the first round questionnaire. The second round, which includes a new young scholar panel as well as all panelists from round 1 regardless of their participation in round 1, yields 96 responses and is still ongoing, hence, additional responses may be expected. Table 1 gives an overview about the characteristics of the respondents of the first and the ongoing second round. It includes the number of years in academia (including PhD years), years in industry/praxis, the last year being involved in SSCM-related research, the familiarity with SSCM, and the institutional sector of current occupation. The descriptive information about the participants helps to consider the respondents’ expertise, which can be estimated based on the responses on, e.g., the degree of familiarity with SSCM-related topics in research and practice. The results are displayed in quartiles to show the structure of the data and reveal focal points within the single characteristics.

The results in Table 1 show that the median of years in academia (round 1: 15 years | round 2: 13.5 years) and praxis (round 1: 2.5 years | round 2: 2.0 years) are highly different and that 75% of the respondents have spent 5 years or less in industry. This is clearly a limitation of the study, which is, however, natural to the choice of experts via research publications. Moreover, the vast majority of respondents (round 1: 77% | round 2: 78%) is currently conducting SSCM research and the familiarity with SSCM (rated on 10 point Likert scale; 0=”completely new to me”; 10=”my area of expertise”) is very high with a median of 8 (round 1) and 8.5 (round 2) and the final quartile exclusively covering respondents with maximum familiarity. These results underline the expertise covered by the expert panel which drives the validity of the study results (Häder, 2014). These figures furthermore validate the expert selection process.

Insights from the first survey round

The first survey round yields the sets of theories and methods currently used by SSCM researchers in different application contexts. These items will be used in the third round to investigate possible research approaches to induce theoretical advancements of SSCM research regarding the identified highly relevant discussion.

The experts were furthermore asked to name academic discussions perceived as highly relevant for future SSCM research. In the analysis of round 1, these discussions have been coded inductively based on the responses. As a result, 19 highly relevant discussions were identified (see Table 2).

Table 2 – Current academic discussions perceived highly relevant for future SSCM research

| (1) Circular economy, industrial symbiosis | (11) Sustainability of fast moving consumer goods |
| (2) Reverse and closed-loop SCM | (12) Local sourcing, reshoring |
| (3) Waste management | (13) Humanitarian logistics |
| (4) Industry 4.0, automation | (14) 3D-Printing |
| (5) Blockchain, distributed ledger technology | (15) Public procurement |
| (6) Stakeholder integration | (16) Traceability |
| (7) Risk management | (17) Big data analytics |
| (8) Urban logistics | (18) Base of the pyramid |
| (9) E-commerce | (19) Modern slavery, human rights |
| (10) Sharing economy | |

From a methodological point of view, the use of formal models and, moreover, the overall practical impact of SSCM research are mentioned as key themes. However, they are not listed as highly relevant academic discussions, since both methods and research contexts will be analyzed with regard to the listed discussions.

Based on the first round results and regarding the maturity and relevance of TBL dimensions and SC levels of analyses, the experts see a clear need for driving the social dimension and extending the scope of researched SC complexity. Both the most relevant academic discussion as well as the results regarding maturity and relevance of TBL dimensions and SC levels of analyses build the basis on the second survey round.
Insights from the second survey round
In the second round, the addressees are asked to (a) select up to 7 of the discussions displayed in Table 2 and, subsequently, evaluate the potential of the selected discussions for inducing theoretical advancements of SSCM research on (b1) environmental and social sustainability, (b2) intra-organizational, dyadic, and multi-tier SCs, and (b3) developing, emerging, and industrialized economies.

Moreover, the experts were provided a list of 13 methods in business research adapted from Bryman and Bell (2011), from which they were asked to select the methods they have used in the last five years of their research. The methods can be assigned to either constructivist or objectivist ontological stances (see, e.g., Bryman and Bell, 2011) that underlie either OM- or OR-based SSCM research. Grounded on this, the respondents could be grouped into “constructivist” (n=48), “objectivist” (n=16) or “intersection” (n=31, meaning no clear tendency in the use of methods) research approaches. According to Okoli and Pawlowski (2004), the size of the (“objectivist”) (sub-)panel lying between 10 to 18 experts, is appropriate to reach a group consensus. Still, we are trying to better balance out the groups by sending further reminders to the researchers that have published on the objectivist side of SSCM.

Subsequently, the tendency of respondents from these three groups to select a certain discussion is analyzed by calculating the mean values that indicate if a discussion was selected (“2”) or not (“1”). This is presented in Table 3, which also indicates the absolute frequencies of the top ten selected discussions.

Table 3 – Cross tabulation of the top ten academic discussions and their selection by the ontologically distinguished SSCM researcher groups

</tbody>
</table>

From Table 3, we can infer that both constructivist and objectivist researchers deem the circular economy/industrial symbiosis as well as reverse and closed-loop SCM as highly relevant fields of future SSCM research. Constructivist researchers also view modern slavery/human rights, industry 4.0/automation, and risk management as pressing topics. In contrast, objectivist researchers see the sharing economy, urban logistics, and big data analytics as highly relevant.

Table 4 shows the top ten discussions and indicates the mean values of the evaluated potential to induce theoretical advancements (rated on 5 point Likert scale; 0=”very low”; 5=”very high”; alternative answer option “no potential”) for (b1) environmental and social sustainability, (b2) intra-organizational, dyadic, and multi-tier SCs, and (b3) developing, emerging, and industrialized economies.

</table>

The figures in Table 4 suggests that the circular economy/industrial symbiosis, reverse and closed-loop SCM, waste management, and urban logistics are most relevant to advance environmental sustainability, while modern slavery/human rights are subject to social sustainability, which is supposed to be tackled by considering multi-tier SCs in developing and emerging countries. Generally, multi-tier SCs feature the highest potential...
Next steps: Preparation of the third survey round

The second round gives an indication of the highly relevant academic discussions, which are evaluated by the respondents regarding their relevance for inducing theoretical advancements regarding the TBL of sustainability, the SC levels of analysis, and the type of economies that need to be considered. Further statistical analyses are planned to make sense of the collected data. Potential statistical tests include, but are not limited to:

- Contingency analysis among the selected academic discussions and regarding the control variables, i.e., the respondent characteristics;
- Kruskal-Wallis-Test to compare the responses among the three different research clusters, i.e., constructivist, objectivist, and both (intersection) research approaches.

The third round is supposed to unveil which theories and methods are deemed useful to conduct research on the highly relevant discussions for future SSCM so that theoretical advancements as well as a high practical impact of SSCM research can be realized.

Conclusion

The paper at hand presents the findings of the first round and the interim results of the second round of a Delphi study on theories, methods, and applications contexts in SSCM research. The findings build the basis for the systematic evaluation of the dominant and underrepresented theories, methods, and application contexts in qualitative and quantitative SSCM research.

From the second survey round, we find that issues relating to a circular economy perspective and approaches to industrial symbioses as well as with regard to reverse and closed-loop SCM are evaluated as most relevance to future SSCM research by focusing environmental sustainability and researching multi-tier SCs.

In the end, the completed Delphi study is supposed to provide a basis to derive guidelines for future SSCM research and a more coherent body of research, ultimately aiming at contributions relevant to academia and praxis. Recent studies particularly called for linking conceptual, empirical, and formal modeling research methods, and, furthermore, to elaborate ways to operationalize the TBL dimensions of sustainability, stakeholder influences, and risks in SSCM (see, e.g., Reefke and Sundaram, 2017; Rebs et al., 2018). Moreover, empirical studies based on or supported by quantitative models...
with regard to the industry specifics of sustainable SCs should be envisaged to give managerial recommendations for different industrial sectors (Rebs et al., 2018).

Research approaches in the relatively young field of SSCM need to be continuously revised and refined to capture the complexities and system dynamics between economic, environmental, and social aspects in SCs (see, e.g., Rebs et al., 2019). The integrative consideration of qualitative and quantitative methods will strengthen the validity and impact of SSCM research in both academia and praxis. This study enables a structured debate by engaging the researchers in the field, i.e., the very nucleus of the current split of approaches.

At the same time, focusing on academic researchers represents one of the major limitations of the study. While the expert panels show high ratings on familiarity with SSCM, current engagement in SSCM research as well as on average 14 years of experience in academia, there is a lack of industry experience in the panel. The research activities of the respondents ensure some contact to practitioners, however, this limits the results of the study to academic issues. Moreover, 54 respondents of the first round (n = 104) also participated in the second round, while 42 new experts only stepped in the survey with the second round. Contrasting the open questions in round 1, round 2 is based on a standardized questionnaire for all participants (as suggested by Okoli and Pawlowski, 2004). Thus, all items and necessary control variables (personal background and use of methods) are answered by all respondents so that further analysis regarding the question of which theories and methods are useful to tackle the highly relevant discussions are enabled. Still, these academic issues are at the heart of this research.

Abstract

With the awareness of “Green” aspect, companies around the world have been focusing on green supply chain as a key factor in achieving competitiveness and stakeholder satisfaction. In this current research, an internal collaboration was studied by adopting social exchange theory (SET). Qualitative information was obtained through in-depth interviews. The data shows that employees with high protection motivation theory (PMT) and environmental specific transformational leadership (ESTL) tend to have green behaviors. Moreover, the organization’s internal social marketing (ISM) acts as a moderator of the relationship between ESTL and EGB. Finally, ESTL and EGB relate to Internal Green supply chain collaboration.

Keywords: Internal green supply chain collaboration, Employee green behaviour, Environmentally specific transformational leadership

Introduction

The Altruism theory (Comte, 1973) states that altruism is where people generate behavior which appears self-interested is a second, therefore; these people are living for others as the first priority. Rand (1968) initially states that prioritizing what is good for oneself after what is good for others is called “altruism”. The previous literatures mainly highlight the green behavior as a result of altruism. According to Stern et al. (1993), based on Schwartz's norm-activation theory, they investigated the role of social-altruism and egoism on green behaviour to see whether socialaltruism is the only driver that affects environmentally friendly market behaviour. They also pointed out that it might not socialaltruism alone as it might be disturbed by egoism in dealing with extra costs of behaving green. Moreover, the study of altruism and theory of planned behavior (TPB) on the hotel guest intention of supporting a green hotel where the results show that all factors namely altruism, subjective norms, and perceived behavioral control have positive impact on hotel guest intention on visiting green hotel.
Social exchange theory (SET) by Emerson (1976), on the other hand, points out that the people who are involved in the interaction are rationally seeking to maximize their profits. Cropanzano and Mitchell (2005) stated that the reciprocal rules in social exchange theory specify that, in bilateral relationship, the favorable action of one person would be resulted in a return of a kind action by the other person. From the studies of Lee and Choi (2003), it shows that, within organization, the way to successfully promote a knowledge sharing culture is not only by having it in the business strategy, however; the employee attitudes and behaviors must be changed to embrace the willingness and consistency of knowledge sharing. The past literatures indicate that an exchange relationship can happen in many forms, for example, in economic resources which involve money; goods; or services, in socio-emotional resources which involve trust, or social-status. Blau (1964) stressed that Exchange behavior is the highlight of a benefit a person can get from engaging in social exchange, for example, a person who share knowledge can expect any kind of help in return from the other as to ensure the supporting of knowledge sharing process that happening (Kollok, 1999). Therefore, it can be seen that there is no pure altruism and everyone is doing something for some returns or expecting some returns in the future.

Moreover, Andersson, Jackson, & Russell, 2013 suggest that to be able to succeed in environmental sustainability, an organization must have individuals with high level of Employee Green Behavior (EGB). Individuals with high pro-social traits are likely more intrinsically motivated to engage in helping behavior whereas individuals with low pro-social traits are likely more extrinsically motivated to engage in helping behavior, which in this research collaboration will be treated as a helping behavior.

Transactional and transformational leaders have been defines as a new paradigm of leadership and gained attention since its introduction. Leadership was categorized into two types; transactional and transformational according to philosophy of the leaders. Bass et al. (2003) defined transactional leaders are those who lead through social exchange whereas transformational leaders are those who stimulate and inspire followers to both achieve extraordinary outcomes and help followers grow and develop individual capability. Polonsky and Rosenberger (2001) point out that all individuals within the organization must not only concern about the commercial aspect but also to be aware of their behavior that can affect environment. In order to change the whole organization to become green, managers play an important role (Chamorro and Bañegil, 2006).

Therefore; in this current study, protection motivation theory (PMT) model has been used for evaluating the degree of motivation under SET and its impact on green behavior (employee green behavior: EGB) and thus; corporate internal green supply chain collaboration. Besides, it also studies the moderating effect of Internal Social Marketing (ISM) on the relationship between ETSL and EGB.

Research Question

RQ: How does protection motivation theory (PMT); threats and coping appraisals, and environmentally specific transformational leadership (ESTL) affect corporate internal green supply chain collaboration through employee green behavior (EGB)?

Contribution

In terms of theoretical contribution, since 2000, the amount of research within the area of GSCM has significantly increased; however, there has been limited progress in the area of GSCC. Moreover, a majority of the studies were conducted mainly under a customer-supplier context or external collaboration, internal collaboration has still been
overlooked. Therefore, the current study provides a clear understanding of green supply chain collaboration within the organization. In addition, this research challenges the theory of altruism by applying the social exchange theory (SET) to investigate the green behaviour of employees. Thus, a new perspective of explaining green behaviour and internal supply chain collaboration is presented.

The managerial contribution of this research has 2 parts. Firstly, this research signals to organisations to pay more attention to corporate internal collaboration by concentrating on employee green behavior (EGB) and how to motivate them through protection motivation theory (PMT), environmentally specific transformational leadership (ESTL), and internal social marketing (ISM) in order to achieve green supply chain collaboration within an organization.

Secondly, this research testing the impact of internal social marketing (ISM) on the relationship between environmentally specific transformational leadership (ESTL) and employee green behavior (EGB), therefore, organization will be able to know how to apply marketing tools for internal marketing. All of these will lead to the higher internal collaboration and thus higher performance as an ultimate goal of an organization.

**Methodology**

This research adopts a case study using qualitative data. Data was gathering from semi-structured interviews to analyse corporate internal green supply chain collaboration. Although, sampling strategies for qualitative research can be random, convenience, or purposeful samples of participants. In this current research, purposeful sampling which is quite a unique qualitative research has been adopted since the study is interested in the specific case/participant characteristics. Three manufacturing companies in Thailand were selected based on the following main criteria;

1. **Types of industries**: The main industries of Thailand that have been contributed to the GDP and involved in both green and supply chain management were chosen namely; Automotive industry, Food industry and Energy industry.

2. **The readiness of Green management**: In this study we adopted ISO 14001 (the International Organization for Standardization) as a measurement for readiness. Because ISO (2019) states that “The purpose of this International Standard is to provide organizations with a framework to protect the environment and respond to changing environmental conditions in balance with socio-economic needs. It specifies requirements that enable an organization to achieve the intended outcomes it sets for its environmental management system”. Therefore; by having ISO 14001 in place, it represents a readiness of a company to embrace green management.

3. **Organizational culture**: Culture can support organizations in adopting a particular strategy if there is a strong relationship between culture and that strategy. In contrast, culture may act as a barrier which can defer an implementation of a strategy (Fernandez et al., 2003). In this study, organizational culture defines upon the nationality of the mother company. Therefore; Thai and Multi Cultures can be defined
Three companies were selected in order to see the differences in the nature of corporate internal green supply chain collaboration within each case. Mainly, they were selected based on types of industries which can be seen in table 1.

Organizations are made of several layers that interacting one another. Layers can be divided into divisions, departments, teams, and individuals, where there is always some degree of interdependence that leads to bottom-up and top-down influence mechanisms. As suggested by Kozlowski and Klein (2000), in top-down effect, teams and organizations are contexts for the development of individual cognitions, attitudes, and behaviors. On the other hand, McGrath et al. (2000) mentioned that, in bottom-up effect, individual cognitions, attitudes, and behaviors can also influence the functioning and outcomes of teams and.

Since this current study will be conducted within the organization context, there are many factors from different levels involved. Qualitative information was obtained through interviews with key individuals involved in corporate internal Green Supply chain collaboration at two levels: the management level and the operational level. Altogether, there were 4 management-level informants and 7 operational-level informants (table 2).

<table>
<thead>
<tr>
<th>Company name</th>

</table>

As mentioned earlier that the informants have been divided into two levels; individual and organization upon the nature of organizational structure (Hitt et al., 2007). The questions for collecting all constructs applied in the interview therefore; align with the conceptual framework, protection motivation theory (PMT), and employee green behavior (EGB) will be applied in the question for individual level and reported by employee whereas internal social marketing (ISM), environmentally specific transformational leadership (ESTL), corporate internal green supply chain collaboration will be applied in the question for organization level and reported by management as shows in table 3.

The in-depth interviews were done with four management level informants and seven employee level informants (operational) to explore the questions according to the construct in table 3. The interviews were recorded and later transcribed for a content analysis. The script of the questions for the in-depth interviews was explained and discussed based on theory (Conto et al., 2016).

The process of analysing the interview transcripts began with condensing all the raw data into code, then provide score for each informant, after that the overall score for each construct will be determined to indicate the level; high, medium, low.
The data obtained in this research were discussed and validated to ensure inter-code reliability (Kurasaki, 2000). In addition, experts reviewed and discussed all processes before proposing the final results.

Results and analysis

Protection motivation theory (PMT) and employee green behavior (EGB)

PMT consists of “threat appraisal” and “coping appraisal” which determine the level of people engaging in risk protective behaviour. The basic idea of PMT is that people engage in adaptive actions when confronted with risks through two main cognitive processes of “threat appraisal” and “coping appraisal” (Rogers, 1983).

After coding each informant, score was provided where pre-determined rules of scoring components for each construct are as follow; + Seldom occur (or strongly disagree), ++ Sometimes (partly disagree), +++ Often (partly agree), and ++++ Every time (or strongly agree). After that the score for each construct will be determined by these following rules; High Mostly +++ or ++++, Medium Mostly ++ or +++, and Low Mostly + or ++. From the results of in-depth interview of seven employees; the relationship between PMT and employee green behavior (EGB) can be analysed using content analysis.

Regarding threat appraisal, higher perceived severity and vulnerability is likely to promote risk adaptive behavior, while higher perceived rewards of current practices will inhibit adaptive behaviour (Bockarjova and Steg, 2014). The results from Org. 2 (automotive) display high tendency of PMT as it presents high scores in overall threats and coping appraisals as seen in table 4.

For perceived severity, it is determined “high” in Org 2 as the informant said “...if talking about environmental issue, I would say that it is very connected to our daily life and it is becoming more serious, for example, the problem of plastic waste which was released to the sea destroying many sea lives.... It makes me feel so emotional...” (Strongly agree + + + +)

For perceived vulnerability, it is determined “high” in Org 2 as the informant said that “...like inappropriate waste management problem, I think it is so closed and affect
our life. My boyfriend says we didn’t throw it away, so no need to concern about it. But I don’t think so…”

For rewards, it is determined “low” in Org 2 as the informant said that “…We can help as much as we can, if we have ability to protect the environment just a little bit, it is still alright. It is better than doing nothing…” (Strongly disagree +)

In Coping appraisal, the probability of enacting the adaptive behavior is increased when high levels of the efficacy variables are predicted. Whereas, it is decreased when high response costs associated with performing the adaptive behavior are perceived (Floyd et al., 2000).

For perceived response efficacy, it is determined “high” in Org 2 as the informant said “...the waste from us just one piece can goes far to the sea. I think if we reduce the waste we throw away, it can help…” (Partly agree + +).

For perceived self-efficacy, it is determined “high” in Org 2 as the informant said “…it is something that we can do…” (Strongly agree + + + +)

For perceived costs, it is determined “low” in Org 2 as the informant said “…it is ok to help protect environment, and at the same time it can also save your money, for example, bringing your own bottle to refill water…” (Partly disagree + + +)

“...it is something that we can do; no need extra equipment or anything. We can do it now…” (Strongly disagree +)

</tr>
</tbody>
</table>

However, the results from Org 1 and Org 3 seem to have low (some medium) in overall threats and coping appraisals for example;

For perceived severity, it is determined “medium” in Org 1 and Org 3 as the informants said
“...it affects our life and other creation...yeah I think it should have the solution for it...” (Employee from Org 3: Partly agree +++) 

For perceived vulnerability, the informant said
“...it partly affects my life because my house located next to the canal...and yeah I have seen some waste...” (Employee from Org 1: Partly agree +++)

For rewards, it is determined “low” in Org 1 and Org 3 as the informant said
“...yeah I have seen a campaign in the department store, like they try to reduce plastic bag buy giving cash back or something, but the understanding of consumer is not 100% correct...” (Employee from Org 1: Strongly agree ++++)

The results from three organisations show the significant differences between two groups; high overall score (Org 2) vs. low overall score (Org 1 and Org 3). It can be seen that in high overall score group, EGB also rated high. The informants mentioned
“...for example, since I am working with a lots of documents, if my boss want to see some information, I will ask which page I won’t print it all out. That way I can save papers...” (Employee from Org 2: Every time ++++)

“...I have used my own bottle for refill water, first I see other people do and I tried that I think yeah it is good...” (Employee from Org 2: Often +++)

On the other hand, in low overall score group, it presents quite low EGB. The informants mentioned
“...we want to save water but...you know it really depends on the technology...if we can have the new technology not the old one...” (Employee from Org 3: Sometimes ++)

Therefore, we can see that results clearly explain the relationship between threats and coping appraisals in PMT and EGB. From the analysis, the higher perceived severity, perceived vulnerability, perceived efficacy, perceived self-efficacy, and the higher the tendency of employee to have higher EGB which aligns with the past researches (Floyd et al., 2000; and Bockarjova and Steg, 2014).

Environmentally specific transformational leadership (ESTL), internal social marketing (ISM), and employee green behavior (EGB)

The evidence has demonstrated that transformational leadership can move followers to exceed expected performance, as well as lead to high levels of follower satisfaction and commitment to the group and organization (Bass, 1985).

The results from the in-depth interviews of three organizations present the positive relationship of ESTL and EGB. The higher ESTL, the better EGB. From employee level interview, the informants said
“... He acts as the role model...he tries to reduce the waste and energy...and yeah he ride hid bicycle to the office during weekend...and that it influences me” (Employee from Org 2: Strongly agree ++++)

“... (Do you have any role model in the workplace?)...Umm I don’t think we do have now...” (Employee from Org 1: Strongly disagree +)

“... No I don’t have (role model)...I do it by myself, for example, reduce the papers...no one influences me...” (Employee from Org 3: Strongly disagree +)
It can be seen that the results support the past literature as researches are demonstrating environmentally specific transformational leadership as a significant predictor of employees’ green behavior at work (Graves et al., 2013).

Moreover, the relationship between ETSL and EGB is strengthening through internal social marketing (ISM). An important role for internal social marketing (ISM) is highlighted in identifying environmentally concerned employees, or ‘internal customers’, creating incentives and removing barriers to pro-environmental behaviour (Smith, and O’Sullivan, 2012). The results align with the previous research as the informants said

“...the corporate value in terms of environment has been informed at the very beginning – orientation training...also there is an environment week that HR informed via email to encourage ideas for improve environment in our company and daily life...” (Employee from Org 2: Strongly agree + + + +)

“...there are some signs to promote ISO 14001 and environmental issues, for example, waste management...I think this kind of communication help encourage green behavior...” (Employee from Org 1: Partly agree + + +)

Even though; ISM can be seen in other organizations as well, the lack of ESTL prevent ISM from moderating the relationship. The information about ISM has been confirmed through the statement of management level as the informant said

“...So, we communicate (the value of the company that related to environments) through the AuditWizard. If something is wrong in the audit, we communicate to the gap. So, like next week we have the environmental week...Oh, this week...” (Management from Org 2: Strongly agree + + + +)

Environmentally specific transformational leadership (ESTL), employee green behavior (EGB) and corporate internal green Supply chain collaboration

Research shows that participative management style and initiation of goal structure by the team leader have a strong influence on internal team dynamics. These characteristics of leaders had a positive effect on functional conflict resolution, collaboration, and communication quality within the team while discouraging dysfunctional conflict resolution and formal communications (Sarin and O’Connor, 2009).

</table>

The results from the in-depth interviews of both managements and employees were presented in table 5. From all three organizations, Org 2: Automotive is the only corporate that has all four dimensions of ESTL; Idealized Influence, Inspirational Motivation, Intellectual Stimulation, and Individualized Consideration; whereas Org 1:
Food and Org 3: Energy have only one dimension each; Idealized Influence and Individualized Consideration respectively.

Therefore, from the content analysis it can be concluded that both ESTL and EGB has a positive impact on corporate internal GSCC. The statement related to corporate internal GSCC can be found from the interview of management level. The informant said

“... (Do you think that the departments in the company, they collaborate in term of the environmental issue?) ... In the company we have, for example, for a new product. After you select the glue, what type of glue and for environmental reason, the company is pushing to get the glue, that best for environment. We have all water-based glue and solvent-base glue, but in term of XXX standard. We need to select that one because it does not impact on that environment. The team works collaboratively to come up with the product decision... ” (Management from Org 2: Every time + + + +)

“... we work together, for example, in every Monday, we will have weekly basis meeting which will occupy some general topics include environmental issues...” (Management from Org 2: Often + + +)

Wong et al. (2015) mentioned the term “Internal GSCI” and defined it as “the strategic collaboration and integration across internal resources, such as top management, management systems, quality control, and functions via an integrated management system for managing the environmental impacts of the supply chain. From content analysis, it can be summarized that ESTP and EGB tend to have positively impact on corporate internal GSCC because they drive all departments to work collaboratively regarding environmental concerns”.

**Conclusion**

The interpretation of data from the in-depth interviews shows that employees with high PMT tend to have green behaviors both in their personal-life and work-life. Employees who perceived high in severity, vulnerability, response efficacy, and self-efficacy and perceived low in rewards and costs will have high tendency to engage in environmental or greening behavior. They recognize that without proper practice, this issue will then affect their lives. Thus, these employees have a tendency to behave greener, which leads to higher corporate internal green supply chain collaboration. The data from the study also points out those organizations with high environmentally specific transformational leadership (ESTL) often lead to higher corporate internal green supply chain collaboration.

Regarding SET, people who are involved in these interactions are rationally seeking to maximize their profits; in this case, employees were influenced by their leaders, and they wanted to act in line with their leaders’ practice and work more collaboratively with different functions/departments in exchange for preference or rewards. Additionally, an organization’s internal social marketing (ISM) has a role in promoting collaboration. With high ISM activities (e.g., vision statement, announcements, special events), employees acknowledge the rewards and drawbacks of green behaviour; thus, they tend to behave greener, which results in higher green collaboration between functions.

Treasure from waste - How Circular Economy start-ups manage their supply chains

Anna Aminoff (anna.aminoff@hanken.fi)
Hanken School of Economics

Maria Holgado Granados
University of Sussex

Abstract

The Circular Economy concept drives innovative practices and business models targeting sustainable economic growth while increasing resource efficiency. The study reported in this paper aims at bringing together supply chain research and industrial cases inspired on circular economy. It represents empirical investigations into the start-up companies, who are using waste or left-over material as a resource and explores how do these companies develop and manage their supply chains. The results of this paper highlight the importance in getting control over the supply and challenges in attracting partners. The study also identifies needs for the future research to support the implementation of circular supply chains.

Keywords: Supply Chain Management, Circular Economy, Start-ups

Introduction

As concerns about the growing global population and over-consumption of finite resources are increasing, it is apparent that today's linear so-called take, make and dispose models can no longer be continued. The industrial supply chains of today are wasteful, and industries need to rethink their approach to resources. There is an urgent need to create new ways for harnessing and using resources (Brown et al., 2019). Circular economy (CE), as an economic system that minimizes resource input into and waste, emission, and energy leakage out of the system is proposed to offer an alternative solution for these challenges (Geissdoerfer et al., 2018). Reuse in different levels lies in the core of a CE: at the product level, i.e. repair or refurbishment; at the component level, i.e. remanufacturing; and at the material level, i.e. recycling (Zink and Geyer, 2017).

This paper represents the first in a series of empirical investigations into the companies, who are using waste or left-over material as a resource. More and more companies are starting to recognize and extract the value that lies in resources (Bansal and McKnight, 2009), and new roles emerge. For example, those called “decomposers” transform or recycle waste resources into new materials or fractions (Ghisellini et al., 2016). Decomposers play a critical role in closing the resource loop, and in upcycling, which refers achieving higher-quality materials and improved functionality (Lüdeke-Freund et al., 2018).

In reality, there are only few examples of successful circular business (Parida et al., 2019). One reason for that is that implementing these new CE activities requires holistic
and sometimes radical changes beyond the boundaries of a single company (Nußholz, 2018). The decomposers do not work in isolation. They integrate into current supply chains, creating certain disruption on those, while at the same time they need to build their own new supply chains.

The aim of the paper is to create new knowledge related to supply chain implications of companies using waste and/or left over material of other companies as input resources to make as high value new products as possible. In specific, we look at companies that are start-ups as those are often performing this decomposer role with innovative upcycled products. The research questions of this paper are: How do start-ups creating value from waste develop and manage their supply chains? What are the main challenges? What research is needed to advance supply chain management in a CE? We follow Carter et al.’s (2015) approach to supply chains and consider them specific to one product and bounded by the visible horizon of the focal company.

This paper contributes to a research gap on implications of circular economy to supply chains, as supply chain configurations that are aligned with the principles of the CE are largely absent in both practice and academia. Instead our current knowledge on supply chains in the CE is fragmented between several fast-growing research streams with some overlapping constructs.

**Literature review**

The CE can be defined as a regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing, and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling (Geissdoerfer et al., 2017). This definition considers both environmental and economic benefits simultaneously under the notion of ‘regenerative performance’ (Lieder and Rashid, 2016). The definition highlights the idea of putting private business into the service of the transition to a more sustainable system and identifies innovative circular business models as important means in the transformation towards circularity (Geissdoerfer et al., 2018). A circular business model term is used to describe business models that are suited for the CE (Bocken et al., 2016). While the proposed CE strategies are not new by themselves, their combination into a single concept provides a platform for academia and practice to engage constructively (Blomsma and Brennan, 2017).

The business model strategies can be categorized according to the mechanisms by which resources flow through a system. According to Bocken et al. (2016) the three mechanisms are:

1. Slowing resource loops, by extending or intensifying the utilisation period of products, e.g. design of long-life goods and product-life extension through repair or remanufacturing.
2. Closing resource loops, by enhancing recycling practices the loop between post-use and production can be closed.
3. Narrowing resource loops, by using fewer resources per product. This paper focuses on closing the loop by recycling. Although material is often recycled because of inefficiencies in current linear supply chains (Bocken et al. 2016), some recycling at the material level will always be needed (Lüdeke-Freund et al., 2018). Recycling can be categorized to down- and upcycling. The former converts used materials into materials of lower value (e.g., turning clothing into stuffing), and the latter achieves higher-quality materials and improved functionality (Lüdeke-Freund et al., 2018), the latter being the scope in this study. Post-society, post-consumer, post-business or own wastes, products and components flow to manufacturers
either directly or via intermediaries, allowing waste to become input for new products (Wells and Seitz, 2005). There is a plethora of actors operating in recycling supply chains, such as waste generators, collectors, processors end users, and entrepreneurs, who are setting up new ventures around recycling (Lüdeke-Freund et al., 2018). Here “scavengers” and “decomposers”, refer to companies that are capable to extract resources out of waste by applying innovative recovery technologies (Ghisellini et al., 2016). Scavengers collect the waste in points of the disposal and redistribute them into the system to companies that can reuse or recycle such materials making their work easier. After the collection of waste materials, some of the scavengers perform dismantling, sorting, and transport to the decomposers in a form that is readily accessible for them to process. The decomposers in turn transform or recycle waste resources into new materials or as fractions of the same input flows for which they were initially designed (Ghisellini et al., 2016).

Supply chains are assumed to be a critical unit of action for the implementation of the circular business, as supply chains keep material circulating and the complexity and interdependencies of a CE mean that no single company can achieve circular business alone (Aminoff and Kettunen, 2016). For example, recycling business models often connect the downstream and upstream ends of supply chains, requiring the capability to organize comprehensive reverse logistics that connect users, raw material suppliers, and parts manufacturers (Lüdeke-Freund et al., 2018). The term circular supply chain management (CSCM) is used to refer the configuration and coordination of the supply chain to close, narrow, slow, intensify and dematerialise resource loops (Geissdoerfer et al., 2018). Geissdoerfer et al. (2018) suggest a framework for CSCM in which they see supply chains as enablers and drivers for the CE in value network level. The research on CSCM is still very nascent, instead current knowledge on supply chains in the CE is fragmented between several fast-growing research streams, with overlapping constructs and a failure to produce consistent findings (Ghisellini et al., 2016; Masi et al., 2017).

A related literature stream is sustainable supply chain management (SSCM), including closed loop supply chains. In the last two decades, interest towards sustainability has increased in supply chain management (SCM) research, and it has moved to the mainstream and is now an area of significant research activity (Beske and Seuring, 2014; Pagell and Shevchenko, 2014). The conventional view of supply chains depicts them as linear flows of physical goods, information and funds between firms and the end users of products. A more recent stream of research is also considering the disposal of the end-of-life products. Products at their end-of-life stage have little value to the end consumer; yet there remains residual value in the waste (Guide et al., 2009). Reverse supply chains reuse, recycle and remanufacture end-of-life products for inclusion in forward supply chains (Govindan et al., 2014). This practice closes the supply chain loop. Although the research related to reverse loops is growing, it is still in a much more immature state than forward SCM (Govindan et al., 2014). Moreover, this stream of literature focuses mostly on the closed systems where the product returns back to the original manufacturer and thus, don’t fully support the decomposers. Genovese et al., (2015) distinguish between open-loop chains (involving materials from several producers) and closed-loop chains (focusing on a particular manufacturer). However, the terminology is not established and research related to open loop supply chains is still scare.

Our research setting is start-up companies. This creates some SCM challenges compared to large enterprises, related to for instance supply chain integration and relationship management (Kanyoma et al., 2018; Vaaland and Heide, 2007). The traditional small and medium sized enterprise (SME) view of SCM seems to be the exertion of power by customers (Quayle, 2003). Similarly, SMEs do not employ supply
chain management, rather they are managed at arm’s length by larger customers. Another view is that failure by a large company could disrupt the entire supply chain but, as few SMEs are unique, if they failed they could easily be replaced (Quayle, 2003). However, in the setting of this paper, the focal start up companies are trying to create new business, conflicting with this traditional view of SCM in the SMEs.

**Conceptualization of a supply chain**

To research the current practice of circular supply chains, we adapt the conceptualizations of SCM developed by Carter et al. (2015) and Sweeney et al. (2015) (as summarized in the Figure 1). Based on Carter et al. (2015), we see the focal company as a node, node being defined as ‘as an establishment which is an agent that has the ability to make decisions and maximize its own gain within the parameters in which it operates’ (Carter et al., 2015, p. 90). Node is connected by links to other companies. Each node in the supply chain has control over resources and has accountability. The supply chain is relative to a particular product and agent and is bounded by the visible horizon of an agent (Carter et al., 2015). We further adopt the four fundamentals of SCM developed by Sweeney et al. (2015), defining the essence of SCM as:

1. (Setting) SCM objectives, which are mostly linked to customer service, financial optimisation and sustainability.
2. SCM philosophy, which is based largely on the integration concept.
3. Managing supply chain flows, particularly material, financial and information flows.
4. Supply chain relationships, in specific their creation and management.

**Figure 1 – Conceptualization of CSC, modified from Carter et al. (2015) and Sweeney et al. (2015).**

**Method**

This study extends and complements earlier literature by adding a new understanding of implications of novel circular business models to SCM, in specific in industrial settings where companies performing new ways of creating value from previously wasted materials. A multiple case study design was chosen to match the state of current theory and the exploratory goals of the study (Yin, 2009). The approach is well-suited to new research areas when new perspectives are sought and/or when there is little knowledge available about the complex phenomenon being studied (Eisenhardt, 1989).

The two case companies where selected based on theoretical sampling (Eisenhardt and Graebner, 2007). We searched for and selected the industrial cases that (1) are creating value from previously wasted materials, (2) have new roles in a supply chain...
(decomposers), (3) are start-ups. Our unit of analyses is one agent and one product, and is bounded by the visible horizon of the focal company (Carter et al., 2015).

Our main data collection method is semi-structured interviews. The interviewees were selected on the basis of their central role in their respective company (see table 1). The interview instrument relied on the conceptual framework (see Figure 1). Following a replication logic (Eisenhardt and Graebner, 2007) the cases are first analysed and coded individually. Afterwards, data is revisited in cross-case analyses where patterns across the cases are matched and explanations are built for the occurrences in the data.

**Table 1 Overview of the studied cases**

*Company Alpha:* Alpha is a start-up that has developed a proprietary technology enabling the transformation of pre-consumer food waste into high-value inputs to agricultural processes, in particular to agri-food. Alpha operates in a challenging regulatory environment due to legal and safety constraints. They are working together with governmental regulators to create updated standards and regulations to cover their activities as well as focusing on achieving scale and raise funding to grow their business. These issues create additional challenges in supply chain management and engaging new partners.

*Company Beta:* Beta collects post-use or post-production textile waste materials, and convert them into high-end consumer products. They gave a strong focus on timeless designs and durability for their final products. Although the company competes with other high-end garment companies, they do not feel direct competition due to the uniqueness of their products (i.e. made out of reclaimed textiles). Additionally, Beta works with a zero waste goal for their manufacturing processes and facilities and their energy use is based on renewable sources.

**Results**

This section presents the findings from the analysis of the two cases and proposes future research needs building on these results. The cross-case analyses is summarized in the Table 2.
### Table 2 – Cross-case table

<table>
<thead>
<tr>
<th>Case Alpha</th>
<th>Case Beta</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CE aspect</strong></td>
<td>Can be considered a case of upcycling. It converts post-use or post-production textile materials into high value consumer products. The final products are life-long durable products; the company also offers repair services for the products. The products cannot be further recycled after use, so the focus of the company is on providing a long-lasting products (made out of reclaimed material).</td>
</tr>
<tr>
<td>Alpha converts (low value) pre-consumer food waste into high value inputs for agricultural (agri-food) industry based on the innovative technology the company has developed. The final product is fully consumed when used as input for agroindustry.</td>
<td></td>
</tr>
<tr>
<td><strong>Business objective</strong></td>
<td>Keeping materials from going to landfill (in the short term) and transitioning towards a systemic closed loop of resources at industry level.</td>
</tr>
<tr>
<td>Reducing environmental impact while bringing more value and higher positive impact into the agricultural food systems. Achieving competitiveness.</td>
<td>To have control over the supply chain. Creating long-term partnerships with the suppliers of waste materials. Beta is vertically integrated, and is doing designs, collection of waste and manufacturing all in-house.</td>
</tr>
<tr>
<td><strong>SCM objective &amp; philosophy</strong></td>
<td></td>
</tr>
<tr>
<td>‘Trying to survive’ in very regulated environment due to technology not being widely use – it is a new market.</td>
<td></td>
</tr>
<tr>
<td><strong>Structure: physical SC</strong></td>
<td></td>
</tr>
<tr>
<td>Upstream Holders: Pre-consumer food waste suppliers are large vegetable packaging and processing companies, up to supermarkets, including transport loses and damages of fruits. Alpha has problems in engaging suppliers.</td>
<td>Suppliers: various waste producing operations (for instance cut-offs from textile processing factories) All input materials (raw material) are reclaimed, even for packaging.</td>
</tr>
<tr>
<td>Downstream Holders: B2B customers: Agri-food manufacturing companies. The end users would be the farms.</td>
<td>B2C customers: Beta sells through their website directly to consumers. They rarely collaborate with carefully selected retailers.</td>
</tr>
<tr>
<td><strong>Structure: Support SC</strong></td>
<td></td>
</tr>
<tr>
<td>Alpha collaborates with investors and governmental regulators. It works together with regulators to advance regulations.</td>
<td>Beta’s scarce collaborations with selected retailers or short-term pop-up sales points are a key part of their support SC.</td>
</tr>
<tr>
<td><strong>Material flow management</strong></td>
<td></td>
</tr>
<tr>
<td>The main challenge is to match supply and demand, i.e. matching food waste availability, which is currently just samples, and feed buy-in (thousand tonnes are required for the technology investment to be viable). Alpha struggles to get a constant food waste flow. Alpha aims to get partners (suppliers) to be more involved.</td>
<td>For Beta, it is important to have control over the supply chain; and the company is vertically integrated. Beta carefully assess opportunities to work with new reclaimed materials, as new input materials will require new designs and manufacturing processes. Beta is concerned about growing and losing the capacity to have full control and visibility over the supply chain.</td>
</tr>
<tr>
<td><strong>Supply chain relationships</strong></td>
<td></td>
</tr>
<tr>
<td>Alpha is trying to balance between the development of the legal framework via engaging with regulators, investors, who require viability proofs and engaging suppliers, and the securement of supply collaborations. The main challenge on the supply side is that potential suppliers of food waste require assurance of this scheme to work and want to wait until the whole supporting system is ready.</td>
<td>Beta considers their suppliers as partners and has established win-win collaborations with them. These relationships are based on trust and strong environmental values. It is difficult to engage big suppliers. Beta needs to prove its reliability by for instance short term contract agreements until it can establish a long-term collaboration agreement.</td>
</tr>
</tbody>
</table>
Next, we rise some interesting observations from the results. These observations highlight both the major challenges in the SCM of these kinds of circular business models and the aspects that would need more research. To streamline the presentation of our findings we link the emergent findings with existing literature already in this section. This tying of emergent findings to the enfolding literature “enhances the internal validity, generalizability, and theoretical level of theory building from case study research” (Eisenhardt, 1989, p. 545).

**Observation 1: The environmental objectives are highlighted instead of financial optimisation.** Even that prior research (Johnsen et al., 2017; Sweeney et al., 2015) has identified sustainability as one of the objectives of the supply chain, the financial objectives almost tend always win (Montabon et al., 2016). However, in our cases the environmental objectives come first, and it seems that financial optimising of SCs is not the priority of the companies.

**Observation 2: Building a supply chain and engaging partners is challenging for companies operating in an unconventional business area.** Both our case companies struggle with how to build a supply chain and attract partners. Both companies find hard to collaborate with big companies and to get their voice heard. Representative of Beta highlighted that some of their potential partners are big companies and it is hard to engage them. Also, collaboration does not happen fluently as the working practices and objectives do not often match well between small and big companies. Due to being a start-up in an unconventional business area, Beta needs to prove its reliability, by for instance engaging in short term contract agreements until it can establish a long-term collaboration agreement. Alpha in its turn struggles to even get the suppliers engaged (to get a contract). The company gets relatively easily samples of food waste for free but struggles more to get (future) contracts for a constant food waste flow. This challenge has been recently addressed also in purchasing and supply management literature, in particular under concept of customer attraction, although the maturity of the literature focuses on the situation where the customer has a power (Hald et al., 2009; Tanskanen and Aminoff, 2015). The key question is how to make the business attractive in the eyes of the potential partners.

**Observation 3: Companies look for partners who share their sustainability values and morality.** In line with the first observation, both of the companies emphasize that they look for partners with similar values. Especially case company Beta found difficult to find partners that share same values and morality. Previous literature (see Johnsen et al., 2017) focuses mostly on price and quality aspects in supplier selection, and the sustainability aspects are often related ‘not selecting (too) unsustainable’ suppliers.

**Observation 4: Getting control over the supply is crucial to build effectively their operations.** Getting control over the supply is one of the main objectives for both of our case companies. For Company Alpha, it is difficult to match the supply and demand, as it only has managed to get samples from the potential suppliers, and at the same time the customers are expecting thousands of tons volume. Company Beta is vertically integrated from raw material collection to final products sales. A key for it is to keep control of the origin of all materials, even the in small quantities, and it has put a lot of effort on it. Beta carefully assess opportunities to work with new reclaimed materials, as new input materials will require new designs and manufacturing processes. The final product will be designed depending on what are the intrinsic properties of the reclaimed materials. Getting material it cannot store or develop a good solution for would not be any use for them. Beta is concerned about growing and losing the capacity to have full control and visibility over the supply chain.
Observation 5: Investors and regulators are identified as important actors in larger support supply chain. Alpha collaborates both with investors and governmental regulators and considers them as part of its wider support supply chain. Collaborating with regulators to solve the regulatory hindrances is one of the main objectives of their SCM. The regulatory unclarities complicates Alpha’s effort to involve partners. Processing the food waste by a novel technological process raises concerns and falls outside current legislation. While there is no evidence that processed food waste could introduce food safety hazards used within this novel approach, there is no evidence of the contrary neither. Taking investors and regulators as part of wider support supply chain would need more attention in academic debate. Also the results of Geissdoerfer et al. (2018) emphasize the importance of a proactive multiple stakeholder management as part of SCM. Carter et al (2015) argue that our current perspective of the supply chain may be oversimplified. According to Carter ‘we tend to think of the members of the supply chain through which products physically flow and generally fail to explicitly take into account the many additional members of the supply chain that play a vital but indirect, supportive role in the movement, storage, and transformation of product across organizations’.

Conclusions
Our research enriches both the current SSCM and CE literature by bringing together concepts from SCM, in particular conceptualizations developed by Carter et al. (2015) and Sweeney et al. (2015), and CE industrial cases. The case companies are start-ups who are using waste or left-over material as their input and are aiming to upcycle, i.e. make high value products out of that. SSCM literature can learn from the analyses of these cases as research in these spaces that try to do things totally differently could help us to identify what the truly sustainable supply chains might look like (Pagell and Shevchenko, 2014), potentially leading to more sustainable supply chains and, in general, to more sustainable industrial systems and defining a way towards sustainable development. The previous research on sustainable supply chains has been criticized to apply an instrumental logic that asks how can a supply chain benefit from addressing environmental or social issues as compared to how can a supply chain become sustainable (Montabon et al., 2016). For instance, the emphasis in supply chain research is often waste reduction within a firm, and supply chain research has not ‘fully won the battle on waste’ (Bansal and McKnight, 2009).

This study links the discussions of CE and SSCM. Although research in supply chains and CE both aim to reduce waste between organizations, and closing the loops, surprisingly little CE research has penetrated the research stream on supply chains. As the linkages of these streams are scare, it may also lead to a fragmented literature, with overlapping constructs and a failure to produce consistent findings.

We identified some major hindrances in achieving efficient supply chains and circularity. More research is needed to provide guidance for companies on how to overcome these hindrances. In particular, following topics raised from our results:
- How to get control over the incoming flow?
- How to build the supply chain and to attract the partners in an unconventional business area? How to involve partners with same values?
- How to manage and collaborate with the various actors in a physical and support SC?

This paper represents the first in a series of empirical investigations into the companies, who are using waste or left-over material as a resource. As a next step we will
have more cases (in total 7-9) to get more in-depth understanding of the supply chain implications and challenges.

Abstract

Circular Economy is one of the more robust pro-sustainability schools of thought. It proposes a change from a take-make-use-dispose economic model in favour of a restorative, regenerative approach and is also applicable to agri-food supply chains, where different CE practices are already in use. The relationship between supplier and buyer plays a role in this adoption process. This paper draws from the literature on CE practices, diffusion processes – drivers, barriers and enablers – to CE and Transaction Cost Economics to propose a framework for the identification of the characteristics and the role of transactions in the diffusion process.

Keywords: Circular Economy, Transaction Cost Economics, Circular Economy diffusion

Introduction

Organisations are increasingly required to prioritise pro-sustainability practices not only into their operations but also in the supply chains they are part of (Batista et al. 2018a; Batista et al. 2018b). Circular Economy (CE) is one of the most robust approaches to such an end, with frameworks supporting managerial and operational practices, like closed and open loops of materials, green strategies, and ‘R’ practices (reuse, reduce, recycle, redistribute, reclassify, etc.) (The Ellen MacArthur Foundation, 2013; Weetman, 2017). CE is understood, therefore, as both a pro-sustainability philosophy and a practical guide for policy, organisational operations and consumption.

Sustainability is a serious concern in the agri-food industry (Dani, 2015), with CE practices being increasingly adopted throughout agri-food supply chains (Vlajić, Mijailovic and Bogdanova, 2018) forming circular agri-food supply chains (CAFSC). This paper offers a conceptual model for the analysis of the diffusion of CE practices in agri-food supply chains, encompassing the identification of CE practices and related drivers, barriers and enablers. The role of transactions in such process is also considered.
Transactions - the exchange of products/services between actors in a supply chain – can also play a role in the diffusion of CE operations. For instance, contractual obligations to specific standards and practices can make organisations adopt CE practices to sell their products. However, previous research (Célio et al., 2018) has shown that contractual obligations can also lead to higher food waste, thus jeopardising one of the central tenants of CE. Adding to the complexity of this issue, it is also possible that transactions and governance structures vary according to different stages of production and supply chain (Maaß and Grundmann, 2018). To better understand the role that transactions can play in CE diffusion in agri-food chains, it is first necessary to clarify the characteristics (dimensions and types of contract) of the transactions in CAFSC. The framework proposed here uses Transaction Cost Economics (TCE) as the theoretical bases to that end.

This paper is structured as follows: Circular Economy overview and practices, Circular Economy adoption, transaction characteristics in CAFSC, proposed conceptual framework and final considerations.

**Circular Economy overview and practices**

Different authors have described CE in various ways, such as a pro-sustainability collection of schools of thought and as a framework for policy, business models, organisational relationships and production (The Ellen MacArthur Foundation, 2013; Ghisellini, Cialanì and Ulgiati, 2016; Michelini et al., 2017; Weetman, 2017). The basic concept, however, remains the same throughout both the history of CE and the different works that discussed it: the change from linear ‘take-make-use-dispose’ production and consumption systems to circular ‘restorative and regenerative’ approaches (Stahel, 1982; The Ellen MacArthur Foundation, 2013).

Urbinati et al. (2017) identified the principles of CE as product life extension, redistribution/reuse, remanufacturing and recycling. Similarly, Batista et al. (2018) pointed out three core elements in CE: closed and open loops, with resources kept in the economy through reuse, repair, remanufacture and recycle of products not only in the original supply chain but also in different supply chains or industries; functionality and experience over ownership of a product; and collaborative and shared consumption models whenever possible. Another relevant characteristic of CE is the possible uses in different industries, whether they are on technical products, (e.g. cars or cell phones) or biological products (e.g. food), although they have different operations associated (The Ellen MacArthur Foundation, 2013; Weetman, 2017).

One of the major themes in the operations and practices regarding CE are the ‘R’ practices. Reduce, reuse and recycle (3Rs) are the more well-known operations linked with CE (Jun and Xiang, 2011; Govindan and Hasanagic, 2018) but other R practices were developed for greater differentiation of possible operations within CE, such as redistribute or repurpose (Ghisellini, Cialanì and Ulgiati, 2016; Jawahir and Bradley, 2016; Kirchherr, Reike and Hekkert, 2017; Weetman, 2017). Other examples of CE practices that are not within the ‘R’ categories also exist, including green-purchasing and audits for CE performance evaluation (Govindan and Hasanagic, 2018; Masi et al., 2018).

In the framework proposed in the present paper, not all ‘R’ practices discussed in CE literature are included. Considering quality standards in food and more importantly, food safety legislation (The European Parliament and Council of the European Union, 2002; Secretary of State, 2013), some of the R were excluded: repair, remanufacture, refurbish and recondition. Table 1 shows the range of CE practices considered in the framework, based on the works cited above.

In summary, to understand the diffusion of CE practices in an agri-food supply chain, it is necessary first to identify what are those practices. Table 1 compiles possible operations, both already used or potentially useful for organisations in those supply chains according to the literature. The next section addresses the adoption of CE practices by organisations and the supply chains they are part.

**Circular Economy adoption**

To understand the diffusion of technologies, practices, operations and other such multifaceted constructs (Eveland, 1986; Peng, 2011) it is necessary to understand the adoption process made by organisations. According to Dossa et al. (2018), several elements can influence the decision maker of an organisation to adopt new technology. Technology is not only hardware or information and communication technologies (ICT), but any application of knowledge to solve a problem, even an operation, a managerial practice or know-how. Therefore, the adoption of CE practices can also be discussed as the adoption of technology and benefit from the use of models linked to this issue.

It is beneficial to use a model to simplify and allow the operationalisation in research or practice considering the complexity involved in decision-making processes. The framework proposed in this paper adapts the model proposed by Dossa et al. (2018) since it is linked with the adoption of new practices and technologies in an agri-food supply chain setting. There are several possible elements influencing decision-makers, and the model proposed by the authors classifies them in three categories: drivers, barriers and enablers.

Drivers (also called motivators) to adopt CE have been considerably investigated and discussed by previous works. Academic papers and policy reports have approached this topic in several levels - organisational, supply chain, sectoral and national - both in academic papers and policy reports (Jesus and Mendonça, 2017). The work of Govindan and Hasanagic (2018) is used as the basis for the list of potential drivers in this proposed framework, and the reasons are twofold: the considerable depth of Govindan and Hasanagic (2018) literature review and the focus on supply chains. Table 2 shows the
different drivers compiled by those authors, divided into five categories: policy and economy, health, environmental protection, society and product development.

| A. Policy and economy                  | A1. Compliance to regulation |
|                                      | A2. Governmental incentives   |
| B. Health                             | B1. Concern to public health  |
|                                      | B2. Concern to animal health  |
| C. Environmental protection           | C1. Fight climate change      |
|                                      | C2. Adapt agriculture         |
|                                      | C3. Reduce environmental impact|
|                                      | C4. Concern with sustainable development |
| D. Society                            | D1. Urbanisation and its influences |
|                                      | D2. Organisations expansion   |
|                                      | D3. Consumer demands          |
| E. Product development                | E1. Increase product efficiency|
|                                      | E2. Increase in product value  |

Source: (Govindan and Hasanagic, 2018)

Not only drivers should be counted when discussing the diffusion of CE practices. Barriers to the adoption also need to be contemplated (and overcome) for the implementation of CE in supply chains. Barriers are obstacles or hindrance that thwart the transition to CE practices (Jesus and Mendonça, 2017). It is possible, therefore, to consider as a barrier any element that can difficult, slow down, increase costs or completely stop the implementation of CE practices in organisations and supply chains. Many works have discussed barriers for CE practice implementation (Jesus and Mendonça, 2017; Govindan and Hasanagic, 2018; Kirchherr et al., 2018; Mangla et al., 2018) using different approaches, such as systematic literature review, expert interviews, organisational surveys, among others.

The framework used for this thesis employs the barriers identified by Kirchherr et al. (2018). The study conducted by the authors allowed not only the identification of barriers but their hierarchy and the relationship among the different types of barriers. Figure 1 presents the findings of the authors. Although they do not specifically address agri-food supply chains, there is no indication that it does not apply to such context.

Figure 1 – Key CE barriers and their interaction (Kirchherr et al., 2018, p. 270).
Enablers are elements that aid in overcoming barriers to adoption. They can be technological, institutional or cultural aspects that facilitate, increase the interest or reduce the risks or costs of adopting CE practices. Table 3 lists the enablers considered in this current paper, based on the work of Mishra et al. (2018) regarding system enablers linked to CE.

When the information presented in Figure 1 and Tables 1, 2 and 3 are considered together, it is possible to construct the first part of the proposed framework, as shown in Figure 2 below. From the Circular Economy theory, a set of operational concepts (OC) are derived, encompassing the practices to be investigated, as well as the drivers, barriers and enablers to the adoption of them.

The next section of this paper introduces the supporting theory to the framework. With it, the final theoretical elements for the model are added to support the use of the conceptual framework.

**Transaction characteristics in CAFSC**

Every time a product (tangible or not) is provided to a client, an (economic) transaction occurs (Douma and Schreuder, 2013). Transactions are defined here based on Dietrich (1994) as the exchange of good and services, as well as their property rights and related contractual obligations. Considering that organisations in a given supply chain continually trade goods, funds and information with clients and suppliers, transactions are a relevant element to be further understood in the discussion of CAFSC. The study of transactions and the economic elements (e.g. costs) associated with it, was introduced by Ronald Coase and further developed by Oliver E. Williamson (Defee et al., 2010; Kolmar, 2017) and is known as transaction cost economics (TCE) or transaction cost theory.

TCE arguably emerged as a theory (or framework) of buyer-supplier interactions, inter-firm governance and vertical integration. While vertical integration was the first problem systematically studied in TCE, it is not the only one, since the theory evolved into a broader explanation of organisations, their boundaries and governance, including property rights, supplier selection, channel structure, among others (Williamson, 1998;
In the framework presented in this paper, the TCE approach is used to explore/discuss the buyer-supplier interaction and inter-firm governance in the CAFSC, following the recommendation of other scholars like Meixell and Luoma (2015) and Maaß and Grundmann (2018).

It is relevant first to understand the characteristics of said transactions to accomplish the identification of transactions role in CAFSC (Maaß and Grundmann, 2018). Two basic underlying assumptions regarding transactions must be clarified for it to be feasible. The first is ‘bounded rationale’ and describes the limited capacity that humans possess to be able to compute large amounts of data and complex problems (Williamson, 1998). It relates to uncertainty and complexity, and the impossibility of accounting for every potential scenario in all situations (Douma and Schreuder, 2013), and how to anticipate that. The second is ‘opportunism’, that is, ‘seeking self-interest with guile’ (Williamson, 1998). Opportunism can be ex-ante (before the transaction) or ex-post (after the transaction) (Douma and Schreuder, 2013; Klein, 2013). All of this is contained and influenced by culture, institutions, traditions, norms, legislation, etc. (Williamson, 1998, 2008; Douma and Schreuder, 2013).

Transaction costs are generated in transactions by several factors such as identification of buyers and sellers and negotiations and successful conclusion of contracts (Davies and Lam, 2001). Considering this context (costs origins and behaviour assumptions), TCE identifies three dimensions of transactions that are critical to discuss their characteristics (Williamson, 1998; Douma and Schreuder, 2013):

- **Asset specificity**: the degree in which resources are tied to a specific transaction, and redeployment to alternative uses is doubtful, leading to a decrease in the value of the asset. It can be human, physical, location or dedication (Jraisat, 2010);
- **Uncertainty**: Often paired with complexity, it relates to the level of possible unexpected changes (disturbances) in the environment surrounding the transaction, leading to difficulty in adaptation, especially if the parts are contract-bound (Williamson, 1998; Wever et al., 2012).
- **Frequency**: how often actors transact with each other (Wever et al., 2012). It is connected with reputation effects and setup costs (Williamson, 2008; Jraisat, 2010). For this paper, its operationalisation is proposed as ‘short’ (<1 year) or ‘long-term’ (>1 year) and ‘sporadic’ (random occurrences) or ‘common’ (regularly repeated).

The final element to be considered are the types of contractual schemes possible. The framework follows Ménard (2004) categories of hybrid organisations plus the pure forms of *spot market* and *hierarchies* as described by (Williamson, 1998, 2008).

<table>
<thead>
<tr>
<th>Table 4 – Transaction characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asset Specificity</td>
</tr>
<tr>
<td>Uncertainty/Complexity</td>
</tr>
</tbody>
</table>

Source: (Williamson, 1998, 2008; Ménard, 2004; Jraisat, 2010; Wever et al., 2012)

The information in Table 4 supports the empirical identification of the characteristics of the transactions occurring in CAFSC. Although it is not possible with such data to compare vertical integration versus market purchase nor test the efficiency of different contracts for CAFSC, it is a first step needed to grasp the role of transactions in the diffusion of CAFSC, following a similar pattern to transaction identification of previous works (Williamson, 2008; Maaß and Grundmann, 2018). Figure 3 shows the second part of the framework, based on the information discussed in this section.
As Figure 3 shows, TCE is the supporting theory in this discussion of CE diffusion in agri-food supply chains. Since it is a well-developed field of research, it is essential to delimit its use to be able to operationalise it as research. Therefore, the OC examines a set of characteristics of transactions with concepts derived from the TCE. The next section presents and discuss the complete conceptual framework.

Proposed conceptual framework

The use of any framework depends on the application to a specific setting. For this particular case, it is recommended the application in agri-food supply chains given the specific issues related to those supply chains (Batista, Saes and Fouto, 2015; Vlajic, Mijailovic and Bogdanova, 2018), such as different CE practices, high environmental uncertainty, location differences, among others. Therefore, the field of application (in this case CAFSC) is the setting where the actors of a given supply chain execute the CE practices, the transactions, and that encompass the drivers, barriers and enablers.

Figure 4 shows the linkage between the parts of the framework. The bi-directional influence between the different OC also needs explanation. Although contractual transactions might drive the adoption of CE practices (consumer demands, Table 3, D3), other roles are possible in this interaction of concepts. For instance, the client might require specific criteria of food standards (e.g. fruit beauty standards), leading to edible food being wasted, thus becoming a barrier for CE-practice (e.g. waste reduction). Formal ties might also enable the adoption of CE practices, such as to share farming equipment (service over ownership).

On the other side of it, it is viable to consider that the diffusion of CE practices might lead to the need for transactions adaptation via contractual obligations. For instance,
increased asset specificity (e.g. investment in silos for grain segregation for traceability) might require adaptation in a buyer-supplier relationship, like increased premiums or third-party usage (e.g. grain storage cooperatives) (Maaß and Grundmann, 2018). Therefore, the role of the transactions in CAFSC can be multiple and vary according to the stage of the supply chain, type of products (e.g. cereal, meat and dairy, fresh products, etc.), different practices, among others.

It is recommended to use the framework with a case-study approach considering the number of possible variations and unknown specific elements per food-type, supply chain design or location. It is also recommended to differentiate the supply chains in terms of location (i.e. different countries) or main agri-food product (e.g. cereal, meat-diary, horticultural products). Different contextual constraints (legislation, institutions, edaphoclimatic elements, among others) can affect the operations and the transactions differently, therefore requiring customised approaches to the topic of CE diffusion.

**Final considerations**

The framework proposed in this paper can be used to investigate CAFSC, both in academic and policy-related research empirically. Its use can bring data that allow the comparison of different agri-food supply chains regarding practices, drivers, barriers, enablers and transaction roles. This especially relevant for actors that wish to promote CE as a pro-sustainability economical system.

Future research should focus on the study of CAFSC cases, thus allowing the specific CE practices, drivers, barriers, enablers and transaction characteristics, to be identified for each agri-food supply chain. With greater specificity, the resources needed to implement CE practices can be used more efficiently if fewer errors happen because of maladaptation. Too many unknown variables in specific industries reduce the possibility of quantitative large-scale CAFSC studies.

Different theoretical frameworks like Resource-Based View (RBV) and Stakeholder Theory can be used to discuss the role of various supply-chain actors in the diffusion of CE practices in supply chains. Nevertheless, TCE has at least three differentiating factors. First, it has a more specific concern in the buyer-supplier relationship if compared to other theoretical options, an element still needed for further clarification within CE theory (Meixell and Luoma, 2015). Second, the amount of microeconomics and finance research in CE is minimal if compared to other areas such as operations or environmental management and the use of a well-established field within microeconomics can improve on that front. Finally, the use of TCE to discuss the role and characteristics of transactions in CE diffusion facilitates future research exploration on costs to implement and govern circular supply chains (Maaß and Grundmann, 2018). Future studies that analyse contractual details of circular supply chains can also benefit from the pre-identified characteristics from the use of this framework.

Some limitations of the proposed model need to be made clear. The model does not attempt to use the entire TCE theory potential. This means that possible TCE studies within CE can be done in the future such as those proposed by Meixell and Luoma (2015). The present paper is constrained to the identification of the characteristics prevalent in transactions in CAFSC and clarify the role of transactions (e.g. contractual demands for CE-related operations) in the diffusion of CE practices.

Abstract

This case study offers empirical insights on how actors of supply chains (SCs) for fair(er) electronics engage in multi-tier sustainable supply chain management. A content analysis was conducted to analyze semi-structured interviews and public documents from companies at multiple SC stages. The results suggest that direct and long-term relationships are essential in order to enhance the sustainability of lower-tier suppliers. Furthermore, differences were found on how companies work with third parties for the management of lower-tiers. The study follows the call to analyze enterprises with a social purpose to gain possible insights on how truly sustainable SCs might be created.

Keywords: multi-tier supply chain management, sustainability, electronics industry

Introduction

The ‘chain liability effect’ (Hartmann and Moeller, 2014) in conjunction with the ‘supply chain position paradox’ (Schmidt et al., 2017) put considerable pressure on companies – particularly on those with a high visibility towards the final customers. Many companies are driven to ensure the sustainability among multiple tiers, as they face the risk of being held accountable for social and environmental issues stemming from other members of their supply chain (SC). However, managing so-called ‘lower-tier suppliers’ has become significantly more difficult because outsourcing and global sourcing trends have led to more complex and longer SC structures in which the visible horizon of firms decreases with the increase of distance (Carter et al., 2015). Especially labor-intensive production activities have shifted to low labor-cost countries, in which low social and environmental legislations are common (Di Mauro et al., 2018).

In recent years, sustainable supply chain management (SSCM) has attracted the attention of industry and academia as a concept to deal with sustainability issues and risks. Despite that the majority of sustainability threats are caused by lower-tier suppliers (Tachizawa and Wong, 2014; Grimm et al., 2014), research on SSCM is still largely centered on the management of direct and first-tier suppliers as well as simple dyadic relationships (Miemczyk et al., 2012). The recently emerged multi-tier SSCM (MT-
SSCM) aims at filling those research gaps by extending the unit of analysis to lower-tiers. However, since MT-SSCM has just started to gain momentum, empirical studies are still quite rare (Villena and Gioia, 2018).

For this reason, this study aims at answering the following research questions (RQs): (1) How is the sustainability managed in multi-tier supply chains? (2) What governance approaches and sustainable supply chain management practices are adopted to manage lower-tier suppliers?

In order to answer the RQs, the study focuses on the electronics industry in which even the large companies frequently struggle to ensure the sustainability of their global and highly fragmented SCs. However, instead of researching conventional SCs, the analysis focuses on three social enterprises (SE) and their SCs that are currently challenging the prevailing management strategies of the industry. The companies with a social purpose search for new and innovative ways to produce their electronic devices as sustainable as possible. Despite of their small size and limited power, the SEs are often regarded as pioneers with respect to sustainability. By analyzing this unique case – SC for fair(er) electronics, the gathered insights might serves as starting points for truly sustainable SCs (Pagell and Shevchenko, 2014).

Theoretical background

Sustainable supply chain management and practices

While the literature on supply chain management (SCM) has grown over the last decades, links have been increasingly made between SCM and sustainability management. This ultimately lead to the development of SSCM that can be defined as “the management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account which are derived from customer and stakeholder requirements” (Seuring and Müller, 2008, p. 1700). In order to successfully implement SSCM, different practices have been identified that can be group into five categories (Beske and Seuring, 2014). The five categories and related practices are presented in the following table:

<table>
<thead>
<tr>
<th>Category</th>
<th>Description of SSCM practices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Orientation</td>
<td>A ‘Dedication to TBL’ and ‘Dedication of SCM’ are both important for the successful and devoted implementation of SSCM. Especially top-management support and the integration of SSCM thinking into the corporate strategy have been found to be crucial success factors. (e.g. Pagell and Wu, 2009; Beske and Seuring, 2014)</td>
</tr>
<tr>
<td>Continuity</td>
<td>This category groups practices which set the structural foundation for SSCM. ‘Long-term relationships’ are important prerequisites for successful SC collaborations and should be established at least with key SC partners. Since the SC performance is defined by its weakest link, ‘SC partner development’ and ‘SC partner selection’ can help to achieve the desired SC performance outcomes. (e.g. Seuring and Müller, 2008; Pagell and Wu, 2009)</td>
</tr>
</tbody>
</table>
| Collaboration| Practices of this category are of structural and operational nature. ‘Technological integration’ (e.g. installing of mutual IT infrastructure) and ‘Logistical integration’ (e.g. collaborative planning and forecasting with suppliers and customers) are practices that support SC collaborations. The actual practices for collaboration are ‘Enhanced communication’ (e.g. sharing of relevant information and knowledge and the ‘Joint development’ (e.g. inter-
Multi-tier perspectives in SSCM

One of the first major MT-SSCM contributions stems from Tachizawa and Wong (2014) who explored how sustainability in multi-tier SCs can be managed. The authors found four governance approaches (‘Direct’, ‘Indirect’, ‘Work with third parties’ and ‘Don’t bother’) that can be applied by companies for the management of lower-tier suppliers and contextual factors (‘contingency variables’) that determine the adoption and effectiveness of governance mechanism. A description for each governance approach is provided in the following table:

<table>
<thead>
<tr>
<th>Governance approach</th>
<th>Description of MT-SSCM governance approaches</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Direct</strong></td>
<td>Companies can reach out to lower-tier suppliers and establish direct contact by bypassing the first-tier supplier. The governance approach is most likely applied when companies possess the required capabilities to manage lower-tier suppliers and face risks related to stakeholder pressure and/or material criticality. (e.g. Tachizawa and Wong, 2014)</td>
</tr>
<tr>
<td><strong>Indirect</strong></td>
<td>Companies indirectly manage their lower-tier suppliers through first-tier suppliers – often to avoid complexities. The application of the ‘Indirect’ governance approach requires some form of power over the first-tier supplier and is most likely used by focal firms that face stakeholder pressure but lack the resources to manage lower-tier suppliers. (e.g. Grimm et al., 2014; Wilhelm et al., 2016b)</td>
</tr>
<tr>
<td><strong>Work with third parties</strong></td>
<td>Companies manage the sustainability of lower-tier suppliers with the help of third parties. For instance, firms engage with third parties (e.g. NGOs, competitors) for their management know-how or to develop sustainability standards. The governance approach is most likely applied when companies face stakeholder pressure but lack SC power or management knowledge. (e.g. Villena and Gioia, 2018; Dou et al., 2018).</td>
</tr>
<tr>
<td><strong>Don’t bother</strong></td>
<td>Companies have no information or intention to manage lower-tier suppliers. They simply focus on the management of first-tier suppliers. This governance approach may be applied by firms that have limited SC power, face low</td>
</tr>
</tbody>
</table>
Apart from Tachizawa and Wong (2014), other authors have also contributed to the MT-SSCM field. For instance, Grimm et al. (2014) identified critical factors that determine the sub-supplier compliance with sustainability standards. Dou et al. (2018) studied enablers for sub-suppliers’ environmental performance improvements and found that especially top-management support is a crucial prerequisite for green multi-tier SCM. Grimm et al. (2016) investigated how the sub-suppliers’ compliances with corporate sustainability standards can be managed and propose assessments (e.g. audits, site-visits, supplier questionnaires) and collaboration (e.g. training, workshops, corrective action plans) as management practices. Wilhelm et al. (2016b) studied the crucial role of first-tier suppliers in the management of sub-suppliers and found that first-tier suppliers can act as agents which fulfill the focal firms’ sustainability requirements and implement those requirements in their suppliers' operations and thus in the lower-tiers of the SC. Based on a multi-case study, Meinlschmidt et al. (2018) suggest different strategic management approaches for lower-tier suppliers and also contextual factors leading to sustainability risks. Sauer and Seuring (2018) explored the major sustainability challenges in mineral SCs and suggest management approaches to address them. Roehrich et al. (2017) studied how supplier selection and value internalization drive green SCM and found both to be crucial mechanisms for performance improvement at second-tier supplier levels. Jia et al. (2018) studied how multi-national corporations facilitate the learning of sustainability practices in multi-tier SCs and suggest that pro-active focal firms adopt a transformational leadership style and directly approach extreme lower-tier suppliers to implement sustainability initiatives. Gong et al. (2018) explored how multi-national corporations arrange their internal and external resources to facilitate the sustainability knowledge in multi-tier SCs and found that many focal companies integrate third parties in the SC to gain the required knowledge for sustainability initiatives. Wilhelm et al. (2016a) explored the MT-SSCM strategies used in different industries and identified that the sustainability focus impacts how focal firms manage the sustainability of sub-suppliers. Villena and Gioia (2018) built a grounded theoretical model for managing the sustainability of supply networks and suggested that lower-tier suppliers engage more in sustainability practices when they serve downstream customers that are sustainability leaders.

Methodology
A case study is conducted in order to answer the derived RQs. Case studies are the detailed and intensive analysis of one or multiple cases (Eisenhardt and Graebner, 2007). The method is particularly suitable when phenomena and contexts are difficult to distinguish – as it is with the global and complex SCs of the electronics industry (Yin, 2014). As previously outlined, the electronics industry was selected due to its highly fragmented and global SCs that are responsible for different sustainability issues (e.g. Brix-Asala et al., 2018). This research follows the design of a single case study with multiple embedded units of analysis. The SCs of three social enterprises in the electronics industry represent the single overarching case – SCs for fair(er) electronics. Individual units of analysis are companies that are members of those SCs. Different to a multi-case study, the data from the SCs are not distinguished or compared with each other. Instead, the results of all actors are pooled together to create a single universal case that enhances the generalizability of results (Eisenhardt and Graebner, 2007; Yin, 2014).
The data sample in this study consists of three Focal firms (FFs) with a social purpose that aim at promoting sustainability changes from within the electronics industry; six Mid-tier firms (MT-firms) that produce intermediate parts or offer assembly services; and three Low-tier firms (LT-firms) that are metal refiners or mining companies. In total, 11 semi-structured interviews (total: 562 min; 2 FFs; 6 MT-firms; 3 LT-firms) were conducted with interviewees at a management level. All interviews were carried out either face-to-face or by phone by two researchers together from April to May in 2018. Furthermore, secondary material (total: 511 pages) stemming directly from the actors was taken into account in order to gain additional insights and to triangulate the primary interview data (Saunders et al., 2016). Even though no interview could be arranged with Focal Firm 3 (FF_3), the company was included in the data sample because it extensively communicates (e.g. via blogs, webpage) about its SC management practices, challenges and shortcomings. Therefore, it seemed justifiable to include the company in the study – despite of the fact that no primary data was gathered.

To guarantee an objective and systematic analysis, a qualitative content analysis following the coding process based on Weber (1990) was conducted to analyze the gathered primary and secondary data. To ensure the validity of the coding scheme, the categories and items were based on two theoretical frameworks. While the categories for the MT-SSCM governance approaches are based on Tachizawa and Wong (2014), the categories for the SSCM practices are based on Sauer and Seuring (2017) who slightly modified the original framework of Beske and Seuring (2014) for mineral SCs. During the coding process, the coding scheme and categories were revised and slightly adjusted to ensure their quality and suitability.

Findings

The results indicate that especially FFs and LT-firms in SC for fair(er) electronics engage strongly in the management of lower-tiers. While nearly all MT-firms have a strategic orientation towards sustainability and engage in activities to enhance the SC sustainability, the results also show that only the two large(r) MT-firms (one mid-sized, one multi-national) have implemented more advanced measures to ensure the sustainability at lower-tiers. Those two companies were the only MT-firms in the sample which also have production facilities outside of Europe.

For the management of lower-tier suppliers, the Direct and Work with third parties governance approaches are the two most common management approaches applied by firms in this study. The application of the Indirect governance approach was found only seldom. In the following, the main findings for each of the three groups of actors in SCs for fair(er) electronics are presented. Due to space restrictions, these findings are not presented in full details, but the most notable results are highlighted.

Focal firms

The FFs generally put a strong emphasis on Long-term relationships with suppliers as part of their strategy to promote sustainability changes and improvements. For that reason, the companies frequently use the Direct governance approach to manage lower-tier suppliers. The FFs engage themselves in the Selective monitoring of lower-tier suppliers to check and evaluate the current sustainability performance of their SC partners. In many cases, the FFs take the opportunity to also engage in Enhanced communication in order to provide sustainability requirements to lower-tier suppliers and raise their awareness for social and environmental concerns. One of the FFs noted: “We find those visits very important, on the one hand, to present once more our idea to the suppliers by a direct conversation and sensitize them for the topic [...] On the other hand,
those visits give us valuable insights with regards to the production method, used materials (raw materials, intermediates), sub-supplier, etc.” (FF_3). Furthermore, FFs are also directly involved in activities to improve the SC performance at lower tiers as part of their strategy to promote sustainability changes from within the electronics industry. For that purpose, they implement practices aiming at the SC partner development of lower-tier suppliers or the FFs collaborate with lower-tier suppliers for Joint development, e.g. “to explore opportunities [...] in sourcing more responsible minerals and developing other types of worker empowerment projects” (FF_2). In order to guarantee that suppliers at lower-tiers meet the specific criteria and/or are willing to engage in the required sustainability activities, SC partner selection is crucial for the FFs. The companies invest considerable amount of time and efforts to determine the suitability of supplier. It is also not unusual that the FFs reach deep into the SC to select directly their lower-tier suppliers. One of the LT-firms told: “In the case of FF_2 was the expectation that we source the material [...] from Africa and ethically okay and conflict free and preferably from the mine which they visited” (LT_3).

It was also found that FFs use the Work with third parties governance approach to manage lower-tiers. Since Stakeholder management and the interaction with non-traditional SC members is crucial for the FFs, it is no surprise that the companies seek the help of third parties (especially NGOs) for their sustainability know-how and experience with the management of (lower-tier) suppliers located in the global South. FFs and third parties collaborate to identify opportunities for SC partner development. Moreover, FFs delegate some responsibilities related to first-time audits of new suppliers and the sourcing of fairly traded minerals to third parties. For instance, one of the FFs noted that they employ a NGO for Selective monitoring in order to conduct social assessments “to understand the current conditions with regards to applicable labor law and best practices. Importantly, it is also a baseline to start working together on improvements, as well as to identify areas for innovation and future cooperation” (FF_2).

Mid-tier firms

As previously indicated, the analysis indicates that most MT-firms engage significantly less in lower-tier supplier management. Particularly small(er) MT-firms in the data sample adopt a Don’t bother governance approach and/or infrequently use the Indirect governance approach, e.g. to demand from first-tier suppliers that lower-tier suppliers are committed to specific Standards and Certification.

In contrast, large(r) MT-firms have implemented more advanced measures to manage lower-tier suppliers. The findings suggest that those companies primarily manage their lower-tiers by adopting the Work with third parties governance approach. Large(r) MT-firms employ certifiers and NGOs that carry out Selective monitoring and ensure that Standards and Certifications are met by (lower-tier) suppliers. In addition, one (multi-)national MT-firm in the data sample also collaborates with other electronics companies (incl. competitors) via industry associations to develop and drive industry-wide Standards and Certifications. The firm stressed this by saying: ”And the best way to do is to deal with it together. And that is something that is very different from other industries. [...] they are way behind the electronics industry in dealing with [sustainability] because they have not got together to set standards. [...] we could not have done it on our own, we all did it together” (MT_6).

The application of the Direct governance approach was also found to be used by larger(er) MT-firms, but it is less frequently applied to manage lower-tier suppliers. For instance, in order to ensure that their sustainability requirements are met, the companies engage also by themselves in the Selective monitoring of (lower-tier) suppliers. While the
large(r) MT-firms have implemented measures to ensure the sustainability of lower tiers, the companies also acknowledge that they do not manage certain suppliers and therefore adopt the Don’t bother governance approach. It was noted that “it is a big effort to monitor also [the first-tier suppliers] supply chain. We do it partially but we cannot always do it. It is also a capacity problem” (MT_5). One company noted that they neglect the management of (lower-tier) suppliers with “highly qualified skilled people [because] there is low risk” (MT_6).

Low-tier firms
Due to the high pressure that is put on LT-firms to source ethically and responsibly, the management of lower-tiers is crucial to them. The companies use the Direct governance approach commonly for Selective monitoring and SC partner selection. One of the LT-firms noted that they combine “mine site visits prior to the first delivery, annual re-visits, plausibility assessments and participation in an acceptable traceability program” to ensure that minimum requirements are met (LT_3). Moreover, the companies engage in Enhanced communication to provide their requirements to miners. The requirements are often defined in Standards and Certifications (e.g. CoC) covering topics such as “labor rights, environmental protection, business ethics and conflict-free origin” (LT_3). LT-firms also engage themselves in SC partner development activities to develop mines and ASMs in order to enhance their economic performance and sustainability. One of the companies noted: “[...] we support the concept of continuous improvement. For example, we had a training with mining engineers last year [...] who are employed at a mine from which we source. And they invited neighboring mines and we provided a three-day course” (LF_3-PrMa, p. 11). SC partner development is also the preferred solution when (lower-tier) suppliers are non-compliant with the requirements of LT-firms. The companies strongly focus on Long-term relationships with lower-tier suppliers not only to ensure supply stability, but also to foster economic development in the global South. One of the companies noted: “It is important to understand that disengagement with mines not conforming with our due diligence criteria is not a solution for [our company]. [...] We have developed tools to appropriately communicate non-conformity situations and outline corrective measures, including remediation, in order to support the mines that are willing to improve the way they operate” (LT_2).

Apart from actions in which the LT-firms are directly involved, the use of the Work with third parties governance approach appears to be equally important for managing lower-tiers. The analysis showed that LT-firms seek the collaboration with third parties (e.g. NGOs, governmental actors, competitors) to develop Standards and Certification for the responsible sourcing of minerals. One of the firms explained: “All our [sourcing] commitments are achieved by the application, maintenance, and continuous improvement of [our] management systems, processes, and procedures. We do this by engaging with the broader industry [...] and by engaging with a broad range of local and international stakeholders” (LT_2). Furthermore, LT-firms also outsource some responsibilities to third parties, which take over tasks that are concerned with Selective monitoring and SC partner development of lower-tier suppliers. For instance, one of the firms mentioned that they employ a third-party consultant who monitors “that there is at least basic safety equipment, helmet and boots and things like that, and that there is also some technical progress. Those are simple tools, that help them to work more efficiently” (LT_3).

Even though the governance approach was seldom found, the Indirect governance approach is also adopted by LT-firms. One notable example is that, first-tier suppliers agree to ensure the compliance of their suppliers (the lower-tier suppliers of the LT-firms) by committing to the Standards and Certification of LT-firms.
Discussion

This study aims to contribute to the relatively new MT-SSCM discussion by providing insights on how companies in SC for fair(er) electronics engage in the management of lower-tiers. Even within the MT-SSCM field, the study is one of only few that gathered primary data from suppliers beyond the second-tier (Villena and Gioia, 2018; Jia et al., 2018; Gong et al., 2018). Furthermore, exploring this unique case can contribute to the understanding of how to create truly sustainable SC (Pagell and Shevchenko, 2014). In SC for fair(er) electronics, lower-tier suppliers are most commonly managed with the Direct and Work with third parties governance approaches.

The results suggest that companies with a strong commitment to ensure the sustainability in multi-tier SC are at least to some extent directly involved in the management of lower-tier suppliers. In order to find suitable and likeminded partners with a similar commitment to sustainability, the direct selection of lower-tier suppliers seems to have strategic importance for companies. In addition, companies seek the direct communication with lower-tier suppliers to raise their awareness for social and environmental concerns and their commitment to engage in sustainability improvements. Such management strategies have been previously found to be significant drivers for sustainability performance improvements in multi-tier SCs (Roehrich et al., 2017). It might be one explanation for how even FFs manage to have a relatively big influence on the sustainability of other SC members, despite of their small size and power. In general, lower-tier suppliers are more likely to engage in sustainability initiatives when the focal companies actively promote sustainability in the SC (Villena and Gioia, 2018; Jia et al., 2018), as it is the case in SC for fair(er) electronics.

Collaborations and the work with third parties has been proposed to be very valuable for companies when the (physical, social or cultural) distance is high and the need for sustainability learning is extensive and complex (Tachizawa and Wong, 2014; Gong et al., 2018). This is most certainly the case for suppliers in countries of the global South. The results support this preposition by showing that firms commonly seek the collaboration with third parties to manage especially those lower-tier suppliers that are located in high-risk countries of the global South. Similar observations have been made in other MT-SSCM studies (Wilhelm et al., 2016a; Grimm et al., 2016). The ‘conventional’ companies (MT-firms and LT-firms) in this study tend to be more indirectly involved in the work of third-party organizations by simply delegating responsibilities (e.g. monitoring, trainings) to them and/or developing sustainability standards and certifications – often by getting together with other industry actors (incl. competitors). In contrast, the FFs are quite actively involved in the activities of third parties even though they also delegate some responsibilities to them. The FFs primarily approach NGOs to identify sustainability improvements and jointly define supplier development plans. Compared to other firms in this study, FFs are not engaged in industry associations because the industry standards and certifications do not meet the sustainability requirements and expectations of the SEs. One of the FFs even noted: “Different to [other companies of the electronics industry], we do not have promising code of practices/code of conducts and we do not belong to any of those half-hearted initiatives. We rather take it seriously and do everything in our power guarantee good working conditions in our supply chain” (FF_3).

Despite that almost all members in SC for fair(er) electronics have a strategic orientation towards sustainability, primarily the FFs and LT-firms are the main groups which engage strongly in lower-tier supplier management. While LT-firms are externally driven by downstream SC members, governmental actors, and the general public to
guarantee that their products are ethical and conflict-free, FFs in this study have a strong internal motivation to enhance the SC sustainability as part of their aim to promote industry changes from the inside out. Those findings are in contrast with the ‘SC position paradox’ proposed by Schmidt et al. (2017), who suggest that firms engage more in sustainability activities the closer they are to the final customer.

Limitations and Research proposals

Even though the validity and reliability were considered throughout the research process, there are limitations that must be acknowledged. The generalizability and thus the external validity of results is limited since the case study focusses solely on the electronics industry and includes only three SCs and their members. Furthermore, even within the electronics industry, SC for fair(er) electronics represent a unique case because their focal firms are SE with a particularly strong emphasis on sustainability. Moreover, the majority of companies in this study are of small- and medium-size, often with limited power and resources. This makes the results quite case specific (Yin, 2014). Finally, a Eurocentrism bias is given because all analyzed firms in this study are European.

By taking those limitations into account, the following research directions can be proposed. Future studies could focus on SCs of conventional and larger electronics companies and/or analyze other industries with global and fragmented SC – such as the textile and automotive industry. This would allow the design of a multi-case study which enables cross-case comparisons that enhance the generalizability of results. To overcome the Eurocentrism bias, studies should include actors from the BoP and emerging economies as well as from different cultural backgrounds. Moreover, it would be also interesting to explore the role of third parties (e.g. NGOs, governmental actors) in multi-tier SCs. Finally, there is still a common perception that SC networks are built around one focal company. Sauer and Seuring (2018) have recently proposed that there are several focal firms at different parts of the SC that interact and delegate multi-tier management responsibilities among each other. The findings in this study indicate similar. LT-firms engage strongly in the management of lower-tier suppliers as they are pressured by downstream SC members. Future studies could adopt a similar network perspective and explore the ‘focal firm-focal firm’ relationship in multi-tier SC.

Abstract

This study investigates at a panel level the relationships between market-based instruments, reduction at source of product packaging, and environmental performance. The research model, grounded on green institutional theory, was tested using a longitudinal data set of plastic packaging produced by 923 firms operating in eight important industries in the Canadian province of Quebec. We found that recycling costs negatively affect reduction at source of packaging. An inverted U-shaped relationship is found between taxation and packaging weight, and between recycling costs and packaging weight. These relationships are intensified by sectorial regulatory stringency. Market-based instruments also affect the environmental performance directly.

Keywords: Reduction at source of product packaging, Market-based instruments, Longitudinal analysis

Introduction

Packaging is increasingly seen as a major issue for today's societies. It represents a significant waste stream that accounts for about 30% to 35% of the municipal waste in industrialized countries and about 15% to 20% in developing countries (Tencati et al. 2016: 35; Wiesmeth, 2018: 1004). Most packages either end up in incinerators and landfills or are thrown into nature (e.g. Yamaguchi et al., 2016). The recent closure of the Chinese waste management market, which was the main buyer of recyclable materials, could aggravate the situation. Many thousands of tons of material are likely to accumulate in sorting centers and cause a multitude of environmental, social and economic problems. This challenge leads academic communities, businesses, and governments to reflect on the environmental impact of packaging (Accorsi, 2014; Pålsson et al., 2016).
According to the Waste Management Hierarchy (Directive 94/62/EC), the best solution is to reduce the amount of packaging at the source by using less packaging materials in manufacturing and in product designs. To encourage firms to adopt this practice many governments in developed countries have launched various market-based instruments (Sharma, 2000). Although several studies have examined the effects of environmental policies on managers' decisions to adopt various environmental practices (e.g., Tsireme et al., 2012; Zailani et al., 2012; Wang et al., 2018), none of them has examined at a panel level the influence of market-based instruments on reduction of packaging at the source. Many scholars have recognized that external factors that induce firms to implement this green practice need to be explored further in future research (Hazen et al., 2012; Bartl, 2014; Çakir et al., 2014; Yamaguchi et al., 2016).

This study seeks to address this research gap by investigating the relationships between market-based instruments, the reduction of packaging at the source, and the environmental performance outcome. We examine these relationships following the green institutional theory. We obtained interesting results from the econometric analysis of a longitudinal data set of the packaging weights of products from 923 firms between 2005 and 2017. This research could help decision makers in companies to recognize the antecedents and the effects of reducing their packaging at the source. Our results are also helpful for policy-makers willing to formulate better targeted instruments.

The remainder of this paper is structured as follows. We outline the theoretical background and the hypotheses development. Then we present the methods and the empirical results and discussion. After that we conclude.

**Theoretical background**

The reduction of product packaging at the source is one of the most important measures of a firm's environmental innovation (Chappin et al., 2009). This practice is implemented through two main approaches: package “downsizing” and package “eco-compatibility” (Hazen et al., 2012). According to Vernuccio et al. (2010), “package eco-compatibility” minimizes the environmental impact of packaging materials by reducing their quantity and variety, while ensuring at the same time that an optimal combination is used to guarantee the effectiveness of the packaging/product pairs. According to Çakir et al. (2014), “package downsizing” optimizes packaging size, volume, and weight. These practices provide more efficient physical distribution of products (i.e., transportation, handling, storage, recovery, or reuse) due to volume/weight efficiency and overpackage elimination. This has direct influence on the performance of sustainable supply chains (Verghese and Lewis, 2007; Accorsi et al., 2014). Many researchers pointed out the need to investigate external factors that induce firms to adopt such green practice (e.g., Hazen et al., 2012; Çakir et al., 2014). As suggested by Hoffman and Ventresca (2002), we explore these external drivers following the green institutional theory.

Institutional theory investigates how external institutional forces influence firms’ decision-making (Seo and Creed, 2002). These forces drive firms to make specific strategic choices and adjust their policies, structures, and processes accordingly (Clemens and Douglas, 2006; Zailani et al., 2012). Many environmental studies use institutional theory because it provides plausible explanations of how firms address green issues and, in particular, how they implement green strategies (Zailani et al., 2012; Liu et al., 2014). However, firms’ strategic choices are heterogeneous depending on how they respond to these various institutional drivers and according to their needs and specificities of the sector in which they operate (Clemens and Douglas, 2006). Liu et al. (2014) add that they would be influenced by the firm’s evaluation of the impacts these choices have on its competitiveness. Otherwise, Wang et al. (2018) pointed out that government incentive-
based measures represent a major formal institutional driving force that induce firms to set up a proactive environmental strategy. That’s why this study will focus mainly on the effect of market-based environmental tools on reduction of packaging at the source.

Governments have launched specific market-based instruments to induce firms to adopt sustainable practices. They are based on price and market mechanisms (Porter et al., 1995; Sharma, 2000) and take a variety of forms including subsidies, tax abatements, or tradable emission permits. According to Porter et al. (1995), these incentives are a major driving force because they enhance economic and environmental performance of firms (win-win theory). However, Chappin et al. (2009) suggest that these market mechanisms present firms with the following dilemma: either decision-makers adopt green practices to avoid potential costs related to environmental sanctions, or they bear these costs when they are lower than those incurred by adopting green practices.

Hypotheses development

Figure 1 presents our conceptual framework. In line with the green institutional theory, we suggest that the external institutional antecedents associated with market-based instruments precede firms’ decisions to implement reduction of packaging at the source. We argue that this practice has an impact on the environmental performance outcome.

- **Effect of market-based instruments on the reduction of packaging at the source**

Several authors argue that manufacturers are responsible for managing the negative impacts that their product packaging generates at the end of the life cycle (e.g., Fullerton and Wu, 1998; Wiesmeth et al., 2018). Particularly in developed countries, many governments have tried to remedy this situation by setting up economic incentives to encourage firms to undertake more appropriate environmental initiatives (Porter et al., 1995; Sharma, 2000). “Extended Producer Responsibility” is one of the main measures that extends the manufacturer responsibility to the post-consumption stage of packaged products. This policy specifies the type of recovery to be used and the recycling objectives to be achieved, and it recommends that the costs of packaging waste be borne by the producers of packaged products. Thus, these producers are induced to make optimal packaging choices related to volume and weight, and to the materials used (e.g., Verghese and Lewis, 2007; Yamaguchi et al., 2016; Arnaud, 2017; Wiesmeth et al., 2018). However, Arnaud (2017) shows that the “Extended Producer Responsibility” policy coupled with "bonus/penalty systems" has proven to be a more effective economic instrument for inducing firms to adopt environmental packaging practices. Moreover, the Directive 94/62/EC on packaging and packaging waste focuses on increasing the recycling of packaging material and reducing the level of packaging waste (Prendergast and Pitt, 1996), and this has major implications for producers’ packaging decisions (Yamaguchi et al., 2016). Therefore, we propose the following hypothesis:
**Hypothesis 1 (H1).** The recycling costs borne by companies are positively related to packaging reduction at the source.

Many researchers have discussed the effect of these price mechanism instruments on firms’ decisions to undertake environmental practices. Lin and Ho (2011) maintain that the regulatory pressure is positively related to the adoption of green practices by Chinese logistics firms. The latter seem to be more encouraged to optimize the ecological quality of their packaging when there are economic incentives. Williams et al. (2011) show that market-based environmental regulation is an important way to encourage managers in food processing industry to adopt environmental packaging practices. Moreover, Zhang et al. (2008) and Tsireme et al. (2012) find that incentive-based environmental instruments play a critical role on managers’ decisions to adopt green supply chain practices. They argue that the high environmental taxes positively affect managers’ decisions to introduce green practices in their supply chain. In fact, many researchers maintain that decision-makers are only willing to adopt environmental packaging practices when the costs are appropriate (e.g. Pullman and Wikoff, 2017; Arnaud, 2017). Kassaye (2001) points out that cutting waste and garbage removal costs is one of the main reasons that large, medium, and small companies engage in green packaging practices. In the same line of thinking, Verghese and Lewis (2007) argue that sustainable packaging innovation is only adopted by firms when it delivers economic benefits such as increased efficiency and cost reductions. Arnaud (2017) shows that manufacturers improve the environmental performance of their packaging when they bear the financial burden of eliminating waste from their packaging. Furthermore, Orzan et al. (2018) find that protecting the environment by implementing ecological packaging practices represents a cost-reducing and profit-maximizing approach particularly when significant economic benefits are expected. Therefore, it is plausible to assume the following hypothesis:

**H2.** The economic incentives based on price mechanisms are positively related to packaging reduction at the source.

Otherwise, Wang et al. (2018) point out that firms who operate in the more stringently regulated Chinese industries are the ones that are more engaged in environmental management practices. This fact is particularly noticed among those who operate in heavy-pollution industries. Consequently, they are obliged to comply with stricter regulations to avoid potential penalties for noncompliance (Zhu and Sarkis, 2014). Conversely, firms who operate in environmentally friendly industries are not subject to stringent regulations. In sum, firms adjust their buying behavior mainly to comply with the level of regulatory stringency they face (Gray and Guthrie, 1990). Wang et al. (2018) and Brunel et al. (2016) capture regulatory stringency influences by using sectorial gas emission. They find that stricter sectorial regulation reduces emissions faster than weaker sectorial regulation. In the same line of thinking, Zhang et al. (2012) explain that local governments implement more specific measures in environmentally disruptive industries to encourage targeted firms to engage in environmental practices. Thus, we propose:

**H3.** The relationship between market-based instruments and reduction of packaging at the source is intensified by the stringency of sectoral regulation.

- **Effect of reduction of packaging at the source on environmental performance**

The reduction of packaging at the source minimizes the environmental impact of packaging materials by reducing their quantity and variety, while ensuring at the same time that an optimal combination is used to guarantee the effectiveness of the packaging/product pairs (Vernuccio et al., 2010). When this practice is adopted, the materials used for the packaging are limited to what is needed to protect products (Accorsi et al., 2014; Molina-Besch et al., 2018). Thus, reducing packaging at the source...
minimizes its negative impact at the end of the life cycle and positively affects the green performance (Prendergast and Pitt, 1996). Prior research has shown that eco-designed packaging has a direct positive influence on environmental performance of industry (Zailani et al., 2012). The environmental performance construct has been studied using a wide variety of measures. It has been linked to the preservation of resource and energy (e.g., Accorsi et al., 2014), to the reduction of waste and the maximisation of packaging material reuse and recycling (e.g., Tencati et al., 2016). It has also been linked to the use of renewable natural resources and to the reduction of industrial gas emissions (e.g., Wang et al., 2018), and to increased compliance with environmental standards (e.g., Zhu and Sarkis, 2004). Thus, we argue that the reduction of packaging at the source positively affects the environmental performance of industry. However, this relationship is contextual because it depends on the economic growth, the productivity, and the competitiveness of each industry. For example, the environmental impact of packaging used for consumer products may differ from the one of packaging used for industrial products (Zailani et al., 2012). Thus, it is plausible to assume the following hypothesis: 

**H4. The reduction of packaging at the source is positively associated with environmental performance outcomes.**

**H5. The relationship between the reduction of packaging at the source and environmental performance is intensified by the importance of the economic growth of the industry.**

- **Effect of market-based instruments on environmental performance outcomes**

Governments put in place green economic incentives through their regulatory agencies mainly to enhance environmental performance (Clemens, 2006). Ren et al. (2018) show that market-based environmental regulation provides economic incentives for firms to reduce the environmental impact of their activities. Based on the prior literature and the green institutional theory, it is plausible to assume that: 

**H6. Market-based instruments positively affect environmental performance outcomes.**

**Methodology / Research design**

- **Choice of area to conduct the research**

The province of Quebec is an interesting study area to conduct the research because of emphasis put on the transition to a green and responsible economy consigned in the Sustainable Development Strategy (2015–2020). The Quebec government has introduced economic incentives to discourage environmentally harmful activities. These incentives mainly involve cost internalization based on the ‘user-payer’ or the ‘polluter-payer’ principle. They include fiscal measures such as taxation and tax exemptions and non-fiscal measures such as regulatory fees and subsidies. Therefore, the province of Quebec provides a relevant setting to examine the relationships between market-based instruments, the reduction of packaging at the source, and environmental performance.

- **Data and sample characteristics**

We used a longitudinal data set for the plastic packaging weights produced by 923 firms operating in the most important Quebec industries (table1) and observed between 2005 and 2017. This data was obtained from Éco Entreprises Québec (ÉEQ), the organization that finances municipal curbside recycling services in Quebec. It should be noted that Quebec companies have the obligation to report the quantity of packaging material that they put on the market. They accordingly pay their contributions to the compensation program of ÉEQ, and the funds are used to finance the selective collection of packaging material. We also used other longitudinal data from the Quebec Institute of Statistics, the
Official Gazette of Quebec, Recyc-Québec, and the Ministry of the Environment and the Fight against Climate Change in Quebec. The use of longitudinal data enhances the size of the data set, which improves the research data representativeness. It allows researchers to examine changes in the phenomenon of interest over multiple periods to determine whether variables have short or long-term effects (Wooldridge, 2010).

- **Description of variables and measures**
  
The selection of variables and their measures were based on our literature review. The collaboration of ÉEQ specialists helped ensure that variables choices and database manipulation are appropriate, which enhances the internal validity of the study.

  **Dependent variables:** The reduction of packaging at the source is the variable of interest in this study. Since one of the important aspects of this practice is the optimization of the weight of packaging, we used the weights of two categories of packaging as a proxy: the high-density polyethylene (HDPE) and the low-density polyethylene (LDPE) plastic packaging. The data were obtained from ÉEQ and present the annual packaging weights of products from 923 firms (table 1) between 2005 and 2017. Regarding the environmental performance variable, we used greenhouse gas emissions by industry. The latter represents a relevant indicator because it is the main regulatory target to protect the environment (Zhang et al., 2012). These variables were log-transformed.

  **Independent variables:** Considering the characteristics of market-based instruments and the accessibility of provincial data, three indicators are retained. First, the tax imposed on plastic packaging, which represents the contribution of firms to the compensation scheme. Second, the share of recycling costs borne by Quebec firms. Third, the sales price index of plastic packaging material on the market.

  **Control variables:** We used three control variables. First, we controlled for the stringency of sectorial regulation by calculating the percentage of variation of greenhouse gas emission in each industry over the past five years, as suggested by Wang et al. (2018) and Brunel et al. (2016). Second, we controlled for the importance of the economic growth in each business sector using the log-transformed GDP at basic prices of each industry. Third, we controlled for the number of firms operating in each industry because there are firms in some industries that are more represented in the sample than others.

- **Regression method**
  
  Because of the high variation in the values of variables between industries, the results obtained by including all industries could be biased. Hence, to obtain more realistic results, we first conducted a Pareto analysis based on the plastic packaging weights values across industries. The retail, the food processing and the chemical and pharmaceutical industries represent the “vital few” industries (Group 1). They are generating around 86%
of the average quantity of the HDPE and LDPE plastic packaging put onto the market every year. The remaining industries represent the “trivial many” industries (Group 2) because they are producing for around 14% of this quantity. Based on these results, we categorize the industries into two main groups. Longitudinal regression models were then employed to estimate relationships among variables. The Hausman specification test for fixed versus random effects model yields a p-value to be greater than 0.05, suggesting that the random effects model represents a valid model (Hausman, 1978).

Empirical results and discussion

Hypothesis 1 was supported. The results show that the recycling costs borne by companies have a significant negative effect on the reduction of packaging at the source in both groups of industries. This suggests that extending manufacturer responsibility to the post-consumption stage plays a significant role in the environmental packaging decisions of firms. This instrument incentivizes companies to use product packaging with optimal weights in order to decrease the disposal costs that they bear at the end of the product life cycle. These results provide empirical support for the effectiveness of the “Extended Producer Responsibility” policy, which provides highly practical economic instruments for inducing companies to adopt sustainable packaging practices.

Hypothesis 2 was not supported. The results show that there is an inverted U-shaped relationship between taxation and the reduction of packaging at the source with turning points of $319 and $610 in Group 1 and Group 2 respectively. In other words, these are the optimal values for taxation to decrease packaging weights. It is important to remember that Group 1 consists of the “vital few industries” that generate around 86% of the HDPE and LDPE plastic packaging on the market every year, and that Group 2 consists of the “trivial many industries” that produce around 14% of this packaging. Because of the high quantities of plastic packaging produced by the industries in Group 1, it is not surprising that the taxation turning point for Group 1 is significantly lower than the taxation turning point for Group 2. This means that firms operating in the industries in Group 1 react quickly to the increase in taxation in order to decrease the costs they bear, but that firms operating in the industries in Group 2 react more slowly to the increase in taxation. Therefore, taxation has significant influence on companies producing high quantities of plastic packaging, and it has less influence on companies producing smaller quantities. Moreover, our study demonstrates that there is an inverted U-shaped relationship between material prices and the reduction of packaging at the source with a turning point of $56 per ton in Group 1. In other words, this is the optimal value for material prices to decrease packaging weights. These results contradict those of Tsireme et al. (2012), for these authors claim that there is a linear relationship between environmental taxes and green practices. Since decision-makers focus predominately on costs (e.g. Pullman and Wikoff, 2017; Arnaud, 2017), they are only willing to adopt policies aimed at reducing packaging at the source if the economic benefits are significant. When this is the case, they take full advantage of economic incentives based on price mechanisms (Chappin et al., 2009).

Hypothesis 3 was supported. The results show that the stringency of the sectorial regulation in the “vital few” industries has a moderating effect. The inverted U-shaped relationship between taxation and packaging weight, or between recycling costs and packaging weight, is intensified by the regulatory stringency. This suggests that the increased regulatory pressure in environmentally disruptive industries strengthens the effect of market-based instruments on the reduction of packaging at the source. As an industry becomes more polluting, the stringency of regulation rises, and this induces firms to adopt more environmental practices. Therefore, our findings provide empirical
evidence to support the claim that firms tend to adopt a proactive environmental strategy (Zailani et al., 2012) when they operate in heavy-pollution industries (Wang et al., 2018).

Hypothesis 4 was not supported in Group 1 but was supported in Group 2. The results show how changes in packaging weights affect environmental performance in each industry group differently. For the “vital few” industries, we find that there is a U-shaped relationship between packaging weight and environmental performance with a turning point of 20.3 tons of plastic packaging. In other words, below this packaging weight value, greenhouse gas emissions decrease, but above this value, both variables increase. These findings suggest that the ecological attributes of the plastic packaging that is used in the retail, the food processing, or the chemical industries can delay the negative effect on environmental performance, but only up to a certain point. This non-linear relationship is not consistent with the findings of Zailani et al. (2012). Indeed, for the “trivial many” industries, we find that there is a significant negative relationship between packaging weight and environmental performance. These latter findings provide empirical evidence for the positive impact of eco-designed packaging on environmental performance.

Hypotheses 5 and 6 were supported. The economic growth of industry strengthens the effect of packaging weight on the environmental performance of industry. These results add empirical evidence to the findings of prior studies (e.g., Seo et Creed, 2002; Clemens and Douglas, 2006). Moreover, the results demonstrate that market-based instruments affect the environmental performance of the industry directly, which validates the findings of Ren et al. (2018). We show that an increase of 1% in the recycling costs borne by companies in the “vital few” industries decreases greenhouse gas emissions by 1%. An increase of 1% in the price of plastic decreases greenhouse gas emissions by 0.1% in the “trivial many” industries and thus improves their environmental performance.

**Conclusion**

To our knowledge, this is the first cross-sectorial empirical study that examines at a panel level the relationships between market-based instruments, the reduction of packaging at the source, and environmental performance outcomes.

- **Managerial and policy-makers implications**

Without effective economic incentives, few companies are likely to deliver optimal packaging weight. Thus, the results of this research are helpful for policy-makers and government agencies to evaluate the implementation effect of market-based instruments. Our study demonstrates the turning points for the inverted U-shaped relationship between taxation and reduction at the source of packaging (i.e., $319 and $610 for the “vital few” and the “trivial many” industries, respectively). Our results also determine the turning point of the inverted U-shaped relationship between plastic price on the market and reduction at the source of packaging (i.e., $56 per ton for “vital few” industries). These results would be of great help for policy-makers to formulate better targeted instruments that encourage companies to reduce their product packaging at the source. Furthermore, policy-makers and government agencies might focus on the crucial role of reduction at the source of packaging in improving environmental performance of industries. Our results demonstrate a U-shaped relationship between packaging weight and environmental performance with a turning point of 20.3 tons of plastic packaging for “vital few” industries. Moreover, policy-makers and government agencies should not underestimate the direct impact of economic incentives on environmental performance of industries. Our results show that an increase of 1% in the recycling costs borne by companies in “vital few” industries decreases greenhouse gas emissions by 1%. An increase of 1% in plastic price would decrease greenhouse gas emissions by 0.1% in the
“trivial many” industries. These relevant results would help advance the cause of effective environmental management. Otherwise, our results would help decision makers in companies operating either in “vital few” or in “trivial many” industries. Since the trend to implement reduction at the source of packaging is intensifying, it is important to understand the antecedents and outcomes of such green practice at the firm level.

- **Limitations and avenues for future research**
  Our study has some limitations. First, qualitative evidence would have been useful to develop deeper understanding of our quantitative results. Future research could conduct in-depth interviews with key informants who are involved in the development of the environmental policy instruments. Furthermore, extensive interviews with managers who are involved in packaging decisions could help to clarify the implementing effect of these instruments in different industries. Second, because of the absence of a direct measure of sectorial regulatory stringency, we used the changes in greenhouse gas emission in each industry over the past five years as a proxy. Future research could further explore how firms in different industries perceive the level of regulatory stringency they face. This would add to our understanding of how the latter strengthens environmental decisions of firms. Third, our study examines the effect of the reduction of packaging at the source on the environmental performance of industries. However, it would be useful, both theoretically and empirically, to examine effects of this practice on firm performance. Future research could shed more light on its effects on the environmental and operational performance of firms by using intra-firm indicators. This could add richness to the measure of performance outcomes. Fourth, firms in developed countries face different incentive-based green instruments. In addition, the idiosyncratic environmental regulations of the developed countries limit the generalizability of our findings to the less developed countries. Future research might collect data from different countries to explore the effects of different incentive-based instruments on reduction of packaging at the source. This could reinforce our findings and provide more in-depth understanding of antecedents and outcomes of this practice in different contexts.

Abstract

This study aims to analyse the dissemination process of sustainability in a supply chain, through the multi-stakeholder partnership roundtable. We conducted a case study with the Brazilian Roundtable on Sustainable Livestock. Preliminary results indicate that Roundtable contributes to the dissemination of definitions, values, successful initiatives, and, therefore, the legitimacy of sustainability among stakeholders in the Brazilian beef supply chains. However, the impacts of this dissemination in the supply chain businesses are mainly related to legislation. Understanding the dissemination process of sustainability seems to be a good direction to recognize the role of different actors for supply chain sustainability.

Keywords: Supply Chain Sustainability, Dissemination of Sustainability, Roundtable.

Introduction

Sustainability in supply chain has become an established area of research (Rebs et al., 2018). Discussions on sustainability and supply chain generally share a focus on concepts that aim to meet economic, environmental and social performance, based on the Triple Bottom Line approach (Elkington, 1998), and investigate this performance over an extended period of time (Pagell and Shevchenko, 2014).

The literature has been highlighting the focal company perspective for supply chain sustainability (Montabon et al., 2016). However, this firm is not exclusively responsible for sustainability in supply chains. Stakeholders also play an essential role to introduce and to disseminate sustainable initiatives in the supply chain (Searcy, 2017). For example, there are cases in which the first movement towards sustainability in supply chain starts from a stakeholder. Thus, the starting point of this study emerges: how does the dissemination process of sustainability occur when the first movement does not start from the focal company?

To develop this understanding, we use institutional theory as theoretical support. Institutional theory provides a lens to understand, for example, the existence of
interorganizational relationships (Parmigiani and Rivera-Santos, 2011) and the adoption of sustainability initiatives in supply chains (Touboulie and Walker, 2015). Based on organizational field, legitimacy and especially isomorphism concepts (DiMaggio and Powell, 1983; Suchman, 1995), we understand that institutional theory supports the analysis of the dissemination process of sustainability in supply chains, including when this process starts from different stakeholders.

We argue that efforts to disseminate sustainability in supply chains are more complex when the first movement does not start from the focal company. Thus this complexity requires the establishment of new discussions and new partnerships between organizations in a supply chain. In this context, multi-stakeholder partnerships (MSPs) seem to be a strategy to deal with the complexity and challenges of the supply chain sustainability, since MSPs provide a way to address complex issues that businesses cannot address on their own (Searcy, 2017). Several initiatives can be considered MSPs, including roundtables. Roundtable is a voluntary initiative aiming to discuss complex issues into a form that improve the participation of all stakeholders and give them equal standing at the table of negotiations (Ponte, 2014).

Even though studies about sustainability in supply chains are growing significantly (Pagell and Shevchenko, 2014), further research is needed on the role played by other elements and actors. Therefore, this study aims to analyse the dissemination process of sustainability in a supply chain, through the multi-stakeholder partnership roundtable. We argue that roundtable analysis can contribute to the understanding of the disseminating process of sustainability in supply chains, particularly when this process is initiated by a stakeholder.

We are investigating the Brazilian beef supply chain. Brazil has the largest commercial herd in the world and the country is considered one of the biggest beef exporting countries (Abiec, 2018; Knoll et al., 2017). Concomitantly, Brazilian beef industry has been facing criticism related to socio-environmental issues along the supply chains. Taken together, these circumstances have created a sense of urgency to re-examine sustainability in this food supply chain (Kirwan et al., 2017).

This paper is structured in four sections in addition to this introduction. Section two presents the theoretical background which supports this study. In section three, we describe the methodological procedures. In section four, we present the preliminary results. Finally, we highlight the final considerations.

**Theoretical Background**

The theoretical background is divided into two topics. In the first topic, we discuss sustainability in supply chains. The second topic addresses the roundtable as a multi-stakeholder partnership that aim to improve the stakeholders’ interaction and their participation in industry, supply chain and organizations decisions.

**Supply Chain Sustainability**

Sustainability in supply chain has become a topic of interest for academics and practitioners in the last decade (Dubey et al., 2017; Gold and Schleper, 2017), since the publication of seminar papers (see Seuring and Müller, 2008; Carter and Rogers, 2008; Pagell and Wu, 2009). Discussions on sustainability and supply chains generally are focused on concepts that aim to meet economic, environmental and social performance, based on the Triple Bottom Line approach (Elkington, 1998). The Sustainable Supply Chain Management (SSCM) concept emerges in this context.

Carter and Rogers (2008) define SSCM as the strategic and transparent integration of an organization’s social, environmental and economic goals in the systemic...
coordination of the key interorganizational business processes, aiming to improve the economic performance. In this concept, the authors highlight the focal company role to the supply chain sustainability. The focal company plays a relevant role in SSCM context, since this company must to manage and coordinate sustainability strategies e operations beyond its own organizational boundaries (Reefke and Sundaram, 2017).

Researchers use different theoretical lenses to understand the supply chain sustainability. Institutional theory tends to be used in studies that explore the complex nature, challenges and drivers of sustainability in supply chains (Touboulc and Walker, 2015). Studies have been using institutional theory to understand and to analyse supply chain sustainability (Sayed et al., 2017; Sancha et al., 2015; Tate et al., 2014).

According to the institutional theory, the legitimacy and other types of symbolic performance (such as status or reputation) are key drivers for interorganizational relationships. Organizational actions are socially constructed and constrained by exogenous forces in the organizational field. The organizational field is formed by organizations that share common meanings systems and interact more frequently with each other than with actors outside the organizational field, thus constituting a recognized area of institutional life (DiMaggio and Powell, 1983).

These exogenous forces – or isomorphic pressures – lead organizations to seek an acceptable template by suffering coercive pressures, mimicking successful cases or following norms. In some organizational fields, the isomorphic template may be related to relationships with certain partners (Parmigiani and Rivera-Santos, 2011). Following Sayed et al. (2017), we mobilized the concept of organizational field to theoretically interpret the supply chain. Therefore, according to the institutional theory, the dissemination process of sustainability occurs through isomorphic mechanisms to gain legitimacy within the organizational field (Alves and De Barcellos, 2017).

Pressures and incentives of governments, customers, rivals and other stakeholders are constantly indicated as pushing focal companies towards the dissemination of sustainability and to take care of the behaviour of other businesses along their supply and demand chains (Gold and Schleper, 2017). However, the adoption of sustainability in supply chains is not exclusively related to the focal company. Silvestre (2016) argues that different supply chain members can voluntarily adopt sustainable practices and then disseminated these practices to the other partners. However, how does the dissemination process of sustainability in supply chains occur – especially when the organization that initiates this process is not the focal company – is a question that still requires further exploration (Silvestre, 2016).

Searcy (2017) affirm that the stakeholders play an essential role to introduce and to disseminate sustainability initiatives in the supply chain, since they are influenced by the supply chain operations, but also can influence these operations. According to the author, stakeholders can especially exert their influence through participation in multi-stakeholder partnerships (Searcy, 2017). These partnerships improve multi-stakeholder interactions by allowing groups to work together to solve a large and complex problem and to exploit new opportunities (Brouwer et al., 2016). Thus multi-stakeholder partnerships are playing an increasing role in supply chain sustainability (Searcy, 2017). We discuss in the following topic the roundtable, a specific multi-stakeholder partnership.

Roundtable: a multi-stakeholder partnership
Multi-stakeholder partnerships (MSPs) have gained popularity as mechanisms to address complex problems whose resolution requires the alignment of different purposes (Fowler and Biekart, 2017). This popularity can be explained by the fact that
MSPs provide a way to address complex issues that businesses cannot address on their own (Searcy, 2017). For example, there are the challenges related to supply chain sustainability, since these issues increase the complexity of the supply chain (Pullman et al., 2009).

MSPs are generally defined as joined voluntary activities in which different sectors of society are involved (Castro and Swart, 2017), including consumers, associations, non-governmental organizations, political actors, research centres, universities, governmental agencies, suppliers, competitors (Roloff, 2008). According to Searcy (2017), MSPs are focused on the collaborative efforts of a range of stakeholders to address shared interests and challenges.

There are several terms and definitions are used to describe partnerships and interactions between multi-stakeholders (Brower et al., 2016; Castro and Swart, 2017). Considering these terms, we are focused on the roundtables. Roundtables have become more common to tackle sustainability issues improving stakeholder interactions (Ponte, 2014). Companies, therefore, are one of the multiple interest groups doing the standard-setting in roundtables (De Man and German, 2017).

According to Schouten et al (2012), roundtables are arrangements based on a deliberative democratic rationality, because of their communicative processes, which include a variety of stakeholders, are able to create a common good and are open, and mainly consensus-based. The roundtable is an open space of multi-stakeholder integration and engagement, enabling them to create shared value by solving a jointly problem or opportunity (Aakhus and Bzdak, 2015).

Compared to others MSPs, a key distinguishing characteristic of roundtables is the equal right to participate for all stakeholders. The development of standards, and the certification and accreditation schemes, is also a common characteristic of roundtables. Additionally, Ponte (2014) affirm that some specific institutional features are required for multi-stakeholder partnership to be considered as roundtables – such as an executive director, an assembly or council, committees or working groups with experts on the concerning topics, and support staff. The management structure is an essential condition for the achievement of the roundtable purposes (Fowler and Biekart, 2017).

In this context, Castro and Swart (2017) define roundtables for sustainability as initiatives consisting of different stakeholders, from different societal levels, which aim to jointly tackle sustainability issues of an industry, supply chain or product mainly by developing and disseminating standards for better sustainable practices. The Forest Stewardship Council (FSC) is considered the first roundtable for sustainability model. This model was applied to a number of initiatives for sustainable agribusiness (De Man and German, 2017), including the livestock activity.

Although studies have been conducted on roundtables, the question of how MSPs contribute to addressing globally relevant and complex sustainability issues remains under discussion among academics, policy makers and managers (Dentoni et al., 2018). Thus we need to move further and recognize the role of different stakeholders for the dissemination of supply chain sustainability – especially when this dissemination is is encouraged by another actor than the focal company.

Moreover roundtables discussions generally are industry-level debates. However, although it occurs at the industry level, the decisions also impact the supply chains and the organizations (Alves et al., 2018). In this study, we focused on the impacts at the supply chain level. We argue that the dissemination of sustainability seems to be facilitated by the roundtable, since this MSPs allows the stakeholder involvement in the discussion of sustainability issues. Based on this facilitation, the dissemination should have a positive impact on the supply chain sustainability.
Method
A qualitative approach is used in this study. To develop this ongoing research, we are conducting a case study (Yin, 2014). Case selection followed three criteria: (a) stakeholder partnership in roundtable format; (b) partnership formed to discuss sustainability issues; and, (c) participation of all stakeholders from the beef supply chain. Brazilian Roundtable on Sustainable Livestock was selected.

In order to achieve research purpose, the research is being conducted in three phases, since June 2018. The first phase aimed to gain an early understanding of the Roundtable and the perception of its contribution to the beef supply chains in Brazil. In this phase, 14 semi-structured interviews were conducted with different experts, Roundtable’s members and professional staff. The second phase aimed at understanding the dynamics of Roundtable discussions and meetings in practice. Thus, six Roundtable meetings were observed using an observation research protocol.

Finally, we are conducted semi-structured interviews with supply chain members aiming to analyse the impacts of the Roundtable meetings at the supply chain level. To date, we interviewed two cattle ranchers, the livestock association director and the sustainability manager of the slaughterhouse, considered a key informant. Following a request from the interviewees, the organizations names will not be revealed. The slaughterhouse is considered one of the three largest companies in Brazil, operating in the domestic and international markets. In turn, the properties have about one thousand hectares of production. In addition, documents are being collected in the three research phases.

Data collected from different sources are being consulted for results confirmation and validation. Therefore, data are being triangulated to ensure reliability and validity. Additionally, data has been discussed in an attempt to understand the complexity of relationships from emerging findings.

Data analysis is being performed based on content analysis. According to Bardin (2011), the content analysis is based on performing a dismemberment of the text into units from the different sense nuclei and then regrouping these units into categories. Categories are classes that gather elements by their common characteristics, and can be derived deductively or inductively. The analysis is providing insights for the understanding of the dissemination process of sustainability in the Brazilian beef supply chain. In the following section, we present the preliminary results of this research.

Findings
In this section, findings are presented in two different topics. First, we present the panorama of the Brazilian beef supply chains. This panorama allows understand the context of these supply chains. Second, the preliminary results related to the Roundtable contributions are presented and analyzed in order to achieve the research purpose.

Brazilian Beef Supply Chain: a ‘sensitive’ supply chain
Brazil has the largest commercial herd in the world with 221.81 million head of cattle (Abiec, 2018). Therefore, the country is considered one of the biggest beef exporting of the world (Knoll et al., 2017). In 2017, beef exports increased 9.6% in volume and 13.9% in sales, reaching incomes of US$ 6.2 billion. Although exports are important, approximately 80% of the Brazilian beef production was destined for the domestic market in 2017 (Abiec, 2018). In the last years, the beef industry has been responsible for approximately one third of the value of Brazilian agribusiness production. Thus, the beef industry is an activity of large representation for the economy and agricultural production in Brazil (Florindo et al., 2017).
Brazilian beef supply chains may be labelled as ‘sensitive’, since its activities are prone to impact the environment and the society as a whole (Gold, 2016). Brazilian beef supply chains have been under pressure from national and international organizations especially because of deforestation (Walker et al., 2013), global warming (Ruviaro et al., 2016) and carbon footprint issues (Florindo et al., 2017). Although the pressures are mostly related to environmental issues, it is necessary to include other aspects for a sustainable beef supply chain. According to Ruviaro et al. (2016), it is important to consider social aspects, such as the promotion of social responsibility, improvement of working conditions, ethical relationships with employees, clients, suppliers and other stakeholders, occupational health and safety at work and compliance with human rights and labor laws.

Motivated by these pressures, organizations have begun to invest in sustainable initiatives in the beef supply chains – mainly after the publication of Greenpeace reports Eating Up the Amazon (2006), A Farra do Boi na Amazônia (or Bull Party in Amazon, free translation) and Carne ao Molho Madeira (or Beef with Wood Sauce, free translation). The organization reported irregularities in the beef supply chains in the Amazon region and highlighted the lack of knowledge of the beef traceability by companies, whose suppliers were involved in illegal deforestation and slave labor (Greenpeace, 2006; 2009; 2015).

In this context, Brazilian Roundtable on Sustainable Livestock (BRSL) was formally constituted in 2009, in São Paulo, Brazil. According to the interviewees, the creation of the Roundtable is related to the publication of the first report by Greenpeace in 2006. The involved organizations decided to discuss sustainability issues in the Brazilian beef value chain in a workshop in 2007, formalizing the Roundtable two years later. The participants of the BRSL are representatives of all stakeholders from the beef supply chains. Among them, we mention: producers, slaughterhouses, producers associations, suppliers, retailers, financial institutions, civil society organizations, government institutions, research centres and universities. As explained by the interviewees, there are two possibilities for participation: members and observers. The members are those who are able to express directly their opinions, understandings and objectives related to the topic discussed. Observers are those who participate in the debate just as listeners.

According to their official website, the main purpose of the BRSL is to discuss and to formulate the common principles, standards and practices adopted by the beef supply chains in order to build sustainable, fair, environmentally correct and economically viable livestock. However, Silvestre et al. (2018) highlight that the multi-stakeholder partnerships might not be always a “good thing” or “as good as they aimed to be”. According to the study conducted with Brazilian beef supply chain and corruption, the authors suggest that multi-stakeholder interaction might lead to unanticipated negative outcomes, i.e., some organizations might maliciously use stakeholder management mechanisms (such as the Roundtable) to deceive the public and to opportunistically manipulate partners to pursue their own self-interests. Considering this context, this study aims to analyse the dissemination process of sustainability in supply chains through the Roundtable.

\textit{Preliminary Analysis}

Preliminary results indicate that sustainability becomes a criterion of legitimacy in the Brazilian beef supply chains mainly due to a report published by Greenpeace in 2006. Interviewees agree that this publication motivated the first stakeholder meeting, since the organizations realized that they individually would not be able to react to the socio-environmental issues indicated in the report. Understanding the complexity of
sustainability issues and the nature of livestock activity, the Brazilian Roundtable on Sustainable Livestock was formally constituted in 2009.

Once sustainability is legitimized in the organizational field, the legitimacy refers to the adoption and the dissemination of sustainability definitions, values and successful initiatives, understood by the stakeholders as being appropriate. Firms seek to adopt legitimized values and initiatives (through isomorphism) or to legitimize their values and initiatives with other stakeholders from the organizational field. These processes occur at the Roundtable meetings. Therefore, the dissemination process of sustainability occurs during the stakeholders’ interactions and discussions at the Roundtable meetings. Being a member of the Roundtable gives legitimacy to organizations, since sustainability is a relevant criteria in beef industry and supply chains, improving their reputation with their stakeholders and the international market.

Roundtable meetings include rounds of discussion among stakeholders. According to the observations, the agenda for the meeting is presented by the Roundtable staffs, and the discussion is open. Roundtable discussions usually focus on the sustainability definitions, values and initiatives in the Brazilian beef supply chains. After rounds of debates, decisions are made and agreements are signed. Therefore, Roundtable meetings allow sustainability to be disseminated in Brazilian beef supply chains.

Thus the impacts on the supply chain analysed are directly related to the participation in Roundtable. Participation allows the sustainability dissemination and the value sharing in the supply chain. The slaughterhouse manager emphasizes that the company follows terms of conduct adjustment, and already adopted best practices to comply with the current environmental legislation. However, the interviewee highlights that the Roundtable must continue to contribute as the open space in which sustainability is discussed and disseminated in the Brazilian beef supply chains.

Posteriorly, organizations evaluate the impacts of the decisions made during these meetings. At this point, we are analysing the impacts at the supply chain level, for the following supply chain members: cattle ranchers, livestock association, and a slaughterhouse. Preliminary analysis indicates that slaughterhouses are more impacted with sustainability issues, especially because of the compliance with legislation.

We have identified that the sustainability issues discussed at the Roundtable are more general, and refer, for example, to the definition of sustainable livestock meaning and sustainability indicators applied to livestock. Thus, we perceive a more general dissemination of sustainability, rather than the dissemination of initiatives to adopt sustainability in the Brazilian beef supply chains business. The impacts of this dissemination in the supply chain businesses are mainly related to legislation. This is an ongoing research.

**Final Considerations**

The focal company perspective has been ostensibly explored in the literature (Montabon et al., 2016). In this study, we investigate the contributions of the roundtable to the dissemination of sustainability in supply chain, following the recommendations on the literature related to the inclusion of different stakeholders’ perspectives (Pagell and Shevchenko, 2014). Managers can be encouraged to interact with stakeholders through roundtables, aiming to become their supply chain businesses more sustainable.

This study highlights the role played by the Brazilian Roundtable on Sustainable Livestock to the sustainable supply chain. Therefore this case study provides some empirical evidences related to the roundtable contribution. Preliminary results indicate that Roundtable contributes to the dissemination of definitions, values, successful initiatives, and, therefore, the legitimacy of sustainability among stakeholders in the
Brazilian beef supply chains. However, the impacts of this dissemination in the supply chain businesses are mainly related to legislation.

Theoretically, this study contributes to the understanding of the dissemination process of sustainability in supply chain when the first movement does not start with the focal company. Considering the starting point question of this research, we identified that the dissemination process occurs during the stakeholders’ interactions and discussions at the Roundtable meetings. Thus we can understand the importance of the Roundtable to the beef supply chain sustainability. Understanding this dissemination process seems to be a good direction to recognize the role and importance of different actors for supply chain sustainability.

Considering the importance of the sector to Brazil and the impacts of livestock activity, we understand that more studies and discussions related sustainability must to be development. In addition, we understand that more studies and discussion about the relation of multi-stakeholder partnership and sustainable supply chain management must to be development. We hope that this study will stimulate future research on the subject.

Abstract

The purpose of this study is to explore the antecedents and consequences of incentive alignment in performing collaborative carbon reduction in supply chains (CCR-SC). To fulfill the research objective, an empirical study was carried out in China, an emerging economy that has in recent years started to undergo a transition towards a low-carbon economy. The statistical technique of structural equation modelling (SEM) was used to analyze the questionnaire data collected from 120 Chinese companies. The research results reveal that incentive alignment has a positive impact on CCR-SC, which is instrumental in the improvement of both financial and environmental performance.

Keywords: Incentive alignment, Collaborative carbon reduction, Supply chain.

Introduction

Incentive alignment refers to the extent to which an organization is able to achieve its goals whilst meeting the requirements of the partner at the same time (Theißen et al., 2014). In the context of supply chain management (SCM), it is recognized as an important factor that motivates the chain members to create value that benefits all members in the supply chain (Simatupang and Sridharan, 2008), ensuring that collaboration outcomes are quantifiably beneficial to all, and securing sufficient levels of cooperation and minimize opportunistic behaviour (Harland, 2004). Given its significance in managing and operating supply chains, particularly its essential role in supply chain collaboration, incentive alignment has received considerable attention from academia. For example, Simatupang and Sridharan (2002, 2005, 2008) recognized incentive alignment as one of the five main elements of the architecture of supply chain collaboration. Chao and Zhang (2011) defined incentive alignment as one of the seven interconnecting components of SCC in a study of the nature of supply chain collaboration and its impact on firm performance. Hinkka et al. (2013) were aware of the role of incentive alignment between buyers and suppliers in supply chains and
explored this issue with reference to inter-organizational system implementation projects.

As awareness of carbon reduction management in supply chains has increased, concern has been raised about the role of incentive alignment in supply chain members performing collaborative carbon reduction. For example, based on a multiple case study, Theißen et al. (2014) ascertained that incentive alignment is one of the five determinants influencing an organization’ readiness to engage in collaborative carbon reduction management. Nevertheless, a close examination of the existing literature finds that the issue remains conceptualized and empirical investigation remains scarce. To fill this gap, this study intends to examine the antecedents and consequences in the setting of collaborative carbon reduction in supply chains (CCR-SC).

The paper proceeds as follows. Section 2 provides a review of the literature on incentive alignment and CCR-SC. The conceptual model and hypotheses of antecedents and consequences of CCR-SC are then presented in Section 3. Section 4 describes the research design for the investigation. Finally, the results and the conclusions of the study are presented. The paper concludes by discussion the limitations of this study and the future research agenda.

**Literature review**

**Incentive alignment**

Incentive alignment is described as the motivation to fairly share the benefits of collaboration among members, and to enable members within the supply chain to self-enforce, aligning their individual decisions with the common goal of increasing total profits (Simatupang and Sridharan, 2002, 2005). According to Simatupang and Sridharan (2005), incentive alignment works as a scheme that motivates chain members to act in a way that is consistent with mutual benefit, including making optimal decisions, revealing accurate private information and calculating costs, risks and benefits. It is necessary to be aware of the effect of incentive alignment in reducing anxiety and uncertainty and increasing the prevalence of trust. Sahay (2003) pointed out that it can be seen as a way of initiating increased trust in supply chain relationships. Sierra (2013) ascertained that in the process of greening suppliers, providing suppliers with incentives is an important approach to the improvement of firm performance. Some studies report the results of misaligned incentives. For example, Narayanan and Raman (2004) reveal that misaligned incentives are the main cause of excess inventory, incorrect forecasts, and poor customer service. Voigt (2014) claimed that credible information-sharing cannot be established if misaligned incentives exist. In addition, Lee and Whang (2004) argued that a well-designed mechanism is needed to align incentives across the supply chain; this should enable chain members to commensurately share gains in terms of their investment and risk. Simatupang and Sridharan (2005) suggested that pay-for-effort and pay-for-performance are two major reward mechanisms.

In initiating CCR-SC, firms often estimate whether they can achieve incentive alignment by assessing the congruence of goals. Incentive alignment can only be built on the basis of identical goals among members in order to achieve shared objectives. Goal congruence is referred to “the extent to which firms perceive the possibility of common goal accomplishment” (Lejeune and Yakova, 2005, p.18). Goal congruence can enable firms to interact synchronously (Angeles and Nath, 2001) and reduce the incentives for opportunism. It is identified as an estimator when calculating the degree of alignment throughout the supply chain. Goal congruence is in conjunction with trust
and information sharing, a low rate of exchange of information will result in behaviour invisibility and thus lead to an absence of goal congruence.

Lejeune and Yakova (2005) considered that the degree of goal congruence varied and assumed it to have three levels, namely absence of congruence, moderate goal congruence, and true goal congruence. In the first two levels, goal congruence is weak or even non-existent in the supply chain. The deficiency of goal congruence can be attributed to an inadequate formulation of supply chain incentives (Narayanan and Raman, 2004). In the context of collaborative supply chains, Lejeune and Yakova (2005) also noted that goal congruence is weak to moderate, mainly because the trust in the collaborative supply chain is limited to its openness component. In the third level, i.e. true goal congruence, firms believe that they can achieve their goals by working simultaneously towards the objectives of the whole supply chain.

**Collaborative carbon reduction in supply chains (CCR-SC)**

CCE-SC has been recognized as an effective way for supply chain members to reduce carbon reduction. For example, Theissen et al. (2014) identified collaborative carbon reduction management as offering firms the ability to establish unique value-added processes through organizational boundaries that better match customer needs. Based on observation and investigation, many researchers support the view that collaboration is a more advanced approach in environmental management. Seuring and Müller (2008) emphasized that cooperation between buyers and suppliers is the only way to achieve an environment-oriented supply chain. Sustainable practices such as carbon reduction require the participation of all members in the supply chain. Chiou et al. (2011) suggested firms solve environmental problems by building a close relationship with their supply chain partners and creating competitive advantages through innovative environmental products. Through joint efforts in the supply chain, firms can simultaneously minimize carbon emissions and climate impacts, reduce waste and energy costs, meet the standards set by policy-makers and improve corporate reputations. To be specific, this includes the process of sharing data, knowledge, assets and other resources related to carbon reduction.

In addition, prior studies also ascertained that CCR-SC is more effective than enforcement under legal compliance, and more likely to produce benefits such as improved public reputation (Sundarakani et al., 2010). Carballo-Penela et al. (2017) demonstrated the effectiveness of CCR-SC through the measurement of carbon footprints. The results of their study show that the lack of mandatory legislation for measuring carbon footprints leads to an unsuccessful CCR-SC. Giurco and Petrie (2007) found that many opportunities for carbon reduction at the supply chain level have been ignored, since most of them focus on the organizational level. To better understand the environmental impacts of products and increase environmental performance, Sharfman et al. (2009) suggested that it is crucial for firms to conduct CCR-SC across supply chains.

**Conceptual development and hypothesis development**

**Incentive alignment and CCR-SC**

Many studies have classified incentive alignment as an important dimension of supply chain collaboration (Simatupang and Sridharan, 2005; Cao et al., 2010; Cao and Zhang, 2011). In order to be effective, an incentive alignment mechanism needs to be designed to correlate overall and partial performance, enabling members to consciously make individual decisions under the overall profit target, thus ensuring the successful implementation of the project (Hinkka et al., 2013; Chen and Lee, 2017).
Chen and Lee (2017) found that a well-defined incentive contract design can effectively avoid incentive misalignment by constructing a two-level supply chain game model. Drawing on the viewpoint on trust, Harland (2004) argued that incentive alignment is a sufficient guarantee for supply chain collaboration and commitment while minimizing the opportunism of members. Simatupang and Sridharan (2008) demonstrated that the effective implementation of incentive alignment can increase the enthusiasm and productivity of supply chain members and create value and benefit for the entire chain. Gunasekaran et al. (2015) highlighted the importance of incentives for green supply chain collaboration.

As such, this study argues that incentive alignment ensures the equitable sharing of costs, risks, and benefits, increases trust in the supply chain, and effectively avoids misalignment and opportunism. This should make companies willing to trust their partners and participate in initiating CCR-SC. Therefore, the first hypothesis in this study is as follows:

H1: Incentive alignment is positively related to CCR-SC.

Goal congruence and incentive alignment
Goal congruence encourages companies to implement incentive alignment to ensure that their members continue to move in the same direction and avoid misalignment. It requires a degree of mutual understanding and consistency in terms of a firm’s attributes, values, beliefs, and practices, which is strongly linked to the scheme of incentive alignment. According to Theißen et al. (2014), the first step when building an effective partnership in supply chains is setting a consistent goal. Lambert et al. (1999) argued that supply chain members should reach an agreement on the management of goals and the key processes to be employed in supporting them. Inconsistent goals can lead to an unreasonable division of work among members, thus reducing efficiency and leading to incentive misalignment. Rossetti and Choi (2008) maintained that incentives work as an intermediation of goal congruence and buyers should consider aligning goals through incentives with their partners. Samaddar et al. (2006) stated that, in the absence of common goals, firms have no incentive to participate in activities such as information-sharing or supply chain collaborations. To a large extent, incentive alignment requires a high degree of information sharing. Governance mechanisms such as goal congruence can mitigate opportunism in incentive alignment. The greater the goal congruence between firms, the greater the strategic nature of their work, and the closer their incentive alignment.

Congruence can lead members to coordinate with each other under the guidance of an overall goal that contributes to the efficiency of incentive alignment. This study therefore argues that goal congruence is an important enabler of incentive alignment if firms are to initiate CCR-SC, hence the following hypothesis:

H2: Goal congruence is positively related to incentive alignment.

CCR-SC and firm performance
Bowersox (1990) pointed out that collaboration can bring economies of scale to firms whilst simultaneously reducing costs and increasing profits. Vargo and Lusch (2004) emphasized the importance of collaboration for a firm’s business strategy and considered collaboration to be a source of competitive advantage. Cao and Zhang (2011) noted that partnerships can increase profits and reduce risk. Effective supply chain collaboration can reduce conflicts and uncertainties, resulting in collaborative advantages and better financial performance. Kalwani and Narayandas (1995) agreed that a long-term collaborative relationship is a unique resource that enables companies
to achieve a higher profit. From a relational perspective, Priem and Swink (2012) elaborated that supply chain relationships between suppliers and buyers can be viewed as intangible resources for value creation. In general, the higher the level of supply chain collaboration, the better the firm’s financial performance. In addition, supply chain collaboration can increase the efficiency of operations management, allowing companies to better respond to market opportunities.

In the context of environment-oriented supply chains, collaboration is also recognized as an effective approach for improving firm performance. For example, some studies have clarified that strategic collaboration among supply chain members allows firms to move beyond organizational boundaries and find new ways to reduce environmental management costs, thereby improving environmental performance (for example Giurco and Petrie, 2007; Theißen et al., 2014). The results of their study confirmed the positive effect of CCR-SC on firms’ performance.

In addition, there is a correlation between environmental performance and financial performance. Carbon reduction has been observed to improve a firm’s environmental performance, which in return strengthens the firm’s financial performance. For example, a reduction of transportation costs in the firm’s logistics will also enhance its financial performance. Previous studies have shown that sustainable management practices, especially supply chain collaboration, contribute to the financial performance of firms (Hollos et al., 2012). On one hand, improving environmental performance can reduce costs and waste, improve resource utilization and operational efficiency, and further improve financial performance. On the other hand, improving environmental performance helps to increase corporate social responsibility and reputation, leading to a growth in market share.

CCR-SC allows firms to obtain economies of scale through resources and knowledge-sharing, both internally and externally. Firms can gain competitive advantages and reduce costs whilst simultaneously improving their environmental performance and financial performance. Thus, three hypotheses were formulated:

H3: CCR-SC is positively related to a firm’s financial performance.
H4: CCR-SC is positively related to a firm’s environmental performance.
H5: A firm’s environmental performance is positively related to its financial performance.

Figure 1 - Research framework of incentive alignment in CCR-SC

Instrument development
Item generation
To achieve the content validity of constructs when generating items, a critical review of the relevant literature, such as research streams regarding CCR-SC (Theißen et al., 2014) and green SCM (Doran and Ryan, 2014) was carried out. After consulting with both academic and industrial experts, 32 measurement items were created for five constructs, namely, CCR-SC, incentive alignment, goal congruence, financial performance and environmental performance. A 5-point Likert scale was used to indicate the extent to which managers agree or disagree with each statement (1 = strongly disagree, 2 = disagree, 3 = neutral, 4 = agree, and 5 = strongly agree).

Sampling design and data collection
A data sample was collected from 900 Chinese companies engaged in SCM and operations. An online survey was used to administer the delivery of the questionnaire. After eliminating invalid questionnaires with blanks and deletions, 120 valid samples were obtained with a response rate of 13.3%.

The target respondents of this study were middle and senior managers in the company, particularly those involved in SCM practices. The sample respondents were expected to have a comprehensive acknowledge of collaborative and carbon reduction management in supply chains.

The non-response bias of samples was examined using the method recommended by Armstrong and Overton (1977). After comparing those responses returned early (80) with those returned late (40), the result of t-test shows there was no significant difference between early samples and late samples when randomly selecting samples, which means that non-response bias is not a problem with a 95% confident interval.

Data analysis and research results
Reliability and validity analysis
In terms of the creation of measurement items, Exploratory Factor Analysis (EFA) and Confirmatory Factor Analysis (CFA) were employed to assess the reliability and validity of the scales developed. The indicators used for assessment include Cronbach’s α, normalized factor loading, composite reliability (CR) and average variance extracted (AVE). All indicators were significant at p<0.01, and all five constructs identified exhibited acceptable fit. The results demonstrated that the model fit indices meet the recommended criteria. Cronbach’s α has a minimum number of 0.821 and a maximum of 0.952; all have alphas greater than 0.70 and are therefore considered reliable. Discriminant validity was tested using the approach recommended by Fornell and Larcker (1981); that is, the AVE of each construct is higher than the shared variances between each of the constructs, as shown in Table 2. Overall, the results show that the scales used had good reliability and validity.
