(iii) **Expected number of customers in the queue** (\( L_q \)), using Equation (6)

\[ L_q = \frac{\lambda \cdot \mu}{(c-1)! (c \mu - \lambda)^2} \cdot p_0 \]
\[ L_q = \frac{17.5702 \cdot 1.0344 \left( \frac{17.5702}{1.0344} \right)^{17}}{(17 - 1)! (17 \cdot 1.0344 - 17.5702)^2 \cdot 0.0226} = 1202.4392 \]

(iv) **Average time a patient spends in the system** (\( W_s \)), using Equation (7)

\[ W_s = \frac{L_s}{\lambda} = \frac{\mu}{(c-1)! (c \mu - \lambda)^2} \cdot p_0 + \frac{1}{\mu} \]
\[ W_s = \frac{1.0344 \left( \frac{17.5702}{1.0344} \right)^{17}}{(17 - 1)! (17 \cdot 1.0344 - 17.5702)^2 \cdot 0.0226 + \frac{1}{1.0344}} = 68.4932 \]
\[ = 01:08:29 \text{ Minutes} \]

(v) **Average waiting time of a customer in the queue** (\( Wq \)), using Equation (8)

\[ W_q = \frac{L_q}{\lambda} = \frac{\mu}{(c-1)! (c \mu - \lambda)^2} \cdot p_0 \]
\[ \frac{1.0344 \left( \frac{17.5702}{1.0344} \right)^{17}}{(17 - 1)! \left(17 \times 1.0344 - 17.5702\right)^2 \times 0.0226} = 68.4363 \]

= 01:08:26 Minutes

Abstract

Societies are considering the accessibility of health services and its impact on environmental sustainability. The services are provided by both mobile and centralised solutions. This study compares the CO₂ emissions of these strategies by applying a geographical information system (GIS)-based route allocation that is referred to qualitative data from focus groups with health care management professionals. The results show that in the sparsely populated case area, the CO₂ emissions can be reduced 49% by applying a mobile health care facility model in primary health care. However, the presented model must be carefully considered to fit to the health service entity.

Keywords: Healthcare logistics, Mobile services, Sustainability, Carbon emissions

Introduction

Healthcare systems and organizations are facing challenges through the needed cost reductions, expected service improvements and also modern requirements for energy efficiency. These challenges are especially emphasised in sparsely populated areas due to the long distances and decreasing population. Proposed approaches to these challenges are managing the locations of health care service facilities HCF (see, e.g., Ahmani-Javid et al. 2017, Kotavaara and Pohjosenperä, 2018) and moving health care service facilities (see, e.g., Caires, 2017, Guruge et al., 2009; Gibson et al., 2014; Kojima, 2017). Both approaches heavily affect the accessibility of the health services and costs of the provided service entity. However, there still remains a gap in knowledge of how these different scenarios affect the total CO₂ emissions of the healthcare system.

This paper compares two service structure strategies for primary healthcare in a sparsely populated area in order to find the minimum level of CO₂ emissions of the system. The case area is Koillismaa, which is formed by the three most sparsely populated municipalities in the region of Northern Ostrobothnia in Finland. In the Finnish healthcare system, the municipalities organise the public primary healthcare services whereas hospital districts handle the special health care in larger geographical areas. The national
government has attempted to combine these in such a way that they can be managed together regionally, but currently the reform is not going further. However, the visible challenges and uncertain situation offer a fruitful case for analysing the accessibility of mobile health care facilities with regard to minimising travel time as well as CO₂ emissions.

The case analysis is performed by calculating the outcome of two scenarios. The first is the ongoing strategy, where the primary health care patients travel to the health centre to be treated and then back home. The second scenario applies a mobile health care model to offer new health care service locations for the population living far from the health centres. The accessibility and the back-and-forth travelling kilometres of both strategies are calculated by using Geographic Information Systems (GIS)-based transport accessibility methods (Miller and Shaw 2001) with actual road and healthcare facility data. Thus, the research utilises accurate location data of both inhabitants and the service network as well as the road infrastructure in the case area. CO₂ emissions are included in road network data as travel cost attributes in addition to minutes and kilometres (see Määttä-Juntunen 2011) by using average CO₂ emissions for different types of vehicles defined by the VTT Technical Research Centre of Finland (cited 19.2.2019).

The purpose of the study is to find an ecologically sustainable model for delivering primary healthcare service through health centres and mobile health care facilities. The empirical results from the case area reflected current literature about mobile health care facilities and were compared to the metrics that are used to estimate the influences of CO₂ reductions. Hence, this research aims to contribute to answering the following questions. How does implementing mobile healthcare facilities affect the CO₂ emissions of the healthcare system? Again, how does optimising CO₂ emissions influence societal sustainability goals? Overall, this study estimates and compares the CO₂ emissions of the two selected service strategies and, thus, opens up discussion about mobile health care facilities’ impact on societies’ reaching their goals concerning environmental sustainability.

Next, the paper presents overview of the literature of mobile healthcare facilities. Then the multidisciplinary research design of using both the GIS-method and qualitative case analysis is explained in Section 3, which also includes an overview of the case area. The case is further analysed in Section 4 and concluded in Section 5.

Mobile health care facilities

The Mobile health care (Caires, 2017) or Mobile health clinics (Guruge et al., 2009) represent transportable healthcare and can also be called Mobile medical clinics (Gibson et al., 2014; Kojima, 2017) or Mobile clinics (Lafuente et al., 2007; Pitt et al., 2012). ‘Mobile health care’ can also be understood in some cases to refer to wireless communications solutions such as health care applications in mobile phones and other wireless interfaces (Khazbak et al., 2017; Mangu, 2017). The mobility of health care professionals on the other hand means the movement of doctors and other health care occupants to provide the demand of health care services (Ribeiro, 2014).

Mobile healthcare clinics are an alternative solution to delivering care to people with transportable healthcare units that enable healthcare offsite from institutions and healthcare agencies to underserved populations that might be difficult to reach (Guruge et al. 2009). They are healthcare strategies that increase access to care by people with geographic, structural and social barriers, therefore decreasing inequality for marginalised groups by implementing the traditional, fixed healthcare media of healthcare (see, e.g., Gibson et al., 2014). Mobile healthcare clinics make it possible to deliver healthcare at a reasonable distance from groups that are restricted by location (Leese et al., 1993; Gibson et al., 2014) or other obstacles such as limited access to transportation (Hastings et al., 2007). They are sometimes described as non-traditional
health care strategies (Gibson et al., 2014). One study found that mobile medical clinics have been especially successful in delivering services to rural (Peritogiannis et al., 2011) and urban minorities (Daiski, 2005). Mobile healthcare can also be favourable for the populations that are vulnerable due to poor traditional healthcare. (Gibson et al., 2014.)

Mobile health care has been implemented for a large variety range of health-related services, including the increase of access to services for the elderly living in rural areas, screening at-risk-populations such as drug users and the homeless, providing maternal health care services, screening for sexually transmitted infections, preventive health care such as dental care, screening for breast and/or cervical cancers and providing crisis care for mental illness. (Guruge et al., 2009.) Mobile medical clinics can be a sufficient means of delivering health care, health promotion and health-related education. They have a tendency to use fewer operators for larger areas in comparison to traditional health care centres, which is extremely practical in areas where the geographical distribution of patients is widespread (Kojima et al., 2017).

One application for mobile healthcare facilities is blood donation logistics. In these systems, cars and personnel drive to locations closer to donors to collect blood that is needed in health care operations. The bloodmobiles can attract more donors than fixed donation points by offering better accessibility by bringing the location closer to the donors, hence saving their time. These bloodmobiles can additionally be served by ‘shuttle car’, collecting the timely critical blood for the depot, allowing the mobile healthcare facilities more time to collect blood (Şahinyazan et al., 2015)

Of these mobile solutions presented above, this paper focusses principally on mobile health care facilities (mobile HCF) that provide primary healthcare for sparsely populated areas. The users of the service are selected by their home location in the case area.

**Case area**

The empirical case area Koillismaa is located in the Northern Ostrobothnia hospital district in Northern Finland. The region itself has 408,752 inhabitants in the area of 40,000 km², which works out to an average population density of 11.2 inhabitants per km². Most of the population is located in city centres, leaving the majority of the region sparsely populated. A total of 392,190 amongst the population (96%) have their home locations within 20 minutes car travel from nearest health centre. Thus, 16,562 inhabitants have over 20 minutes’ travel time to a health centre and the longest times reach 77 minutes or 82 kilometers.

Nearly half of these far distance inhabitants (7,805 people) live in three municipalities: Kuusamo, Taivalkoski and Pudasjärvi, which form the area of Koillismaa, located in the northeastern part of the region. The 27,261 inhabitants live in the area of 14,327 km², resulting in a very sparsely populated area (1.9 inhabitants per km²) which is also characterised by old age structure (28.2% are age of 65 or over) with high demand on health services.

**Methodology**

To find relevant empirical background for the study, a qualitative case approach is implemented as the issue is in the developmental stage, rather complex and alternates between the empirical field and different theoretical frameworks (Voss et al., 2002; Yin, 2009). The empirical data of the study is collected through various methods and multiple sources to add breadth and depth in understanding the phenomenon (Yin, 2009). By applying both the GIS and qualitative case methods, this study aims to increase both the research and managerial relevance of the research (see, e.g., Ketokivi and Choi, 2014).

Data collection methods contain interviews and forms of group discussions. Focus groups are especially useful in identifying important qualifiers or contingencies that may be associated with an answer to a structured question. Furthermore, focus groups offer an
opportunity for feedback from and response to the comments of others (Stewart and Shamdasani, 2014, p. 178).

The mobile health care facility strategies and their affect on CO₂ emissions are empirically discussed in focus group discussions with the research project ideating group (3) and steering group (3), which include professionals from both public and private healthcare organisations from the case region. Furthermore, the accessibility of primary healthcare services and mobile strategies are discussed in five focus group discussions/semi-structural interviews with health care professionals in the case region.

In this study, opportunities to reduce CO₂ emissions and increase service accessibility by extending health services close to rural areas with service vehicles were tested with Geographic information Systems (GIS)-based transport accessibility analyses (see Miller & Shaw 2001). Transport GIS-based analyses enable the measurement of travel distance, time and emissions for different types of vehicles routed from origins to destinations in a graph model of a road network. Analyses are executed with the ESRI ArcGIS Network Analyst extension, and are home to service site routes and customer potential which are generated with Location-Allocation analysis and a Vehicle Routing Problem method is applied to generate tour-based service routes. A passenger car travels from a home location to the closest health service locations, which are estimated to compare the service efficiency of different service scenarios in terms of accessibility. To produce a scenario for rural health services based on service vehicles, service routes were generated and optimised to satisfy service demand with minimised travel time.

In producing a service vehicle scenario, first a small rural population concentration which needs more than 20 minutes travel time to health centres cluster in the centres of built-up areas, villages, hamlets and commercial activity sites. Populations closer than 15 minutes are first allocated to these 66 local service points, resulting in customer potential levels between 333 and 11. Secondly, service vehicle routes were optimised to cover these service points. The maximum time of each route is limited to 9 hours due to EU driving time legislation. A weekly demand evaluated on the basis of estimated average service time consisting of population outside labour, an annual service which is used at a rate of 3.4 times per person (see Lankila et al., 2016) and 20 minutes’ average service time. Thirdly, service efficiency of health centres and service vehicles assessed by measuring driving and service time, travelled kilometres and CO₂ emissions.

Spatial data consists of Digiroad network data (Finnish Transport Agency, 2018) including all regularly used roads and speed limit data, locations of health centres, YKR population grid cell data (2017) and YKR data of built-up areas, villages, hamlets and commercial sites (2015). Road network data enables estimation of travel times (see Kotavaara et al., 2017), which were estimated for passenger cars and service vehicles, for which travel speeds were estimated at the level of a delivery van or smaller truck, and the maximum speed was limited to 80 km/h. Turn penalties are defined according to Jenelius and Koutsopoulos (2013), 10 seconds to left turn, 7 seconds to right turn and 30 seconds for a right turn when crossroads without a turn take 3 seconds. CO₂ emissions included road network attributes in addition to minutes and kilometres (see Määttä-Juntunen, 2011). The VTT Technical Research Centre of Finland (cited 10.4.2019) has evaluated CO₂-emissions for different types of vehicles and travel cost attributes for passenger cars and van with a full mass of 2.7 tonnes.

**Case analysis**

This study examines two scenarios for providing primary health care services in the case area. In the first scenario, the patients travel to health centres that are located in the centre of the municipals. Each trip is made using passenger cars. As a simplification, this case does not take into account the use of other transport modes as taxis, buses, motorcycles,
bicycles, walking, et al. as the distances are long and public transportation is very limited. The home locations and straight lines to health centres are illustrated in Figure 1.

Figure 1 – Scenario 1: Accessibility of the health centres

In scenario 2, the same health centres serve the patients within a 20-minute time range. However, patients living more than 20 minutes away from the health centre are served through mobile service facilities, i.e., vans that drive the calculated routes once a week. The calculated locations for mobile facilities and their accessibility are illustrated in Figure 2. Some of the most distant locations are far from these mobile locations and are therefore calculated to use the health centres.
The van routes are calculated to cover the mobile facility locations once a week with maximum 9 hours working time per day. The van starts from a local health centre and returns to the same location at the end of each day. The 15 routes are illustrated in Figure 3 and are detailed in Table 1. All the routes can be covered within five working days with three vans, one per municipality. Each route requires between 1.5 and 4.2 hours of driving time, leaving 4.6-7.2 hours to operate as a mobile health facility.

In scenario 2 most of the population (76%) live within 20 minutes accessibility from the health centres and, thus, uses the health centres as in scenario 1. The patients who live more than 20 minutes away from a health centre are now served through mobile HCF, which decreases the CO₂ emissions that they produce while using the service. However, scenario 2 also produces CO₂ emissions through the vans that drive the routes. The detailed driving time, kilometres and CO₂ emissions of scenario 2 with HC users, mobile HCF users and the routes is presented in Table 2. The digits are transformed to an annual scale by multiplying the weekly routes by 52 and by multiplying the hours, driving distances and CO₂ emissions by 3.4, which is the amount each citizen in Finland uses to reach primary health care services annually (Lankila et al., 2016).

**Concluding discussion**

This paper explores ecologically sustainable model for delivering primary healthcare service in sparsely populated area. The case analysis is presented to compare the centralised and mobile health care facility models. Our study thus illustrates how mobile health care facilities can be considered one method for achieving a decrease in CO₂ emissions by the primary health care system. The empirical results show 49% decrease in CO₂ emissions if the patients over 20 minutes driving time from the health centres are served through mobile health care facilities.

For the discussion of mobile health care facilities, this paper brings new methods of taking account of CO₂ emissions. The results show that strategic change from a centralised to a mobile model can have an impact on driving distances, driving time and CO₂ emissions. Managerially, this study offers a vision for developing health care systems that are part of societies that aim to achieve ecological sustainability. The reduction of 170 CO₂ is somewhat notable when considering the quite small population in the case area.

The presented model aims to minimise CO₂ emissions. Certainly, the results need to be further considered to fit the nuanced entity that the health care system is. Relevant questions include, for example, what kind of call-based system is required to manage the system and also whether the population in the area justifies the need for three mobile health care facilities with the needed personnel.

This research studies the service strategies in one particular geographical area (three municipalities), which puts limits on applying the results universally. However, on both a national and global scale, the case area is very sparsely populated, which intensifies the effects of the initiatives on reducing CO₂ emissions. Hospitals, hospital districts, city organisations and privately-owned healthcare services can use the results in developing their services to reach the set and aspired goals in environmental efficiency. Especially in Finland, the current healthcare reform offers momentum for renewing the health service structure to match the service needs as well as the goals of lower CO₂ emissions. Overall, this provides an example for societies aiming for environmental sustainability. Future studies can highlight the energy efficiency of other mobile health care solutions as the
mobility of health care professionals and using data connections in some parts of health services.

Abstract

The use of Digital Technologies (DT) in healthcare industry is contributing to change the way care process activities are accomplished. Although stating that their implementation improves operational outcomes is quite instantaneous, evaluating improvements in terms of patient safety represents a hurdle. By including into the discourse the healthcare resilience dimension, our goal is to shed light into the relationship between DT and patient safety, providing a different point of view from which to consider how technology can help healthcare organizations to deal with care process failures. A multi-respondent survey provided us with data that we used to test a theoretical framework, using the structural equation modeling procedure.

Keywords: Digital Technologies, Healthcare Resilience, Absorptive Capacity

Introduction

A number of care processes involves the usage of Digital Technologies (DT); consequently, understanding the impact of DT into the healthcare operations becomes a necessity for scholars and managers (Chaudhry et al., 2006). In particular, as regards to patient safety, previous studies have shown contrasting results, e.g. Froehle and White (2014) and Sharma et al. (2016).

In this paper we change the point of view from which to look at the relationship between DT and patient safety; by exploring how this group of technology enables physicians and nurses to be more resilient we were able to better unravel this link. In fact, during the delivery of healthcare services, because of their innate complexity, lots of failures may occur. Among them, the operational failures, such as patient identification errors or missing equipment (Tucker et al., 2008) can have a very strong impact in terms
of patient safety, causing the so-called adverse events (Halbesleben et al., 2008; Stevens and Ferrer, 2016). It is practically impossible to avoid all these failures occur (Hollnagel, 2008), so healthcare organizations have strengthened their capability to manage them (Tucker, 2009) or to assimilate stress and carrying on activities and tasks even when something negative occurs (Weick and Sutcliffe 2011). We suppose that this focusing on this capability, named resilience, can help to better understand the relationship between DT and patient safety. In particular, we see resilience as a dynamic capability, namely a capability that allows organizations to integrate, build, and reconfigure internal and external competences to address rapidly changing environments (Teece et al., 1997).

To the best of our knowledge, no previous studies have analysed the relationship between DT and resilience seen as a dynamic capability. To comprehend this linkage, we use the notion of absorptive capacity (ACAP); in fact, having the capacity to acquire and use knowledge, in particular the patient-specific knowledge, readily and rapidly, can help physicians and nurses in managing operational failures, avoiding they cause an adverse event (Hopp et al., 2018).

To study this phenomenon, based on dynamic capability view, we defined a conceptual framework where ACAP mediates the relationship between DT and resilience. We collected data from 159 respondents of 53 Italian healthcare organizations, which were studied using the structural equation modelling technique.

Theoretical Background and Hypotheses Development

The Dynamic Capabilities perspective

Teece et al. (1997) introduced the concept of dynamic capabilities, defining them as those capabilities that allow an organization to address rapidly changing environment. To do so, companies change their ordinary procedures (Lavie, 2006) by modifying their available assets (Helfat et al., 2007).

A number of papers within the management area of knowledge refers to dynamic capabilities (e.g. Dabhikar et al., 2016; Dobrzykowski et al., 2016), because in sub-fields such as supply chain management or healthcare operations management, the environment where workers operate is turbulent, and the need to have this kind of capabilities may represent a significant source of competitive advantage.

Generally, the studies that focus on dynamic capabilities use this concept as a “view”, in order to frame and justify the linkages among different dimensions (e.g. Chowdhury and Quaddus, 2017). In this paper, we use the definition provided by Barreto et al. (2010) of the dynamic capabilities (the firm’s capabilities to resolve problems in a systematic way) and of the firm tendencies that enable these capabilities (sense opportunities and threats, make timely choices, make market-oriented choices, modify firm’s assets). In this way we were able to frame the constructs and their relationships being studied in a comprehensive way.

Resilience and Patient-Specific Knowledge ACAP

Dynamic capabilities are a significant means that healthcare organizations should have in order to cope with the uncertainty. In fact, the professional nature of healthcare services, characterized by high level of process variation, makes their progress really difficult to foretell (Dobrzykowski et al. 2016); subsequently, considering that dynamic capabilities enable the workers to sense and solve very different problems (from a missing syringe to
patient condition never treated), they represent nearly a mandatory ability that healthcare workers should have.

In the recent years, because of its similarities with the concept of dynamic capability, the resilience, defined as “the ability to anticipate, prepare for, respond and adapt to events—both sudden shocks and gradual change; that means being adaptable, competitive, agile and robust” (British Standard Institution, 2014), has been considered as a dynamic capability (Dabhilkar et al., 2016; Sutcliffe and Vogus, 2003), and in this paper we do the same.

In accordance with the definition by Barreto et al. (2010), in order to be resilient it is important that workers are able to make decisions when dealing with uncertainty; in particular, care processes calls for a number of decision-making tasks which are based both on workers’ expertise and knowledge base (von Nordenflycht, 2010). Among the different kinds of knowledge, the one concerning the patient, based on specific data collectable through sources such diagnostic exams, lab test, etc., enable healthcare organizations to make care process more effective (Chakravarty, 2014). Specifically, in case of operational failure occurrence, to have a satisfactory amount of patient-specific knowledge and being able to exploit it can meaningfully help healthcare providers to cope with the problem, avoiding it transforms in an adverse event. Because of this, in this paper we use ACAP concept in order to link DT and resilience. In fact, ACAP may be defined as the capability of an organization to acquire and exploit knowledge (Zahra and George, 2002); furthermore, as a dynamic capability (as it has already been considered in different papers), it can enable to make well-timed decisions (Barreto, 2010).

Because of what above mentioned, the first hypothesis is:

\[ H1: \text{The patient-specific knowledge absorptive capacity of a healthcare organization is positively associated with its resilience capability.} \]

**Digital Technologies and Knowledge and ACAP**

A number of studies focused on the relationship between technologies and patient safety, with opposite results (Chaudhry et al., 2006; Sharma et al., 2016b). These studies often focus on technologies used to cope with patient safety, but not used by line professionals during their operational activities, such electronic health record. Conversely, there are a number of DT that can have a positive impact in terms of patient safety even if they are not specifically for this goal. This because this group of technology has an impact on the daily activities executed by professional, enabling them to be more resilient by increasing the amount of available patient-specific knowledge. The impact of DT on knowledge has already been studied, e.g., by Sher and Lee (2004), who underlined the possibility these technologies have to enhance dynamic capabilities, or by Hopp et al. (2018), who highlighted how the DT can improve the acquisition of patient-specific data and, consequently, information and knowledge.

In healthcare, other than the simple and obvious adoption of technologies, there are two different mechanisms that allow a healthcare professional to implement DT in a meaningful way in order to increase the ACAP. The first concerns with the extensive usage of the technology within the organization, which can have an impact in terms of learning and accumulating knowledge (Queenan et al., 2011). Several DTs, for instance those used for diagnostic exams or lab test, surely improve patient-specific information
stream (Bardhan and Thouin, 2013) and facilitate the decision-making process that is executed by the line professionals in case of an operational failure occurrence.

Second, the level of accessibility of DT, namely how easy and quick is for physicians and nurses to approach the DT, is a crucial enabler of patient information availability and is fundamental in order to exploit the acquired knowledge in a significant way (Roberts et al., 2012). In fact, one of the characteristics of healthcare context is the high level of collaboration and communication among workers (Mihailidis and Bardram, 2006), and there are a number of DT which potentially may improve these strong and mandatory relationships.

Thus, the other two hypotheses are grounded on the possibility that DT usage and DT accessibility may improve the patient-specific knowledge ACAP by means of the mechanisms of the usage of and the accessibility to the DT:

\[ H2a: \text{Digital technology adoption is associated with patient-specific knowledge absorptive capacity through the mechanism of digital technology usage.} \]

\[ H2b: \text{Digital technology adoption is associated with patient-specific knowledge absorptive capacity through the mechanism of digital technology accessibility.} \]

**Research Method**

*Questionnaire design and data collection*

We defined a multi-respondent survey composed of three different sections in order to collect data. The unit of analysis is represented by the single healthcare organizations, while the respondents are different for every section. The first focuses on DT adoption, accessibility and usage, the second focuses on the PSKACAP assessment, while the third focus on the degree of resilience.
The population is composed of 575 Italian public-private hospitals. The choice to focus on this kind of healthcare organizations concerns the dimensions we wanted to study. In fact, our research focus is on patient safety with particular regards to related operational facets. Subsequently, we needed to ask questions to workers and management figures in direct contact with day-to-day operations. Considering that part of the survey questions is directed to managers, we needed they were in daily contact with the organization’s operations; this condition was not satisfied in pure public healthcare organizations mainly because of their size.

In order to provide the survey, we started from a dataset we downloaded from the Italian Ministry of Healthcare website containing the data of the whole Italian population, then we contacted the Clinical Risk Manager (CRM) of every organization through email or phone, explaining the study and providing him the survey through email. We collected 159 responses, which constitute full responses from 53 healthcare organizations.

### 3.3. Variables and Measures

#### 3.3.1. Resilience

The dependent variable of the model is the resilience. In order to assess it, we focused on the happening of the so-called cascade event (Levinson, 2010), which are a particular kind of adverse event which originate from an operational failure, which generate another operational failure, and so, as a “cascade”, causes harm for patients. A resilient organization has the ability to stop the cascade, consequently the less their number, the more the organization is resilient. Relying on Levinson’s study of this typology of events, through the coding methodology, we defined six groups of cascade events, which different each other on the basis of the beginning operational failure. Finally, we assessed resilience by questioning CRM the occurrence of each category (table 2).

#### 3.3.2. DT adoption, DT usage and DT accessibility

In order to assess the DT adoption, the survey contains a number of healthcare information technology/system, listed the Health Information Management System Society (HIMSS) dataset (https://www.himss.org), and the IT manager was asked to flag those present in his healthcare organization. We selected 32 typologies of system/technology that better fit with the scope of the study. Example of these technologies/systems are: Room allocation systems, Discharge reporting, Surgical report management, Health records, Specialist examination management, Ward “take in charge”, Surgical operations and diagnosis, Hospital discharge form closing, DRG computation, Interface with lab, Interface with radiodiagnostic. This course of action was already followed in other studies aiming to assess the adoption of information technology in healthcare context (Sharma et al. 2016; Bardhan and Thouin, 2013).
To assess the DT usage we used two items, with the goal to evaluate how many wards within the healthcare organization use how many IT functionalities. To define the questions, we based on the work of Queenan et al. (2011) (table 2).

Finally, to assess accessibility we focused on the existence of devices which allow line professionals to have an easy access to information. In this case, we started from the statement of e-health functionality (Ruiz Morilla et al., 2017) and, relying on the contribution of two experts, we were able to create three items (table 2).

3.3.3. PSKACAP
The PSKACAP was operationalized using six different items (table 2). The first three in order to evaluate the capability of the organization to acquire patient-specific knowledge in particular the facility in getting it (Lichtenthaler, 2009; Zahra and George, 2002). The other three to assess if the line professionals are able to use the available knowledge in a meaningful way (Jansen et al., 2005; Pavlou and El Sawy, 2006).

3.3.4. Controls
The four control variables that we used are in some way related to the level of patient safety or organization resilience. We used an item to assess the usage of information technology closely related to patient safety but not to operational activities. The second one is the number of bad, which is closely related to the healthcare organization size which can potentially be linked to the complexity of the activities executed in the hospital and, consequently, to patient safety. The third is the case-mix index, which is a proxy of the gravity of patients’ disease. Fourth, we asked the number of adverse and sentinel events occurred, because of its possible correlation to the cascade events occurrence.

Results
We used the Structural Equation Modeling (SEM) to verify the hypotheses before stated. Every item was assessed by using a five-point Likert scale; the only exception is represented by the DT adoption whose items are binary (yes/no). Considering its number of items, we decided to create 4 parcels and assign each one of the 32 items to one parcel whose value is defined by the sum the value of the related items (Garver and Mentzer, 1999).

The Confirmatory Factor Analysis (CFA) brought us to cross four items, while undimensionality, reliability and convergent validity were all confirmed (table 3a). The discriminant validity of the dimensions presents some problems for the couple PSKACAP-DT, because the value of the AVE is a bit bigger than their correlation (table 3b; table 3c), but considering the very small difference and the relatively small number of sample units, we decided to not modify the model. Finally, all the CFA indices (table 3a) are acceptable.

*p<0.05; ** p<0.01

Figure 2 depicts the structural model. In the first version we included the four control variables, but considering their relationships with the other dimensions are not significant, we dropped them from the model (Cao and Zhang, 2011).

Model fitting statistics suggests us the model fits the collected data (Figure 2). Analysing the path coefficients, we can state that, as hypothesized, the linkage between PSKACAP and resilience is significative and negative (the minus sign because the more the organization is resilient, the less is the value of the items), finally the two linkages between DT adoption and DT usage and DT accessibility are positive and significant. The only linkage which is not statistically significant is the one from DT accessibility to PSKACAP. The direct consequence is that, starting from DT adoption, the only pathway that leads to resilience goes through DT usage and PSKACAP.

![Structural Model Diagram](image)

* indicates loadings significant at p<0.10; ** indicates loadings significant at p<0.01

(χ²(114) = 133.73, χ²/df = 1.173, GFI = 0.96, TLI = 0.947, CFI = 0.956, RMSEA = 0.057, SRMR = 0.092)

Figure 2 – Structural model

Finally, analysing the values of the indirect effects (table 4), what is most interesting is the linkage between DT usage and resilience, which is significant. This suggests there may be other mechanisms/dynamic capabilities, apart from resilience, which being
enabled by DT adoption and DT usage, can improve the capability of the healthcare organizations to be more resilient.

**Discussion and Conclusion**

This research enlightens how the implementation of DT in healthcare increases the resilience of an organization, partially by means of its PSKACAP. This result is valuable for research dealing with patient safety, because of its contribution to clarify the positive impact the adoption of DT may have on it. In particular, the ways the technologies impact on resilience/patient safety follow previous results, which highlighted the importance to decompose the interaction of line professionals with technologies (Queenan et al. 2011). Furthermore, the proposed operationalization of resilience in healthcare (looking at the list of cascade events) represents an important contribution for scholars who aim at quantifying patient safety in a complementary way to the previous measures (such the occurrence of adverse events), that do not enclose the resilience capability of healthcare organizations. Furthermore, the introduction of PSKACAP within the frame of the ACAP theory can provide a meaningful instrument to study the role of patient information in healthcare, which could have a key role in the next future because of the increasing implementation of IoT technologies, which enable the collection of a huge patient-specific amount of data.

Finally, the outcomes of this research should lead managers to consider the capability of DTs to increase resilience when they have to choose whether to adopt them or not. In fact, the adoption of “classical” technologies in support of clinical risk management is essential, but the need to be resilient for line professionals force managers to consider how other technologies can enable the implementation of resilient behaviour, in order to cope with operational failures in a meaningful way.

Abstract
This research aims to study the role of the staff competency as a mediator to determine the relationship between procurement performance and the influencing factors to obtain procurement performance. The research applied a Partial Least Square based structural equation modelling (PLS-SEM) method to analyse the data collected from the questionnaire survey. The results show that staff competency acts as a full mediator between the procurement performance and e-procurement, procurement policies and producers and organization structure. While it is only partially mediating between the procurement performance and quality management and planning.

Keywords: Procurement Performance, Healthcare sectors, Performance Measurements, Staff Competency.

Introduction
Measuring procurement department performance nowadays become essential to any organization to have a competitive advantage. Procurement is essential to organizations, and its strategies became part of the business achievement. It improvements efficiency and competitiveness and to understand these, it is important to give weight about the strategic factors that influence the performance of the procurement function (Walter et al. 2015). Internal and external forces are influencing the ability to identify the procurement objectives. Relates between different factors such as procurement planning, staff competency, procurement procedures, E-Procurement, procurement planning, and
procurement quality management, all have an impact on the performance of the public procurement function and therefore they need further research attention (Kim et al. 2013).

**Healthcare sectors in the United Arab Emirates**

Over the past five years, the healthcare sectors in the United Arab Emirates (UAE) have evolved very fast. In 1971, the country used to have seven hospitals and 12 health centers (U.S.-U.A.E. Business Council, 2018). Currently, the country has 126 public and private hospitals with a joint volume of over 12,000 beds according to the statistics authority Business Council, 2018). The healthcare sectors in the UAE are overgrowing to meet the needs of population growth and the nation’s goals to become the national medical tourism center. This rapid expansion led to many challenges to respond to the increased demands by providing the right products and services with sufficient costs and high quality (Bienhaus and Haddud, (2018) and thus warrant for further research.

**Literature Review**

According to Smith and Conway (1993), to have a successful procurement department, the organization needs to measure its performance using seven success factors: procurement strategy, information management, control system, skilled staffs, corporate management role, risk-taking and positive approach, coordination and focused effort. Procurement performance effected by these procurement processes, effectiveness and efficiency (Van, 2006). The performance of the procurement is the primary driver to gain competitive advantage and improve the quality of the product or services. Continuance assessment of procurement performance will help the organization to minimize the spending, reduce cost, increase profitability and approved suppliers. Comprehensive public procurement policies and practices are essential elements of good governance. Therefore, any unnatural procurement activities in government sectors might lead to a waste of public resources and money.

**E-Procurement**

E-Procurement is one of the most crucial factors influencing procurement performance. E-procurement the use of technology systems in procurement functions such as placing orders, tendering, negotiations and sourcing materials (Croom and Brandon-Jones; 2007). Public and private sectors use e-procurement for important reasons such as (1) cut in cost, (2) real-time bidding, (3) process transparency, (4) decrease purchasing cycle-time, (5) increase suppliers database and (6) suppliers quality control (Wu et al. (2015). It helps to have full access to suppliers and buyers all over the world and the selection of modern products with sufficient product information. Therefore, e-procurement has a significate influence on procurement performance in government sectors.

**Procurement policies and procedures:**

Procurement policies and procedures are the guidelines for the staffs to follow to perform activities and constraints on how the procurement should function to achieve the organization strategy (Moncska et al., 2010). Organizations use standard procurement procedures to cover all features of the procurement cycle, including a selection of vendors and suppliers, contracts negotiations, placing orders and payments control (Oumaand Jennifer, 2014) to ensure the efficiency of the procurement department. Without clear
policies and procedures, the procurement department will not function correctly, and that might cause business failure.

**Statement of the Problem**

Procurement function is one of the essential functions in any organization no matter its core business. Procurement department has enormous contributions to organizational effectiveness and efficiency (Croom and Jones (2007). If the procurement department performs inefficiently in its procurement activities, all other departments will be affected, and consequently, the impact will be excessive on the organization’s Supply Chain (Snider and Rendon, 2008). In order to keep the procurement department functioning effectively and efficiently, the performance of this department needs to be monitored and measured to cope with the rapid changes in the supply chain. This study aims to study the research question of: what factors are influencing procurement performance in the UAE healthcare sectors?

**Research Objectives**

The main objectives of this research are:

- To identify which factors have the most significant influence on the procurement performance in UAE healthcare Sectors.
- To provide a framework to help overcome the adverse side effect of the factors influencing the procurement performance in UAE healthcare Sectors.

**Research Design**

The following hypotheses are developed;

H$_{1}$:  
\begin{align*}
\text{a.} & \text{ There is a significant effect of E-Procurement on procurement performance in the UAE healthcare sectors.} \\
\text{b.} & \text{ There is a significant effect of procurement policies and procedures on procurement performance in the UAE healthcare sectors.} \\
\text{c.} & \text{ There is a significant effect of procurement organization structure on procurement performance in UAE healthcare sectors.} \\
\text{d.} & \text{ There is a significant effect of quality management on procurement performance in the UAE healthcare sectors.} \\
\text{e.} & \text{ There is a significant effect of procurement planning on procurement performance in the UAE healthcare sectors.}
\end{align*}

H$_{2}$: There is a significant effect of staff competency on procurement performance in the UAE Emirates healthcare sectors.

H$_{3}$:  
\begin{align*}
\text{a.} & \text{ Staff competency acts as a mediator between E-Procurement and procurement performance in the UAE healthcare sectors.} \\
\text{b.} & \text{ Staff competency acts as a mediator between procurement policies and procedures and procurement performance in the UAE healthcare sectors.} \\
\text{c.} & \text{ Staff competency acts as a mediator between procurement organization structure and procurement performance in the UAE healthcare sectors.} \\
\text{d.} & \text{ Staff competency acts as a mediator between quality management and procurement performance in the UAE healthcare sectors.}
\end{align*}
e. Staff competency acts as a mediator between procurement planning and procurement performance in the UAE healthcare sectors.

The conceptual model is presented in Figure 1 as follows.

Figure 1 The Conceptual Model

Research Methodology

A survey questionnaire is designed to get the required data about the dependent and independent factors affecting the procurement performance in UAE healthcare sectors. The questions based on the Likert scale with the aim of determining the factors affecting the procurement performance in healthcare sectors.

Data Collection

This research study used primary and secondary data to fulfill the research objectives. The primary data collection tools are a questionnaire survey containing closed-ended questions. The questionnaire survey questions were constructed to obtain information on factors influencing procurement performance in healthcare sectors in the United Arab Emirates. The questionnaire survey consisted of seven sections, and each section consisted of questions related to the factors influencing the procurement performance. The questionnaire allowed better consistency in the way questions were placed, ensuring greater compatibility in the answers. The use of close-ended questions on the questionnaire allowed for consistency of answers to questions. Secondary data was collected through desk search methods from published reports that include journals, periodicals, and supply chain and procurement publications. The questionnaire was distributed by emails to the disciplines using web link using Qualtrics.com website.
From the targeted healthcare sector in the UAE, total number of 127 complete responses were received which represents 47% response rate. The collected data was analysed by using the Smart PLS v3 and the results are represented in Figure 2, indicating the direct and indirect relationships.

**Validity and Reliability**
This research project carried out a pilot study to validate the questionnaire. To start the validation process of the research tool, the research required opinions of experts in the field of the research study, especially the researcher’s supervisors. This helped the necessary revision and modification of the research tool thus enhancing validity. This simplified the necessary review and alteration of the research tool so increasing validity. A group of 10 individuals will be used as a pilot group from the study population to test the validity and reliability of the research tool. The clearness of the tool items to the respondents was started to enhance the tool’s validity and reliability. Reliability was attained by correlating the scores of each questionnaire for each variable. Cronbach’s alpha value above 0.70 as a threshold value was considered to test for internal consistency (George and Mallery, 2003).

**Data Analysis and Presentation**
The collected data was summarized, coded and tabularized to be used with SmartPLS v3. This software will be used to process the data to be analyzed using descriptive statistics. The descriptive statistics will include means, standard deviation, and hypothesis test was used to analyze the data to establish the extent to which factor affects the procurement performance.

**Hypothesis Testing of Structural Model**
Results relating to the Hypotheses shown in Table.1, demonstrating the significance level of the final model (Figure. 4-2) with statistical p-value and t-value having the staff competency as a mediator and with a direct impact by the independent factors to the dependent variable. The model results proved that hypotheses H3a, H1c, H3c, H1e, H3b, H1d, and H2 are non-significant when they are tested in a relationship with the staff competency as a mediator and against the procurement performance. Only H1a (E-Procurement > Procurement Performance), H3e (Procurement Planning > Staff competency) and H1b (Procurement Policies and Procedures > Procurement Performance) are found to be significant with a satisfying p-value (p < 0.05) and t-value (t > 1.976). These results are bootstrapped by increasing the sample size up to 1000 (Figure. 4-2). A high t-values indicates that the groups of people participated in the survey are different and small t-values indicates that the groups of people are similar.

From the analyzed data for the full model with the independent's factors linked to the staff competency and linked to the dependent factor, the results show that only four factors do have a significant effect toward the procurement performance, which is E-Procurement, Procurement Planning, Procurement Policies, and Procedures and Quality Management. The staff competency has a non-significant and negative impact toward the procurement performance. As a result, the hypotheses with a significant impact can be accepted and the hypotheses non-significant impact will be rejected.
Table 1. Hypothesis Test Results for the Structural Model

| Model path functions | Hypothesis | Original Sample (O) | Sample Mean (M) | Standard Deviation (STDEV) | T Statistics (|O/STDEV|) | P Values | Significance |
|----------------------|------------|---------------------|-----------------|---------------------------|---------------------------|----------|--------------|
| E-Procurement > Procurement Performance | H1a | 0.464 | 0.441 | 0.202 | 2.296 | 0.022 | Significant |
| E-Procurement > Staff competency | H3a | -0.057 | -0.014 | 0.208 | 0.275 | 0.783 | Non-significant |
| Organization Structure > Procurement Performance | H1c | -0.087 | -0.064 | 0.13 | 0.667 | 0.505 | Non-significant |
| Organization Structure > Staff competency | H3c | 0.124 | 0.138 | 0.118 | 1.05 | 0.294 | Non-significant |
| Planning > Procurement Performance | H1e | 0.069 | 0.071 | 0.199 | 0.348 | 0.728 | Non-significant |
| Planning > Staff competency | H3e | 0.379 | 0.365 | 0.12 | 3.154 | 0.002 | Significant |
| Policies and Procedures > Procurement Performance | H1b | 0.358 | 0.323 | 0.173 | 2.076 | 0.038 | Significant |
| Policies and Procedures > Staff competency | H3b | 0.082 | 0.09 | 0.192 | 0.43 | 0.667 | Non-significant |
| Quality Management > Procurement Performance | H1d | 0.227 | 0.28 | 0.203 | 1.123 | 0.262 | Non-significant |
| Quality Management > Staff competency | H3d | 0.469 | 0.419 | 0.152 | 3.077 | 0.002 | Significant |
| Staff competency > Procurement Performance | H2 | -0.105 | -0.12 | 0.208 | 0.503 | 0.615 | Non-significant |

According to Baron & Kenny, (1986), a mediator impact is experimented by running the model with the mediator in the structure to determine how much the mediator influence the independent variable and the dependent variable. In this research, It was established that staff competency has a limited influence against the procurement performance with a negative impact. The results from Figure 2, shows that among all the factors influencing the procurement performance with the staff competency as mediator are E-Procurement, policies and procedures and organizational structure where the direct path t-values are 1.333, 1.253 and 1.765, which are less than the accepted threshold values for a t-value of 1.976 according to Hair, Sarstedt, Hopkins, and Kuppelwieser (2014).
Figure 2. Direct, indirect and total effect of procurement functions with staff competency as mediation factor

Although the literature did support the positive and high influence against the procurement performance, the research study results did not support that. Staff competency according to the literature is the factor that controls and influence other factors. The reasons could be that the staffs are not empowered to perform by themselves as the results showed that the policies and procedures have a high influence against their performance. It could be these policies and procedures are not robust to guide the staffs to enhance the performance as much as to control them to do the job.

This research showed the importance of measuring the procurement department performance. The targeted sectors have problems with the current performance. The research study determined that performance measurement was neglected in these sectors which led to this results. The reasons were discussed earlier need to be more investigated which will reveal the root cause of these problems and might discover new once, also new factors affecting the procurement performance. The performance of any organization relies on the functional department's performance, and continuous measurement to the performance will help to eliminate the negative effects and will help to use the positive effects to improve the performance.

**Conclusion**

The research study developed a framework for the factors influencing the procurement performance with a mediator. The analysis confirmed that factors such as E-Procurement
policies have a significant positive influence against the procurement performances. Also staff competency acts as a full mediator against the procurement performance. The research study was limited to the United Arab Emirates region concerning its geographical coverage. The results of this research could be used by organizations that are seeking to improve their procurement department performance and its functionality. This research study is the first to examine and determine the factors influencing the procurement performance in United Arab Emirates healthcare sectors.

The outcomes of this research study have some managerial implication for the healthcare sectors in the United Arab Emirates at large and to procurement department management in particular. The research study found out that E-Procurement, policies, and procedures as the most critical factors affecting procurement performance. Procurement department managers from different level mainly need to work on these factors to mitigate their effect ultimately to improve the work performance of the procurement unit.

Abstract

This article empirically examines the relationship between leadership behaviours and the implementation level of Lean Healthcare (LH). At three points in time, with a six-month interval between each point, we surveyed and interviewed 12 leaders from a Brazilian public hospital adopting LH. Our findings indicate that leaders who actively adopt LH practices also demonstrate more task- and relations-oriented behaviours, whereas low LH adopters may drop their display of those behaviours over time. This finding parallels with Kübler-Ross’s change curve that describes how an individual’s confidence, morale and effectiveness levels may vary as a change process, such as LH implementation, unfolds.

Keywords: Lean healthcare, Leadership, Behavioural change.

Introduction

Studies trying to understand the determinants of the successful adoption of Lean Manufacturing (LM) practices have increased significantly over the last few years (e.g., Shah & Ward, 2003; Marodin & Saurin, 2013; Netland et al., 2015; Tortorella et al., 2015). LM has been adopted in several sectors and its implementation involves various challenges (Danese et al., 2018; Nordin et al., 2012). To succeed, the literature emphasizes the importance of an underlying LM culture, which is considered a fundamental element for its long-term sustainability (Hines et al., 2004; Bhasin & Burcher, 2006). Leaders are fundamental for establishing such a culture (Shook, 2010; Marodin & Saurin, 2015a; Alagaraja, 2014); they have the responsibility of influencing individuals and guiding them to achieve strategic and operational objectives.

According to House et al. (2004), LM implementation creates expectations regarding leaderships’ behaviours. Mann (2009) reinforces that twenty percent of the effort in the lean transformation process relates to the implementation of practices and tools, while eighty percent focuses on changing leaders’ behaviours, including cooperation, delegation and high motivation of personnel (Emiliani, 2003; Angelis et al., 2011; Pamfilie et al., 2012). Further evidence suggests that in order to implement a change
process successfully, such as LM, organisations need to have transformational leaders at the top (Suresh et al., 2012) who emphasise the desired behaviours toward the expected culture and outcomes, which must be carried out by leaders in middle management ranks (Emiliani, 2008; Van Dun et al., 2017). Among others, also Gelei et al. (2015) investigated which leadership behaviours contribute to successful lean implementation.

LM has been particularly widely integrated into the management of healthcare organisations over the last ten years. Lean Healthcare (LH) (Young et al., 2004; Kim et al., 2006; Graban, 2011) is a means for delivering higher quality and more efficient care (Trisolini, 2002). Therefore, to enable patients and healthcare organisations to reap the benefits from LH implementation, proper leadership behaviours must be demonstrated accordingly within the usual highly-complex healthcare context. Thus, the research question of this study is: How do leaders’ behaviours change throughout the lean implementation in a healthcare organisation?

A longitudinal study was conducted to identify not only how leaders’ behaviours change as lean practices are implemented in a healthcare organisation, but also with variations in practice adoption throughout the LH implementation journey. Our results integrate change management theory into the field of operations management.

**Literature review**

**Lean healthcare**

A challenge when describing lean implementation is that there is no consensus on how to define lean, since its principles can be expressed and understood in several different ways (Souza, 2009; Pettersen, 2009). Although Liker’s (2004) and Womack et al.’s (1990) descriptions of lean have been cited frequently, they have been criticised for not paying attention to human resources in a lean organisation (Hines et al., 2004). Shah and Ward’s (2007) definition does include employee involvement in problem solving, but they do not address decentralized participation in decision-making, which is also an important aspect in the healthcare context.

The difficulty in implementing LH successfully and thereby achieving long-term benefits can be further explained by the discrepancy between an organisation’s strategy and the actual change (Sull, 2007). Such a strategy-to-performance gap usually occurs during LH implementation due to the primary focus on technical aspects and short-term results, rather than on developing sociocultural factors that support the change process (Kaplan et al., 2014). A more holistic change approach is thus required in order to obtain long-term improvements in the core processes (Mazzocato et al., 2010).

Establishing a LH organisation means lean practices must be part of a comprehensive management system that is supported by committed leaders (Kaplan et al., 2014; Mann, 2009; Steed, 2012). However, only a few empirical studies looked at the specific leadership behaviours that positively affect successful LH implementation (Almeida et al., 2018; Crema & Verbano, 2013; Holden, 2011). Table 1 consolidates the most frequent lean practices evidenced in the literature. As these practices have been found across different industry sectors, they may be representative of LH implementation.

**Lean leaders’ behaviours**

As noted before, leadership is a critical variable for successful LH implementation (e.g., Young et al., 2004; Jimmerson et al., 2005; Womack et al., 2005; Souza & Pidd, 2011; Steed, 2012; Kaplan et al., 2014; Samuel & Novak-Weekly, 2014). Mann (2009) suggested that leaders are not only responsible for making strategic plans but also for guiding the actual organisational transformation towards a lean enterprise. Managers’ support and commitment are also seen as key factors for enabling staff to improve their

</table>

processes and obtain sustainable results (Grove et al., 2010; Crema & Verbano, 2013). But it remains unclear what such leader support may entail in a healthcare setting.

Some regard strong, charismatic relations-oriented leadership as necessary for successful LH implementation (Grove et al., 2010). At ThedaCare, for instance, the change from autocratic, task-oriented leadership to relations-oriented behaviours such as mentoring, facilitating, teaching and supporting was seen as a determining factor for their success (Toussaint & Berry, 2013). Healthcare leaders must create a shared vision that inspires followers, encourages desirable behaviours and fosters an organisation’s capacity for change (Oxtoby et al., 2002). However, LH inherently also requires leaders to focus on task improvement (Birken et al., 2012).

In order to retrieve healthcare-specific behaviours associated with an effective lean leader, we performed a systematic literature review (see for a full documentation: Tortorella et al., in press). Twenty-seven studies were selected and content-analysed. Table 2 highlights the fifteen most cited lean leadership behaviours constituting both task- and relations-oriented behaviours. Despite the growing body of knowledge on the topic, none of these studies analysed how leadership behaviours might shift throughout different stages of LH implementation. Following Liker (2004) and Liker and Meier (2006), our aim was to investigate whether people gradually start to change their behaviours and mindsets as new workplace practices are introduced.
Method
A longitudinal, mixed-methods study was conducted among ten hospital-based leaders who led the lean initiatives within their departments. The research expands upon the study of Tortorella et al. (in press) by presenting additional analyses.

Sampling
We selected individual leaders from a public hospital that had started implementing LH two years prior to this study and had collaborated with our previous research. Hence, the respondents’ work context was similar, including organisational culture and hospital-wide support for LH implementation. The leaders had a middle managerial position as this is a key role for innovation in healthcare organisations (Birken et al., 2012). The final sample consisted of twelve leaders. Most respondents were nurses (33%) and 42% of them had up to five years of leadership experience. The majority (92%) were older than 30 years and led teams with more than five members (58%).

Data collection procedure
The data was personally collected from each leader at three points in time, with a six-month interval between each time. The first questionnaire was conducted in June 2017 ($t_1$), the second one in December 2017 ($t_2$) and the last in July 2018 ($t_3$). The printed questionnaires were completed by the leaders during individually scheduled meetings. This procedure avoided non-response bias.

We also collected qualitative data by conducting semi-structured interviews with each respondent. When building theory, augmenting quantitative data with qualitative data is usually encouraged, since it helps to check and explain results (Voss et al., 2002). The approximately thirty-minute interviews occurred at each questionnaire appointment in order to complement the information gathering.

Measures
The first part of the questionnaire collected the respondent’s demographic information. The second part measured the degree of adoption of the 17 lean practices listed in Table 1 since it represents the level of LH implementation within each respondent’s department. Previous studies suggest that the evaluation of pre-defined practices can be considered as an effective approach to identify the organisation’s maturity level regarding lean implementation (e.g., Shah & Ward, 2007; Netland & Ferdows, 2014; Marodin et al., 2015). A five-point Likert scale was applied to each item, whereby ‘1’ denoted no evidence of implementation and ‘5’ referred to full implementation. The final part was a self-assessment of the respondent’s task- and relations-oriented behaviours based upon the adoption frequency of the fifteen behaviours of lean leadership displayed in Table 2. The respondents indicated on a Likert scale ranging from 1 (never adopted) to 5 (always adopted), how frequently they demonstrated each behaviour. All the Cronbach’s alphas were satisfactory (lean practices: 0.969; task- and relations-oriented behaviours: 0.999 and 0.809, respectively).

Data-analysis
We first clustered the data according to the adoption level of lean practices. Thus, we considered LH implementation to be a single dimension based upon the total scores of each respondent at a specific moment of data collection ($t_1$, $t_2$ and $t_3$). The consolidation of a holistic set of practices into one single lean dimension is a common approach (e.g., Marodin et al., 2016). The respondent’s total scores were regressed on each of the time intervals using ordinary least square (OLS) regressions, resulting in unstandardized
coefficients associated with each of the twelve respondents (see Table 3). Based upon the unstandardized coefficients’ median (15.5), we determined the high lean adopter (HLA) respondents whose coefficients were greater than the median, i.e., a more pronounced growth in terms of LH practices adoption during the study. In turn, low lean adopters (LLA) were the ones whose coefficients were lower than the median and presented a slower increase in their LH practices adoption levels. We also standardized the coefficients in order to find the leaders with the strongest LH adoption, i.e., above 1.0. They showed a big leap in terms of LH practices and, hence, were denoted as extremely high lean adopters (EHLA). Five respondents were categorized as LLA, four were all grouped into as HLA and only two respondents were considered to be EHLA. One respondent was excluded from the database since the standardized coefficient value was not significant.

Subsequently, we calculated the means for the level of LH adoption as well as the task- and relations-oriented behaviours of each group of respondents (EHLA, HLA, LLA). Table 4 shows the group means at each point in time. The behaviours (dependent variables) of each group were plotted separately in a scattered graph against their respective means for LH implementation (independent variables). Based upon a curve fitting with interpolation, we verified the mathematical function that best fitted the data points in order to visualise the data (Arlinghaus, 1994; Hauser, 2009). Using Microsoft Excel, the fitted curves were extrapolated beyond the range of the inputted data in order to understand the possible trend of these behaviours better with respect to extensive LH implementation. The interview data were transcribed and content-analysed.

Results

Figures 1 and 2 show the results of both the relations- and task-oriented behaviours within the LLA, HLA and EHLA groups. Polynomial curves were found for all three respondent groups where $R^2$ equals to 1. Using the obtained mathematical functions, we extrapolated the data in order to identify and sketch a behavioural pattern. Both relations- and task-oriented behaviours appear to have similar trends as LH implementation evolves, regardless of their group. Although HLA and EHLA show similar curves, EHLA leaders have more accentuated relations-oriented behaviours in
the long term than HLA ones. The same pattern is not observed for task-oriented behaviours. These outcomes suggest that leadership behavioural changes are actually more prominent in the long run. This result is somewhat aligned with D’Andreamatteo et al. (2015) who suggested that changing leaders’ behaviours is time-consuming and cannot be significantly shifted in the short-term. The EHLA findings also support Van Dun et al.’s (2017) and Tortorella et al.’s (2017) conclusions that effective lean middle managers demonstrate relations-oriented behaviours more frequently.

Additionally, the results indicate that leaders who fully embrace LH implementation (i.e., EHLA and HLA) tend to adapt their behaviours towards both a task- and relations-orientation with more-or-less the same intensity. These leaders may be able to situationally adopt different kinds of behaviours. An explanation for such variations among the respondent groups was found in the interview data (see Table 5). The EHLA and HLA leaders indicated that their followers were really committed to LH implementation and embraced the lean culture of continuous improvement. They also argued that, as implementation advanced, they as leaders acquired new, valuable change and managerial skills. In turn, the leaders who implemented lean practices (LLA) poorly complained about the lack of senior management support during the implementation process and their difficulties in engaging their followers in continuous improvement activities. This shows the rather poor relationship between LLA leaders and their followers as well as their higher-level leaders.

Overall, our findings of the perceived leadership behaviours throughout the LH implementation show parallels between the change curve theory developed by Kübler-Ross (1969) and later enhanced by Zell (2003), Hazen (2008) and Rosenbaum et al. (2018). It is widely accepted in the change management literature that the levels of an
individual’s confidence, morale and effectiveness vary as a change process unfolds (Elrod II & Tippett, 2002). Five change stages are suggested, beginning with denial and anger, moving towards bargaining for support, depression and, finally, acceptance. On the one hand, the LLA leaders’ behavioural variation in our study can be associated with the denial and stages, respectively: After the initial high expectations of LH, these leaders are still struggling to accept and comprehend the behavioural requirements for a successful LH implementation. On the other hand, EHLA and HLA leaders, who are rapidly implementing LH practices, seem to overcome those initial change stages towards the acceptance stage, which gives them the confidence to explore new behaviours thereby becoming active change agents.

**Table 5 – Examples of LLA, HLA and EHLA comments throughout the study**

</table>

**Conclusion**

This research describes the perceived behaviours of leaders over the course of one year, within a public hospital adopting LH, but our findings may apply to a wider population. Our results offer insights into the entailed changes within LH implementation, indicating that leader behaviours may (or must) shift as LH advances in maturity. In fact, our findings indicate that the effect of LH implementation on the leadership behavioural shift can be underpinned by the change curve theory (Kübler-Ross, 1969); i.e., leaders who embrace the necessary change and are positioned at the exploring or acceptance stages of the change curve are more likely to demonstrate both task- and relations-oriented behaviours. In turn, hospital’s leaders who struggle with implementing lean practices could be positioned at the denial and anger stages. Over time, leaders are likely to adopt both task- and relations-oriented behaviours intensively. However, as LH implementation evolves it requires significant changes in leadership behaviours whereby effective LH leaders are likely to demonstrate more prominent relations-oriented behaviours than those who are less active in adopting LH practices.

Senior healthcare managers in organisations interested in LH transformation can use our findings to understand their middle managers’ behaviours better as the implementation evolves. Furthermore, by identifying the leaders who are making smaller leaps in LH implementation, senior management can anticipate necessary countermeasures to develop and enhance their soft skills, thus enabling a smoother and less conflicting change. Additionally, our study indicates that it is necessary to have a
reasonable combination of different leadership behaviours (task and relations) to enhance the chances of a successful LH implementation; although relations-oriented behaviours seem to be more prominent in the long-term. This fact is especially important for healthcare middle managers, whose intense technical background usually lack leadership aspects that might enhance their daily-routine management.

This study’s small sample size limited any sophisticated data analysis techniques to give more robust empirical evidence. Moreover, extending the data collection period would have enabled better inference about the leader behavioural changes derived from LH implementation that typically take (more) time. Therefore, future research should not only increase the number of respondents, but also improve the data collection to gather more information on both leadership behaviours and LH implementation throughout the change process. Such studies could verify the validity of our outcomes, enriching the insights into theory and practice.

Abstract

The use of the Internet of Things and the demand for quality services in the healthcare is increasing. This study proposed to carry out a bibliographic review on the subject. The methodological approach adopted was the bibliometric. Databases used were ISI Web of Science, Scopus, Lilacs, PubMed and Cinahl. The analyses suggest that the continuous improvement of processes and the quality of services offered are factors that influence the development of teams that direct their efforts towards patient safety. However, when processes are associated with cyber physical systems, they have difficulties in establishing reliable levels of patient data security.

Keywords: Healthcare Operations Management; Operations Innovation; Technology Management in Operations.

Introduction

Process reengineering methodologies have become an international management phenomenon (Waring and Bishop, 2010), as there is increasing pressure on health services to increase their efficiency. In an effort to achieve this goal, health services have sought alternatives to traditional models, where lean manufacturing stands out as a process improvement methodology (Radnor et al., 2012) associated with Internet of Things (IoT) which seeks to improve the user experience of health services in relation to the occurrence of failures, making it more efficient (Lin et al., 2017).

The connection between lean healthcare (LH) - a derivation of lean manufacturing applied in healthcare - and the IoT allows services to be interpreted from the perspective of value creation, where the value created is valued by customers as a way to qualify the service offered, in a way that this service has as available resources (Wetter-Edman et al., 2014).

The lean methodology is considered a radical alternative to the traditional mass-production model, whose goal is to maximize operational efficiency, quality, speed and cost of operations (Holweg, 2007). The lean approach finds popular appeal in healthcare since it aims to redesign clinical practices and resources around simplified, efficient and value-added care (Waring and Bishop, 2010).
The approach adopted in health systems is different from that adopted in manufacturing systems, since the processes are different, with the particularity of working with human lives. The definition of lean for health systems varies in interpretation and practice, and is commonly called lean healthcare. LH is neither an adapted manufacturing tactic nor a cost reduction program; it is a management strategy that is based on process improvement in a system (Nelson-Peterson and Leppa, 2007). The management practice is based on the philosophy of continuously improving processes, reducing activities with little or no added value to the patient, changing processes and precarious working conditions (Radnor et al., 2012).

It promotes a structured approach to problem solving and improvement efforts linked to hospital strategy (Mazzocato et al., 2012) and illustrates the desire of policymakers to reorder clinical work by introducing managerial philosophies and techniques, involving the systematic evaluation of the existing work process to determine the evidence of its waste and inefficiencies, increasing productivity and efficiency according to the new evidence (Waring and Bishop, 2010).

Given this diversity, and in addition to standardization efforts, interoperability plays a key role in the success of health systems. This leads to a heterogeneous mix of traditional technologies and processes, generating a new way to implement internet-based quality systems, as well as their integration into other media, a clear challenge (Rahmani et al., 2018). Under this new perspective, a design for service emerges, which provides approaches, skills and tools capable of allowing the actors involved in the process to be part of a new service system design (Wetter-Edman et al., 2014).

Health professionals need to be aware that lean helps in process improvement and value stream mapping, offering many opportunities for health organizations and their continuous improvement initiatives (Vats et al., 2012). When applied correctly, they help evaluate the value of each step in the process, as well as measure and identify the variation of a process for conducting positive and repeatable results (Vats et al., 2011). The physical environment in which a service is delivered or an experience is created is often considered a key variable that influences customer perceptions and behavior (Zomerdi and Voss, 2010).

Three key aspects were identify for lean methodology to be introduced in a hospital: the evaluation of existing processes, the adoption of process improvements and the monitoring of performance on the improvements implemented (Radnor et al., 2012). This add the need and willingness to improve organizational performance, creating alternative solutions, and increased team communication (Mazzocato et al., 2010).

The use of differentiated, disruptive methodologies assists in the creation of new values associated to the services offered, so that connectivity and information sharing between top management and clients are positively related (Gunasekaran et al., 2017). This makes companies increasingly innovate with differentiated offerings for consumers, creating more complete solutions that combine product and service components, shifting the product-centric perspective to a solution-oriented perspective (Costa and Patricio, 2018).

From this perspective, a growing trend is seen with the use of technologies in health services, which allows a transparent and intelligent interaction between the computational elements and the medical devices. Based on the discipline of computing, sensing, communication and embedded systems technologies, cyber-physical systems (CPS) are part of a natural evolution resulting from the rapid development of information and communication technologies (Gu et al., 2017).

The concept of IoT arises in this context, which should be seen as a multilayer architecture (Lin et al., 2017). The basic difference between CPS and IoT is that the CPS...
is considered a system (Lin et al., 2017) which includes several devices connected to the internet, where the devices are also included (Mahmood et al., 2017) while IoT is considered pure internet (Lin et al., 2017) and includes a large number of devices that can communicate through different networks (Mahmood et al., 2017).

Web-based health systems of IoT are proliferating. Many of these systems have a high degree of complexity due mainly to the characteristics of human health and physiology, all complex and dependent on the person (Stankovic, 2016). These complexities give rise to many new research problems, emphasizing the gap between methodologies of service management, quality management and information technology.

To fully realize the potential benefits of lean, organizations need to minimize the impact of barriers and provide specific conditions to the local context (Mazzocato et al., 2012). In a hospital, the work of multidisciplinary teams is also important for the good acceptance of the different methodologies and technologies.

The transformation of the quality system must be part of a comprehensive management system, within an institutional culture of support and with committed leadership. Quality improvement specialists do not work in isolation, but rather in collaboration with operational leaders (Kaplan et al., 2014).

Many clinical leaders motivate teams to develop improvements rather than a unified improvement program with other departments or organizational units (Radnor et al., 2012) by simply adopting specific lean techniques to solve a specific problem within a unit or specific department (Mazzocato et al., 2010). This makes the professionals offer resistance to change, being reluctant to adopt new working procedures (Nelson-Peterson and Leppa, 2007) and new technologies.

**Methodology**

The methodological approach adopted was the bibliometric. The keywords of the search were: ‘breakthrough technologies’, ‘internet of things’, ‘lean healthcare management’ and ‘healthcare services’, all related to each other and searched with the ‘AND’ connector. The search was performed in five different databases: ISI Web of Science, Scopus, Cinahl, Lilacs and PubMed, because of their relevance to the health area.

The initial survey of the sample, considering all articles, resulted in 2870 articles. After analyzing the filters considered in each database, this number dropped to 937 articles. The duplicate articles were disregarded, leaving 755 articles, which composed the final base. The articles of the final base had their abstracts evaluated, allowing to fit the articles really relevant to the proposed theme, which resulted in 125 articles. Figure 1 shows the main topics covered in the articles throughout this period.

*Figure 1* - Subjects covered in the articles, from 2007 to 2018.
Considering the period from 2007 - first article about the theme, until 2018, studies that involved processes improvement (33 articles), breakthrough technologies in healthcare (22 articles), quality in services (18 articles), add value to services and efficiency (16 articles each) had the largest amount of publications. In contrast, articles discussing lean and six sigma have little relevance in the period.

To complement the analysis, the Bradford Dispersion Law was used, since it allows analyzing the relationships between the articles with the highest number of citations and the respective journals where the article was published (Araújo, 2006). In this study, articles with 30 citations or more were considered, which correspond in 19 articles, 66.92% of all citations of the sample. Table 1 shows the most cited articles and their respective journals.

The number of citations is an important factor, since it reflects the impact of the article in the considered study environment (Haunschild et al., 2016). The metadata was imported with VOSviewer software, version 1.6.9, and network analysis was performed with Netdraw software, version 2.158.

Results
The sample of the publications shows a map oriented for the period from 2007 to 2018. The first article published with greater relevance was in 2007. From this year, there was an increase of the publications in the health area and, from 2017, in IoT, with a considerable number of publications.

The database search occurred in April 2018. Have a peak of publications in 2017, with 33 publications, which corresponds to 26.40% of the final sample. Of the 2017 sample, 33% of the publications correspond to articles directed to the theme of IoT. In 2015 and 2016, articles of this theme were not published, according to the keywords used in the search. This reflects the importance of the proposed study and a greater direction to the conjuncture of the use of these technologies in healthcare.

Figure 1 show the areas of processes improvement correspond to 26.40% of the sample, breakthrough technologies in healthcare, 17.60%, quality in services, 14.40%, add value to services and efficiency, 12.80% each. These articles represent 83.34% of sample and all topics are related to the improvement of processes focused on the quality and level of satisfaction of services.

In addition to the selected articles, the sample highlights that 11 different journals published 52.35% of the articles, with emphasis on the journal BMC Health Services Research, with 17 publications. That shows the importance of quality in the processes in healthcare services. Table 2 shows a summary of journals with the highest number of publications.
The analysis of the keywords was performed considering a minimum relation of five connections between them and shows a network where the technologies of rupture have a strong influence, relating to all the other and emphasizing the connections with the words decision-making, impact, quality improvement and clinical practices. This highlights the importance of these factors in the study, since it has strong affinity with lean principles. Figure 2 show a keywords network.

![Keywords network](image)

**Figure 2 - Keywords network**

It is also worth noting that the implementation of the technologies of rupture occurs from the factors related to quality, lean healthcare, services offered and a culture of impact in clinical practices, directing to the correct allocation of resources, i.e. the provision of patient-oriented health services.

**Discussion**

Lean is applied successfully in a wide variety of health settings and, while emphasizing a holistic view, most reported cases show restricted technical applications with limited organizational reach (Mazzocato *et al.*, 2010; Radnor *et al.*, 2012).

The address lean healthcare as a difficult subject to be deployed in hospitals (Waring and Bishop, 2010), where a critical look at lean healthcare and its association with other quality methodologies (Young and McClean, 2008).

The application of lean as a methodology for improving the quality of health services has been shown to be of significant importance, since the methodology is approached from different perspectives, according to the needs of each institution. Lean healthcare fits into this niche, notoriously when applied in process management.

These challenges are also related to lean, which works in the fine line between efficiency and poor process management, standing out for having strong relationships with patient safety and health worker involvement. The first is to emphasize the importance of patient safety and the second to validate the importance of patient safety, highlighting the involvement of health professionals in achieving satisfactory levels of safety.

So, there are a lot of difficulties encountered to implement the lean methodology in the health sector, in such a way that is an element of resistance on the part of the
professionals involved (Waring and Bishop, 2010; Mazzocato et al., 2012; Radnor et al., 2012; Kaplan et al., 2014; Moraros et al., 2016).

When lean methodology if not applied properly, does not generate significant results, since this methodology consists of multiple elements that interact with each other (Andersen et al., 2014). The problems presented by lean are due when not deployed with the necessary resources, emphasizing the difficulty in different working groups interact for the methodology (Mazzocato et al., 2012; Radnor et al., 2012; Andersen et al., 2014). Lean, when applied in isolation, produces little or no significant results (Young and McClean, 2008).

The relationship between healthcare, reengineering and service performance shows that processes that influence institution structures, when applied correctly, impact good performance in quality management.

To alleviate health problems, technology development plays a key role in improving the infrastructure used, such as automated health monitoring technologies, so that medical device systems can increase the efficiency and safety of health care, and help specialists overcome critical problems related to medical devices (Dey et al., 2018). This shows that the use of lean tools has great insertion capacity, mainly for the continuous improvement of processes.

Health sector is composed of a series of processes or actions aimed creating value for patients with thousands of processes interacting with each other (Nelson-Peterson and Leppa, 2007), in a such way stating that lean has been expanded to the health sector (Moraros et al., 2016).

The lean methodology adopts as a precept the importance of value, i.e. the search for the elimination of waste and the aggregation of value to all processes (Brackett et al., 2013). Lean simplifies the standardization of tasks, processes, and reduction of bureaucracy, with a successful implementation of these improvements releases organization resources, which are redirected to the provision of direct patient care (Grove et al., 2010), generates value in services for patients (Nelson-Peterson and Leppa, 2007; Mazzocato et al., 2010; Waring and Bishop, 2010; Radnor et al., 2012; Seidl and Newhouse, 2012).

The same process is occurring with internet technologies, where CPS and the IoT can provide secure, efficient and intelligent services, sharing and managing resources and data between different networks, providing high quality (Lin et al., 2017) and a re-design in services. The development of these new service systems solutions has the potential to allow greater value and increase the competitiveness of companies (Costa and Patricio, 2018) whatever the field of activity.

In today's medical technologies, rapid progress has led to a new generation of health care as well as new treatment strategies (Dey et al., 2018). The design and delivery process helps patients and institutions to create the desired experiences (Teixeira et al., 2012). The benefits are mainly increasing by the agility, flexibility and delivery options made possible by the interconnected services (Yang et al., 2017).

However, the increasing and continuous use of these technologies imposes a challenge on the amount of data generated (Gu et al., 2017) and on the safety of these data, since it is patient information (Rahmani et al., 2018). Traditional analytical techniques are unable to cope with the complexity of the CPS, as well as not being able to predict system behavior with respect to security, reliability, and privacy (Dey et al., 2018).

Among the security issues facing these systems is the fact that operators of such systems are likely to have limited knowledge of the security and privacy of CPS (Almohri et al., 2017). As a result, a sequence of unanswered executions required of the system may simply jeopardize the patient's privacy and/or safety.
The amount of information collected by CPS in hospital settings is vast. An increasingly common source of data for predicting clinical risks, presenting unique analytical opportunities and challenges (Goldstein et al., 2017).

However, health care monitoring data transmission using low-cost sensors and various media was directed to a major concern with the prevailing platforms, leading to inefficient processing of the massive amount of real-time data (Dey et al., 2018).

When health services become more complex, the amount of data received from the patient overloads an already flooded environment of information, where life-critical requirements are critical, since the system can not directly or indirectly cause life-threatening (Stankovic, 2016).

The internet potential of IoT in healthcare is very great and can provide a revolution in the way processes between management, healthcare professionals and patients happen.

Internet and computing revolutions have opened up a vast array of new control potentials that can impact human life, including the health sector (Dey et al., 2018). Lean healthcare, on the other hand, is a theme based on subjectivity between different terms, elements and a certain difficulty in quantitatively measuring the real benefits that the methodology can bring to health systems.

Therefore, the application of lean healthcare, associated with IoT technologies and within a context of interaction with health professionals, shows relevant difficulties in the process of applying continuous improvement methodologies focused on quality.

**Conclusion**

The work had as objective to analyze the literature on lean healthcare and the integration with the IoT in hospital services. It sought to identify the main elements and aspects related to the proposed theme, as well as the research gaps. Descriptive analyzes showed an overview of lean healthcare and interactions with CPS, the relationships between authors and the main internet-related topics of things.

The lean healthcare research stands out on three main fronts: processes, quality and services. Health institutions that adopt lean healthcare for continuous improvement in products and services need the support of management to implement the methodologies, since they often break down internal obstacles, both in infrastructure and human resources. Improving lean efficacy in health care needs to involve management in continuing problem solving (Mazzocato et al., 2010).

For hospital institutions, safety and patient care, coupled with the perspectives that CPS and lean systems generate, are fundamental, since they allow to evaluate their application in two different perspectives: the improvement of processes and the addition of value to the patient. However, this understanding can be variable, since hospitals have different human resources, which are influenced by different organizational forms. Thus, the team plays a fundamental role in the implementation of lean methodologies and CPS.

The empowerment of the team is able to enable leaders to disseminate learning and the sustainability of the improvements on an ongoing basis (Morrow et al., 2014). However, lean can change the roles, responsibilities, and characteristics of health worker (Drotz and Poksinska, 2014). In face of this contradiction of ideas, future work can deepen the relations between the implementation of lean and CPS and the work done by the teams, especially when related to the improvements proposed by both.

Lean applications emphasize, in most cases, waste reduction, since lean is a managerial concept (Nelson-Peterson and Leppa, 2007; Radnor et al., 2012). However, patient safety, coupled with ease of access to services over the internet, has been increasing its influence on the subjects studied, since it directs the focus to the patient. Future studies can deepen
the analysis between patient relationships and the level of security of their data. This issue is worrying, needs more attention, being little explored in the literature.

A better approach is needed in the relationship between worker qualification, the use of lean and internet methodologies as a way to evaluate productivity in the health environment, the relationship with patients and suppliers, and the development of systems capable of stimulating the innovation of processes in search of continuous improvement.

The study has some limitations. It should not be generalized, since the database studied comprises a restricted set of articles, selected from the keywords used in the search. The articles in which the abstract was directed to the proposed theme were selected, without the complete reading of the study. It may have occurred that some important works in this field have not been evaluated.

Abstract

This paper is an attempt to provide regression analysis for the Length of Stay (LOS) of Neo-natal Jaundice (NNJ) patients in a northern Indian rural hospital considering data of three months. The Cause and Effect analysis is done in order to find the root cause/s of the longer LOS. The waiting time for registration (WTR), waiting time for tests (WTT), waiting time for phototherapy (WTP) and time for discharge implementation (TDI) are found responsible parameters for longer LOS. The first and second order regression equations are developed and percentage errors between predicted and observed values have also been calculated.

Keywords: Regression Analysis, Neonatal Jaundice, Length of Stay

Introduction

Healthcare quality is a matter of serious concern as there is continuous increase in the investment with little interest towards quality. In year 2000, US Institute of Medicine (IOM) released some reports; which highlight the necessity of safe and quick healthcare system. If specifically talk about one of his report released in 1999, the authors estimated that medical errors leads to 98,000 patient’s death per year. All these reports clearly states that there is importance of building quality healthcare system where the patients can get faster and safer recovery.

The importance of quality initiatives in healthcare can be realised from severity factor. As compared to other service sectors, the need of implementation of quality initiatives in healthcare is much more important. For example, if we specially talk about pizza delivery service, there is a requirement to deliver the pizza in 30 minutes. In case, the delivery is not attempted within specified time, it can lead to loss of customer but does not cause any loss in terms of life whereas in case of healthcare, the delay of one or two minutes can make a difference in terms of life or death.
This paper is an attempt to do the regression analysis for the Length of Stay (LOS) of Neonatal Jaundice patients in a northern Indian rural hospital. Regression analysis basically helps to predict the certain variable based on the input of some independent variables. Detailed procedure of NNJ patient starting from their entrance to departure is observed and cause and effect analysis is done in order to find out the root cause of the longer LOS.

**Neonatal Jaundice (NNJ)**
Hyperbilirubinemia or NNJ is an excessive level of accumulated bilirubin in the blood and is characterized by jaundice, a yellowish discoloration of the skin, sclerae, mucous membranes and nails. Other symptoms may include excess sleepiness or poor feeding. Complications may include seizures, cerebral palsy, or kernicterus. This disease occurs in 60% of the term and 80% of preterm neonates. However significant jaundice occurs in 6% of the term babies.

In many cases, there is no specific underlying disorder. In other cases it results from red blood cell breakdown, liver disease, infection, hypothyroidism, or metabolic disorders. A bilirubin level more than 2 mg/dL may be visible. Concerns, in otherwise healthy babies, occur when levels are greater than 18 mg/dL, jaundice is noticed in the first day of life, there is a rapid rise in levels, jaundice lasts more than two weeks, or the baby appears unwell. In those with concerning findings further investigations to determine the underlying cause are recommended.

For the treatment of NNJ, most commonly used treatment is phototherapy where baby is kept in a machine for specific period of time. Phototherapy is treatment with a special type of light. It's used to treat new-born jaundice by lowering the bilirubin levels in your baby's blood through a process called photo-oxidation. Photo-oxidation adds oxygen to the bilirubin so it dissolves easily in water. This makes it easier for your baby's liver to break down and remove the bilirubin from their blood.

**Literature Survey**
Thrope (1988) made use of regression analysis to determine hospital payment. In this paper, the author used regression correctly to establish reimbursement rates for hospitals under prospective payment system. Skrifvars et al. (2003) developed multiple logistic regression models for the survival at six months in patients resuscitated from out of hospital ventricular fibrillation. This study suggested that in-hospital factors are associated with survival from out-of-hospital cardiac arrest.

Heuvel et al. (2005) reduced the length of stay (LOS) in children department. The authors identified that there was significant decrease in LOS when patients were allowed to stay with their admitted children during night. It also caused annual saving of $30,000. Drenckpohl et al. (2007) utilised Six Sigma methodology in order to reduce errors in breast milk administration for neo-natals. The authors discussed the possible hazard due to inappropriate administration of breast milk. At the end, errors were reduced to less than 3.4 defects per million opportunities. Gregori et al. (2011) provided a review on regression model for analysing costs in healthcare sector. The authors showed that how methods can produce different results depending on the degree of matching between the underlying assumptions of each method and the specific characteristics of the healthcare problem.

Ligher et al. (2014) utilised Six Sigma in Akron children’s hospital and there was 90% decrease in waiting time for MRI in the radiology department. This increases the opportunities of more number of MRIs of patients with increased revenue. Combes et al. (2014) predicted the length of stay in emergency department using regression model.
These models were validated and successfully applied to the classification and prediction of the LOS in the Pediatric emergency department at Lille regional hospital centre, France. Bebbington and Furniss (2015) provided a linear regression analysis in order to predict a large increase in demand for elective hand surgery in England. They analysed the data for carpal tunnel syndrome, cubital tunnel syndrome etc. from 1998 to 2011 and with the help of linear regression, they estimated trends in both diagnosis and surgery until 2030.

Barrios and Jiménez (2016) applied Six Sigma methodology to shorten the appointment lead time in Obstetrics outpatient department of maternal child hospital in Colombia. Al-Khatib et al. (2016) implemented multivariable regression analysis for the assessment of the generation rate and composition of hospital solid waste for the design of sustainable management system in the developing countries. Redondo-González (2017) performed validity and reliability of administrative coded data for the identification of hospital acquired infections using regression analysis. It is found that administrative coded data may not be sufficiently accurate or reliable for the majority of healthcare associated infections.

Meadows et al. (2018) predicted the length of stay of intensive care unit following cardiac surgery using regression analysis. They showed that both the additive and logistic EuroSCORE can be used to stratify cardiac surgical patients in various predicted length of stay in ICU. Valsamis et al. (2019) developed segmented linear regression models for assessing change in retrospective studies in healthcare. The authors aimed to develop a rigorous mathematical method to analyse temporal variation and overcome limitations in the retrospective studies.

About the hospital
The hospital under study is rural government Indian hospital situated in northern hill region. The hospital has bad capacity of 120. Along with well-equipped machines and equipment’s, the hospital has positive attitude workers and staff.

Procedure to Treat the NNJ Patient
Figure 1 shows the procedure to treat the patients staring from their entrance into the department to their discharge. It is clear from the flow chart that as the patient (i.e. parents with their child) enters into the department; they have to go through the registration process. After that, child is examined by the doctor. On the basis of examination, doctors calls for TSB (Total Serum Bilirubin) test, in order to check the bilirubin level in the body. The result of the TSB test decides that whether the patient should go through phototherapy or should discharge after medication. If the bilirubin level is abnormal, then the child goes through phototherapy where the child is kept for 8 to 12 hours depends upon the bilirubin level in the body. The procedure of phototherapy and TSB test is repeated until the bilirubin level is not normal in the child. Finally the baby is discharged after proper medication.

Cause and Effect Analysis
The data related to LOS of 105 children is conducted over a period of 3 months. The average LOS and standard deviation is found out to be 34.53 hours and 20.01 hours respectively. It is clear from the observed states that there is lot of variation in the data which needs to be control or minimised. The calculated range of the LOS is 101 hours with 116 hours and 15 hours as maximum and minimum readings.

Figure 2 shows the cause and effect diagram for the LOS of NNJ patients. The detailed discussion is done with doctors and staff members in order to identify the
possible causes; enlisted in cause and effect diagram. The causes such as ‘Waiting Time for Registration’ (WTR), ‘Waiting Time for Phototherapy’ (WTP), ‘Waiting Time for Tests’ (WTT) and ‘Time for Discharge Implementation’ (TDI) are validated by statistical analysis. The other potential causes such as ‘Familiarity with Equipment’, ‘Staff Availability’, ‘Lack of Positive attitudes towards Work’, ‘Bad Ergonomics’, ‘Availability of Technician’, ‘Doctors Preferred Setting’ etc. could be validated by only through monitoring the process i.e. GEMBA.

In the GEMBA method, the process is observed for specific period of time in order to find out the availability of specific cause. So some of the causes are validated through GEMBA and rest are validated by statistical analyses. The process is monitored for specific period of time and results of GEMBA are summarized in Table 1. The data for WTR, WTP, WTT and TDI are individually collected for each of the patients and summarized in Appendix A. It is found that 28.77% of average length of stay is due to these four potential causes. Individually, the average LOS is affected by 5.79%, 6.64%, 6.65% and 9.77% from WTR, WTT, WTP and TDI respectively. So, these four factors are taken for regression analysis of the Length of Stay (LOS)

**Development of Regression Model**

Regression analysis is a process of predicting the relationship between two or more variables. In this, one variable is dependent variable and other variables are independents variables. In our case the LOS is dependent variable & WTR, WTP, WTT and TDI are independent variables. In Simple linear regression, there are only two variables and in multiple regressions there are two or more variables. Basically multiple regressions are an extension of simple regression. So the regression model helps us to predict the value of specific variable based on the values of others variables.

The functional relationship between dependent output parameter (Klocke, 2001) Rawlings et al. (1989) with the independent variable under investigations could be postulated by

Equation (1):

\[ y = A.(X_1)^a(X_2)^b \ldots \ldots \ldots \ldots (X_n)^n \]

Where, \( y \) is dependent output variable such as LOS and \( a, b, \ldots, n \) are the exponents of independent variables. \( X_1, X_2, X_3, \ldots \ldots \) \( X_n \) are independent variables. A logarithmic transformation can be applied to convert the non-linear equation into linear form as shown below:

Equation (2):

\[ \log y = \log A + a.(\log(X_1)) + b.(\log(X_2)) + \ldots \ldots \ldots + n.(\log(X_n)) \]

The Equation (2) can be rewritten into the following linear mathematical model

Equation (3):

\[ \eta = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots \ldots \ldots + \beta_n X_n \]

Where, \( \eta \) is a logarithmic scale of Length of Stay. \( X_1, X_2, X_3, \ldots \ldots X_n \) are logarithmic transformations of different independent variables. The corresponding parameters \( \beta_0, \beta_1, \beta_3, \ldots \ldots \beta_n \) need to be estimated.
Due to experimental error, the true response is: \( \eta = y - \mathcal{E} \). Where, \( y \) and \( \mathcal{E} \) are the logarithmic transformations of the measured output and the experimental error respectively. For simplicity the Equation (3) is rewritten as

Equation (4):
\[
Y = b_0 + b_1X_1 + b_2X_2 + \ldots + b_nX_n
\]

Where, \( Y \) is the values of predicted LOS, after logarithmic transformation and \( b_0, b_1, b_2, \ldots, b_n \) are estimates of the parameters, \( \beta_0, \beta_1, \beta_2, \ldots, \beta_n \) respectively.

The detailed data for WTR, WTP, WTT and TDI are collected and summarized in Appendix A. The functional relationship between dependent output parameters and the multiple independent variables is estimated by using equations (1) to (4). The values of \( b_0, b_1, b_2, b_3 \) and \( b_4 \) can be found out by linear regression analysis, which is conducted with Minitab software (Minitab 17.0 for windows). The Table 1 presents the empirical expression developed by 1st order model for four variables.

**Table 1** Empirical expression developed by 1st order model for first project

<table>
<thead>
<tr>
<th>Predictor</th>
<th>Coefficient of LOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>( X_1 )</td>
<td>-19.93</td>
</tr>
<tr>
<td>( X_2 )</td>
<td>4.50</td>
</tr>
<tr>
<td>( X_3 )</td>
<td>12.16</td>
</tr>
<tr>
<td>( X_4 )</td>
<td>7.58</td>
</tr>
</tbody>
</table>

The developed empirical model by 1st order model for length of stay can be expressed as.

Equation (5):
Length of Stay = -19.93 + 4.50 WTR + 12 WTT + 7.58 WTP + 0.12 TDI

Or \( Y = -19.93 + 4.50X_1 + 12.16X_2 + 7.58X_3 + 0.12X_4 \)

The developed empirical model by regression analysis for LOS is given below.

Equation (6):
Length of Stay = \( A (X_1)^a (X_2)^b (X_3)^c (X_4)^d \)

Where \( A = -19.93, a = 4.50, b = 12.16, c = 7.58, d = 0.12 \)

With the help of the observed data of Appendix A and the above mentioned equation, the relative error between measured output values and predicted output values of LOS can be calculated. The average percentage error between predicted and observed values is calculated to be 26.83%. The detailed data of predicted & observed values and percentage error between for first order model are not shown in this paper due to limitation of pages. However, the same is shown for second order model in Appendix B.

The developed first order empirical model for LOS reveals lack of fitness due to high prediction errors i.e. 26.83%. As a result, second order model has been developed as given below in Equation 7:

Equation (7):
\[
Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_{12}X_1X_2 + b_{13}X_1X_3 + b_{14}X_1X_4 + b_{23}X_2X_3 + b_{24}X_2X_4 + b_{34}X_3X_4 + b_{11}X_1^2 + b_{22}X_2^2 + b_{33}X_3^2 + b_{44}X_4^2
\]
The values of coefficients for LOS can be found out by linear regression analysis of second order model using the experimental data. The logarithmic values of experimental data given in Table 2 are used to formulate empirical equations.

<table>
<thead>
<tr>
<th>Table 2 Value of coefficient of LOS by 2nd order model</th>
</tr>
</thead>
<tbody>
<tr>
<td>Predictors</td>
</tr>
<tr>
<td>Coefficients</td>
</tr>
</tbody>
</table>

Predicted output values for LOS are calculated with the help of Equation 8. Relative error between predicted and measured output values for LOS is calculated and presented in Appendix B. The average percentage error between predicted and observed values is reduced to 17.58% which was 26.83% with first order model.

**Validation of Regression Model**

The model equation is validated, using the coefficient of determination ($R^2$) and the F-test from the analysis of variance (ANOVA) methods. The coefficient of determination ($R^2$) is simply square of the correlation coefficient ($r$). It is used to judge the model equations whether they are significant or not, in explaining the relationship between the design input variables and objective functions. The larger $R^2$ is, the better the model. The value of $R^2$ lies between 0.0 to 1.0. It is very much clear that second order model is more accurate than first order model. So validation is done for second order model. The value of $R^2$ is computed as 0.766 (From Minitab) for this condition. So, the derived model equations are valid, according to this method.

Using the ANOVA method, it is observed that the formulated multivariable linear regression equations are significant at 0.05 level of significance in explaining the relationship between dependent variable and input design variables.

From the regression model, the calculated F value ($F_{cal}$) (From Minitab ANOVA table) comes out to be 20.99 whereas the tabulated F value ($F_{tab}$) is 1.81. Since $F_{cal} > F_{tab}$, the model is significant at 95% confidence level.

**Sample Calculations**

The calculation for predicted length of stay for second order model (Appendix B) for observation number 1 is as

Equation (9):

Length of Stay (LOS) = 41.09 + (-9.06) $X_1$ + (-14.27) $X_2$ + (-10.72) $X_3$ + 0.218 $X_4$ + 0.108 $X_1^2$ + 3.99 $X_2^2$ + 1.06 $X_3^2$ + 0.95 $X_4^2$ + 1.74 $X_1X_2$ + 3.93 $X_1X_3$ + 0.096 $X_1X_4$ + 3.64 $X_2X_3$ + (-1.40) $X_2X_4$ + (-1.39) $X_3X_4$

The values of $X_1$, $X_2$, $X_3$ and $X_4$ are taken from Appendix A for observation number 1. After putting the values:
LOS = 19.89 hours.

Now, the percentage error in prediction of observation number 1 is calculated as follow:

Equation (10):

\[
\text{Percentage error} = \frac{\text{Predicted Value} - \text{Observed Value}}{\text{Predicted Value}}
\]

Predicted and observed values are given in Appendix B.

Percentage error = \(\frac{19.89 - 17.57}{19.89}\) = 0.1166 = 11.67%

**Conclusions**

This paper is basically an attempt to implement regression analysis in rural Northern Indian Hospital. The detailed study of the procedure to treat the neonatal jaundice patients along with cause and effect analysis helps to find out the factors affecting the length of stay. Finally, the first and second order regression model is developed for LOS of NNJ patients with waiting time for registration, waiting time for tests, waiting time for phototherapy and time for discharge implementation as independent variables. The percentage errors between observed and predicted variables are also calculated. It is observed that second order model is more accurate than first order model. Finally the validation of the model is also done with coefficient of determination (R²) and the F-test from the analysis of variance (ANOVA) method. The regression model will helps the doctors and staff to assess and control the length of stay by controlling and minimizing the above mentioned four independent variables.

Dr. Deoraj Prajapati (Corresponding author) is a Professor in the Department of Mechanical Engineering, Punjab Engineering College (Deemed to be university), Chandigarh (India). He has teaching and research experience of more than 22 years and published more than 128 research papers in international and national journals of repute and in the proceedings of the conferences. He is also reviewer of 8 international journals. He also guided 4 Ph.D. and more than 25 Postgraduate theses and guiding 4 research scholars at present. He has also chaired international and national conference in India and abroad. He also organized two short term courses and two national level Conferences for the faculty of technical institutions and industries. He is also recipient of first D. N. Trikha research award for excellent research publications in international journal for the year 2009 in Punjab Engineering College (Deemed to be university), Chandigarh (India).

Gaurav Suman is a research scholar in Department of Mechanical Engineering, Punjab Engineering College (Deemed to be university), Chandigarh (India). He has published more than 5 research papers in international and national journals of repute and in the proceedings of the conferences.

Humanitarian Operations and Crisis
Building social capital in humanitarian-business partnerships

Abstract

Although NGO-corporate partnerships can bring many advantages for both the humanitarian organization and the commercial organization, research showed that these partnerships are still limited. While these NGO-corporate partnerships can easily be compared with buyer-supplier partnerships in business supply chains, the literature specifically indicates several additional challenges to achieve effective and efficient partnerships between humanitarian organizations and business corporations compared to commercial partnership contexts. To overcome these challenges, our research wants to understand how value can be gained, in terms of resources and assets, from these partnerships. We also aim to analyse the required relationship characteristics and partnership mechanisms that support the management of these partnerships. Through a social capital lens, we study the particularities and contingencies that affect the effective development of cross-sector partnerships between NGOs and business corporations. From a practitioners view, we do not only want to acknowledge the complementarities of NGOs and business corporations for implementing socially sustainable supply management practices, but also understand how NGOs and corporates could successfully implement these understudied cross-sector partnerships.

Keywords: Social Responsibility, Partnering, Case Studies; Qualitative Data Analysis

Introduction

Across the world, humanitarian relief and development challenges call for collaborative endeavors by all potential actors. As the problems are multifaceted, wicked and resource demanding, these challenges are known as complex and turbulent (Van Wassenhove, 2006). Moreover, scholars and leaders agree that dealing with climate changes, urbanization, poverty, natural disasters and conflicts are not a duty of a single government or a traditional humanitarian actor. While dealing with these relief and development challenges was traditionally the role of national governments and humanitarian organization, it is nowadays acknowledged as a common responsibility. Depending on the severity of the disaster or development challenge as well as the resource of the government, the affected country could also call for international humanitarian actors as well as businesses to contribute to the relief and recovery operations. These organizations might provide access to infrastructure and experiences in timely delivering goods to beneficiaries. Therefore, different types of organizations should be sought-after to...
contribute in managing these worldwide disasters and developing challenges (Demiroz and Kapucu, 2015). In other words, inter-organizational collaborations, and in particular NGO-corporate partnerships, are becoming essential to deal with these complex and turbulent disasters and development challenges (e.g., Kovacs and Spens, 2007; Nurmala et al., 2018).

Although NGO-corporate collaborations are believed to be important for improving the effectiveness and efficiency of humanitarian activities, there are only limited numbers of successful cases (Maon et al., 2009; Rueede and Kreutzer, 2014). This evaluation should not only be based on financial contributions of business corporations, but also on the potential transfer of knowledge and expertise from the business sector to the NGOs and vice versa. From a supply-chain perspective, partnerships between commercial and humanitarian organizations are a reasonable thought as most supply chain elements are similar in business and humanitarian sectors. Therefore, academics believe that these and methods developed for business supply chains could be adapted to humanitarian relief chains (Beamon and Balcik, 2008; Van Wassenhove, 2006). Additionally, the involvement of the business sector in relief operations could enable faster response times as some critical infrastructures that affect public well-being are owned by the business sector (Stewart et al., 2009). While in business organizations, supply patterns are generally stable, inventory can be easily monitored and lead times are predictable (Oloruntoba and Gray, 2006). Consequently, humanitarian organizations can learn about quality, productivity and efficiency from working with business organizations (Jensen, 2012). This will help them to improve the effectiveness of their distribution network, inventory management and technology (Rueede and Kreutzer, 2014; Pettit and Beresford, 2009). Meanwhile, business supply chains can learn from humanitarian organizations how to increase the flexibility and reliability in uncertain ad hoc environments. Time pressure in humanitarian operations is for instance high as high risks are involved, while demand and supply patterns are unpredictable (Kovacs and Spens, 2007). However, NGO-corporate partnerships are still far from straightforward (Nurmala et al., 2018), despite the multiple endeavors from NGOs. For example, statistics show that the contribution of business corporations to NGOs are currently still limited to 6.6% of the total contribution (Global-Humanitarian-Assistance, 2016).

The difficulties in setting up NGO-corporate partnerships motivate us to look at some successful NGO-corporate partnerships to shed light on opportunities, as well as the challenges. As such, the aim of this paper is to understand contingencies and impediments within these NGO-corporate partnerships to enable our knowledge on how to set up successful partnerships among actors with different goals, challenges and objectives. As setting up inter-organizational relationships has its roots in social capital theory, our research is analyzing how different NGOs and corporates are setting up relational, structural and cognitive capital to support this endavour towards successful partnerships.

Challenges for NGO-Corporate Partnerships
Humanitarian–business partnerships are still far from effective. Recent research (e.g., Nurmala et al., 2017) identified several challenges to achieve effective and efficient partnerships between humanitarian organization and business corporations.

The first challenge for humanitarian organizations relates to differences in mandates and goals. Humanitarian agencies are mandated by their vision of saving lives (Van Wassenhove, 2006). As such, the strategic goals of managing humanitarian supply chains relate to cost reduction, capital reduction and service improvement (Beamon and Balcik, 2008). On the other hand, business organizations are instructed by their vision of acquiring profit. The strategic goals of the business sector are described based on the
financial returns for shareholders (Beamon and Balcik, 2008). These conflicting goals may create challenges for these humanitarian-business partnerships. For example, humanitarian organizations may find it difficult to select partners in time-pressed situations (Kovács and Spens, 2009).

A second challenge relates to image and customer’s perceptions. Although humanitarian organizations want to receive resources and knowledge from business organizations, they also want to be independent (Rueede and Kreutzer, 2014; Thomas and Fritz, 2006). Meanwhile, business corporations might worry that a partnership with a humanitarian organization might be seen as a simple solution and as such being perceived as a lack of capabilities and professionalism (Rueede and Kreutzer, 2014; Thomas and Fritz, 2006).

A third challenge relates to differences in working rhythms and culture. For humanitarian organizations, partnerships with business corporations could bring cultural and technical problems (Haigh and Sutton, 2012). While humanitarian organizations view supply chain management as an individual responsibility, commercial organizations are used to manage supply chains with multiple partners. Consequently, humanitarian organizations can learn from commercial organizations how to collaborate with other partners in the supply chain and become more effective by relying on partners in the supply chain (Schulz and Blecken, 2010).

A final challenge relates to the resources available for developing and maintaining these crucial partnerships. As NGOs and business corporations feel sometimes uncomfortable with upfront payments for uncertain event (e.g., earthquakes, tsunami, etc.), funding often only starts after the occurrence of the event. As such, there is little effort and money allocated to building partnerships in the preparedness phase (Fawcett and Fawcett, 2013; Tatham and Pettit, 2010), resulting in ad hoc decisions when unexpected disruptions happen (Fawcett and Fawcett, 2013). On top, humanitarian organizations have little resources to invest in IT solutions, which might enable humanitarian organizations to create visibility in their supply chain.

**Theoretical Background: Social Capital Defined**

Social capital represents the “assets and resources made available through partnerships within the social structure of the collective that can be utilized by the collective” (Payne et al., 2011, 497). It thus provides a theoretical perspective from which to understand the value gained through social networks (Carey et al., 2011). Social capital can accumulate value, which represents the “sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit” (Nahapiet & Ghoshal, 1998, 243).

Social capital has also been defined as an antecedent of collaboration and coordination, which can eventually increase the performance of teams or organizations (Adler & Kwon, 2002). Among the benefits of social capital are the generation of positive economic and emotional returns (Gulati & Gargiulo, 1999) and the establishment of value and competitive advantage through collective and effective relationships among organizations (Nahapiet & Ghoshal, 1998; Villena et al., 2011).

Nahapiet and Ghoshal (1998) propose three dimensions of social capital, namely, the structural, relational, and cognitive dimensions. These concepts closely relate to the concepts of reach, richness, and receptivity at the network level, as described by Gulati et al. (2011).
Relational Capital

Relational capital refers to qualities of the relationship that enable collaboration and the sharing of resources among partners. By enduring, frequent and intense interactions, partners can build up strong ties. Often these interactions are complex in nature, i.e., involve different persons and different forms of communication and exchanges. The relational dimension describes the quality of connections by characteristics such as trust, reciprocity, and intimacy (Nahapiet & Ghoshal, 1998). Trust is considered a core element of successful buyer–supplier relationships and reduces the risk of opportunism (Morgan & Hunt, 1994; Uzzi, 1996; Krause et al., 2007).

Relational capital is specifically important for communicating knowledge that is difficult or impossible to codify (Hansen, 1999; Reagans & McEvily, 2003). This positive effect that comes with strong relationships is also associated with trust (Krackhardt et al., 2003), reducing the need for formal control systems and contracting, as well as extensive monitoring (Adler & Kwon, 2002). Strong relationships are more committed to maintain the relationship, to recognize its importance and to make adjustments for ensuring its continuity. Strong ties also increase the willingness to share resources (Lin, 2008), including the sharing of tacit or sensitive information (Nahapiet & Ghoshal, 1998; Gao et al., 2015), or leverage the diverse knowledge assimilation and recombination (Gao et al., 2015) and the collaboration in complex problem solving activities, such as product innovation (Carey et al., 2011; Villena et al., 2011).

Structural Capital

The structural dimension refers to the configuration of a network and is used to examine the extent to which people in the network are connected as well as the patterns and usefulness of these connections (Bolino et al., 2002). Carey et al. (2011, 279) indicated that structural capital “describes the extent to which actors are linked in a relationships and how they come to understand ‘who knows what’.” Structural capital refers to the degree to which an actor’s network is expansive and diverse, as grounded in theories pioneered by Granovetter (1983) and Burt (1992). It looks for instance at the reach of the network, i.e. how partners increase the direct and indirect connections to different communities.

Cognitive Capital

The cognitive dimension concerns the degree to which connected parties share a common perspective. Cognitive capital is often measured as shared vision, which is further conceptualized as the “collective goals and aspirations” that affect knowledge transfer among members in a network (Inkpen & Tsang, 2005, 157). In a supply chain setting, the common goal is often set by the focal firm (Krause et al., 2007). In addition, Tsai and Ghoshal (1998) discuss the cognitive dimension as the existence of a common code of understanding.

Cognitive capital allows partners to have a common understanding of goals and develop common goals (De Carolis and Saparito, 2006). As a result, it enables coordination among partners (Handfield and Nichols, 1999), forming a synergy among partners’ activities to work towards the shared goals (Villena et al., 2011), facilitates the exchange of resources and information among partners (Nahapiet and Ghoshal, 1998; Tsai and Ghoshal, 1998; Preston et al., 2017). The lack of collective goals may result in conflicts among partners (Inkpen and Tsang, 2005; Rossetti and Choi, 2005).

Interaction between Social Capital Dimensions

While previous scholars often focused on one dimension (e.g., the relational dimension)
(Cousins et al., 2006; Yu & Huo, 2018) or two dimensions (Lawson et al., 2007) of social capital, Krause et al. (2007), Carey et al. (2011), and Whipple et al. (2015) studied all aspects of social capital simultaneously. Besides examining the effect of each dimension on the performance of inter-organizational networks or dyads, these scholars specifically call for exploring the interaction among social capital dimensions (Gulati et al., 2011, Johnson et al., 2018).

Although Tsai and Ghoshal (1998) emphasized potential interdependency among the three dimensions, such interaction was relatively underexplored (Carey et al., 2011). Acknowledging the multidimensional nature of social capital, Carey et al. (2011) proposed that the relational dimension mediates the association among structural and cognitive dimensions and the performance of buyers in buyer-supplier relationships. Gulati et al. (2011) propose a moderation relation among the three dimensions. For instance, the rich (structural capital) increases the impact of richness (cognitive capital) on the network performance, or receptivity (relational capital) enhances the partners’ ability to use the potential value of inter-organizational network, but their success depends on richness (cognitive capital) of accessible resources.

**Method: Data Collection and Analysis**

Given the limited theory on NGO-corporative partnerships, case study-based methodology is the appropriate choice to refine theories (Siggelkow, 2007), to develop frameworks and ideas (Edmondson and McManus, 2007; Mahapatra et al., 2010; Martinez et al., 2011; Yin, 2014), and to provide practical insights for humanitarian donors and managers (Greenwood and Levin, 2006). More specific, multiple case study design is used for investigating a selected number of focal NGO-corporate partnerships. To understand the dyadic nature of the partnership, nested case study analysis is conducted in which the unit of analysis is a partnership between an NGO and a firm acting as a corporate partner.

To set our sample of European NGOs, we consulted the member lists of the International Council of Voluntary Agencies (ICVA) and the Voluntary Organizations in Cooperation in Emergencies (NGO Voice). In total, 18 NGOs accepted our interview invitation. In our first interview with these NGOs, we talked about partnership formation with corporates. The NGOs provided an overview of all the partnerships. This enabled us to check whether these partnerships are strategic in nature, i.e. not solely rely on short-term financial support or entail long-term commitment of both partners on activities such as mutual consulting (e.g., CSR or risk management), knowledge sharing, product development and/or capacity building. From these interviews, we learned that NGO-corporate partnerships at the strategic level are rather rare. Many NGOs reported transactional collaborations with customized projects, but not strategic in nature. In the end, we were able to identify 13 NGO-corporate partnerships. To investigate the dyad, we also contacted the corporate partner for an interview. Four corporate partners have not replied to our interview requests. As a result, nine NGO-corporate partnerships were investigated, in which both the NGO and the corporate were willing to collaborate and provide in depth information. To validate our findings, we compared our data with four collaborations that are not strategic in nature. To gather this similar dyadic information, we consulted NGOs as well as corporates as respondents for our control cases.

We interviewed 27 managers, with responsibilities in setting up and/or maintaining these partnerships: 13 managers from the NGO side and 13 Managers from the corporate world. Throughout the case studies, we collected data through interviewing informants, studying documents, meeting notes, presentations, and websites and news articles. As such, we used several alternative data sources for triangulation purposes (Jick, 1979): (1)
corporate materials, including corporate CSR reports, home pages, and other Internet sources; (2) documents provided from the interviewees; (3) interviews with NGOs to acquire a more in-depth understanding of the institutional context of each NGO and its specifics regarding humanitarian products or services; and (4) publicly accessible reports and statistics on the humanitarian context. These additional data sources also helped us to validate the insights that we received from our main informants.

Our analysis started by understanding the timeline and resources invested for each dyad. This is called the within-case analysis. Next, we determined the patterns across dyads, equivalent to a cross-case analysis. The purpose of our within-case analysis was twofold: deeply understanding the underlying research phenomenon, and building an explanation of how partnerships are set up within an NGO-corporate setting. The cross-case analysis was used to compare and contrast the explanations of each dyad in order to establish a replicated pattern of how successful partnerships are build (Yin, 2014).

While the first round of interviews focussed on identifying the partnership relationship development trajectory and the different social capital dimensions, later interviews, through a replication logic, were used to classify the social capital resources required for developing towards these partnerships. Finally, these patterns and social capital elements were compared with dyads characterized as non-strategic collaborations. This analytic strategy allowed building a theoretical framework of social capital resources required for setting up partnerships between NGOs and corporates. Similar as in the coding phase, the results of two researchers performing the analyses were compared, while disagreements were discussed.

Results
While we investigated 9 NGO-corporate relationships, we will describe in this paper only the 3 most advanced partnerships (given the page limitations). However, in formulating our results, we also took the other cases into consideration. For each of the cases, a small description of the evolution of the partnership, the collaborative practices and the aim of the partnerships are described. Table 1 represents the social capital dimensions for each of the cases.

**NGO 1-Corporate 1**
In 2013, the top management of NGO 1, the leading global independent children’s organization, and corporate 1, a science-led global healthcare company, formed an ambitious and strategic global partnership. As the corporate strategy states that 20% of profits from developing countries should be reinvested in those developing countries to support local healthcare systems, the corporate decided to partner with NGO 1 on a more strategic level than previously. While these institutions have collaborated for many years, their collaboration was purely philanthropic and project-based. The main concern of this collaboration was to raise funding and to create awareness. From the beginning onwards, both partners have stressed the importance of clearly articulating the aspirations and expected outcomes of the partnership. Using their combined expertise, resources and influence, the partnership aim is to help to save one million children’s lives. More specifically, the partners are looking for new ways to help reduce child mortality with a specific focus on the health of children below the age of five. This vision was written down in a contractual agreement that is renewed every three years. Reporting is performed on an annual basis with clear objective measures and is supported by an open communication policy.

Both the local office and the coordination center of the NGO have dedicated teams focusing on this partnership. At the corporate, the partnership touches almost all areas of
the business, using expertise in R&D, immunization and supply chain logistics to help save children’s lives. Their on the ground presence and expertise in child survival provides a local perspective on child mortality to help the partnership reach some of the most vulnerable children with life-saving interventions. With the large global footprint of both organizations, the partnership intends to scale up and replicate its successes for the benefit of communities most in need. To date, the partnership has already reached 2.6 million children. They focus on reducing child and infant deaths by developing child-friendly medicines, by more vaccination, by better training of health workers and by helping children affected by humanitarian crises or disasters in terms of health. In total, ten work streams, ranging from R&D, purchasing and communication to supply chain management, were formulated for working together. Another example is a negotiation training that the corporate organized for the purchasing team of the NGO. Through universal panels, the platform also aims to raise awareness in order to influence other corporates around the world.

NGO 2-Corporate 2.
This partnership started based on short-term programs in the life saving response and recovery phases of humanitarian operations to support the needs of communities close to their own businesses and communities. The corporate runs an initiative called Shelter in a Storm. This initiative aims to provide assistance to victims and is funded by both the corporate and its employees. Using the expertise of the NGO in disaster relief enables IHG to deliver aid (accommodation, financial support or needed supplies) in efficient and effective ways when disaster strikes – either directly or through appropriate partners in the affected area.

As the partnership has grown, its scope has been extended to cover long-term programs in disaster preparedness and longer-term community resilience. The partnership supports both the business goals and values of the corporate and in addition assists the NGO in reaching its global program goals.

NGO 3-Corporate 3.
In 2010, these members began a global collaboration including a wide range of projects. A key target of these collaborative initiatives is to address youth unemployment worldwide. In this vein, the NGO has a Youth Economic Empowerment program to support youth with skills and training. The corporate also has a corporate citizenship initiative, which aims to assist more than three million people worldwide in developing skills to get a job or build a business. The partnership allows them to build on the corporate’s core strengths, utilizing their technical skills, research expertise and global networks, and the NGOs grassroots presence and local knowledge on youth employment programming. In another project, the corporate supports the development of a digital birth registration system to ensure all children are counted and can access their rights. That collaboration has included large youth employment programs in, for example, Indonesia, Philippines, Vietnam, and in Eastern Africa.

Since 2013, these partners started more indepth collaborations, which was formalized by a three-year contract in 2016. The corporate has engaged in organizational development and knowledge management projects supporting the NGO in improving its organizational processes. Both partners also find it important to present the collaboration initiatives at each other's relevant forums or stakeholder events.

|                   |                       | - Trust and trustworthiness  
|                   |                       | - Reciprocal commitment  
|                   |                       | - Friendship, respect, and reciprocity  
|                   | Both organizations stress the importance of a global (similar) reach.  
|                   | - They conduct frequent exchanges through site visits, roundtable meetings and feedback rounds, and writing blogs.  
|                   | - They conduct intense interactions to work together on projects, knowledge, and capabilities.  
|                   | - They have long-term project commitments in multiple disciplines (communication, purchasing, emergencies, innovation, etc.).  
|                   | - Corporate employees work on projects with NGO  
|                   | - A central coordination office in the NGO links the different projects together.  
|                   | - Different pillars with different managers involved create cross-functional collaboration among the partners.  
|                   | - The partnership enables the NGO to reach and convince other pharmaceutical companies and to influence political choices.  
|                   |                       | - Both organizations have dedicated people to work on the partnership.  
|                   |                       | - They are pro-active helping one another.  
|                   |                       | - Trust and open communication are the keys to a successful partnership.  
|                   |                       | - The partners rely on each other’s competence and knowledge.  
|                   |                       | - The corporation respects the ethical standards of the NGO.  
|                   |                       | - They adapt to work as a team.  
|                   |                       | - Their communication and soft skills have increased.  
|                   |                       | - Benefits go both ways (win–win situation).  
|                   |                       | - Both organizations have common interests.  
|                   |                       | - Their influence has become greater by being together.  
|                   |                       | - The added value to what they do individually is crucial in the collaboration.  
|                   |                       | - Their projects are attached to their core business.  
|                   |                       | - The partners understand each other’s working methods and environments.  
|                   |                       | - Both organizations obtain much sectoral knowledge.  
|                   |                       | - The partnership supports the priorities of both organizations.  
|                   |                       | - The partners have a deep understanding of how each other's organization works.  
|                   |                       | - The partners communicate well on how the partnership benefits both parties.  
|                   |                       | - The partnership can affect the world.  
| NGO2 – Corporate2 | Both organizations have more than 80 local offices.  
|                   | - They are interested in partners operating in similar global areas.  
|                   | - They have the ability to collaborate across the global supply chain.  
|                   | - They work closely with each other.  
|                   | - They have a good communication flow among their partners (e.g., Web sessions to exchange information).  
|                   | - They have a joint presence at external round tables.  
| NGO3 – Corporate3 | Both organizations have a global presence (operations and market).  
|                   | - Both organizations have regular calls and meetings to evaluate the partnership.  
|                   | - Company matches the partnership goals and activities within its global social initiatives.  
|                   | - Both organizations have mutual trust.  
|                   | - They have developed a transparent partnership.  
|                   | - The partners work closely to achieve the agreed outcomes.  
|                   | - The partners are open to taking risks.  
|                   | - The partners consider the partnership to be unique.  
|                   | - The end result can affect the world.  
|                   | - They have an overarching vision for the partnership.  
|                   | - The partners understand each other.  
|                   | - They communicate in a similar language.  
|                   | - They have similar mission statements.  
|                   | - Their messages are similar.  

Discussion
Non-governmental organizations (NGOs) conduct emergency relief operations or implement development programs to save or enhance the quality of life in developing countries or countries affected by disasters. NGOs are confronted with challenges such as responding to the complexity and increasing demands of disaster and development management—a function that extends beyond their limited supply chain capacity. If these organizations want to systematically deal with such complexity and demands, they need to join or form cross-sectional partnerships with corporates. On the basis of a supply chain-oriented lens, corporates can enhance NGO capacity by providing donations, in-kind supplies, pro-bono resources, low-cost consulting, transportation services, or sharing knowledge on supply chain processes and digitalization. All this extra support from corporates advance the operations of NGOs while increasing the impact of the projects. On the other hand, scholars suggest that NGOs are part of companies’ supply chains and influence the sustainability efforts of these firms (Hyatt & Johnson, 2016). Collaborating with NGOs can therefore serve as a means of overcoming environmental and social challenges within the global supply chain of corporates. These relationships can also affect companies’ core businesses (resilience, innovation, market development) and enhance the response of both partners to social issues.

We argue that these cross-sectional partnerships present benefits for firms and NGOs, depending on the type of partnership established and the contribution of each partner to the relationship. As more and more NGOs are engaged in cross-sector partnerships and incorporate supply chain thinking and engagement into their approach, there is a need to study the approaches towards partnership arrangements, in relation to social capital formation and performance outcomes (Johnson et al., 2018). To analyse the ideal circumstances in which these NGO-corporate partnerships can operate smoothly, this study adopts a meta-level view of the short- and long-term cross-sectional programs through which NGOs and corporates collaborate. These cross-sector initiatives were analyzed using a supply chain perspective, and NGO–corporate partnerships were scrutinized on the basis of social capital theory. The current research contributes to scholars in supply chain management by examining the antecedent of value creation within cross-sectional interactions. Specifically, we categorized NGO–corporate relationships within socially sustainable supply management using the dimensions of time orientation and value creation. We employed the social capital perspective to explain the factors that influence the formation and performance of different cross-sectional relationships, as an extension to previous studies at the individual (Stolze et al., 2018), functional, cross-functional (Frankel and Mollenkopf, 2015) and firm level (Autry and Griffis, 2008) and as a response to the call made by Johnson et al. (2018) and Rodriguez et al. (2016).

The study reveals that either NGOs or corporates can initiate cross-sector relationships and that their interactions can take place at different levels.

Previous research also showed that there is a turning point and that too much social capital also has a destructive impact on the performance of the partnerships (Villena et al., 2011). While these findings were found in collaborations among commercial corporations, these results do not seem to be valid for NGO-corporate partnerships. It seems that these NGO-corporate partnerships who succeed in lifting the partnership to a strategic level are able to build extra social capital that can be translated into impactful sustainable actions, valued by both partners in the supply chain. These strategic partnerships also make clear that the benefits of relational, structural and cognitive capital might reinforce one another in a stronger way than for commercial partnerships, as earlier suggested by Gulati et al. (2011). Our research for example shows that NGO-corporate
partnerships who succeed to increase their relational capital might also increase their performance by working together on a broad scale of projects, even in collaboration with other partners, i.e., adding the structural capital to the partnership, will release additional benefits of social capital that are more than the sum of the individual forms of capital.

In addition, our research clearly distinguishes how specific characteristics of the partnership can be established. More specifically, our cases show that continuity i.e., the ongoing, long-term commitment, fosters cognitive capital, while the reciprocal supply chain capability building efforts accommodates the development of structural and relational capital.

On top, social capital building within NGO-corporate partnerships also creates a shift in the focus of joint initiatives from responsiveness to preparedness. This additionally improves the resilience of communities in facing disasters or development issues and creates additional value in for all partners in these cross-sector supply chains.

The Hunger of Nations:
Gender Inequality, GDP and the Environment

Paul D. Larson (larson@cc.umanitoba.ca)
University of Manitoba

Natalie M. Larson
University of Manitoba

Abstract

The UN Food and Agriculture Organization (FAO) estimated that 815 million people suffered from chronic undernourishment in 2016, and named poverty the principal cause of hunger. According to the World Bank, 767 million people live on less than $1.90 per day, i.e. below the international poverty line. Other causes of hunger include conflict, political instability, food and agricultural policies and climate change. To these causes, this paper adds gender inequality. The study uses regression analysis of secondary data to test the influence of gender inequality, income and environmental performance on hunger. Results confirm interrelationships among several sustainable development goals (SDGs).

Keywords: Hunger, Gender Inequality, Environmental Performance

Introduction

There are hundreds of millions of hungry people in the world today. Inspired by the SDGs and the triple bottom line (TBL), this paper investigates the influence of national income, gender inequality and environmental performance on the hunger of nations, focusing on the developing countries.

The second section defines hunger, discusses its causes, and links these causes to the SDGs and the TBL framework. Next, the third section describes the variables and outlines statistical testing methods. Sections four and five present the statistical results and offer a summary discussion, focused on implications for public policy and academic research, respectively.

Hunger

What is hunger?
According to the National Research Council (2006, p. 48), hunger is an individual-level concept. It is a “potential consequence of food insecurity that, because of prolonged, involuntary lack of food, results in discomfort, illness, weakness, or pain that goes beyond the usual uneasy sensation.” Beyond the hunger of any individual, the problem can be aggregated to the community, the nation and the world.
Insufficient intake of nutrients needed by the body leads to malnutrition. The most critical type of malnutrition is protein-energy malnutrition (PEM), i.e. a lack of calories and protein. The human body converts food into energy; energy contained in food is measured by calories. Protein is necessary to perform many bodily functions, including development and maintenance of muscles. PEM can be lethal. It is the primary concern in discussions on world hunger (https://www.worldhunger.org).

For the individual, the hunger end-game is starvation, which is a severe deficiency in the calories needed to maintain the body, for a prolonged period of time. The starving body takes measures to moderate its metabolism and re-allocate energy distribution to its vital systems to survive. Non-essential processes slow down as caloric expenditure is reduced. With the lack of nutrients, organs such as the heart, lungs, ovaries and testes weaken and shrink. Blood pressure lowers as the heart rate slows and heart volume – the volume of fresh blood pumped per beat, lowers. The immune system becomes impaired and kidney function is reduced. The individual starts to feel cold, as the body’s heat regulation demands are lowered. Less energy is deployed toward rebuilding muscles, and physical exhaustion ensues (Lieberson, 2004).

A typical healthy man who weighs 70 kilograms has sufficient fuel reserves in the form of carbohydrates, fats, and muscles, to starve and still meet caloric needs for 1-3 months (Berg et al., 2002). During these periods of caloric deficiency, the body has an agenda of energy sources to prioritize. It switches from readily available glucose, to stored carbohydrates, to fat derivatives, and then on to proteins. In the final stages of starvation, the body begins to eat itself through catabolysis – the breakdown of fat and muscle tissue to stay alive.

The first priority of the metabolism is to provide enough glucose to the brain and tissues that are dependent on the fuel, like red blood cells. In the early fasting state, blood-glucose levels drop, decreasing insulin secretion and causing the pancreas to secrete more glucagon. This is the signal for the starved state. Without readily available blood glucose, carbohydrates stored in the liver as glycogen are used for fuel. Glucagon acts as the stimulator for the breakdown of glycogen into glucose. The only other potential glucose source comes from amino acids, produced in the breakdown of proteins. This is very hazardous because it can cause muscle atrophy and loss of organ function. Thus, as a second priority, starved metabolism preserves protein by shifting its fuel source from glucose to fatty tissue. Fatty acids and ketone bodies are compounds produced during the metabolism of fats. Within several weeks, ketone bodies become the major fuel of the brain. Once fat stores become depleted, the only remaining fuel source is protein. Degradation begins with the proteins that have a rapid turnover rate, such as those in the intestinal lining. In the late stages of starvation, the metabolism accelerates protein breakdown to the muscles, heart, liver and kidney. At this point, the body is at risk of organ failure and death (Berg et al., 2002).

What are the causes of hunger?
The FAO and its partners have identified the following causes of hunger: poverty, war and conflict, political instability, food and agriculture policy, and climate change (FAO, 2017; FAO et al., 2018). This sub-section briefly discusses each of these causes.

Poverty is the principal cause of hunger. The causes of poverty are lack of resources, unequal distribution of income, war and conflict – and hunger. By compromising health, energy levels and mental functioning, hunger fuels poverty as it reduces an individual’s ability to learn and earn money by working.

Conflict interferes with food production, due to destruction of the land and logistics infrastructure. It also often increases the cost of food, making it less affordable for
hungry people. Political instability typically brings economic decline, reducing strength of a nation’s currency, yielding higher food prices and lower availability. Job losses further compromise the affordability of food for individuals and families.

Lack of adoption of more productive agriculture technology in lower-middle-income countries contributes to large differences in the volume of food production compared to higher income countries. Further, agricultural policies and practices designed to increase crop yields have had unintended consequences in terms of land and soil degradation, as well as depleting or polluting available groundwater. This affects future food production capacity, as these resources may be non-renewable.

Climate change is yet another cause of food shortages and hunger. Unstable weather patterns can bring drought. On the other hand, hurricanes and cyclones cause flooding, along with harm to livelihoods, reduced agricultural production and rising local food prices. Climate change also contributes to political instability and mass migration.

*Ecofeminism* lays a theoretical foundation for the link between gender inequality and environmental degradation. According to Metz (2008), “ecofeminism embraces the idea that the oppression of women and the oppression or destruction of nature are closely connected;” i.e. that gender discrimination is related to exploitation of the environment. Parsons (2011) argues that eco-feminist and Indigenous ethos intersect on themes of respect for women and the earth. One fundamental concept tying these two perspectives together is *inseparability* and an *economy of affection*, as opposed to separateness and an economy of exploitation (Kelly, 2018). Separateness of nature and humans, and of women and men, endorses environmental exploitation and gender inequality. In turn, environmental harm and discrimination against half the population enables movement away from, rather than toward, the goal of zero hunger.

**Sustainable Development Goals (SDGs)**

The causes of hunger reveal important interrelationships among the following SDGs (UNDP, 2019).

- **Goal 1: No poverty** – end poverty in all forms and dimensions by 2030. The UNDP links poverty to reduced access to nutritious food, clean drinking water and sanitation.
- **Goal 2: Zero hunger** – end all forms of hunger and malnutrition by 2030. Extreme hunger and malnutrition are huge barriers to development in many nations, often partly due to environmental degradation, drought and biodiversity loss.
- **Goal 5: Gender equality** – “end all discrimination against women and girls is not only a basic human right, it’s crucial for sustainable future.” The UNDP notes that 35 percent of women have experienced physical and/or sexual violence. In addition, women earn only 77 percent of what men earn for doing the same work.
- **Goal 13: Climate action** – to mobilize US $100 billion per year by 2020 to enable developing countries to better adapt to climate change and invest in low-carbon development. Average annual economic losses from climate-related disasters are estimated to be hundreds of billions of dollars.

**Triple Bottom Line (TBL)**

The three principle causes of hunger considered in this study also represent the TBL dimensions of sustainability: social, environmental and economic. These dimensions are frequently referenced as the three Ps: people, planet and profits. Slaper and Hall (2011) discuss challenges and opportunities of measuring the TBL, whether as an index or from a total cost perspective. It is not easy to measure people and planet in the same units as profits, i.e. in terms of dollars (Anonymous, 2009).
Theoretically, the TBL attempts to account for total costs of operations. Thus, it is akin to the balanced scorecard. The idea is: what is measured will receive managerial attention. Organizations that measure their social and environmental impact are more likely to become socially and environmentally responsible. Traditionally, cost-cutting and the “bottom line” were the top priorities of business, to the neglect of environmental and social costs of moving production and service operations to nations with low costs, and lax social and environmental standards; leading to exploitation of cheap labor and natural resources (Anonymous, 2009).

Methodology
The methodology involves regression analysis of secondary data. This section describes the dependent and independent variables, along with their sources.

Global Hunger Index (GHI)
The dependent variable is the International Food Policy Research Institute’s Global Hunger Index (von Grebmer et al., 2016). GHI measures hunger at the global, regional and national levels each year, using four indicators:
- Undernourished people as a percent of the population;
- Proportion of children < 5 who are wasted (have low weight for their height);
- Proportion of children < 5 who are stunted (have low height for their age);
- Mortality rate of children < 5, which reflects poor nutrition and sanitation.

The index does not include “rich” countries, such as Sweden and the United States, where the prevalence of hunger is assumed to be very low. The 2016 GHI is available for 118 nations.

Gender Inequality Index (GII)
According to the United Nations Development Programme (UNDP), gender inequality is a major barrier to human development. Women and girls face ongoing discrimination in terms of health, education, political representation and labour market participation, with negative impact on development of their capabilities, along with their freedom of choice. Constructed by the UNDP, the Gender Inequality Index (GII) estimates gender inequality across three important aspects of human development: health, empowerment and labour market participation (http://hdr.undp.org/en/content/gender-inequality-index-gii). Higher GII scores imply greater gender inequality. The 2016 index is computed for 159 countries, revealing gender gaps and pointing to possible public policy options for overcoming obstacles faced by women.

Environmental Performance Index (EPI)
The EPI rates national performance on environmental matters in terms of protection of human health and ecosystems. It scores performance across nine issue areas, made up of twenty specific indicators. These nine issue areas are: health impacts, air quality, water and sanitation, water resources, agriculture, forests, fisheries, biodiversity and habitat, and climate and energy. The EPI uses primary and secondary data from multilateral organizations, government agencies and academic collaborators. All its data sources are publicly available. The Index enables cross-country comparisons and comparisons over time. According to Hsu et al. (2016), the EPI “was created with the aim to shape data-driven environmental policymaking.”

The EPI report contains only two mentions of “gender inequa(ity);” arguing that “poor sanitation degrades the quality of life for millions of people, exacerbates gender inequality, and stunts economic development” (Hsu et al., 2016, p. 55). The report notes
a positive relationship between EPI and GDP/capita among included countries. It also
suggests something other than economic development may be important for improving
environmental performance. Perhaps this “something” includes gender equality. The
2016 EPI is calculated for 160 countries.

Results
Table 1 reveals the regression results. The three independent variables (GII, EPI and log
(GDP/capita)) explain 72 percent of the variance in GHI (adjusted R-square = .718) and
overall fit between the data and model is significant (F = 69.713; p-value = .000). The
results provide evidence indicating a lack of issues of autocorrelation in the regression
residuals, as the Durbin-Watson statistic (1.968) is close to 2.0. Table 1 also shows the
variance inflation factors (VIFs) to assess possible issues of multicollinearity among the
independent variables. According to Akinwande et al. (2015), VIF between 5 and 10
indicates high correlation that may be problematic, and VIF > 10 suggests the regression
coefficients are poorly estimated due to multicollinearity.

*Dependent variable = GHI

This regression confirms support for the link between gender inequality (GII) and the
global hunger (GHI). The t-statistic (2.826; p-value = .003) is significant at the .01 level
of alpha. Gender inequality and the hunger of nations appear to go hand-in-hand.
Environmental performance (EPI) is also significantly related to hunger (t = -3.070; p-
value = .002). Poor environmental performance is another friend of hunger. Finally, as
expected, the link between GDP/capita and hunger is also significant (t = -3.315; p-
value = .001). This evidence supports the close connection between poverty and hunger.

In summary, results based on regression analysis support the following relationships:
- Gender inequality is linked to the hunger of nations.
- National income (GDP/capita) is inversely linked to hunger.
- Environmental performance is inversely linked to hunger.

The results confirm important inter-relationships among the sustainable development
goals (SDGs); specifically no poverty (SDG #1), zero hunger (SDG #2), gender equality
(SDG #5) and climate change action (SDG #13). Reducing poverty, promoting gender
equality and addressing climate change are steps on the path toward zero hunger.

Implications

For policy
Regarding concepts such as the SDGs and the TBL, Slaper and Hall (2011) suggest that:
“Policy-makers use these sustainability assessment frameworks to decide which actions
they should or should not take to make society more sustainable.”

Study results confirm important inter-relationships among several of the sustainable
development goals (SDGs). In terms of public policy and sustainable development, the
findings suggest government policy makers and NGO leaders and donors should include a focus on eliminating gender inequality as they work to end poverty and hunger. This is the long game, solving a lingering large problem rather than treating its symptoms. In addition, investments in climate change mitigation can facilitate movement toward zero hunger. While sending food and money may reduce hunger this month, eliminating exploitation of women and nature may be needed to eliminate hunger by 2030.

For research
Future research is needed to better understand the interplay between hunger, obesity and food waste. The World Food Program (WFP) lists food waste among the causes of hunger (http://www.wfp.org/hunger/causes). Over-eating and obesity can be viewed as a form of food waste. Further, there appears to be a paradoxical link between obesity and food insecurity (Dhurandhar, 2016), which leads to hunger.

This study may be among the first to include both environmental performance and gender inequality in the world hunger conversation. One future research opportunity would involve including more variables (e.g. elements of national culture) among the predictors of hunger. Another opportunity is to focus on individual nations or a small group of nations to understand unique cultural and political challenges in the fight against poverty, hunger and gender inequality.

Climate science and humanitarian supply chain: The use of climate information in humanitarian relief efforts

Qifeng Yan (qifeng.yan@hanken.fi)
Hanken School of Economics

Abstract

This paper provides a systematic literature review of the state-of-the-art applications of climate information in humanitarian relief efforts in order to further the understanding of how climate science can be better integrated into the decision making process of humanitarian supply chain. By delivering an overview of the current applications and challenges of climate information, this literature review intends to develop a conceptual framework as well as research agenda for future contributions.

Keywords: Disaster management, Humanitarian logistics, Sustainable supply chain

Introduction

In the past few decades, the threats of climate change have been identified and understood thanks to the numerous researches conducted on climate risks. A report published recently by the Centre for Research on the Epidemiology of Disasters and UNISDR (2018) reveals that in the last twenty years, climate-related disasters have resulted in direct economic losses amounting to $2245 billion, which make up 77% of the total economic loss of all disasters. 91% of all disasters were due to extreme weather events, the frequency and severity of which increased by climate change (CRED & UNISDR, 2018), which has become a pressing challenge for supply chain resilience (Papadopoulos et al., 2017).

Humanitarian supply chain, responding to disasters including climate related disasters but in the meanwhile affected by climate risks (Halldórsson and Kovács, 2010; Kovács and Spens, 2009), calls for an updated design in order to adapt to climate change (Kovács and Spens, 2011). One of the recommendations for humanitarian supply chain to achieve better performance is to utilize “technology and emerging best practice” (Majewski et al., 2010), in particular climate science in order to cope with complications resulting from climate change (Braman et al., 2010). A review study on sustainable humanitarian supply chain has also acknowledged that climate change adaptation should be integrated into sustainable humanitarian supply chains (Dubey and Gunasekaran, 2015).
However, even though given the research gaps identified in the past years, the number of contributions to sustainable humanitarian supply chain in the face of emerging threats remains relatively small (Dubey and Gunasekaran, 2015). There are examples of using climate applications in the field, such as that taking climate factors into account in decision support systems in warehouse location selection (Charles et al., 2016), but a state-of-the-art review is yet to be conducted.

To fill this gap, this article provides a review of the current applications of climate information in humanitarian relief efforts in general and to draw links between applications in humanitarian relief efforts and existing as well as potential applications in humanitarian supply chain, as humanitarian supply chain is a key ring of humanitarian relief efforts.

The article aims to answer two research questions:

• How is climate information being used in humanitarian relief efforts and humanitarian supply chain?
• What are the challenges encountered by the current applications and the potential solutions to these challenges?

By answering these research questions, the article intends to develop a research agenda for future contributions to the field.

Methodology

Systematic literature review, originally used in medical science as an evidence-based approach to improve the quality of literature review (Tranfield et al., 2003), has been also applied in the field of management studies because of its transparent and inclusive principles that enables a more comprehensive inclusion of literature selected by a relatively objective and replicable manner (Denyer and Tranfield, 2009).

Systematic literature review is used here because it can effectively prevent the loss of knowledge which is already available (Tranfield et al., 2003). Because of the fact that humanitarian supply chain is a young field and that to best knowledge of the author, the number of research conducted which is directly relevant to both climate information and humanitarian supply chain is not large, each relevant article may provide valuable insights and should not be neglected if possible.

Initially, a number of search terms were developed by the author by brainstorming process. The list was later modified and refined based on recommendations and advice from experts in the field. A final list includes two sets of strings. Set A includes “climate information”, “climate science”, “climate forecast”, “climate prediction”, “climate service”, “seasonal forecast” and “weather forecast”. Set B includes “humanitarian”, “disaster relief”, “supply chain” and “logistics”. Each of the strings in Set A was then combined with each of those in Set B by using the boolean “AND” (e.g. “climate information” AND “humanitarian”), resulting in 28 search terms in total. These search terms were then applied to databases to generate the initial search results.

The databases used for the search are Emerald Insight, Springer Link and Science Direct. The rationale for using these databases is that the focused issue concerns a transdisciplinary study that requires to take researches from supply chain and operation management as well as research from climate science into consideration, and the databases mentioned above represent a good mix of both areas.
The inclusion criteria for this study is based on that used by Collicchia and Strozzi (2012) in their review:

- Select articles are journal articles in English published between 2000 and 2018
- The title or abstract of the select article must contain at least one of the string of the search term (e.g. “climate information” OR “humanitarian” should be found in either the title or the abstract)
- Articles should be excluded if only concern narrow aspects or context
- Articles should be of substantive and empirical relevance

The rationale for setting the time range of the literature to be between 2000 and 2018 is that humanitarian supply chain is a relatively young field, and therefore there is very little literature available before the year 2000.

The 28 search terms returned in total 1149 items. After screening, applying the inclusion criteria and excluding the identical results, 41 articles were selected.

Findings and Discussion

Current applications of climate information

There is no unified definition of climate information, which in a broad sense refers to all kind of climate related information, for example precipitation and air temperature. The common applications of climate information in humanitarian relief efforts are in the form of forecast, in different time ranges and developed to aid different stages of disaster preparedness and response (Goddard et al., 2014; Fall et al., 2007). The stages covered by climate forecast can be from early warning to recovery (Alfieri et al., 2018). Climate information is also applied across spatial contexts. Even though the most literature found focus on rural context, climate information based decision support systems to mitigate disaster risks are not just developed for rural areas, but also for urban contexts (Baklanov et al., 2018).

Climate forecast is used to monitor risks of varied types of disasters. Rainfall forecast is a common way to provide information on drought and flood risks, using predictors such as sea level pressure, air temperature and relative humidity (Djibo et al., 2015). The development of geospatial technologies based on climate information can help monitor drought (Vicente-Serrano et al., 2012) and flood risks in real time (Koriche and Rientjes, 2016). It may provide insights for decision making in inventory levels (Taskin and Lodree, 2011) warehouse location (Davis et al., 2013; Morrice et al., 2016) in the face of hurricane and storm threats.

Climate information is applied both in a macro, long term scale, such as to map the hotspot of humanitarian crisis and therefore direct more attention to the more vulnerable regions susceptible to climate threats for better preparation (de Sherbinin, 2014), and in a micro, short term scale, such as to help public health systems to address weather-related emergency (Runkle et al., 2018) or just to be in understandable terms that can be accessed shared on social media to mitigate damage of natural disaster (Mesmar et al., 2016). Weather and climate information can also be applied using big data techniques (Ali et al., 2016).

In the recent years, climate information has been directly integrated into the operations of humanitarian organizations. A forecast based financing scheme is developed to distribute funding to humanitarian organizations in advance to the actual materialization of the disasters based on climate forecast in an automated manner, and
thereby enabling humanitarian organizations to adopt early actions (de Perez et al., 2015, cited in Lopez et al., 2018). The scheme of forecast based financing is further developed by Lopez et al. (2018) by introducing a valuation approach to select the forecasts to trigger humanitarian actions to help various types of users to determine what thresholds should serve as the triggers for early actions.

**Challenges and potential solutions**

Even though there are multifold benefits to apply climate information in humanitarian relief efforts (Tall, 2010), there are also many factors that hinder the use of climate information and prevent it from being applied in some cases.

One commonly found factor that hinders the use of climate information is the discrepancy in perception. Humanitarian organizations, the end user of products developed based on climate information, may not perceive the value of these products the same way as the climate scientists, the developer and provider of these products (de Perez and Mason, 2014). This may be due to their different perception of climate risks. People who lack awareness or accessibility to such information, or if they have received false information in the past tend to be indifferent to weather forecast (Hossain and Paul, 2018). In addition, risk is perceived in relativity and the political context would also influence decision making. Therefore, it is suggested that other than the climate forecast, the context and disaster setting are also very important (Ramírez and Briones, 2017). In some regions the perception towards climate risks is politicized and thus hinders a just judgement of climate information by decision makers (Oloruntoba, 2013).

The potential solutions include helping end users organizations better understand the usefulness of climate products (de Perez and Mason, 2014; Tall, 2010; Njau, 2010), providing information in a understandable way for practitioners (de Perez and Mason, 2014; Tall, 2010; van Aalst et al., 2008), facilitating partnership between science workers and humanitarian organizations (de Perez and Mason, 2014; Hansen et al., 2014; Tall, 2010). Examples include a serious game developed to help humanitarian workers better understand the value of climate information (Parker et al., 2016). Communication is not only done between science workers and local organizations, but also between climate information providing scientists and scientists from local communities at risks (Lyon et al., 2014).

Discrepancy also exists between what end users want and what scientific community is able to offer (Giannini et al., 2016). A mismatch between what is provided and what is needed or can be used by the local organizations and communities has also been identified (de la Poterie et al., 2018; Carr and Onzere, 2018) which is due to the communication gaps between science workers, the provider of climate information, and the local communities, the end users of climate information (Baudoin and Wolde-Georgis, 2015). Such gaps also exist between science workers and humanitarian organizations (Parker et al., 2016). It can be dangerous when end users misunderstand the climate information and make decision based on the misinterpretation (de la Poterie et al., 2018). Climate information may also only exist in forms that are incomprehensible and therefore not usable for local communities (Tschakert et al., 2010). A discrepancy between how climate risks is perceived and how local communities respond to the perceived risks. Even though the climate risks have been
recognized by certain communities, very few plan to integrate newly developed climate information into their hazard mitigation plans (Stults, 2017).

Therefore, it is essential to provide training for end users of the products based on climate information (Vicente-Serrano et al., 2012). The mode of training provided by climate scientists to practitioners also switches to user-driven. End users of climate information are involved in the early stage of the training to ensure that the training is designed in a way that the local needs are met (Mantilla et al., 2014). This mode of early engagement of user communities has also been confirmed to be important by the stakeholders (Giannini et al., 2016).

To better address this problem, scientists also call for a different approach in terms of knowledge production and climate products development and design. A bottom-up approach is also suggested to facilitate community based risk reduction (van Aalst et al., 2008). Co-production of knowledge is encouraged. Local traditional climate knowledge should also be incorporated into the co-production of knowledge to better tailor the climate information products to meet local needs (Egeru, 2016). Hazard information is found to be most useful and more likely to be used if combined with local information (Alfieri et al., 2018). A study identifies the main challenges faced by co-production of actionable climate science as the scattered information flow within organization and between humanitarian organizations and scientific community (DeCrappeo et al., 2018). A deeper mutual understanding is yet to be between the local communities and scientific workers. It is crucial to understand how the vulnerable groups respond to disasters (Tschakert et al., 2010). Pressure hindering applications of climate information also comes from peers, who are more conservative to embrace new ways of practice, within the community. Understanding how to alleviate this pressure is critical to the usable design of products based on climate information (Carr and Onzere, 2018).

Accessibility is another challenge for climate information applications. The availability and access of climate information is absent in some parts of the world, especially the rural communities and therefore a decentralization of climate information dissemination is needed (Njau, 2010). Digital platforms on which climate information is made available and accessible for non-climate specialists are developed to aid humanitarian works (Blumenthal et al., 2014). Some scholars also advocates a real time release of climate information (Vuillaume et al., 2018). However, channels to disseminate climate information should adapt to local conditions. For example, community meeting is a better channel to disseminate climate information than radio in some communities (Egeru, 2016).

Furthermore, the definition of the “end user” of climate information varies. In some studies, the end user of climate information refers to humanitarian organizations (de Perez and Mason, 2014). While in some other studies, the end user of climate information refers to local communities (Baudoin and Wolde-Georgis, 2015). Another study identifies three types of end users, namely the local communities, the humanitarian managers who make policies and large-scale policies, and the humanitarian workers who do not make decisions themselves but apply policies made (Djenontin and Meadow, 2018). The different positioning of end users may affect the design approach and prioritization of interest.

Across regions, stakeholders perceived the effectiveness early warning system based on climate information quite differently, and the results contradict that of certain official
reports (Lumbroso et al., 2016). It can therefore be indicated that the effectiveness of climate information based systems should be further evaluated in different regions to obtain a better idea of what can be improved. The evaluation of the performance of products based on climate information is also key to build trust between providers and end users, which will further facilitates the use of climate information based products (Alfieri et al., 2018). Some techniques are still in development and not very mature. For example, downscaling seasonal forecast, originally aiming to provide forecast at a higher solution for local uses, is found to be sensitive to region and dataset and not as reliable as the coarser resolution forecast in place (Nikulin et al., 2018). In locations where the conditions do not allow good enough forecast, decision makers should be cautious before making decisions based on climate information (de la Poterie et al., 2018). It is therefore recommended that decision makers should clearly identify local needs and determine if and to what extent climate information should be applied.

There is a lack of “interoperability” among government bodies and NGOs working to relieve disasters (Shareef et al., 2018). Institutional and informal setup are crucial to determining the best approach to address risks (Vicente-Serrano et al., 2012).

Recurring themes
From the findings above, several systemic elements are found to be recurrent and can be clustered in to a theme. Three themes have been identified, namely collaboration, usability and coordination, which can be considered to be construct a conceptual framework for future research.

For the purpose of this study, collaboration is defined as: “the ability to work across organizational boundaries” (Fawcett et al., 2008). In this context, the interoperability between governments and NGOs, the partnership between scientific communities and humanitarian organizations, the improved accessibility and schemes for information sharing are challenges and solutions of collaboration.

For the purpose of this study, usability is defined as “how science is produced and how it is needed in different decision contexts” (Dilling and Lemos, 2011). In this context, the co-production of knowledge, the mutual understanding process and the trust building among scientific workers, humanitarian organizations, local governments and communities are challenges and solutions of usability.

For the purpose of this study, coordination is defined as “managing dependencies between activities” (Malone and Crowston, 1994). In this context, the actionability of plans and perception alignment and compromise are challenges and solutions of coordination.

Conclusion
Even though not without challenges and risks, climate information is being applied in various ways in humanitarian relief efforts. However, researches focused on applications of climate information in humanitarian supply chain in particular are still rare. There are very few examples found to be directly related to humanitarian logistics. It is recommended that more researches that connects humanitarian supply chain with climate science to be conducted. Three recurring themes have been identified from the literature review, namely collaboration, usability and coordination. These recurring themes can be considered to be used to construct a conceptual framework.
Limitations
Limited by the subjectivity of choosing a limited number of search terms, the article may not represent an exhaustive review of the field. By including more search terms to widen the literature, the review results may be different. Further research is needed to draw a conclusion that reflects a more comprehensive perspective of the field.

Sustainable Innovations for Humanitarian Operations in Refugee Camps

Lysann Seifert (Lysann.seifert@gmail.com)
University of Kassel, Germany

Stefan Gold
University of Kassel, Germany

Nathan Kunz
University of North Florida, US

Abstract
Refugee camps were originally built up as temporary emergency relief ‘safe spaces’ assuming that refugees may return to their home country in the short-term. However, statistics show that refugees stay in camps for an average of 17 years, which means that the management of camps is a medium to long-term commitment that requires specific strategies and operational resources to be sustainable. By means of case study research in two refugee camps in Jordan, we examine major operational innovations and their sustainability effects, potential trade-offs and dilemma situations that arise from restricted resources and conflicting goals.

Keywords: sustainable innovations, humanitarian supply chain management, refugee camps

Introduction
“Being well prepared before the refugees arrive is key in order to welcome and treat them with dignity.” (Camp Management, Organisation A)

There is a need to develop innovations towards sustainability (Tidd & Bessant, 2014). On the one hand, the lifestyles in countries of the global North use the resources of 1.7 planets (Watts, 2018). If the emerging countries follow the same path, a resource use of 2.5 planets is predicted for the year 2050 (WWF, 2010). On the other hand, many important external energy and raw material resources are becoming more and more scarce (Brown, 2011). War, persecution and climate change are among the triggers for forced migration. As a consequence, host countries, like Jordan, set up refugee camps to manage high influxes of refugees. Refugee camps were originally built up as temporary emergency relief ‘safe spaces’ assuming that refugees may return to their home country in the short-term. However, statistics show that refugees stay in camps for an average of 17 years, which means that the management of refugee camps is a medium to long-term commitment that requires specific strategies and operational resources to be sustainable (Lahn & Grafham, 2015; Oloruntoba & Banomyong, 2018; Ossenbrink et al., 2017).

We studied the sustainability of these camps by means of case study research in two refugee camps in Jordan, we examine major operational innovations of the last past five years and their sustainability effects as well as potential trade-offs and dilemma situations that arise from restricted resources and conflicting goals (Hall, Matos, Gold, & Severino, 2018). This paper aims to answer the following research questions:

This paper aims to answer the following research questions:
1. What are the major operational changes of the last past five years that help to make supply chains in refugee camps more sustainable?

2. What are the performance implications of these solutions on the economic, environmental and social performance dimension?

3. Are there any trade-offs that cause dilemma situations?

**Literature Review**

According to the Brundtland Commission (1987) sustainable development is defined as “a development that meets the needs of the present without compromising the ability of future generations to meet their own needs”. In the economic field, the concept of sustainability was later operationalised by the Triple Bottom Line (TBL), which requires an even and simultaneous pursuit of the social, environmental and economic dimensions of sustainability (Dyllick & Hockerts, 2002). Slack & Lewis (2008) developed the operations strategy matrix for the private sector (Annex A). It brings together the two perspectives of market requirements and operations resources. The latter can acquire different capabilities through accumulation of their resources and skills. The organisation’s operations shape these capabilities by making a number of decisions over time. The matrix describes and visualises an operations strategy as the intersection of a company’s performance objectives (quality, speed, dependability, flexibility and costs) with its decision areas (capacity, supply network, process technology, and development and organisation). Performance objectives address customers’ needs and the general classification by which competitive factors are grouped. Operation strategy decision areas are groupings of decisions that shape the operating resources. An operational strategy reflects how an organisation creates value for its customer, itself and the ecosystem it is embedded in, through the specific combination of performance objectives and those decisions areas that affect, or are affected by, the company’s strategic resources. (Slack & Lewis, 2008)

While there is an urgent need to lead operations strategies towards sustainability, (sustainable) innovations are key drivers for creating value in the long-term. The word **innovation** comes from the Latin word, *innovare*, and is all about change. Tidd & Bessant (2014, p.3), defined innovation as “[…] the process of creating value from ideas.” According to Silvestre & Tirca (2019), there are four types of innovations in sustainable development (Fig. 1), categorized along the dimensions “Social Emphasis” and “Environmental Emphasis”.

![Figure 1: Typology of innovations for sustainable development by Silvestre & Tirca (2019)](image_url)

Depending on their nature and the primary challenges they aim to address, the different types vary in terms of low to high emphasis on environmental and/or social challenges and their...
implications for the planet. Traditional Innovations (low/low) have a primary focus at the economic dimension and associated concerns and neglect the ecological and social components. While the focus of Green Innovations (low/high) mainly lies on the environmental dimension (e.g. low-carbon), Social Innovations (high/low) contribute, for example, to the welfare of society, improvement on social capital and trainings and empowerment (Linnenluecke & Griffiths, 2010; Silvestre & Tirca, 2019). Sustainable innovations (high/high) consider all three dimensions as equally important and are consistent with the TBL of sustainability (Elkington, 1997). The latter type is more difficult to achieve, due to its complexity, dynamics and uncertainty, e.g. its wider range of stakeholders or more ambiguous and contradictory demands of different parties (Silvestre & Tirca, 2019). At the same time, more holistic innovation approaches are needed to uncover opportunities that include solutions to resource instability and scarcity, energy security and system efficiency for their supply chains (Nidumolu, Prahalad, & Rangaswami, 2009; Silvestre & Tirca, 2019).

Theoretical framework: Operations strategy in the context of a refugee camp

Based on the operations strategy model of Slack and Lewis (2008) and the sustainable development innovations framework by Silvestre & Tirca (2019), this research study investigates operation innovations in refugee camps. An operations strategy of a refugee camp must be aligned with the short and long-term humanitarian needs, as well as the resources available to humanitarian organisations. (Kunz & Reiner, 2012; Seifert, Gold, & Kunz, 2018) Alignment is the state where an operation’s capabilities match the operation’s requirements (Slack & Lewis, 2008). Alignment should be achieved through reconciliation of the humanitarian needs and humanitarian operations resources. Continuous alignment results in sustainable performance over time (Kunz & Gold, 2017). Existing trade-offs could complicate such alignment. The attempt to strengthen the balance between humanitarian operational capabilities and the special needs in the field through an innovation process is referred to as a ‘dynamic approach to sustainability’ (Slack & Lewis, 2008). The extent of alignment within an organisation’s operations strategy can be assessed by analysing it using the operations strategy matrix.

Since refugee camps cannot be compared with organisations in the private sector that compete in the marketplace, we adjusted the initial framework by Slack & Lewis (2008) accordingly. International (humanitarian) organisations, such as UNHCR are usually managing refugee camps. Thus, we adapted the performance objectives by using the UNHCR’s global strategic objectives (UNHCR, 2009, 2017b) and aligning them with the humanitarian needs in the field. Reaction Speed is the amount of time it takes to respond to needs. It leads and coordinate humanitarian operations. Humanitarian organisations strive to respond to the needs of beneficiaries in the shortest possible time. Operations Costs: A good cost management is important for (humanitarian) organisations involved in camp and project management. Due to limited financial resources and the dependence on donor funding (Seifert et al., 2018), efficient OM/SCM processes are essential to secure financial resources of organisations. With Safety and Security precautions, humanitarian organisations ensure that refugees have access to safety and are protected from return into situations of harm in the short- and long-term (UNHCR, 2017b). According to the international humanitarian law that applies in armed conflicts, refugees have a right for special protection under the Fourth Geneva Convention and Additional Protocol I (ICRC, 2015). Reliable communication and information are important when delivering assistance in emergencies and development aid operations to beneficiaries and host communities. Policies and sustainable standards for humanitarian operations in refugee camps have to be set up by international organisations and national authorities (UNHCR, 2017b). To have a perspective for a job, to participate in further education or to build up resilience and empowerment as well as integration and long-term inclusion in the host societies are decisive long-term Qualities of Life for refugees. Instead of focusing on the four initial decision areas (Capacity, Supply network, Process technology, and Development and
organisation), as proposed for organisations in the private sector by Slack and Lewis (2008), we concentrate on the two decision areas *Supply network* and *Process technology*, since we believe they are the most relevant dimensions in respect to refugee camps. Although the survival of the involved organisations is important, too, their performance against competitors does not lie in the focus as much as the well-being of beneficiaries and host-communities. Therefore, we amended the overall goal ‘market competitiveness’ with ‘mitigation of the suffering of forcibly displaced persons’. The framework of the matrix for operations innovations in refugee camps is shown in Figure 2. The initial operations strategy model by Slack and Lewis (2008) can be found in Annex A.

![Figure 2: The Operations Innovations framework for refugee camps](image)

**Design/methodology/approach**

**Selection of Method**

Innovation in refugee camp operations is a complex and context-specific subject that has been rarely investigated on empirical grounds, amongst others due to challenging field access (Seifert et al., 2018). Therefore, we use an explorative multiple embedded case study approach. The two largest refugee camps in Jordan, the Zaatari and the Azraq camp, represent our cases, and operation-related innovations are the units of analysis. The explorative multiple embedded case study approach is considered suitable for investigating complex subjects within their specific contexts (Yin, 2009), such as operations strategies and incorporated sustainable innovations in different refugee camps. Such a methodology allows to investigate particular situations in-depth (sustainable innovations) and immerse into complex social phenomena in order to develop an understanding about the operation strategies in refugee camps and their interconnected actions and relationships (Yin, 2009). As a basis for the empirical analysis, we have developed a theoretical framework that locates humanitarian operations innovations within major operations management decision areas and conceptualizes its effects on various sustainability performance dimensions. This framework has been derived from key literature (Silvestre and Tirca, 2019; Slack & Lewis, 2009) and adapted to the specific features of refugee camps. It served as a foundation for the development of the interview guide.

**Sampling**

Syria and Jordan belong to the "Fertile Crescent" in the Middle East, the birthplace of agriculture, where the rich and fertile soils irrigated by the Tigris, Euphrates, Nile and Jordan. Important crops such as barley and wheat are cultivated there (Salamini, Özkan, Brandolini, Schäfer-Pregl, & Martin, 2002). This area feeds millions of people (Jaradat, 1998), however,
the situation is changing since recent droughts and rising temperatures continue to affect once fertile soils (Kitoh, Yatagai, & Alpert, 2008). Jordan and Syria are the countries most affected by the current decline in precipitation (Erian, W., Katlan, B. and Babah, 2010). Due to multi-faceted causes of climate change, unemployment, food insecurity, corruption and repression (EJF, 2017), the war in Syria started in connection with the Arab Spring in March 2011 (Azmeh, 2014). Since then, a full-scale civil war has impelled around 13 million people to flee the country or to be forcefully displaced within the country (OCHA, 2017; UNHCR, 2017a). To date, the Syrian war is already in its ninth year and has resulted in more than 500,000 deaths (IamSyria, 2016). Besides the millions of people that have been internally displaced (IDMC, 2017), some hundred thousand emigrated to Europe and over 5.5 million people are residing in camps in neighbouring countries (IRC, 2017), such as Jordan. Jordan was selected as our focus country since it is one of the neighbouring countries of Syria that is most affected by the Syrian civil war and the associated refugee movement. With a Gross National Income (GNI) per capita of 3920 USD in 2017, Jordan is considered as a ‘lower-middle income country’ by the World Bank (Bank, 2017). It manages the second highest proportion of refugees compared to the world population, 89 refugees per 1,000 inhabitants (UNHCR, 2018). Some 670,000 Syrian refugees are registered in Jordan, most of whom live in the Amman governorate (UNHCR, 2019). Recent figures show that only 126,131 refugees live in camps and the remaining 83.2% of refugees live outside the camps in urban areas near the border to Syria (Healy; & Tiller, 2013; UNHCR, 2018). To reduce the impact of the influx of refugees into the cities, Jordan established the Zaatari camp (Mafrak Governorate) in 2012 and the Azraq camp (Zarqa Governorate) in 2014 beside other smaller camps (Healy; & Tiller, 2013; UNHCR, 2019). For our multiple embedded case study, we selected the two largest refugee camps in Jordan, Zaatari and Azraq, as cases since they are particular important for investigating operations innovations. Since we draw conclusion on how to improve operations in camps, we define the units of analysis as the multiple innovations for sustainability. The embedded units are the organisations as well as employees belonging to the ecosystem of the camps and having a focus on running camps in a sustainable way. Numerous humanitarian organisations are active in both refugee camps, working in logistics, supply chain and operations management. Prior to the empirical data collection, we analysed the humanitarian organisations that are managing and implementing projects in the camps and whose work is linked with camp operations. Interviewees were selected based on their role in camp management and by using the snowballing technique (Bryman & Bell, 2015).

Data Collection, analysis and quality
In the course of the field work, data was collected through participatory observations and semi-structured interviews with selected refugee camp staff, logistics and operations managers, following a key informant approach. By means of a prior developed interview guideline, 21 interviews were conducted with humanitarian organisations in Jordan between January 24th and March 03rd 2019. A summary of the interview notes is shared with the interviewees for accuracy checks. Annex B provides the list of interviews, including the organisation, function and level of interviewees. Secondary data were gathered from global institutions in order to realise an appropriate analysis of sustainable innovations and the operations strategies in camps and to facilitate data triangulation (e.g., Hakim, 2000). By means of the software Atlas.ti, data is analysed through qualitative content analysis, following a combined deductive-inductive approach that departs from the framework developed from literature as described above (Mayring, 2000). We followed a structured and reliable research design to ensure valid and reliable findings. Each case, the associated challenges and the gained insights are discussed and coded among three researchers. The units of analysis are presented following a similar structure, including background and their implications on economy, environment and society, in particular the five pre-defined performance objectives as well as potential trade-offs and dilemma situations.
Empirical findings and analysis
This section presents the data collection and analysis in Azraq and Za’tari camp. First, we examine the influencing factors for the development of both camps, which also provides explanations regarding the forms of various innovations. Then, we analyse the relationships between each performance objective and decision area of sustainable supply network and process technology innovations as well as challenges and trade-offs we identified during the field work. In the following we present an excerpt of the results. For the presentation at EurOMA2019 we will provide the detailed analysis and results.

Za’tari and Azraq camp
Both camps have been set up according to the Sphere standards that concern Water, Sanitation and Hygiene (WASH), food security and nutrition, shelter and settlement as well as health (Sphere Association, 2018). Za’tari and Azraq provide similar products and services to beneficiaries, however, the different configuration of the two camps is based on their developments and that the experiences of Za’tari were taken into consideration in the development of Azraq. Za’tari started as a transit site with District 1 and 2. Up to 3000 people a day have arrived in Za’tari during the emergency phase. UNHCR provided tents and later caravans and built communal latrines and kitchens according to the Sphere guidelines. After reaching 140'000 refugees in Za’tari, the Jordanian government decided to build the second camp, Azraq, in which they incorporated the lessons learned from Za’tari. After a construction time of around one year, Azraq has finally a capacity of twelve villages (140.000 people). Since Azraq is located in the middle of the desert and exposed to cold winters and hot summers, a special isolated T-shelter (transitional, sealed shelter in cement) has been developed that can’t be dismantled or moved. Compared to Za’tari where some facilities can only be found in certain districts, each village in Azraq includes a police station, community centres, schools, hospitals and markets, mosques. Another challenge represents the so-called spaghetti structure in Za’tari camp. Refugees relocated their shelters at night to create the environment they like. Due to the large number of people who arrived daily during the emergency phase at Za’tari, the camp management were not able to handle the relocations of shelter and hence, the modification of camp layout. The spaghetti structure of roads led, for example, to a delay in rapid response to an emergency. Furthermore, the management had to face challenges when implementing the water network and water-waste-management process. In the Azraq camp no communal facilities, like kitchens and bathrooms have been built as they were not being accepted by the refugees in the Za’tari camp. “[...]in Za’ tari all the communal facilities have not been used properly or have been rejected by the refugees because of cultural preferences.” (Head of Technical Unit, Organisation A)

Process technology innovations
(1) Iris Scanning
“The Iris Scan is a very complex system. It helps to speed up the service processes, and to avoid mistakes from our side, but also to avoid fraud or duplication, since every eye is unique. [...] Iris Scan is used in the registration centers, supermarkets and distribution area. Beneficiaries scan their eyes and automatically have access to their file. They can print their birth certificate or any other personal document. It is like a kiosk.” (Logistics Manager, Organisation B)

The Iris Scanning and EyeCloud scanners are used for biometric registration and the delivery of financial assistance to refugees (Leo, 2018). More than 2.3 million Syrian refugees in Jordan and the region are registered with the irisguard system, allowing them to scan their eyes to withdraw cash at ATMs from the Cairo Amman Bank or pay for goods in camp supermarkets. Refugees often do not have access to a traditional bank account to access benefits, save money, or make payments. By registering for Iris Scanning, refugees are granted access to a bank account and a system that will provide them with all their personal and official documents. In
addition, Iris Scanning replaces the usage of cash, vouchers and e-cards since it has been implemented in supermarkets of both camps by the World Food Programm (WFP).

- **Reaction speed:** Iris Scanning has increased the responsiveness of organisations and reduced the waiting time of refugees to a minimum. The verification of refugees' identity and payment at the checkout is faster than with e-cards or vouchers. Operations staff have reported that they had to make overtime in the past without the Iris Scanning and were only able to handle half the cases per day. “Initially, we had to check the person, his proof of registration and had to compare the information with our shared desk. It took a long time to identify the eligible cases and that the person in front of you is the right person who should receive the items.” (Distribution area staff, Organisation C)

- **Operations costs:** “This process is faster, much more efficient, reliable and safer.” (Operations Manager, Organisation C) In addition to minimizing working time and saving overtime, UNHCR also benefits from the database and the reports and evaluations it generates. The data allows conclusions to be drawn about the preferences of beneficiaries and enables UNHCR to adapt its operations processes to the needs of refugees as well as save operations costs.

- **Safety and security:** With Iris Scan fraud is minimised. “[...] Very often people come with an ID and a name to pick up the items. But the same person can come again, just with another ID to get wrongly more items. [...] or people share their kids to increase their family size and to receive more items. But now with the Iris Scan you can't cheat.” (Head of Technical Unit, Organisation A) “The refugees have real trust in this system. if you ask them, they'll say ‘yes you can trust me but we're happy that you're using iris on everybody else because A.T.M. cards are traded and sold’. There is a big black market for them. So, they are, first of all, pleased with a no cash in hand type of transfer. Because they trust an A.T.M. machine over somebody handing them cash. And they trust the iris that it's giving the money to the right people and that we care enough to ensure that there's no fraud in that.” (Head of Humanitarian Assistance, Organisation A)

- **Reliability:** “So, we can say that Iris Scan has an impact on reliability, since all important documents are always available and accessible and stored in one place that is only accessible by the specific person him or herself.” (Operations Manager, Organisation C)

- **Quality of life:** ‘Iris scan increases the comfortability. It is easier for the refugees, too. Their waiting time is much shorter.”

- **Challenges:** In addition to the positive feedback, Iris Scan is also heavily criticized regarding how power is exercised by institutions over individuals. With the Iris Scan and the generation of codes, identities are created and imposed on individuals. This approach enables institutions to categorize individuals in order to integrate them into management systems (Schoemaker & Currion, 2018). The attributed legal identity of the "refugee" allows access to services for those in need, but also limits their mobility. For example, refugees must always apply for an exit permit when leaving the camp.

**Expected findings**

Through our theoretically framed exploratory research design, we aim to increase our understanding in how far changes of operations (i.e. innovations) affect operational, economic, ecological and social performance of the humanitarian operations, which means in how far they may be categorized as “sustainable innovations” (Silvestre & Tirca, 2019). In addition, we aim to generate knowledge under which conditions innovations contribute to various performance dimensions or lead to trade-offs and dilemmas (cf. Hall et al., 2018). More precisely, we strengthen insights on how operation innovations of a refugee camp affect: reaction speed, operations costs, safety and security for refugees, reliability of processes as well as quality of life for refugees and host communities.
Our research investigates successful, partly successful and unsuccessful operations innovations in the two Jordanian refugee camps and provides advice to camp management on planning and implementing innovations that simultaneously benefit various performance dimensions.

We propose future research on how humanitarian organisations can ‘do better’ by implementing sustainable innovations in camps and on how they may rethink their underlying knowledge architecture to continuously improve processes and management structures.

Motivation and job satisfaction of humanitarian logisticians

Jana Abikova (jana.abikova@vse.cz)
University of Economics, Prague, Department of Logistics

Abstract

The turnover of logistics staff is significant challenge for humanitarian organizations. Understanding what motivates logisticians to join the humanitarian sector, which factors influence their motivation and job satisfaction could help the organizations to struggle with the extremely turnover they have to face. Up to now, the performance of humanitarian logisticians and needed skills were examined. Also, the motivation of humanitarian workers are noticed in previous research. Therefore, the aim of this research is to extend the knowledge about the human resources in humanitarian sector.

Keywords: Humanitarian Logisticians, Motivation, Job Satisfaction

Introduction

Each humanitarian operation is reliant on logistics. Effective procurement, knowledge of transport conditions and the needs of the affected population, or the arrival of supplies at the right time are essential for the success of humanitarian operations. At the same time, growing number of disasters together with failure of humanitarian aid lead to rising attention about humanitarian logistics (Meduri, 2014). Logistics activities are always connected with logistic staff. For effective functioning, it is crucial to “hire, develop and retain the ‘right’ person at the ‘right’ time in ‘right’ numbers” (Meduri, 2014, p. 139).

Humanitarian workers operate in complex environments with various challenges and demanding working conditions. Up to now, the performance of humanitarian logisticians (Chaikin, 2003) and needed skills were examined (Kovács and Tatham, 2010; Kovács et al., 2012). Previous research has revealed importance of functional logistics skills, as well as additional skill sets related to the context of humanitarian operations (Kovács et al., 2012). Remington and Ganapati (2017) examined the required sets of skills of recovery workers in general. Authors recognized five main categories of skills that are needed in post-disaster context – communicative skills, leadership skills, emotive skills, technical or job specific skills, and field experience. Already in 1999, McCall and Salama found that vital characteristics of emergency workers include leadership skills, e.g. adaptability, flexibility, and technical expertise as well.

One reason why identifying the required logistics skills, together with motivation and job satisfaction, is important is the low level of permanent staff in the humanitarian sector. Indeed, staff turnover in humanitarian logistics is extremely high; workforce rotation of field logisticians can reach 80% (Thomas, 2003). In the end, the turnover has negative impact on the performance of organizations. However, “optimal turnover is not the lowest turnover that can be achieved” (Loquercio et al., 2006, p. 2). According to Loquercio et al. (2006), humanitarian agencies welcome a degree of workforce rotation due to e.g.
more flexibility in relocating staff. The retaining workers who have lost their motivation is harmful for the organizations (Loquercio, 2006) as well.

On the other hand, motivation of humanitarian workers (mostly medical workers or volunteers) has been examined before. Previous research reveal motivators as ‘compassion/imparting love to those in need’, ‘God’s calling to help others’, ‘giving back’ (Putman et al., 2009), ‘solidarity’, ‘feeling compelled to address the rights of others’, ‘charity and philanthropy’ (Asgary and Lawrence, 2014), ‘a desire to make contribution’, ‘a desire to make a difference’ (Bjerneld et al., 2006), ‘altruism’ (Bjerneld et al., 2006, Oberholster et al., 2013), ‘career development’, ‘international experience’, ‘escapism’, and ‘outsider support’ (Oberholster et al., 2013). Participants of Asgary and Lawrence’s study also mentioned that “a sense of personal responsibility driving their humanitarian work” (2014, p. 3) and “values from family, community, early education, or experiences with colonial history” contribute to their motivations (p. 4). Albuquerque et al. (2018) track the changes of motivators of nurses over time. At the beginning, the participants of authors’ study wanted to discover new things and feel the worthiness. On the other hand, nurses with more experience wanted to continue to challenge themselves and they enjoyed stimuli from the fieldwork.

Identifying the differences motivation of humanitarian workers can support the effective recruitment, training and career management (Oberholster et al., 2013). These aspects are crucial especially because one of the main challenges for humanitarian organizations is a high workforce rotation (Albuquerque et al., 2018).

**Methodology**

In this research, combination of qualitative and quantitative research has been used. The data are obtained through the semi-structured questionnaire. This questionnaire is completely anonymous and consists of 40 questions and can be split into six parts: (1) general information (e.g. sex, age, education), (2) work-related information including information about training (e.g. current position and job placement, work experience), (3) motivation and job satisfaction (e.g. the reason why participants have decided to join this sector, which factors affect their motivation and job satisfaction), (4) statements (14 statements in total), (5) perception of their job, (6) trauma events and mental health. Some of the questions are relevant only for workers with field work experience or address the previous question. Therefore, the number of answers to various questions or parts of the questionnaire can vary. In some questions, respondents have to indicate how much they agree or disagree with the statements using a 7-point scale according to Diener et al. (1985). The questionnaire reflects the previous research about motivation, job satisfaction or psychological conditions of humanitarian workers (Bjerneld et al., 2006, Imai et al., 2010, Oberholster et al., 2013, Jones and Williamson, 2014, Akintola and Chikoko, 2016). Therefore, it is possible to compare the results of logisticians with other workers in humanitarian sector. The questionnaire was piloted, and the minor changes were done.

To ensure the completely anonymity of the participants, the statements of the participants will not be linked up with their affiliation or any other personal information from the first section of the questionnaire. The questionnaire was distributed to international, national non-governmental organizations, UN agencies, International Federation of Red Cross and Red Crescent Societies, Logistics Cluster, and Humanitarian Logistics Association with request to ask logisticians to get involved in this research. The data collection has begun in the middle of November 2018. Only logisticians with at least one year of work experience can participate in this research.

In total, four research questions and three hypotheses were defined:

- RQ1: What is the motivation of humanitarian logisticians?
- RQ2: Which factors influence the level of job satisfaction of humanitarian logisticians?
logisticians?

- RQ3: How do humanitarian logisticians perceive their job?
- RQ4: How does the immediate family and friends influence the humanitarian logisticians?
- H1: The salary negatively influences motivation of humanitarian logisticians and the job satisfaction as well.
- H2: The organization can influence the motivation and job satisfaction of logisticians through the culture and conditions within.
- H3: The stance of family members or friends mostly negatively affect the level of motivation of humanitarian logisticians.

The results of parts number four and six of the questionnaire which are focused on the statements and mental health will not be presented in this paper. These information are not focused directly on motivation and job satisfaction of humanitarian logisticians.

Results

In total, 79 participants filled out the questionnaire. Two of these responses, P1 and P70, had to be excluded from the analysis due to unclear answers of the respondents. As a result, 77 participants participated in this research. Most of the respondents are men (51 overall; 66.2% compare to 26 women, 33.8%). The average age is 42 (maximum 72, minimum 23). The Table 1 represents the results of first part of the questionnaire.

<table>

Most of the respondents are married (29 men, 6 women), followed by respondents without any relationship (10 men, 14 women), people in relationship (3 men, 5 women), and 5 respondents are divorced (4 men, 1 woman). No respondent is widowed. In total, 42 respondents graduated from university (28 men, 14 women), followed by 24 respondents with postgraduate education (13 men, 11 women), and 11 respondents with high school education (10 men, 1 woman). Participants stated 33 countries of origin. The average amount of years of work experience is 17.3 years with minimum 2 years and maximum 52.5 years. The respondents work in average for 2 organizations and on their current position are in average for 3 years. This average is driven by 14 respondents with more than 5 years on the current same position. However, the highest number of participants has been on their current position for one year (24 overall) or two years (13 overall). One respondent did not answer this question. Table 2 includes other results from the second part of the questionnaire.

</table>
Most of the participants work for international NGOs and in the field. Two respondents responded they work for INGO and for UN agency at the same time. Most of the respondents with field work experience are expatriates (63 overall; 81.8%), compare to 11 local workers (14.3%). Three respondents do not have work experience from the field. In total, respondents mentioned 46 various position they currently hold, for example hospital logistician, logistic coordinator, cluster logistic coordinator, supply chain advisor, logistic manager, all round logistician, logistic assistant, storekeeper, water and sanitation manager, logistic project manager etc.

**RQ1: What is the motivation of humanitarian logistics?**

In the third part of the questionnaire, the respondents firstly answered on question “What was the reason why you have decided to join humanitarian organization?”. Respondents have 11 defined options. They were able to choose more than one option or mention other motivators because the question was open-ended. Their most important motivator was ‘the chance to help people’, ‘the chance to change the world and make some contribution’, and ‘the chance to gain international experiences’. Table 3 includes the full lists of answers.

Table 3 – Motivation to join humanitarian organization (amended from Bjerneld et al., 2006, Imai et al., 2010, Oberholster et al., 2013, Jones and Williamson, 2014, Akintola and Chikoko, 2016; personal collection)
11 respondents also gave their own answer, for example: “the interest of discovering the supply chain management of NGO” (P11), “believes that practises in humanitarian jobs are more transparent” (P15), “dream of my youth to spend a few years for humanitarian work” (P18), “fed up with corruption and exploiting staff in my previous position” (P23), “to step out of the capitalistic system” (P52) etc.

Another question was “What keeps you involved?” followed by “Have you had periods when you have struggled to stay involved? Why? What has kept you involved?” The answers of the respondents can be splitted into some groups. The first group includes participants who want to help people, and this is the main motivation for them, e.g. “the needs are still there, I am still motivated” (P7), “motivated to help the people…” (P60). The second group includes people who are motivated by their job itself, e.g. “The fact that I am living my dream of being a humanitarian loggie in an emergency response.” (P55), “... I have realised that supply chain functions are very important to the success of any humanitarian operation.” (P69). Other workers keep themselves motivated by their co-workers, e.g. “…the feeling that I can do a great job with the rest of the team together” (P18), “the good spirit of my team” (P19). Some other respondents displayed the desire for challenging work environment, e.g. “the challenges faced constantly” (P64), “I love the constant challenges of the job…” (P67). Another often stated reason was the humanitarian organization participants work for, e.g. “I have big trust in what [the organization] doing. “ (P37), “I work for an organization that does good work.” (P38). Some respondents mentioned also financial aspects, sometimes in the opposite ways, e.g. participant P67 stated “…I love the fact that I am not working for money, but to contribute to the well-being of people”, while participant P23 stated “money” as an aspect which keeps him/her involved in this job. In total, 21 respondents (27%) stated they have not struggled while doing this job. The respondents who have experiences with struggling periods, mentioned the reason like ‘the disconnection from family’, ‘bureaucracy’, ‘problems with management of organization’, ‘waiting too long for missions’, ‘stress caused by high workload’, e.g. respondent P28 stated “feeling that it is an endless job”. The main cited factor that kept them involved, where seeing results of their job.

The respondents had to choose the factors which positively and negatively affect the level of their motivation. The most cited factor with positive effect is ‘the chance to help people’, followed by factors ‘the possibility to make a difference’ and ‘the reputation of the organization and the organizational culture’. Whereas factors as ‘salary’, ‘stance of my superior’, and ‘the living conditions during missions in the field’ affect negatively the level of motivation the most. Table 4 includes the whole list of these factors and results.

Table 4 – Factors which positively and negatively affect the level of motivation of humanitarian logisticians (amended from Bjerneld et al., 2006, Imai et al., 2010, Oberholster et al., 2013, Jones and Williamson, 2014, Akintola and Chikoko, 2016; personal collection)

<table>
<thead>
<tr>
<th>Factor</th>
<th>Positively (overall)</th>
<th>Positively (%)</th>
<th>Negatively (overall)</th>
<th>Negatively (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The stance of my superior</td>
<td>27</td>
<td>35.1%</td>
<td>26</td>
<td>33.8%</td>
</tr>
<tr>
<td>The reputation of humanitarian organization and the organizational culture</td>
<td>45</td>
<td>58.4%</td>
<td>12</td>
<td>15.6%</td>
</tr>
<tr>
<td>The unpredictable conditions in the field</td>
<td>26</td>
<td>33.8%</td>
<td>9</td>

<td>20</td>
<td>26%</td>
</tr>
<tr>
<td>The possibility (impossibility) to make a difference</td>
<td>50</td>
<td>64.9%</td>
<td>16</td>
<td>20.8%</td>
</tr>
<tr>
<td>Job security (insecurity)</td>
<td>11</td>
<td>14.3%</td>
<td>17</td>
<td>22.1%</td>
</tr>
</tbody>
</table>
The (limited) chance to help people 58 75.3% 17 22.1%
The stance of my family members 11 14.3% 10 13%
The living conditions during missions in the field 14 18.2% 21 27.3%
Salary 16 20.8% 27 35.1%
The possibility and necessity to stay busy 16 20.8% 3 3.9%
The (limited) chance to be “somebody” in the community 10 13% 1 1.3%
Fear that my family or friends do not understand my decision 1 1.3% 7 9.1%
The level of recognition of my abilities by the organization 23 29.9% 13 16.9%
The potential risks and challenges of the field work 29 37.7% 9 11.7%
Concerns that insecurity would affect my work performance 1 1.3% 10 13%
Fear of being socially alienated upon returning back home 6 7.8% 14 18.2%

As obvious, these factors do not affect the motivation both negatively and positively with the same extent. The fact that factor ‘the possibility and necessity to stay busy’ positively affects motivation of logisticians is in compliance with statements of respondents that they ‘perceive their previous job as routine and boring’ one. Participants also mentioned some other factors which positively (e.g. “to learn always new things” (P27), “the quality of the humanitarian programme” (P63)) or negatively (e.g. “…unfair treatment/unqualified leadership” (P18), “not getting the correct position in your mission” (P37), “Unprofessionalism of the organisation. Lack of qualified colleagues.” (P45), “waste, inefficiency, and poor leadership and management” (P54)) affect their motivation.

RQ2: Which factors influence the level of job satisfaction of humanitarian logisticians? The options of questions which focused on job satisfaction were defined according to Minnesota Satisfaction Questionnaire (University of Minnesota, 1977). The most important factors which positive affect the level of job satisfaction of humanitarian logisticians are ‘the chance to do things for other people’, ‘the chance to make use of my best abilities’ and ‘the relationship with my co-workers’. On the other hand, the factors ‘the way my boss handles his/her employees’ and ‘job insecurity’ negatively influence the level of job satisfaction the most. Table 5 includes the full list of factors and results.

Other factors that respondents stated, and which have positive effect on their job satisfaction are “The ability to make a difference to the lives of others and not for the purposes of making money.” (P46) or “inclusion in team settings and decisions” (P52).

On the other hand, participants also mentioned “sometimes long-term planning is missing…..even in short term mission we should have somehow a clear view for the future” (P19), “not family friendly” (P25), “arrogance of the leadership” (P48), as factors which negatively influence the level of their job satisfaction.

**H1:** The salary mainly negatively influences motivation of humanitarian logisticians and the job satisfaction as well.
As mentioned before, 16 respondents (20.8%) stated that salary positively affects the level of their motivation, compare to 27 respondents (35.1%) who stated the opposite. Other 34 respondents (44.1%) did not find any importance in the relation to the level of their motivation. In total, 14 respondents (18.2%) stated that salary has the positive impact on the level of their job satisfaction, compare to 20 (26%) who stated the opposite. The level of job satisfaction of other 43 respondents (55.8%) is not affected by salary. According to these results, this hypothesis is proven to be false.

**H2:** The organization can influence the motivation and job satisfaction of logisticians through the culture and conditions within.
The factor ‘the reputation of humanitarian organization and the organizational culture’ positively affect the level of motivation according to 45 respondents (58.4%), and negatively according to 12 respondents (15.6%). The factor ‘the policies and practices toward employees of the organizations’ positively affect the level of job satisfaction of 17 respondents (21.1%) and negatively of 21 respondents (27.3%). The influence of culture and conditions within the organizations will grow if other factors as ‘the (limited)
opportunities for career advancement', 'job security (insecurity)', 'the working conditions', 'the chance (impossibility) to try my own methods of doing the job' etc. will be included. According to these results, this hypothesis is proven to be true.

RQ3: How do humanitarian logisticians perceive their job?

The respondents also had to choose which factors make the job of humanitarian logisticians exacting and stressful. In total, 70 participants answered to this question and the results are obtained in Table 6.

**Table 6 – Perception of the job** (amended from Bjerneld et al., 2006, Imai et al., 2010, Oberholster et al., 2013, Jones and Williamson, 2014, Akintola and Chikoko, 2016; personal collection)

</tbody>
</table>

Some respondents also added other aspects, e.g. “lack of understanding of the dangers of untrained people undertaking certain types of high-risk work” (P40) or “interpersonal relations, mostly on the HQ level. Cold-heartedness of managers.” (P75) etc.

As is obtained in Table 6 above, the most exacting aspect of job of humanitarian logistician according to the respondents in this study, is the ‘level of resources (funding, human resources)’, ‘the fact that your job is never done’ or ‘the disorganized environment inside the organization’. Factors ‘the excessive workload expected by the organization’ and ‘the impossibility to combine this career with family and personal life’ have also significant importance. These factors are also reflected in the previous parts of the questionnaire. Logisticians appreciate the technical aspects of the job, they are aware of the importance of logistic operations for humanitarian projects. They welcome the unpredictability and changing environment of these projects as well as the opportunities to travel and take international assignments. On the other hand, logisticians struggle with level of bureaucracy, and processes or relations inside the organizations. Some participants stated: “abusive bossy attitudes”, “the UN is a corrupt system”, “humanitarian world is becoming a business” or “the majority of the INGOs recruitments are not based on what you know it matters who you know” (because of the nature of the statements, author did not mention the indications of respondents neither). In general, for humanitarian logisticians is very important the culture and reputation of organizations they work for.
RQ4: How does the immediate family and friends influence the humanitarian logisticians?

The linkage between motivation of humanitarian logisticians and stance of family members or friends will be described below. However, respondents stated that the separation from their family or friends led to the periods of struggling. Also, one participant P33 noted he/she struggled “due to family response”. However, one respondent mentioned that “…have family obligations, kids school fees to pay…” (P16) keep him/her involved. Specific aspect is possibility to combine this job with family and personal life. 41.4% of respondents think that ‘the impossibility to combine this career with family and personal life’ makes their job exacting and stressful. Respondent P45 mentioned that “moving with my partner and the difficulty of being separated for long periods of time” lead to struggling and that “having a husband that is also [humanitarian worker] and understands the drive, needs, etc it is easier”.

H3: The stance of family members or friends mostly negatively affect the level of motivation of humanitarian logisticians.

As mentioned before, 11 participants (14.3%) stated that ‘the stance of family members’ positively affect the level of their motivation compare to 10 participants (13%) who felt that this factor negatively affects their motivation. Other 56 respondents (72.7%) did not choose this factor. On the other hand, only one respondent (1.3%) perceive the influence of factor ‘fear that my family or friends do not understand my decision’ positive compare to 7 participants (9.1%) who perceived the influence as negative one and 69 participants (89.6%) who did not perceive any influence. Also, 14 participants (18.2%) stated that ‘fear of being socially alienated upon returning back home’ negatively influence the level of their motivation, compare to 6 respondents (7.8%) who stated the opposite and 57 participants (74%) who did not choose this factor at all. According to these results, this hypothesis is proven to be false.

Conclusion

The presented research is still ongoing. The author would like to involve higher number of respondents, especially from national non-governmental organizations or local workers. However, the obtained data evince the degree of consistency. Respondents stated similar reasons why they have decided to join humanitarian sector, why they struggle or factors which keeps them involved. Their answers are also similar and comparable with answers of other humanitarian workers examined in previous research.

Author would like to examine the gained data through regression analysis more deeply, examine the reactions on statements of respondents, and compare it with previous research. However, this paper does not provide enough space for this analysis. The factors which affect the motivation and job satisfaction of humanitarian logisticians can be divided into two groups. The first group includes factors which organizations cannot completely influence, e.g. the unpredictability, the stance of family member or friends of logisticians, the disorganized environment or pressure in the surrounding of the organization etc. On the other hand, organization can influence factors as working conditions, the stance of managers, the job security, the pressure and disorganized environment inside the organization etc., and these factors affect well-being of humanitarian logisticians in significant degree.

The results also show that logisticians are driven not only by their will to help people, but they also want to gain new work or international experience and they reflect the possibilities for career advancement. This is necessary to reflect because human resources are crucial for humanitarian operations. Also, according to Kovács and Moshtari (2018),
the research should be motivated by practical problem. During the data collection, HR and logistic specialists stated the important of examination of the motivation and job satisfaction together with fact that turnover is a big problem for them.

Acknowledgments

The author would like to express her gratitude to all organizations and respondents for their time, willingness, sincerity, and kindness. The author would like to thank Marek Prokůpek for his comments which greatly improved the paper. The research project is financed by the University of Economics, Prague.

Abstract

This paper provides insight into the context of coopetition among organisations in the humanitarian supply chain (HSC). Through the use of 44 semi-structured interviews, the study identifies various strategies used by humanitarian organisations to develop “swift trust” between those operating in the HSC, thereby improving the performance of the entire supply chain. A number of barriers to swift trust development in HSCs are also identified. A significant finding from this study is that while developing swift trust is possible within HSCs, short-term swift trust can quickly develop into longer-term distrust if humanitarian organisations do not manage their activities carefully.

Keywords: Humanitarian supply chains, Coopetition, Swift trust

Introduction

Humanitarian supply chains (HSCs) operate in a complex international environment and must link diverse actors across national boundaries and cultures (Kovács and Spens, 2007; Day et al., 2012). Against a backdrop of high uncertainty, limited institutional learning, and a lack of local infrastructure and funding, HSCs work to save lives and improve wellbeing during or following disasters (Tomasini et al., 2009; Day et al., 2012). These goals are achieved by developing cross-sector relationships with different actors (e.g. governmental, military, other non-governmental and private organisations) to harness their respective competencies and resources (Stadtler and Van Wassenhove, 2016). Managing these relationships is difficult, as actors need to develop a level of trust to facilitate coordination relating to humanitarian relief, whilst also competing for scarce resources (e.g. donations) and media attention (Van Wassenhove, 2006; Kovács and Spens, 2010). This environment can lead to coopetition; collaboration between competitors for mutual benefit (Stadtler and Van Wassenhove, 2016). To facilitate coopetition in HSCs, the notion of ‘swift trust’ is a key consideration; a phenomenon by which relationships are developed quickly in pursuit of a common goal (Tatham and
Kovács, 2010). An understanding of the coopetition phenomenon, particularly the logic behind these unique relationships, may help humanitarian organisations to tailor their partnership and coordination strategies to better meet the needs of beneficiaries. However, the empirical evidence for coopetition in the context of HSCs is underdeveloped.

By drawing on the theory of coopetition, we present the results of a multiple case study analysis to explore coopetition and discuss its implications for HSCs. Thus, the study aims to contribute to both HSC and coopetition literature by addressing the following research questions:

RQ1: What does coopetition look like in cross-sector relationships within HSCs?
RQ2: How does coopetition influence complexity in HSCs?

Literature Review
While our understanding of traditional commercial supply chains has improved significantly over the past 25 years, with established bodies of literature in areas such as information transparency, collaboration, and performance management (Delen et al., 2007; Ramanathan et al., 2014; Bendoly et al., 2007), HSCs have only recently become a recognised field of research. As a result, we have far less understanding of their operations when compared to their commercial counterparts.

Several key barriers to successful HSCs exist. The most obvious challenge is the time, location and magnitude of a disaster; these things are difficult to predict, and as a result the majority of disasters occur with very little warning (Oloruntoba and Gray, 2009; Tatham and Spens, 2011; Whybark, 2007). Those operating within HSCs often have limited information as to how many people will be affected by the disaster, and where those people are likely to be located during and after the disaster strikes (Heaslip et al., 2012; Scholten et al., 2010). Supplier relationships, inventory management and quality management (all of which are comparatively simple to manage and maintain in a relatively stable commercial environment) become almost impossible to efficiently manage in HSCs (Beamon and Balcik, 2008; Ilhan, 2011; Maon et al., 2009), especially when damaged infrastructure in the affected area can lead to a sheer lack of transportation options (Fawcett and Fawcett, 2013; Jahre et al., 2009; Pettit and Beresford, 2005).

Despite the need for highly accurate information in order to make key decisions within a short space of time (Yates and Paquette, 2011), most decisions in the field must be made using information that is incomplete or highly inaccurate (Maon et al., 2009; John and Ramesh, 2012; Perry, 2007). This lack of accurate information leads to uneven distribution of aid (Perry, 2007) and high levels of frustration among beneficiaries (Tapia et al., 2012). Information systems used throughout HSCs are also incompatible (Yates and Paquette, 2011; Overstreet et al., 2011), with tight budgets compounding this issue as humanitarian organisations are reluctant to invest their hard-earned capital in sophisticated technologies or unable to do so because of earmarked donations (Maon et al., 2009; Scholten et al., 2009). High staff turnover due to the stressful operating conditions is commonplace in organisations responding to disasters, with some scholars suggesting that this is as high as 80% on a yearly basis (Sheppard et al., 2013; Tatham and Spens, 2011). As a result, humanitarian organisations struggle to replace the significant experience that is lost when these individuals leave (Chandes and Pache, 2010; Tomasini and Van Wassernhove, 2009), leading to a widely held view that there is a serious skills shortage in the field (Akhtar et al., 2012; John and Ramesh, 2012).

Resources are also a challenging issue, with humanitarian organisations having to raise large amounts of funding in a short space of time once a disaster has occurred (Chandes and Pache, 2010; Oloruntoba and Grey, 2006). Donations are highly unpredictable (Day
et al., 2012; Tomasini and van Wassenhove, 2009), and donors wield significant power over where their donations should be spent (Pettit and Beresford, 2009; Sheppard et al., 2013). Finally, and perhaps most importantly, competition between humanitarian organisations is fierce (Herlin and Pazirandeh, 2012; Oloruntoba and Gray, 2006), with each organisation having to emphasise their own contribution, leading to self-interested behaviour (Fawcett and Fawcett, 2013). Competition for media coverage in particular becomes increasingly intense, with media attention likely to increase the amount of donations these organisations receive from the potential donors (Wakolbinger et al., 2013; Van Wassenhove, 2006).

Coopetition and Swift Trust

One method of overcoming these resource issues is the concept of coopetition. Coopetition is the concept of organisations cooperating with other organisations whilst simultaneously competing with them; a common form of such an act would be sharing knowledge with your competitors whilst attempting to use said knowledge to outperform them (Tsai, 2002). This relationship is well understood by all parties and is not seen as a “devious” alliance but more of a method of absorbing the skills and knowledge of other organisations in an attempt to improve the efficiency of the entire supply chain (Hamel et al., 1989). Research has shown that such relationships can offer organisations numerous benefits such as increased knowledge flows into the organisation (Tsai, 2002), increased access to key resources (Gupta et al., 1999), increased technology adoption and market expansion (Lado et al., 1997), and increased supply chain resilience (Bakshi and Kleindorfer, 2009), all of which would be useful for humanitarian organisations.

Many methods of coopetition exist, but one method that has gained significant interest within HSCs is that of “swift trust”. Swift trust was first identified as a potential concept of interest in the HSC field by Tatham and Kovács (2010) who suggested that while commercial supply chains have the luxury of growing trusting relationships between organisations over a period of time, HSCs are effectively “hastily formed networks” and therefore do not have the time to create the high levels of trust between actors that are required for strong team performance. Their argument was that the concept of swift trust can be applied to HSCs if certain conditions are met; firstly information must be shared freely between the various actors within the HSC. Secondly, employees of all organisations within the HSC should be encouraged to change their mindset, allowing them to become more trusting of others. Thirdly, rules should be put in place and adhered to so as to prevent “maverick behaviour” of any HSC actors. Fourthly, organisations should seek to increase the dialogue and understanding between themselves, so as to minimise any biases or preconceived ideas of how others will act in certain situations. Finally, all humanitarian organisations should attempt to increase their employee competencies (via training and formal qualifications) so that others will trust that they are dealing with professional individuals who “know what they are doing”.

Following on from this study, Hyllengren et al., (2011) identified factors impacting on swift trust within the military setting, while Curnin et al., (2015) found that clarifying actors’ roles is highly important for the effective development of swift trust. Perhaps most significantly, Lu et al. (2018) empirically showed that swift trust leads to improved coordination effectiveness within HSCs; they found that being introduced to another actor in the HSC by a trusted third party can increase swift trust, while having similar rules, procedures, and organisational values can also increase swift trust development between humanitarian organisations.
Methodology
This study was conducted utilising a case study methodology, due in part to the extensive support for such a method in operations management research (McCutcheon and Meredith, 1993; Voss et al., 2002). According to Yin (2014) a case study is “an empirical enquiry that investigates a contemporary phenomenon within its real-life context” (p. 14). In this study, the unit of analysis was a particular event (i.e. a natural disaster) rather than a particular organisation or person (Bryman, 2012); the 2 case studies used for this research were the Haiti earthquake of 2010 and the Pakistan floods of 2010. Haiti and Pakistan were highlighted as two natural disasters in the same year that resulted in very different responses from the international humanitarian community.

The semi-structured interview approach was selected as interviews are the most widely employed qualitative research method in general (Bryman, 2012) and are among the preferred research methods of logistics researchers (Larson and Halldórsson, 2004). Interviews are also the most commonly used method associated with case study research (Yin, 2009). A broad interview guide was used to guide the interviews (as recommended by Bryman (2012) and Easterby-Smith et al. (2012)) but departures from this guide were encouraged during the interviews. In total, 44 semi-structured interviews were conducted using a combination of theoretical sampling and snowball sampling. The aim was to interview actors in a variety of roles within humanitarian organisations that might not necessarily be described as logisticians or supply chain managers (e.g. pharmacists in charge of stock-keeping and ordering medical supplies). The selected interviewees worked both in agency headquarters and in the field, as well as in a range of organisations, which provided a rich and varied picture of the humanitarian context. The interviews were recorded and the transcripts were entered into NVivo for data analysis, as recommended by Fielding and Lee (1991) and Kelle et al. (1995). Data coding followed the recommendations of Corbin and Strauss (2008) and Saldanha (2016) whereby the codes initially emerged from the extant literature, before going through a 3-stage cycle whereby emergent themes were discovered from data (Miles and Huberman, 1994).

Findings
Data analysis reveals a dynamic paradox inherent in coopetition in HSCs, indicating that cooperation and competition exist simultaneously among humanitarian organisations. There are clear parallels to previous work on multi-company, commercial/humanitarian cross-sector partnerships (Stadtler and Van Wassenhove, 2016). While details vary, many of the codes and dimensions evident in the 2016 study have been found in the current dataset, particularly Tensions, Behavioural Responses, and Task Context. However, there was limited evidence of the dimension of Organisational Context as humanitarian organisations represented in the sample had little to no formal rules in regard to coopetition behaviour and there was no evidence of top management messages on the matter, or clear training and mentoring. While interviewees in the 2016 study exhibited Paradoxical Frames through developing nested identities or segmentation of their cooperative and competitive roles, there was no clear evidence of this in the present study.

The results are now presented under the headings of tensions, behavioural responses, and task context below. Interviewees’ are anonymised and only the participant number is given after each quotation in order to protect their identities.

Tensions
Corporate profiling
Interviewees described a highly competitive landscape where “every organisation wants to be seen as leading the way” (#32) resulting in an inherent distrust in many humanitarian agencies, particularly less established ones who are seen to be lacking essential expertise and networks. Nevertheless, interviewees acknowledged that trust is desirable as “a lot of projects across all agencies need the same things and if we could collaborate more, that would be easier” (#37).

Knowledge sharing
The UN Logistics Cluster as an attempt to facilitate formation of trust was largely derided amongst interviewees who felt “it doesn’t organise anything, it’s just another way for people to feel important” (#32) and “you’re just literally going round in circles saying the same thing every meeting” (#8). This was particularly evident from organisations that perceived themselves as being advanced in their logistics performance who felt “it’s not necessarily advantageous for us, but it can be advantageous for the others” (#13). Smaller or newer organisations were trusted the least, with some suggesting “only those agencies with operational experience and a proven record in the sector should be involved in cluster meetings” (#44).

Role conflicts
Several participants described the operational context as a “project environment” (#20). This was emphasised because of its implications for the longer-term operations of humanitarian organisations, as interviewees felt they went “from one project to the next and no continuity” (#4) and that “it looks like we are doing a lot of firefighting.” (#9) Interviewees stressed that this leads to a management approach that lacks consistency and clear, achievable performance targets for individuals as well as on an organisational or interorganisational level. Concerns were raised that this attitude is “not necessarily focused on the long-term improvement of the process” (#5) and as such might encourage a more competitive nature than what would be most beneficial. The planning horizon is typically severely constrained with priority being given to quick fixes rather than overall optimisation.

Behavioural Responses
Integrating
Building trust with the local population was regarded as essential and failure to do so cited as showing “how the international aid industry [...] can create even more of a disaster” (#27), particularly in Haiti. “Collaborating and developing something together” (#38) was also seen as culturally sensitive, highlighting an important dimension of trust in HL. Particularly in areas that have seen much humanitarian aid over the years, there is an awareness of the quality differences and a wariness of the intentions of the incoming organisations, so it is essential “to prove [...] we’re not fly-by-nights, we’re not going to come and go” (#8). Many organisations seek to facilitate that trust by including beneficiaries as committee members or in similar roles, particularly for continuity and sustainability, acknowledging that “requests from the local community change” (#18).

Seeing that there is strong competition and much distrust, many organisations bypass the issue of building swift trust by attempting to build long-term relationships. This can take the form of long-term engagement in a region, which can result in preferential treatment like an organisation that had been “working in the country for 25 years at the time of the earthquake [...] were able to get pretty much blanket authorisation to import [...] because we were trusted” (#35). Another area are global sourcing contracts with trustworthy partners that provide appropriate quality and quantity when needed.
Demarcating
Any form of working together “gets political very quickly” (#11), indicating that swift trust is not developed sufficiently, as “it’s important for every organisation to get a foot in the door, on their own, with their logo on it” (#42). This is particularly pertinent in humanitarian responses that engender a significant media presence, such as Haiti, which makes it essential for individual organisations to have their presence noticed as part of wider competitive agendas in terms of donations. Interviewees confided that such competitive elements can overshadow cooperation in favour of raising the profile of individual institutions— “There is so much arrogance... They all have to be seen to be pissing on all the trees” (#11).

Task Context
Other stakeholders
Humanitarian organisations face significant scrutiny, both from donors and from within the humanitarian community. Interactions with other parties are often a matter of principle. “Neutrality as a core humanitarian principle can be difficult to uphold amidst the realities of humanitarian responses, but can also be vital to operations as it is often...essential. You have to be impartial just to gain access to an area” (#42). On the donor side, not aligning humanitarian work with political priorities can mean that organisations forgo governmental donations in part or entirely. Some organisations strongly assert their neutrality, saying “we don’t work with any political parties in the country that we work in. We do work with the party that happens to be in power at that moment in time” (#19). Neutrality can be a concern in cooperative behaviours, particularly where the military is concerned and there is often an intense politicity to working with other parties: “we are probably a more political organisation than anything else” (#43). Furthermore, there is an inherent political impact of humanitarian work, whether that is as a showcase of values and material advantages of the donor countries over the host country or through lobbying and support. Cooperation can enhance both the risks and the impact achieved.

Social causes
Interviewees expressed a strong desire to improve the situation of the beneficiaries in each response. “We are all about empowering people. That’s very important for us and we engage with civil society for that” (#27). While this can be an incentive for more cooperative behaviours, it can also increase competition, as working with any external partners is seen by some as a loss of focus on the beneficiaries as “firstly you miss the neediest, because it is directed according to other priorities, and secondly, you actually make the aid itself ineffective, because the identity and perception of those who are delivering the aid becomes compromised in the mind of the recipients” (#41).

With the significant impact humanitarian missions can have on the local economy, an added level of complexity is the long-term impact the work has on the recipient country. Humanitarian organisations often directly work with and shape the practice of institutions like the national health service, the ministry of education or the ministry of agriculture. There is clear evidence of an intense awareness of the longer-term impact of their operations. While timely emergency response was important, respondents described a quick transition into setting up projects that were developed to have a sustainable impact on the local economy and highlighted that they had to balance immediate response “with support of local agriculture and economies as well, because potentially the amount of
“food we could buy could be a really big support to the local agricultural and economic system” (#28).

Furthermore, many organisations are advocates of societal change, but also acknowledge that cooperation with local stakeholders can hamper this. “we will speak out about issues we encounter and often we will be the first to tell the rest of the world what is happening. That has retributions... It is not always possible to speak out. You have to balance if we’d do more good drawing attention to an issue” (#42).

**Discussion and Conclusion**

The goal of cooperation is problem solving and value creation by uniting different actors’ competencies and resources. HSCs require actors to work together and develop a solid level of ‘swift trust’ between them, while building trust with the local population is essential, as failure to do so adds greater complexity to the HSC.

Overall, the findings show that humanitarian organisations are willing to develop swift trust within the HSC, however they are very open and honest about the numerous barriers that currently limit the degree of its development. The major barrier in this setting is that actors are still relatively wary of their “competitors” as many are still of the opinion that they have to be highly visible by being “first on the scene”, especially when there is a media opportunity that may garner additional donations from the public. One method of circumnavigating this issue could come from the donors themselves; given the level of influence they have, they could insist that their donations are used on collaborative efforts that include more than one humanitarian organisation. Another potential solution would be to force humanitarian organisations to pool their resources by using schemes such as shared appeals for donations; this way, the organisations are not only cooperating with their competitors, but they are also potentially increasing the amount of donations they are likely to receive.

Although swift trust has been acknowledged as desirable, humanitarian organisations also face conflicting organisational interests in a competitive setting, resulting in the phenomenon of ‘swift distrust’ in many humanitarian organisations, particularly less established or smaller organisations that are perceived as lacking essential expertise and networks. Similarly, the ‘swift trust’ that is built up between the humanitarian organisations and the beneficiaries can quickly and easily be eroded if promises are broken. In this sense, coopetition in HSCs appears as a dynamic phenomenon. That is, short-term ‘swift trust’ quickly develops into longer-term ‘swift distrust’. In recognising that there is strong competition and much distrust, the findings highlighted that participants were bypassing the efforts involved in building ‘swift trust’ by attempting to build long-term relationships. Examples of such activities included long-term engagement in a region and developing global sourcing contracts with trustworthy partners that provide appropriate quality and quantity when needed. This is an interesting finding as it suggests that humanitarian organisations may feel that ‘swift trust’ can only develop their relationships so far; rather than wasting time developing ‘swift trust’, these participants seem to want to develop lasting, long-term relationships from the get-go.

The findings also highlighted some methods being used by humanitarian organisations in order to increase ‘swift trust’; many organisations seek to facilitate ‘swift trust’ development between themselves and beneficiaries by including the beneficiaries in official roles, particularly for continuity and sustainability purposes. Not only does this make the beneficiaries feel that their opinions are being listened to (and that the humanitarian organisations are taking their situation seriously), the increased transparency allows the beneficiaries to understand exactly what is going on in the relief operation, thereby taking ‘swift trust’ to the next level and creating stronger bonds.
between the humanitarian organisations and the beneficiary community (particularly when humanitarian organisations are working in the area for long periods of time).

This study has increased our understanding of the prevalence of coopetition in cross-sector relationships as well as the implications for HSCs. The study adds to the extant literature on HSCs by highlighting the dynamic paradox inherent in coopetition in cross-sector relationships. To promote ‘swift trust’, humanitarian organisations could, for example, include beneficiaries as committee members. At the same time, they also need to be aware of the fact that they are still competing with each other, a fact that could quickly lead to ‘swift distrust’. Furthermore, these organisations should take heart that it is possible for them to go beyond the short-term ‘swift distrust’ phenomena to build effective long-term relationships, as long as they approach these relationships in the correct manner. This research also has implications for how humanitarian organisations can better tailor their partnership and coordination strategies in disaster relief operations, an important area for further work.

Future research in this area should look to further understand the relationship between ‘swift trust’ and ‘swift distrust’, in particular the activities currently being adopted by humanitarian organisations in order to maximise trust and minimise distrust. Another avenue for future research would include investigating the different models of coopetition used by the various non-governmental organisation (NGOs) operating in HSCs, as well as their opinions on how effective they believe such models are. Data collection in this field is very difficult, especially given the extreme conditions these organisations have to operate in. But if we are serious about increasing our understanding of this field to match our understanding of traditional, commercial supply chains, gaining the opinions of those in the field is of the utmost importance.

Abstract
This study identifies the main characteristics of value co-creation within the humanitarian setting, analysing the key factors that enable value co-creation of professional service providers, working with beneficiaries for long-term integration programmes. The practices of co-creation are analysed and the perception of both actors are explored to determine key factors which influence the value co-creation process. Given the novelty of the subject and its intrinsic characteristics, we conducted a qualitative study through a case study. The findings of the research clearly show that the success of the programme, namely the achievement of the full integration of the beneficiary into the society, not only depends on the trust, self-motivation, cultural background and education of the beneficiary, but also on her/his level of commitment, interaction and participation with the professional service provider during the design and delivery of the service.

Keywords: Humanitarian Supply Chain, Value Co-Creation, Professional Services.

Introduction
Indisputably, the rise of the Mediterranean migration phenomenon poses new challenges to traditional integration mechanisms and processes of welcoming and reception. From 2015, more the one million refugees, migrants and asylum seekers arrived by sea and landed to the south of Europe (Greece, Italy, Malta, Spain and Cyprus) (UNHCR, 2019). This phenomenon has driven policy makers and scholars to define structured plans for beneficiaries’ integration (referring to refugees, asylum seekers and any kind of people who need to socially integrate themselves into a host country) through improving the long-term integration programmes (L-TIPs) within the recovery phase of the humanitarian supply chain. L-TIPs are measures, often funded by governments, aim at ensuring the social, professional and economic integration of both migrants and refugees within the society. Through L-TIPs beneficiaries can access different professional services such as interpretation and linguistic-cultural mediation services, legal counselling, teaching of the hosting Country’s language, health assistance, socio-psychological support, counselling on the services available at local level, as well as information on recreational, sport and cultural activities. However, L-TIPs are often falling short in achieving the desired outcome, i.e. the refugee integration. Furthermore, satisfy beneficiaries primary needs and delivering professional services to them is not sufficient in order to fully achieve the social integration goal; a real “welcoming” attitude and context by the hosting community is
strongly required to support and encourage beneficiaries to achieve long-term stability. Thus, services that are delivered to beneficiaries need to be properly designed to foster the integration process in a more effective way. L-TIPs involve organisations that increase the real value of the professional services they are delivering to beneficiaries, where the real value means they reach social integration.

Previous studies in the area of humanitarian operations management have mainly focused on logistics aspects of disaster relief operations that deliver first aid and restore basic conditions (Galvagno and Dalli, 2014; Kovacs and Moshtari, 2018; Kumar and Kushwaha, 2018; Seifert et al., 2018). However, the specificity of the humanitarian crisis related to the refugees’ integration within the European society asks for a deep investigation of other operations management aspects; namely not those related to the basic services for refugees’ survival but those related to the professional services delivered within the L-TIPs.

In sum, one of the main challenges in facing the Mediterranean migration humanitarian crisis is to improve the success and the effectiveness of refugees’ integration programmes; while dealing with this important social challenge, this research wishes to contribute to the literature on value co-creation, in the area of professional services. Specifically, we will try to understand how the professional services, which are aimed at fostering the integration of beneficiaries within the hosting country, are designed and delivered; also, to understand the mechanisms underlying value co-creation processes of service design/delivery in the humanitarian context. Our research questions are:

*RQ1. Do humanitarian professional services’ providers co-create value with and for beneficiaries in the context of refugees’ L-TIPs. If yes, how?*

*RQ2. What are the enablers of beneficiaries’ participation and commitment in the value co-creation process?*

In what follows, we introduce a few theoretical concepts and background where we anchored to for conducting the case study presented in this paper.

**Theoretical foundation**
Coherently with the aim of this study, in order to frame our research within the operations management literature, we briefly analysed three literature streams: humanitarian operations and supply chain, professional services operations management, value co-creation in service operations.

**Humanitarian Supply Chain and Operations**
According to Seifert et al., (2018) providing assistance to vulnerable people is the core of humanitarian supply chain management. The humanitarian supply chain is composed of five phases: mitigation, preparedness, immediate response, reconstruction and recovery (Abidi et al., 2013; Haddow et al., 2018). The mitigation and preparedness phases aim to avoid the impact of a disaster with a strategic vision, establishing an adequate regulatory framework to manage the emergency in the disaster management cycle, impeding the reoccurrence of a disaster and/or to prevent it. The immediate response phase is characterised by short duration, high urgency and large uncertainty, thus entailing operations management challenges such as efficient purchasing, logistics of in-kind donations, etc. The reconstruction phase deals with the immediate disruption, damage, and other effects of the disaster (Asian Development Bank, 2004). The last phase, the recovery, tends to satisfy the main need of the victims to restore basic conditions. In the human migration crisis context the recovery phase includes long-term
integration programmes (L-TIPs) that differ from recovery programmes aim at restoring basic condition immediately after the emergency in other humanitarian contexts. In fact, the L-TIPs enable new opportunities to integrate beneficiaries in the local context for a new start in a hosting country. While, usually, the response phase and the recovery phase provide rescue operations and restore basic conditions and immediate needs, the L-TIPs focus on the effective integration of beneficiaries into the host country by delivering professional services such as educational support (e.g. language courses, counselling, education, vocational orientation), social support (e.g. assistance in entering labour market and legal support) healthcare and specialised services (e.g. women at risk, children at risk). In other words, the aim of L-TIPs trough their professional services, is enabling beneficiaries starting a new life in a new country and not restoring their basic conditions.

**Professional Services Operations Management**

In Operations Management literature professional services are defined as generic service types characterised by a high level of knowledge, with high levels of customer contacts consisting in flexible processes with low capital and high labour intensity (Schmenner, 2004; Lewis and Brown, 2012). Despite the wide range of diversity and application domains, professional services are commonly characterized by a high degree of ongoing interactions, interpersonal communications and organizational/personal relationships (Patterson, 2016; Bagdioniene and Valkausiene, 2018). Moreover, professional services are characterized by the ability of professionals to receive information from customers and transform this information into useful services (Baltova and Baltov, 2017). Consequently, they consist on complex operations and the performance depend on the tasks’ outcome of both customers and professionals (Damali et al., 2016).

In the L-TIPs context, the main aim of professional services is to support beneficiaries on their integration, offering services that could allow them to increase the quality of their lives through their integration into the local context. During interaction between customer and professional, various form of tacit and explicit knowledge and personal attitudes are constantly mixed, redefined, linked and enriched from both parts. It is also particularly emphasised the “guiding, nudging and persuading” of professional employees rather than the implementation of standard operating procedures and, of course, customers play a critical role because their presence is a necessary and sufficient condition to define a production process as a service process (Sampson and Froehle, 2010).

Prior studies on business professional services focused on the role of professionals as a primary source of value co-creation, ignoring customers role, form of involvement and participation (Damali et al., 2016a). Human relations in these types of services, and especially in the humanitarian setting, influence the design of processes and consequently the outcomes.

**Value co-creation in service operations**

Value co-creation has become a central theme in service management and marketing literature (Grönroos and Voima, 2013; Galvagno and Dalli, 2014; Vargo and Lusch, 2016). Although many scholars have focused on the study of co-creation process and have developed systematic approaches to service innovation, the concept of co-creation is still not clearly identified (Yu and Sangiorgi, 2018). Indeed, according to Oertzen et al. (2018), there seem not to be a shared and accepted definition about “co-creation” in services design. In few words, the idea of co-creation is to bring something into existence as a result of often coordinated actions or processes and could be considered as important manifestation of customer engagement, resulting from motivational drivers (van Doorn et al., 2010; Galvagno and Dalli, 2014). In sum, it is a joint, collaborative and peer-to-
peer process where both customer and provider integrate their own resources (Prahalad, C.K. and Ramaswamy, 2004; Galvagno and Dalli, 2014; Bagdoniene and Valkauskiene, 2018), but it is also influenced by the emotional, cultural and relational experience of the customer (Grönroos and Voima, 2013; Mustak, Jaakkola and Halinen, 2013; Yu and Sangiorgi, 2018) and of course involvement and participation seem to be necessary prerequisite-forms for the co-creation of service to occur (Oertzen et al., 2018). Thus, value co-creation could be considered as a paradigm describing how providers and customers are involved, like active and participant actors, in the design and development service (Prahalad and Ramaswamy, 2004), where motivational drivers seem to be key elements to reach personal, cognitive and social benefits (Oertzen et al., 2018). Service value co-creation research tends to focus on the customer's role (Damali et al., 2016a) and has not yet been specifically examined in the context of humanitarian organisations. In this context, however, the specificities of the customers (refugees), the complexity of the delivered services, the priority of designing and delivering effective services (i.e., reaching the refugee’s integration goal), the need of actively involving the refugee and the other stakeholders for creating real value, make the exploration of value co-creation very interesting.

**Research methodology**

Being the empirical context under investigation specific and multifaceted and given the exploratory nature of the study (Voss, Tsikritsis and Frohlich, 2002) the research was conducted using qualitative methodology in the form of case study. The qualitative methodology is appropriate when the researcher wants to understand comprehensively a less-investigated topic and the case study strategy is justified by the non-conventional nature of the environment (Eriksson and Kovalainen, 2015; Bagdoniene and Valkauskiene, 2018) apparently characterized by a form of closing attitude to the external elements. The case study strategy with an outgoing and kindly approach helped authors to break down current barriers, allowing and building a basic trust relationship between professional service provider’s operators (mainly lawyers, medical doctors and cultural-linguistic mediators) and beneficiaries. Furthermore, the case study method is also justified by the goals of this research, providing a deep insight about the concept of value co-creation and the main factors enabling value co-creation.

The case study focuses on a professional service provider (PSP) working into the humanitarian field. The case location (Sicily), as well as the participants, were chosen using selective sampling (Teddle and Yu, 2007). The location was suggested by the presence in this geographical region of a diffuse reception system due to the geographical centrality of Sicily within the Mediterranean human migration flow. The selected PSP, named Centro A, offers a complex services portfolio aimed at refugees’ integration. It helps beneficiaries by delivering a list of professional services, starting from welcoming to health screening, language lectures, legal assistance, job placement assistance, cultural mediation, after-school child care to psychological assistance. Data have been collected between October 2018 and January 2019. In that period, the authors visited, deeply observed, attended at events, wrote personal notes during their visit and planned and conducted semi-structured interviews with directors, cultural-linguistic mediators, professionals and volunteers, as well as beneficiaries of these services. Authors also invited the organisation to contribute in the research. Two different research protocols, one for beneficiaries and the latter to PSP’s operators were drafted. Specifically, authors conducted and recorded semi-structured interviews with 1 director, 4 professionals, 2 cultural-linguistic mediator and 4 beneficiaries, lasting from 20 to 70 minutes. The recorded interviews were transcribed and analysed with the qualitative data analysis
software ATLAS.ti. Authors performed the coding activity through labelling raw data, organising them into a pattern of concepts and categories with the respective proprieties (open coding), then connected categories, sub-categories and dimensions (axial coding), finally selecting core category and systematically relating them in other categories (selective coding).

Additionally, authors analysed the engagement approach and the perspectives used by PSP’s operators during their interaction with beneficiaries. As Dabhilkar et al., (2016) suggest, studying and observing processes, as constituted by various practices, may help to develop a deeper understanding. Consequently, a case study research approach results as suitable method for attaining as much information as possible from operational activities and tasks for the purpose of exploration (Voss, Tsikritksis and Frohlich, 2002). The study allowed authors to absorb tacit knowledge about the phenomenon from the perspective of their experience.

Case analysis
While the literature recognizes that in professional services, significant customer participation is required in order to co-create value, the mechanisms through which this is practically obtained need further investigation (Damali et al., 2016). Human relations in professional services influence processes and consequently the outcomes (Jaakkola and Alexander, 2014). This is mainly due to the interaction between the provider and its customers, basically given by the high heterogeneity of the offered services and the high level of customization required. After analysing data and interactions between PSP’s operators and beneficiaries, different key factors emerged as crucial to facilitate value co-creation process. Some factors are often related to beneficiaries’ self-motivation and cultural background, others due to the PSP’s operator attitude and capability that could have a different impact on enabling value co-creation processes. In additional to, others are related to the service design sphere.

Factors enabling value co-creation
The value co-creation process, at Centro A, starts getting beneficiaries involved for a first meeting. One of the PSP’s operator explains the beneficiary how he/she could be involved in the activities of the centre and which types of services will be offered. In order to understand beneficiaries’ needs and provide customized professional services the PSP allows interactions with each beneficiary. Before to understand the main needs and the goals that each beneficiary wants to reach, it is crucial to build trust and build a personal relationship with each beneficiary:

<… they have recently landed…. let's say, they are muddled people who have no idea about their rights, their needs... thus in that status, they don't really know what they have to do, where they have to go, they need to trust in someone…> (PSP’s operator A);
<… If they do not trust in me, my work becomes complicated. I am not able to exactly translate what they need to. But once trust is established, they can communicate …> (PSP’s operator B).

Even from the beneficiaries’ point of view, trust is recognized as a primary factor to allow participation during the value co-creation process:

<… for me trust is important, I feel supported…> (Beneficiary A);

Thus beneficiaries could uncover their needs:
<… once trust is established, they can communicate us their problems…> (PSP’s operator A).
<… we always start from the personality of the guys, to understand what their experience is, let’s take stock of the skills to understand what their experience is…> (PSP’s operator C).

Despite trust is recognised as a primary element from both PSP and beneficiary perspectives, it is reached by an empathetic and open approach in addition to fairness, relational capability and continuous interactions. Often these interactions are stimulated by the PSP’s operator in order to involve the beneficiaries in meetings and events with other stakeholders. In other words, having the beneficiary engaged in the process is not always obvious and the operator has to encourage the beneficiary interaction in order to build trust thus to make her/his needs and desires come out:

<… what we do here is to hear each beneficiary stimulating their interaction, we undercover their needs speaking, if they are looking for a job or want to go away…> (PSP’s operator B);
<… Sometimes you try to involve them for example going to the cinema, during the spring we go with them to see the botanical garden, also to make him understand where they are, in which context and we understand if our professional services match their needs…> (PSP’s operator C).

Moreover, certainly the level of beneficiary’s language and communication ability, but also her/his cultural background and relational attitude influence the intensity of the interactions with the PSP’s operator and their participation and commitment during the value co-creation process. In fact, some of them do not like to get involved either for lack of self-motivation or because he/she does not want to integrate into the hosting country:

<… the relationship with these people is not simple, some of them want to go away from the hosting country, they are subjected also to the pressure of their families…> (PSP’s operator B).
<… usually depends on the predisposition of the beneficiary and their cultural background, the socio-economic context…> (PSP’s operator C).

Apart from the PSP’s operator skill and ability to enable interactions and consequently build a trusted relationship with the beneficiary, other service design aspects of the PSP emerged to be as crucial in the value co-creation process. The first aspect is related to the number of beneficiaries that directly interact with the PSP’s operators. Indeed, according to some of the operators, working with a single beneficiary or interacting with a small group of them in a family-like dimension force beneficiaries to communicate and interact with them and also increase interaction with locals outside their community, thus mainly exploring the context. This service design dimension allows providing better services:

<… the advantage of working on small numbers allows us to achieve a better service…> (PSP’s operator A).
<… working on small numbers, this is the winning thing, working creating a relationship with people…they are integrated when they know how the local system works, they know who they can ask for help, they know where to go if they need a postal service… they must enter in a critical condition to be able to struggle> (PSP’s operator D)

Another element of the provider organization concerns human resources’ expertise and capabilities. Indeed, the researchers noted some elements such as participation and
customers’ commitment are pushed by the expertise and capabilities of the PSP’s operators:

<… We seek to be promoters of opportunities to exchange, to try to promote the individual, the individual in a social context that is not his community…> (PSP’s operator C);
<… Integration means maintaining own identity, exploring their reality, understanding their uses, customs, working to involve them peacefully and continuously…> (PSP’s operator D).

Discussion
This case study sought to comprehend the characteristics of the value co-creation processes within a third sector organisation that provide professional services to beneficiaries into the humanitarian L-TIPs. Baltova and Baltov, (2017) suggested that the concept of value co-creation was considered like a necessity than a choice for business oriented organization and could be beneficial for all engaged parties in many ways. As this case study shows, into the humanitarian setting, value co-creation seems to be a clear choice to find beneficiaries’ participation and their commitment in order to deliver better professional services, potentially increasing the probability of their integration.

Centro A offers a vast list of professional services aimed at fostering the integration and inclusion of the beneficiaries in the local context. These professional services range from healthcare, legal, education and job placement requiring extensive customer inputs and interactions to be successful and effective towards the final objective, which is the beneficiaries’ integration. While the professional service literature recognizes that significant customer participation is required in order to create value, the mechanisms through which this is practically obtained needs further investigation (Damali et al., 2016).

The main findings of the case research are: 1) trust is a basic element to enable participation during the value co-creation processes; 2) trust is enabled by a continuous interaction between PSPs and beneficiaries; 3) interaction depends both on self-motivation, personal attitude, cultural background of the beneficiary and on interpersonal skills, experience, availability and capabilities of the PSP’s operator; 4) the service design sphere could affect the service quality.

Already past studies have revealed trust seems to be a key factor to enable value co-creation processes (Aarikka-Stenroos and Jaakkola, 2012; Damali et al., 2016a; Kohtamäki and Partanen, 2016; Bagdoniene and Valkauskiene, 2018), this also emerged in our case study. Howden and Pressey, (2008) state trust is an interaction driver, and fairness and capability are important sources of value in professional service relationships. Correspondingly, Strokosch and Osborne, (2016), observed that building trust is important both for consumer and service provider in business-oriented context. Nevertheless, trust is crucial to build a personal relationships with beneficiaries to ensure their participation into the value co-creation processes. These insights lead to the following proposition:

**Proposition 1:** Humanitarian professional service providers, by building empathetic and open approach relationships with their beneficiaries (in addition to fairness and relational capability) increase their participation and commitment during the value co-creation processes.

Furthermore, interaction is the first enabling element to allow trust. Interaction is a mutual action getting involved parties in each other’s practices. Many scholars (e.g. Prahalad and
Ramaswamy, 2004; Grönroos and Voima, 2013) claim that the use of interaction is the crucial element to enable value co-creation, thus identifying value as a function of interaction between operators and beneficiaries (Grönroos and Voima, 2013). In the humanitarian context the following proposition could be propose:

**Proposition 2:** The level and intensity of interaction with beneficiaries increases when the humanitarian professional service provider organizes regular meetings and events with local society: this will help the beneficiaries feel part of a wide community.

Most of the times interactions are pushed by the humanitarian professional service provider, this asking for a high level of adaptation (e.g., the way of communicating) with respect to the beneficiary’s cultural and educational background. Moreover, as Prahalad and Ramaswamy, (2004) suggest, “each person's uniqueness affects the co-creation process”. A humanitarian professional service provider mainly fosters value co-creation processes thanks to the engagement of individuals increasing expertise and capabilities:

**Proposition 3:** Cultural differences and educational background gap are avoided by the development of new professional skills (e.g. cultural, linguistic) and the adoption of new methods and tools of beneficiary involvement, allowing beneficiaries to start interaction.

The customer’s self-motivation is the starting point for value co-creation in professional services (Hoyer et al., 2010). Often, it is determined by the social and economic aspects of the local context (Bagdoniene and Valkauskiene, 2018). In the case study the researchers have found that beneficiary’s self-motivation often depends on the emotional pressure they have in the pursuit of a job, to support their families in other countries, and on socio-economic condition of the local context. Considering beneficiary’s self-motivation is an enabling factor of the interaction between PSP’s operator and beneficiary, the following proposition is proposed:

**Proposition 4:** Due to the main beneficiary concern, the development of a network of stakeholders could increase the ability to perform work experiences for beneficiaries while sharing more information about the local context.

The researchers found another crucial aspect related to the PSP during the value co-creation process. It is the service design dimension, intended as the number of beneficiaries that directly interact with the PSP’s operators during the participation into the value co-creation process. Indeed, working with a small group or with a single beneficiary force him/her to estrange himself from the context in which he is hosted, starting to communicate with the PSP’s operator increasing their individual autonomy and explaining own needs in an easily way, outside the community by abandoning patterns and preconceptions:

**Proposition 5:** Abandoning a family environment or their community push themselves to interact individually avoiding cultural patterns and preconceptions, ensuring its participation
and a high degree of commitment during the value co-creation process, increasing service quality.

Conclusion
While the literature recognizes that in professional services domain, significant customer participation is required in order to co-create value, the mechanisms through which this is practically obtained need further investigation (Damali, et al., 2016), especially in the humanitarian context. The case study showed that value co-creation processes seem to be the result of a relationship based on trust, reached after continuous and intensive interactions. The relationship between actors in professional services domain will continue to shift and acquire new forms and manifestations (Baltova and Baltov, 2017). Other interesting aspects that emerged in this research are related to the PSPs’ expertise and the service design. The main driver to build trust thus enabling value co-creation processes, are education, open dialogue and an open approach discovering different cultural background.

This research wishes to contribute to the body of knowledge on value co-creation by providing an exploratory view on value co-creation processes into the L-TIPs. Nevertheless, this case study has limitations that constitute possible lines of research for the future. The authors also recognise that this is as a single case study with limited diversity of involved participants. Moreover, the study is focused on a small sample selection. It would be interesting to investigate the value co-creation processes comparing different organization and investigate value co-creation process in a structured manner. In addition, related to the aim of L-TIPs could be interesting explore other mechanisms allowing service effectiveness in the humanitarian organizations hoping that could increase beneficiaries’ integration into the hosting countries.

The role of unmanned aerial vehicles in mapping and search and rescue in response to natural disasters

Abstract

This paper intends to present the implications of deploying UAVs in assisting mapping and search and rescue in immediate response to natural disasters. For doing so, empirical data has been collected from three organizations with real deployment experience. Evaluation framework (Piotrowicz & Irani, 2010) have been used to classify the impacts. Findings indicate that on strategic level, intangible and non-financial benefits, challenges and risks dominate whereas on tactical and operational level, tangible and non-financial impacts outnumber. Considering these impacts, the study identifies areas for improvement. Moreover, it modifies and extends the evaluation framework for use in humanitarian sector.

Keywords: Unmanned aerial vehicles, mapping, search and rescue

Introduction

Every year, sudden onset natural disasters cause deaths, causalities and often result in significant economic and financial losses (Shavarani & Vizvari, 2018). For international NGOs and aid organizations, these disasters restrict their ability to access the affected areas and collect up to date information about the situation (Haavisto et al., 2016; Erdelj et al., 2017). Since first 72 hours are crucial for searching victims post disaster, therefore collecting accurate and timely geospatial information becomes critical for coordinating rescue operation and delivering need based response. Several studies indicate the usefulness of mini and micro Unmanned Aerial Vehicles (UAVs) in bridging knowledge gaps in immediate response phase and enhancing data collection and information sharing capabilities of first responders and humanitarian organizations (Sakr et al., 2016). While each methodology has different impacts, this research intends to present the benefits, challenges and risks of the using UAVs in disaster response, particularly in mapping and search and rescue.

Evaluation Framework

Since UAVs can be used to strengthen the capabilities of Geographic Information System (GIS) by collecting and transmitting remotely sensed spatial data, therefore we decided
to use evaluation framework (Piotrowicz & Irani, 2010) to identify and classify implications of the use of UAVs in disaster response. This framework takes into account the technology related flexibility and can be used to present impacts that cannot be measured through conventional evaluation techniques (e.g. cost benefit analysis).

For this research, we have the modified dimensions of framework to incorporate unique characteristics of humanitarian sector and our research aim. The dimensions of this framework are explained below.

**Strategic, tactical and operational impacts**

Strategic impacts are linked with the objectives of organization and represent the long term impacts. They affect performance on tactical and operational levels (Gunasekaran et al., 2001). In case of humanitarian organizations, these impacts can be affected by the time and socio-political and economic conditions of the country in which disaster strikes (Pettit & Beresford, 2009). Tactical impacts are linked with resource, process and task requirements and affect medium (short terms) success of project. Operational impacts represent requirements that must be fulfilled on daily basis for successful completion of a project (Gunasekaran et al., 2001).

**Impact characteristics**

Impacts experienced at each level can be categorized based on the extent to which they can be measured indirectly or directly (Gunasekaran et al., 2001). Tangible (T) impacts can be experienced and measured in a direct manner whereas intangible (INT) impacts cannot be assessed directly (Piotrowicz & Irani, 2010). Tangible and intangible impacts may indicate financial (F), or non-financial (NF) repercussions of innovation decisions (Gunasekaran et al., 2001).

**Balanced Scorecard (BSC) dimensions**

Piotrowicz & Irani (2010) have used BSC dimensions to present distribution of benefits in areas such as financial, internal business processes, customers and learning and growth (Kaplan and Norton, 1996). Due to immense importance of donors and beneficiaries in humanitarian sector, several humanitarian organizations consider them as their customers. Donors provide funds and influence humanitarian decision making (Beamon & Balcik, 2008) therefore, we chose them as customers. As the main objective of humanitarian organizations is to save lives and reduce suffering of victims, their main responsibility is also towards beneficiaries (Beamon & Balcik, 2008). Thus, we also regarded beneficiaries as customers.

**Unmanned aerial vehicles (UAVs)**

UAVs are aerial vehicles without passengers and crew onboard. They can be dispatched autonomously or semi-autonomously to perform sensory operations (Sakr et al., 2016). In this research, we aim to analyze the implications of micro and mini UAVs because they are preferred for use in disaster response from regulatory point of view due to their size and weight (OCHA, 2014). The maximum take-off weight of mini UAV is less than 30 kg whereas that for micro UAV is less than 5 kg (Bendea et al., 2008; Giordan et al., 2018). Several humanitarian organizations and emergency management organizations such as International Organization for Migration (IOM), World Bank and Greater Manchester Fire Rescue Service (GMFRS) have used them (both fixed wing and multi-rotor) for mapping and search and rescue in immediate response to disasters (Soesilo et
Mini and micro UAVs can easily be transported to disaster site and perform challenging tasks such as search and rescue (SAR) (Tanzi et al., 2014; OCHA, 2014). They are more affordable to use for mapping and SAR operations compared to other types such as High Altitude, Long Endurance (HALE) and Medium Altitude, Long Endurance (MALE). Small rotary wing UAVs cost around US$2,000, whereas high endurance fixed wing models cost around US$130,000,000 (Tatham et al., 2017). DJI’s phantom (multi-rotor UAV) costs around €500-€1500 and MikroKopter’s ARF OktoXL 6S12 (multi-rotor UAV) costs approximately €6,500 for mapping. Fixed wing UAVs (for mapping) range from €10,000 (Danoffice IT’s Cumulus 1) to €20,000 (SenseFly’s eBee). The cost of UAVs for live feeds during SAR can range from €42,000 (Microdrones’ MD4-1000) to €40,000 (Sky-Watch’s Huggin X1). These cost variations are due to brand, type of UAV (fixed wing or multi-rotor) and sensors used (Soesilo et al., 2016).

Limited endurance of mini UAVs (<2 hours) and micro UAVs (around 1 hour) affect their ability to fly longer (Bendea et al., 2008) and support SAR and mapping operations without a charging arrangement or extra capacity. Their limited payload capacity restrict their ability to carry the number and type of sensors and cameras. However, the development of miniaturized and custom designed thermal sensors as well as multi and hyper spectral cameras have enhanced usefulness of these platforms (Giordan et al., 2018).

**Mapping and SAR challenges in immediate response phase**

Immediate response to disaster involves multi-dimensional activities to reduce disaster impact, save lives and prevent further damage. Despite the critical need to rescue victims and provide relief, humanitarian organizations have to face significant challenges in conducting immediate response activities, particularly with first 72 hours. This is because disasters most often damage physical infrastructure and cut off affected areas (Haavisto et al., 2016). Inaccessibility to affected locations coupled with inaccurate understanding of situation limit the ability of humanitarian organizations and first responders to collect up to date spatial data. Most often in response phase, humanitarian organizations are receiving information from deployed assets and reports from the community. The collected information is sometimes inaccurate or incomplete (Griffin, 2014).

**Benefits of UAV assisted mapping and SAR**

The availability of accurate and up to date information is critical for rescuing victims and providing relief (Griffin, 2014). In this regard, images or live video feeds streamed by mini and micro UAVs from disaster site can improve situational awareness of humanitarian actors (Shakhatreh et al., 2018). These videos can also increase the flexibility of first responders in improvising SAR operation (Tanzi et al., 2014); thereby improving SAR time efficiency (Shakhatreh et al., 2018). Sending data acquisition plan to satellites and collecting data from them takes several days whereas UAVs can be deployed on demand for multiple observations of disaster affected area. Mini and micro UAVs carrying IR camera and LiDAR can be quickly dispatched to scan the disaster affected site and collect data even during night time and adverse weather conditions (Shakhatreh et al., 2018). This can improve mapping time efficiency (Nedjati et al., 2016). UAV based images can be used to create maps and other information products (such as DTM and DSM) which can be used to conduct risk assessment, damage assessment and plan need based relief efforts efficiently (Hashemi-Beni et al., 2018). Their use can also reduce the overall response time (Tanzi et al., 2014). Up to date UAV based spatial data
can strengthen GIS and can be used to improve other immediate response activities (Gomez & Purdie, 2016).

Autonomous mini and micro UAVs can reduce operating costs of UAVs because these vehicles are less costly as compared to helicopters and airplanes (Soesilo et al., 2016). Low cost and off the shelf sensors and cameras have also reduced unit cost of these vehicles (Sakr et al., 2016). Moreover, autonomous systems reduce the need of trained pilots to operate the vehicles and decrease the total manpower required to perform UAV based mapping. Micro and mini UAVs can also enhance victim detection and mapping accuracy. As compared to other remote sensing platforms such as airplanes, helicopters and satellite, mini and micro UAVs can fly at low altitudes (30-150 meters) and capture high resolution images from different angles (Soesilo et al., 2016). Sensors carried by these vehicles allow them to locate and detect victims with accuracy (Tanzi et al., 2014). UAVs as a platform can overcome coverage issues due to atmospheric conditions (such as cloud cover and dust whirls) (Soesilo et al., 2016).

**Deployment risks and challenges in disaster response**

Regulations present a major challenge in deploying UAVs for disaster response (Gomez & Purdie, 2016; Shakhatreh et al., 2018). Every country has different regulations and several countries in which humanitarian organizations operate do not have UAV laws (OCHA, 2014; Tatham et al., 2017). Compliance with local regulations is necessary for operationalizing the technology in a safe manner. However, the lack of UAV laws can raise the level of uncertainty regarding their use in disaster response. Since UAVs can collect, store and transmit significant amount of big data, their use has raised concerns regarding data security and privacy of victims (Tatham et al., 2017). This data upon leaking or hijacking can lead to intrusive monitoring of people and observed areas and can also cause personal harm to people (Erdelj et al., 2017). In addition, UAVs have a negative image due to their prior association with the military and their use in modern warfare. For humanitarian organizations, such an image becomes a critical issue that must be managed to retain their image as an independent and impartial entity (OCHA, 2014).

Mini and micro UAVs are sensitive to heavy rains and strong winds (Shakhatreh et al., 2018). Such weather conditions can change the pre-determined flight path; thereby, affecting the coverage of observation area (Shakhatreh et al., 2018). UAV based operations required highly trained pilots and technical staff available, particularly within first 48 hours (Soesilo et al., 2016). In addition, integrating UAVs as a supplementary tool requires significant costly preparations beforehand to ensure timely results. UAV based operations also demand managing (or overcoming) long data processing and energy constraints (Shakhatreh et al., 2018). In case of UAV based SAR, managing coordination between technical team and first responders or humanitarian staff is critical for ensuring success of operation. Lack of clarity about roles and priorities can reduce the possibility to find victims in time and save lives (Soesilo et al., 2016). While the technology is still evolving, technical risks such as limited communication range, need for robust collision avoidance solutions, use of low cost and risky off the shelf components and unexpected sensor failure present challenges related to public safety (Erdelj et al., 2017).

**Methodology**

Empirical data has been collected from a purposeful sample of three humanitarian organizations (HOA, HOB and HOC) with actual deployment experience in disaster response. HOA and HOC are based in Central and Southern Europe respectively. HOB is based in North America. Multi-case study design has been used to enhance generalizability of findings and compare implications across cases. Constructivism
paradigm have been used to guide research process, data collection and data reporting. Altogether 3 skype based individual interviews have been conducted from 3 respondents in humanitarian industry using an interview guide. All respondents are UAV experts who have used the technology and have participated in real deployment experience of case organizations. Apart from the interviews, written communication in the form of UN reports, documents published on websites of case organizations and previous studies were used for data triangulation.

Findings

*Humanitarian Organization A (HOA)*

HOA use UAVs as a supplementary tool for mapping only. It uses satellites, on ground team with COBO (Company Owned/Business Only) phone or tablet with GPS and UAVs for collecting spatial data and supporting GIS analysis. Before implementing UAVs, HOA considered cost comparisons between satellites and UAVs, frequency and resolution of observations required, and finance. In addition, an assessment of best tools in terms of days or duration of project was also made. The report was first submitted to the program manager and then to the mission manager in Haiti. After gaining approval, HOA collaborated with a private company named SenseFly to source micro-UAVs and software. After receiving field validation reports from teams on ground, HOA conducted test flight with UNOSAT in the aftermath of Hurricane Sandy (2012). To make sense of spatial data, HOA collaborated with Pix4D and converted raw data or images into accurate 2D maps (orthomosaic) and 3D models (DEMs). For digitizing images and conducting GIS analysis, HOA hired a specialized team from Open Street Map (OSM). It then reduced the size of each UAV based imagery and maps (<50 Megabytes) and shared this information freely (open source) through humanitarian data exchange (HDX platform) and OSM with relevant stakeholders (volunteers, local government, humanitarian partners and civil protection bodies).

UAVs showed advantages during first deployment as it provided the data faster (29th October) than satellite (2nd November). Cost wise UAVs gave a more detailed overview as compared to satellites on km\(^2\) basis. Upon realizing benefits from this experience, HOA began developing in house UAV capacity. It sourced more vehicles, servers and formed a specialized team in house. Later it deployed UAVs in response to Hurricane Matthew (2016) to verify satellite data, improve situational awareness, collect baseline data to identify hurricane pattern and support damage assessment and plan response (in terms of NFI and food distribution). The respondent mentioned that UAV based operations are challenging because the technology can be deployed only if the Government requests and allows their use. Their use also requires considering and complying with laws regarding data management (storage, filter information and processing). Moreover, cases in which Government receives reports of misuse of UAV sourced data, improvising the situation becomes problematic.

*Humanitarian Organization B (HOB)*

HOB use UAVs as a complementary tool for mapping only. HOB does not replace satellite, manned aviation assets or ground based surveys with UAVs. It uses them for data triangulation or bridging knowledge gaps. HOB prefers to use UAVs for direct live feeds or improve situational awareness of an area when satellite images are inadequate. UAVs provide high resolution images (1.5 to 10 cm) that are accurately geo-referenced. These vehicles are used when HOB has the capacity to use the technology in terms of
funds, vehicles and technical staff available. UAV are preferred for small scale (10 km) localized assessments as compared to ground based survey. An aerial image sourced from UAV can be cheap as compared to satellite images. Moreover, UAVs provide flexibility to HOB for on demand and efficient mapping. However, the preparation for UAV based operations can be very costly in terms of acquiring the technology, permits and developing or hiring technical staff. Regulations for UAVs are more restrictive than satellites in terms of data management and use of vehicle. If preparations are not done before deploying UAVs in immediate response then, UAV based response can take long time. Even with preparations done, data processing stage can be significantly time consuming if HOB is covering large areas with UAVs. Thus, with 72 hours, it is hard to conclude that UAVs can be effective in delivering the maps. It can be useful with 72 hours provided the vehicle streams live video feeds to the team. Furthermore, the use of UAVs requires collaborating with the technical team or technology providers on site. Challenges and risks mentioned by the respondent deals with ethical implications (such as privacy of victims, data protection and management), lack of uniform standards, long processing time (e.g. 3-4 days to map 10 square kilometers), harsh weather conditions, overhyped product capabilities, costly preparations, lack of experience of technology providers in emergencies and regulatory restrictions. She mentioned that some countries do not even have UAV regulations and several do not have streamlined processes to gain approval for UAV, pilot and operator. It usually takes several weeks to go through several registration processes and certifications.

*Humanitarian Organization C (HOC)*

HOC has been using UAVs as a supplementary tool for mapping and improving visibility of national partners at lower costs. However, it has been supporting local Governments, National Disaster Management Organizations (NDMOs) and first responders in SAR by prepositioning lower cost UAVs ($2000/ UAV) and localizing skillsets through training programs. For mapping, HOC has prepositioned equipment at six regional bureaus (Panama, Bangkok, Cairo, Johannesburg, Nairobi and Dubai). It has been conducting capacity building workshops for HOC personnel, cluster partners and the Government. For localizing UAVs, HOC is working with civil aviation authorities to get clearance.

Before deployment, HOC defined expectations at programme level in each country of operation. Decision to use the technology was based on the comparative analysis of the end product price vs methodology. End product price was measured on project or unit cost basis. For mapping HOC analyzed cost effectiveness of UAVs i.e. it compared quality and accuracy vs cost per hectare of land.

HOC have used UAVs in Philippines after Typhoon Haiyan (2013) to map out millions of damaged coconut trees and to support efforts to enable reuse of farmer lands. In Columbia, HOC used UAVs to track displaced population in the aftermath of Hurricane Irma (2017). In Mozambique, it mapped 14000 km² of River Delta (2018) to assess damages in the aftermath of floods (2018). In response to Hurricane Maria (2017) in Dominica, HOC used UAVs to support Government and rescue teams. For map generation, HOC use LiDAR, photogrammetry software and high processing power computers to create orthomosaics, Digital Surface Models (DSMs) and Digital Elevation Models (DEMs). It then freely shares the generated information products with national partners to improve situational awareness. HOC use micro UAVs (less than 1kg) and sensors such as Near Term Digital Radio (NTDR) and Unreal Development Kit (UDK) camera for thermal imagery. For observing large areas (e.g. 500 hectares), HOC use fixed wing UAVs. The benefits reported by the respondent include workload reduction,
improvement in inter-agency coordination and information sharing and strengthening GIS. UAVs improved mapping and SAR accuracy, flexibility and capabilities. The challenges and risks that HOC reported include ensuring the appropriate equipment (UAV) for use, retention of technical knowledge and staff, timely communicating with civil aviation authorities for safe operations and assuring safe operations across the cluster.

**Discussion**

Table 1 & Table 2 presents classification of reported benefits, challenges and risks based on the framework dimensions (Piotrowicz & Irani, 2010). Majority of the reported benefits can be categorized as strategic and operational whereas most of the challenges and risks can be classified as strategic and tactical. On strategic level, UAVs mostly improve: inter-agency coordination and information sharing and other immediate response activities. These findings are in line with previous research (Gomez & Purdue, 2016; Soesilo et al., 2016). On tactical level, UAVs can reduce map procurement costs (HOA, HOB & HOC) and improve GIS data collection and information system (HOA & HOC) on organizational (HOA) and multi-agency level (HOC). These findings are supported by previous studies analyzing the impact on intra organization (Sakr et al., 2016) and inter-organization level (Soesilo et al., 2016). On operational level, UAVs can be used to enhance capabilities and accuracy of mapping (HOA, HOB and HOC) and SAR operation (HOC). All these findings are similar to observations made in previous studies (Nedjati et al., 2016). On strategic level, the main challenges and risks mentioned by all cases include concerns regarding: regulations and data protection. Limited resource capacity, lack of deployment preparedness and data management were found common challenges and risks among several cases on tactical level. On operational level, technical team dependence, long processing time, and weather conditions can be categorized as main challenges and risks. These findings have been confirmed by previous studies (Bendea et al., 2008; Erdelj et al., 2017). We found some new challenges and risks such as retaining technical knowledge and staff, monitoring risk and assuring safety at multi-agency level, dependency on agency request and gaining approval internally. On strategic level, intangible and nonfinancial benefits, challenges and risks were found dominant. Majority of benefits, challenges and risks on tactical and operational levels were identified as tangible and non-financial in nature. We found donor and learn and growth as main improvement areas in all organizations. Moreover, findings revealed learn & growth, internal process and beneficiary as the areas that require the most attention to reduce risks and overcome challenges.

**Conclusion**

Findings have revealed the difficulty in measuring benefits, risks, and challenges for humanitarian organizations on strategic level. Most of the implications on strategic level (such as improvement in inter-agency coordination and information sharing and regulations) are intangible and non-financial in nature. Although their impact is difficult to measure, these outcomes can greatly impact the performance of humanitarian organizations in immediate response. On tactical and operational level, tangible and non-financial impacts dominate tangible and financial as well as intangible and non-financial for all organizations. Evaluation framework enabled us to indicate intangible and non-financial implications of UAV assisted response. These impacts cannot be captured by conventional evaluation techniques (e.g. cost-benefit analysis) and operational measures.

Abstract

The purpose of this study is to understand how service triad members in humanitarian supply chains (HSC) contribute to the value co-creation of continuous aid process. This study implements semi-structured interviews to humanitarian service triad members. The sample from non-governmental organizations, service providers and the beneficiaries are selected through purposive sampling and snowball sampling. By identifying the best practices and bottleneck points, this study contributes to the development of an understanding in HSC literature for the continuity of aid in the value co-creation process in humanitarian service triads.

Keywords: Value Co-creation, Service Triads, Humanitarian Supply Chain

Introduction

Recent changes in the global environment has increased the importance of supply chain management, not only in commercial setting but also in humanitarian setting. Humanitarian aid services, which includes security, education, health, nutrition and human rights, is becoming more crucial in enhancing livelihoods of people in need (UN OCHA, Turkish Red Crescent Community Centers) as the humanitarian crisis has increased in terms of number and duration.

The HSC consists of several actors, such as donors, aid agencies, non-governmental organizations (NGOs), governments, military, logistics service providers and suppliers (Kovács and Spens, 2008). Besides, the beneficiaries are introduced as the end-users of the products or services, whose needs are not predetermined and must be accommodated in a limited time (Altay and Green, 2006; Kovács and Spens, 2007; Oloruntuba and Gray, 2009).
The direct contact between the service provider and end user is entailed by service triads (Li and Choi, 2009), and this concept has a unique approach in HSC, since the components of the triad do not rely on linear links; instead, extends across multiple links in the triad (Heaslip and Kovács, 2018).

Recently, the attention to the roles and contributions of the HSC members in the humanitarian aid delivery process is increased in humanitarian supply chain management (HSCM) literature (Makepeace et. al, 2017; Oloruntoba and Banomyong, 2018; Seifert et. al, 2018). However, the research on the service concepts in HSCM literature is still in its infancy (Heaslip, 2013; Heaslip and Kovács, 2018), and empirical studies are needed to advance theory on service delivery process in HSC.

HSCM involves providing services in disaster relief operations as well as in continuous aid operation with long-term goals (Kovács and Spens, 2007). The purpose of this research is to understand how service triad members in continuous aid HSC - humanitarian organizations, implementation partners of the humanitarian organizations and the beneficiaries - contribute to the value co-creation of aid process and to assess the continuity of aid services in HSCs before and after they are provided to beneficiaries (e.g. capacity building through job trainings). Thus, the research raises two research questions:

- How does value co-creation operationalized in humanitarian service triads?
- How does the benefits generated by the value co-creation utilized by the beneficiaries and sustained by the humanitarian service triad?

By identifying the best practices and bottleneck points, the research contributes to the development of a novel framework in HSC literature for the continuity of aid in the value co-creation process in humanitarian service triads. The empirical basis of the research relies on semi-structured interviews (Eisenhardt et. al, 2007; Flick, 2014) with humanitarian service triad members, that is, humanitarian organizations, service providers and the beneficiaries.

The paper is structured as follows: in the following section, the literature review on value co-creation in HSCs is discussed. Then, the relevant literature for value co-creation in HSCs is synthesized. In the methodology section, qualitative methodology adopted for the study is elaborated. In the last two sections, findings and conclusions are presented.

**Theoretical Perspectives of Value Co-Creation in HSC**

Recent developments and studies demonstrate that there is a shift toward service dominant logic in HSCM (Heaslip, 2013; Heaslip et al., 2018). Even with the new implementations, such as the cash-based approach, humanitarian organizations enable beneficiaries to access markets on their own (Heaslip, 2015). This also shows a transition from push principles to pull principles in HSCM, since the organizations start trying to fulfill the actual need of beneficiaries (Heaslip et al., 2018).

HSCs can be set up for various reasons, and they can have short-term and long-term goals. Following a rapid-onset disaster, such as earthquakes, hurricanes and floods, HSCs can be set up in a few days in order to provide basic relief services to the beneficiaries (Kovács and Spens, 2007). However, HSCs can also be set up for providing continuous aid, which has long-term objectives, such as for reconstruction and rehabilitation of affected regions (Matopoulos et al., 2014; Oloruntoba and Kovács, 2015), as well as for development programs. While short-term HSCs are agile (Oloruntoba and Gray, 2006; Van Wassenhove, 2006), long-term continuous-aid HSCs, or preparation and reconstruction HSCs are lean (Taylor and Pettit, 2009; Cozzolino, 2012). Although collaboration among members in HSC
has been seen as a challenge due to the different mandates of humanitarian organizations (Balcik et al., 2010), there has been a call from donors for their integration in HSC (Moshtari, 2016).

Value Co-creation in HSC
Value co-creation and its role in a supply chain (SC) and its processes have been studied through various aspects. Furthermore, the degree of collaboration in a SC has been investigated in terms of value co-creation (Jin et. al, 2013; Sandberg et. al, 2018), and collaboration is found as one of the key antecedents of value co-creation and service delivery in humanitarian setting (Moshtari, 2016; Prasanna and Haavisto, 2018). Supply chain performance and on-shelf availability (Ehrenthal et. al, 2014; Tuan 2017) and customers’ loyalty and their contribution to the overall process (Thiruvattal, 2017) were some of the topics that has been analysed under the concept of service dominant logic based on value co-creation in supply chain management (SCM) literature. In addition to value co-creation literature, Grönroos (2011) more specifically defined the customer is a co-creator of the value as well as the firms.

HSC consists of different actors providing different services to each other as well as to the beneficiaries with the aim of bettering the conditions of beneficiaries. Thus, value co-creation process can take place among the different members in HSCs. Despite being recognized as one of the key concepts in the literature, value co-creation has not been analyzed sufficiently in HSC literature until recently (Heaslip and Kovács, 2018). Heaslip (2015) highlighted the gap in the HSC literature as the value constellations to be the growing phenomenon.

Service Delivery Process and Service Triads in HSC
There are different types of HSCs (Oloruntoba and Kovács, 2015) ranging from short term to long-term continuous aid HSC, where there is more time to assess the actual needs of beneficiaries. Continuous aid HSC can be set up for different objectives such as a part of recovery and rehabilitation of affected region due to a disaster or a conflict (Matopoulos et al., 2014). There is a debate on the role of beneficiaries as the customers of HSCs; beneficiaries are not viewed as the regular customer as they have to accept what they are offered in terms of services (Oloruntoba and Gray, 2009), however there are also studies which consider beneficiaries as customers (Heaslip, 2015; Heaslip et al., 2018; Scholten et al., 2018).

On the one hand, service triads have been defined as the relationship among services buyer, supplier and the end customer (Li and Choi, 2009). Service triads cover when firms serve their customers through the third party service providers. Triadic relationships based on service dominant logic covered on purchasing and retail performance (Chuang et. al, 2016; Broekhuis and Scholten, 2018), socially responsible operations (Jung et. al, 2015) individuals with caregiving relationships with the customer (Roetzmeier-Kueper et. al, 2018). On the other hand, in HSCs, humanitarian organizations start offering services to each other (Heaslip, 2013). In Heaslip and Kovács (2018)’s study, the authors provide a service triad of implementing partners, donors and UN agencies/International Humanitarian Organizations/Logistics Service Providers, and they examine the financial, contractual and physical flow among these three.

This study focus on a service triad in a HSC setting as in Heaslip and Kovacs (2018)’s study. However, in this study, beneficiaries are included in the service triad rather than
Therefore, this study focuses on a service triad of beneficiaries, service providers and NGOs in a HSC setting.

Methodology

This study has an explorative nature and applies qualitative research methodology (Flick, 2014) to humanitarian service triad members through semi-structured interviews. Qualitative methodology provides participants with flexibility and freedom to talk about their experiences and discuss implications effectively, as well as allows us to understand their contribution to the value co-creation process (Eisenhardt et. al., 2007).

The sample from NGOs, service providers and the beneficiaries are selected through purposive sampling (Palys, 2008). Statistical data gathered from UN High Commissioner for Refugees (UNHCR), International Committee of Red Cross (ICRC), International Federation of Red Cross (IFRC), The International Red Cross Red Crescent Movement (IRCRCM) and IOM (International Organization of Migration) show that İzmir is a preferable baseline to conduct the study. Therefore, data collection took place in İzmir, which is among the top ten cities with the highest amount of refugees in Turkey (Interior Directorate General of Migration Management, UNHCR Turkey). Moreover, snowball sampling (Patton, 1990) is used during data collection until a state of data saturation was reached (Eisenhardt, 1989). The interviewees are selected from the three triad categories (6 beneficiaries, 4 NGOs, 6 service providers), since each of them represent distinct components of the service triad. The first group, beneficiaries, are chosen based on their demographic features (age, gender) and the time spent as a refugee. The following group is NGOs which receive their donation through several funding sources, such as governmental, institutional or private sources (Heaslip, 2013; Oloruntoba and Gray; 2009). Last group is service providers, which act as intermediaries between NGOs and the beneficiaries (end users) of the service delivery process in HSC by providing job trainings.

In semi-structured interviews, triad members’ current practices in HSC service triad are questioned. All interviews are recorded and transcribed. Content analysis (Graneheim et. al, 2017) is used for analyzing the data. In the first stage, through a line by line analysis, the patterns, concepts and their properties are described. In the second stage, comparisons of the labeled concepts are made and grouped, if necessary (Eisenhardt, 1989, Miles and Huberman, 1994). Then, their contribution to the value co-creation in the humanitarian service triad is explored. This framework is extended towards after-service process, where the effectiveness and continuity of humanitarian aid process is further pondered, and the expected value co-creation environment in the humanitarian service triad is revealed. In order to ensure validity and reliability, the data is coded by two researchers and inter-rater agreement is achieved through “discursive alignment of interpretations” (Seuring and Gold, 2012). Further, the data is triangulated (Denzin, 2017) with observation and publicly available documents gathered from websites.

**Findings and Discussion**

The coding process revealed seven main categories of value co-creation of continuous aid process in humanitarian service triad (Figure 1). Among these categories, humanitarian service planning, humanitarian service reachability, and humanitarian service effectiveness are co-created as value by mutual contribution between two of the triad members. Collaboration in humanitarian services, humanitarian service motivation, ethical issues in humanitarian services are co-created with joint contribution of triad members, and enhances all value components across the triad. After care in humanitarian services is found to be a generic component, which influences other components and enhances the value co-created across the triad for the continuity and continuous improvement of the service delivery process.

Humanitarian service planning is one core value co-created across the triad, with mutual contribution of NGO and service provider. The important focus in planning is needs assessment and arrangement of services based on the concerns of beneficiaries, as the value co-created by effective planning is directly utilized by the beneficiary.

Humanitarian service reachability is another important value, co-created across the triad by mutual contribution of the NGO and beneficiary. NGO sets the link between the service provider and beneficiary for raising awareness on the service by announcing the service through various communication channels, while beneficiary contributes by spreading the service through word-of-mouth.
Humanitarian service effectiveness is value co-created during the actual service delivery to the beneficiary, and generated by mutual contribution of the service provider and beneficiary. On one hand, service provider contributes by providing quality of the service provided, which is enhanced by the expertise and experience, while beneficiary contributes by effectively receiving the service and empowering his/her skills.

It is evident in the analysis that collaboration is a critical component in humanitarian services (Moshtari, 2016; Prasanna and Haavisto, 2018). However, the integration of beneficiaries and society to humanitarian service delivery process is outlined to be an essential value for generating effective collaboration in the service triad. On the other hand, beneficiary, service provider and NGO contributes to value co-creation from different perspectives for raising motivation to humanitarian services by creating trust and satisfaction.

**Figure 1 – Value Co-creation in Humanitarian Service Delivery Process**

HSP: Humanitarian service planning
HSE: Humanitarian service effectiveness
HSR: Humanitarian service reachability
ASC: After service care
environment across the triad. Furthermore, ethics is found to be another value co-created by joint contribution of the triad members to protect the rights of the beneficiaries, remove gender discrimination, and empower marginalized groups.

Another value component in humanitarian service is after service care, which is associated with the follow-up of the beneficiary (e.g. employment, adaptation and satisfaction) and the continuity of information sharing after the service is delivered.

The synergy created by the interactions of the value components co-created across the humanitarian service triad elevates the service delivery process in the entire triad and enhances continuous improvement.

Conclusion
This research contributes to the literature by analyzing how a continuous aid in value co-creation can be provided in such a dynamic environment of a humanitarian setting. By detecting the bottleneck points with the empirical analyses, it aims to contribute to the practice by the development of a value co-creation understanding in HSCM.

This study is one of the few studies that examines the value co-creation process (Grönroos, 2011) in HSCM that includes beneficiaries. Recently, there is an increasing trend from both practitioners and academics towards improving services in the HSCM (Heaslip, 2013; 2015; Heaslip and Kovacs, 2018. Findings of this study shed light on the understanding of services provided to end users (beneficiaries) in HSC, and advances knowledge on this concept for the continuity of the humanitarian aid process, as well as provides useful and profound information to the practitioners in humanitarian setting. For further studies, focusing on the effect of the harmonization period of the beneficiaries could be a good starting point of a phenomenological study. Current trends in HSC and considering value co-creation as a complementary part of the continuous aid process could enable humanitarian organizations further develop impact analyses in their working space.

Abstract

The disaster response faces several problems related to the management of different stakeholders. On the one hand, integrated frameworks that could support the management of these stakeholders lacks adherence to the disaster and humanitarian context. On the other hand, the Humanitarian Supply Chain Management (HSCM) research is currently composed of several thematic independently Systematic Literature Reviews (SLR). This paper combines different thematic SLRs in the HSCM to develop an integrated framework, which brings additional value not achieved by the SLRs independently. Future research embraces the framework validation and its expansion to other disaster lifecycle stages.

Keywords: Stakeholder Theory, Stakeholder Management, Process Management

Introduction

Operations in disaster response demand interdisciplinary, and a high interaction among stakeholders from the public and private sectors, and the society. Moreover, the coordination of such stakeholders depends on a broad comprehension of the stakeholders themselves, as well as the disaster response processes (Nirupaman and Etnikin, 2012; Tatham and Spens, 2016; Fontainha et al., 2017). Nevertheless, maintaining a productive relationship remains a challenge because of the large number and diversity of actors with distinct organizational cultures and structures (Caruson and MacManus, 2011; Leiras et al., 2014). The consequences of such complications in the stakeholder management are observed in increased inventory costs, longer delivery periods and other logistics inefficiencies (Tatham and Pettit, 2010). Consequently, the management of these stakeholders, of different profiles, cultures, and interests is continually recognized as a critical issue that deserves further investigation (Heaslip et al., 2012; Leiras et al., 2014; Tatham e Spens, 2016).

In a general Systematic Literature Review (SLR) in the area of Humanitarian Supply Chain Management (HSCM), Behl and Dutta (2018) observed the recurrent use of SLR.
addressing a variety of emerging topics, stressing the importance of integrating these different topics to bring innovative discussions in the HSCM research and practice. Thus, this paper brings a Stakeholder Theory embedded approach to discuss the connections between four essential topics in disaster response operations. These topics involve stakeholder identification, stakeholder satisfaction, process management, and strategies for stakeholder collaboration, which can be combined into an integrated framework.

After this introduction, this paper presents the results of recent SLRs grouped in dimensions associated with traditional frameworks, more specifically the Performance Prism. Then, the paper presents the conceived integrative framework. Last, the paper gives the main conclusions and indication of future research.

**Literature review**

This section presents the results of SLRs in the field of HSCM associated to the dimensions of the Performance Prism, which is reflected in dimensions related to (i) the identification of the stakeholders in the HSCM, (ii) the stakeholder’s satisfaction in disaster response operations of HSCM, (iii) disaster response process model in HSCM, and (iv) strategies for collaboration in the HSCM.

According to the Performance Prism structure, the first dimension to improve operations is the identification of who are the organizations' stakeholders. In this sense, Heaslip et al. (2012) explain the importance of understanding the roles of each stakeholder to build a new model, claiming that visual representations are essential tools to improve the operations, both from academics and practitioners' perspectives. Aligned with this, Tatham and Spens (2016) also noted that, despite the recent increase of research in the subject, it lacks a common understanding of the inter-relationships related to the management of stakeholders in disaster and humanitarian operations, and common vocabulary and its meanings. In the literature, there are some models discussing the engagement of all stakeholders from different perspectives, such as the ones presented by Kovacs and Spens (2007) and Balcik et al. (2010). More recently, Fontainha et al. (2017) performed an SLR to identify the patterns among the stakeholder models in the academic literature of HSCM. The authors proposed the Public-Private-People Relationship (3PR) Stakeholder Model by the identification of ten main stakeholders: government; military; legislative and regulatory; media; private sector; direct supplier; international air network; local aid network; donor; and beneficiary.

The stakeholder satisfaction is also an essential dimension discussed in the Performance Prism, which addresses the relationship between the organizations according to two perspectives: the dyadic and complex relationships. This approach is relevant for disaster response operations because organizations usually understand well only their own operations and are unaware of other stakeholders' roles (Nirupaman and Etnikin, 2012). To answer this research gap, Fontainha et al. (2018a) performed an SLR to synthesize the stakeholder satisfaction in disaster response according to the perspective of all stakeholders identified in the 3PR Stakeholder Model. This SLR synthesizes 29 satisfactions of stakeholders interacting in complex relationships.

Another dimension discussed in the Performance Prism is related to process management. In this aspect, several important researches on disaster response process models are identified in the academic literature with a broad and diverse perspective regarding modelling notation, respect to the principles of modelling, method for collecting the data or the source of the data, the extension of the model content, the disaster type and site, and the stakeholder that is the focus of the models (e.g., Oloruntoba, 2006; Charles and Lauras, 2011). Nevertheless, Aldin and Cesare (2011) explain that identifying patterns among previous models is the natural path to developing generic and
reference models to overcome such limitations. Fontainha et al. (2018b) developed a SLR on the existing process models and identified patterns among them, which served as the basis for the development of a model of reference processes for disaster response. The main processes are “Recognition of the disaster occurrence”, “Assessment of the current situation”, “Search and rescue”, “(R)establishing infrastructure in the response”, “Resource request for the response”, “Resource transport during response”, “Service to the population”, “Demobilization of the operations”, and “Response support operations”. Moreover, Fontainha et al. (2018b) argue that the model allows different flows among these processes, since, depending on the specificity of the disaster, because some processes can be implemented or not in the response to the disaster. The authors explain that this model is the first one suitable to all stakeholders and that can be used as a reference and tool to improve the planning of disaster response.

Besides the previous dimensions, the strategy is also a dimension discussed in the Performance Prism. Regarding the ODH context, Moshtari and Gonçalves (2016) analysed the collaboration strategies between international humanitarian organizations and identify that collaboration as a strategy is affected by three groups of factors: contextual; interorganizational; and organization. Considering collaboration strategies between international aid networks and direct logistics providers, Bealt et al. (2016) identified that the goals of involving direct suppliers of logistics in HSCM vary between strategic decisions, corporate social responsibility, publicity, commitment to help vulnerable people to start operations in the country or region, among others. Jahre (2017) analyses strategies considered by several stakeholders involved in collaboration in the HSCM and conclude that the strategies represent decisions that different stakeholders can develop when acting in response to disasters. Regarding the collaboration strategy, Jahre (2017) identified the following collaborative elements: coordination; supplier’s relation; commercial-humanitarian cooperation; collaborative procurement; civil-military collaboration; adaptability; orchestrating networks.

**Framework**

Inspired by the work of Neely et al. (2008), the interaction of the results observed in the previous SLRs is conveyed in a four-dimension framework discussed in an integrated approach presented in Figure 1.

![Figure 1 – Integrated framework for stakeholder collaboration in disaster response.](image)

Besides the independent analysis of each dimension, which is already discussed in the separated researches, their interaction also brings additional value to academics and practitioners. For instance, the combination of the stakeholder and the wants and need dimensions allows the identification of which needs must be met according to the
identification of which stakeholders are involved in the disaster response. The combination of the wants and needs and the process dimensions allows a more objective understanding of stakeholders' wants and needs in the planning of disaster response operations according to a process perspective. The combination of the stakeholder and the process dimension allow the identification of which stakeholders are involved in each disaster response process. All of these dimensions and discussions are subsidiary in the debate of which and how the collaborative strategies are implemented in the disaster response, which is in the centre of the framework.

After analysing the three dimensions, it is possible to discuss the collaboration strategically in disaster response in an integrated way. At this point in the analysis of the integrated framework, the seven elements of the collaboration strategy identified by Jahre (2017) can be discussed with regard to the need to involve specific stakeholders if these elements of the collaborative strategy are affected by the wants and needs of stakeholders, and if the collaborative strategy elements are considered in the planning of the disaster response processes to be executed.

Finally, considering the nature of the models and syntheses that support the dimensions of the integrated framework, it can be considered a reference in the discussion of collaboration in disaster response. This is reinforced by the flexibility adjustability of its application to any stakeholder/organization and disaster scenario faced.

Conclusion
As discussed in the paper, the integrated framework is conveyed as an essential tool to discuss collaboration in disaster response operations in HSCM mainly for two reasons. First, the framework provides the context specificities required by practitioners in the field, as indicated by Vries and Van Wassenhove (2017). Second, the framework enables the discussion of essential issues further than the ones already discussed by the SLRs/dimensions independently. Besides, considering the integrated framework proposed in this paper, suggestions of future research are related to the use of other research methods to aid the validation and evaluation of each dimension and their combination in the integrated framework based on the perspective of academics and practitioners. An additional future research proposal is the analysis of the capacity dimension of the stakeholders, as indicated by Neely et al. (2008), and how this dimension can help to improve the discussion of stakeholder collaboration in disaster response.

Abstract

The convergence of unsolicited non-priority in-kind donations has been coined as the second disaster wave. It hampers the delivery of critical supplies to disaster-affected locations and obstructs efforts in meeting demand with supply in humanitarian emergencies. Based on eliciting the opinions of two expert panels, the present research puts forward potential combinations of supply chain configuration-strategy that allow better management of unsolicited donations. The paper identifies supply chain capabilities and related practices needed in each combination. As such, supply chain researchers and practitioners can prioritise the most relevant supply chain capabilities, considering the constraints of the prevalent conditions.

Keywords: Humanitarian Supply Chain, Supply Chain Configuration, Supply Chain Strategy

Introduction

In August 2005, hurricane Katerina struck the Gulf Coast of the United States, affecting Louisiana, Mississippi and Alabama. Buildings, infrastructure and facilities were severely damaged to an extent that communication infrastructures were not reliable to guarantee effective coordination between different organisations (Wachtendorf et al. 2010). With a death toll of over 1300 casualties and an estimated $96 billion dollars of property damage, an overflow of unsolicited in-kind donations started to converge at the disaster-affected locations. There was lack of a functional system able to register the requests for supplies, and the information about the donations or requested supplies delivered to disaster-affected areas was scarce (Holguín-Veras et al. 2007). Given the absence of the communication infrastructure, media messaging was the main source of information (Holguín-Veras et al. 2007), yet low control over the information disseminated in the
media, has led to a surge of unsolicited non-priority donations, making Katerina one of the catastrophes where the convergence of unsolicited donations generated huge damages (Wachtendorf et al. 2010), and earned the label ‘the second wave of disaster.’ This phenomenon exists in the aftermath of almost every disaster, where there is often a spontaneous flow of supplies from multiple sources to the disaster-affected area that is known in disaster management literature as material convergence (Fritz and Mathewson, 1957). The magnitude of the implications of such phenomenon has encouraged the United Nations Office for Coordination of Humanitarian Affairs and the Logistics Cluster to establish a strategic plan for limiting the flow of unsolicited donations and developing tools for a better management of donations in disaster-affected locations (OCHA, 2013).

Though the convergence of unsolicited donations has attracted the attention of practitioners, it is still an unexplored topic in humanitarian supply chain literature, as put by Holguín-Veras et al. (2014, p.2) as “the most unique, overlooked, and poorly understood disaster phenomena.”

To this end, this study investigates the phenomenon of unsolicited non-priority in-kind donations from a humanitarian supply chain perspective (for simplicity, henceforth referred to as unsolicited donations). The findings of our literature review on such phenomenon suggest that managing unsolicited donations needs a holistic approach that incorporates supply chain design and strategy. Hence, the decision to explore the potential combinations of configuration-strategy of humanitarian supply chain to manage the surge of unsolicited donations. In this paper we attempt to investigate the main research question, RQ1; How potential combinations of supply chain configuration and strategy can allow better management of unsolicited donations? Answering the main research question has helped us in addressing the secondary one, RQ2; What is the level of supply chain capabilities utilised in each potential configuration-strategy combination? The research respects the context-sensitivity of managing such phenomenon according the varying disaster characteristics. Hence, our analysis considered the disaster characteristics and potential disaster scenarios.

**Literature Review**

Our approach for this literature review is twofold. On the one hand, we wanted to explore the supply chain configurations that could be adopted for better mobilisation of resources and positioning of stocks, and the supply chain strategies that are better suited in emergency situations. On the other hand, we also wanted to identify the supply chain management practices and capabilities that can help manage (mitigate or eliminate) the material convergence phenomenon. We noticed academics, especially those in disaster management literature stream, tend to use the terminology ‘material convergence’, while most practitioners in the humanitarian logistics tend to use the terminology ‘unsolicited donations’ to refer to the same exact phenomenon. Hence, the decision to use both as keywords in our literature search “material convergence” OR “unsolicited donations” AND “manag*”. For configuration-strategy combinations we used “humanitarian supply chain strategy” OR “humanitarian supply chain design”, “humanitarian supply chain configuration”, “humanitarian logistics strategy”, “humanitarian logistics design”, “humanitarian logistics configuration”. Scopus and Google Scholar databases were used for the purpose.

**Managing the convergence of unsolicited donations**

A high percentage of in-kind non-or-low-priority donations arriving to the humanitarian site gets classified as unsolicited if they were not requested by any humanitarian actor or local authority, hence, usually they do not meet the exact needs of the affected population
Further, their existence creates stagnation issues at the entry points, especially if the humanitarian site has a single point of entry (Holguín-Veras, 2014), or as in the case of catastrophic disasters such as hurricane Katrina where the infrastructure was almost completely destroyed (Wachtendorf et al., 2010). The consequences are time delays and problems of storage, space and congestion. Furthermore, there were excessive delays caused by a lack of training of field personnel and of proper purchase agreements with suppliers (Holguín-Veras et al., 2007), hence, leading to impeding the efforts to deliver critical high-priority supplies.

Given the high complexity of the phenomenon, and the issues it generates, the literature review was focused on the identification of supply chain practices that can help managing unsolicited donations. The first practice introduced is donations management. Its importance is recognized by different authors who consider it a critical success factor in humanitarian logistics (Yadav and Barve, 2015) for providing guidelines to match the needs with the donations (Holguín-Veras et al. 2014, Arnette and Zobel 2016). A closely linked practice to donations management is how to manage the excessive unwanted received donations, hence, the relevance of waste management practices (Trivedi et al., 2015). Further, Vaillancourt (2016) and Mutlu et al. (2010) found that the adoption of material consolidation practices improves the management of material donations producing benefits in terms of costs and time. Moreover, other authors stress the importance of making needs assessment even before a disaster occurs (Tomasini and Van Wassenhove, 2009), training the staff to provide them the necessary skills to help the beneficiaries and to handle unwanted donations (Yadav and Barve 2015, Varella and Gonçalves 2016) and of developing a plan for responding to a crisis before it arises (Kovacs and Spens 2007, Natarajarathinam et al. 2009). Therefore, actual needs assessment, training & skills and planning for effective response are introduced as supply chain practices that can mitigate material convergence.

Given the heterogeneity of the actors involved in a disaster response, different authors recognize the importance of improving collaboration (Tomasini and Van Wassenhove 2009, Yadav and Barve 2015, Varella and Gonçalves 2016) and communication among them (Houston et al. 2014, Yadav and Barve 2015, John et al. 2018).

Supply chain configuration and strategy

The configuration settings of a supply chain shape the inter-organisational relationships between its members, determine the physical flow, how upstream or supply network is designed, as well as how the delivery of products/services to the end customer, downstream or distribution networks are designed, and therefore, it impacts on supply chain performance (Chandra and Grabis, 2007). Configuring supply chains as networks of interconnected companies, can be challenging. The configuration (or design) of supply chains need adequate flexibility, and configuration decisions should be as dynamic as possible to cope with the changes in their environment (Sabri et al., 2018). In the humanitarian supply chain context, the configuration largely impacts the level of preparedness and response (Kunz and Reiner, 2012). Further, logistics represent a huge part of the costs of humanitarian supply chains, hence, it becomes necessary to focus the attention on how the supply chain could be configured (Tomasini and Van Wassenhove, 2009b), while considering the need to simultaneously respond quickly and being cost efficient (Jahre et al., 2009).

Humanitarian supply chain configurations can be identified as a dichotomy from centralized to decentralized (Salvadò et al., 2016, Gatignon et al., 2010). The adoption of a centralized or decentralized structure is based on deciding which resources and activities can be kept in a central geographical location, and which ones in a decentralized hub.
Gatignon et al. (2010) explain how the International Federation of Red Cross Red Crescent Societies (IFRC) moved its supply chain configuration from centralized to decentralized. In a centralized configuration, a Field Assessment Coordination Team (FACT) is in charge of assessing the needs of beneficiaries and operates in central Head Quarter (HQ) in a developing country. Further, FACT collects all the necessary information and manages the operations in the sites that are far from the field (Salvadò et al., 2016). All the information was centralized in a Relief Mobilization Table at the IFRC Geneva headquarters and then was transferred to suppliers, National Societies (NSs) and donors. Materials flow from suppliers to the affected population through different country coordinators. The centralised configuration results in a slow fulfilment, risk of receiving the same items since donors send materials independently (Gatignon et al., 2010).

The IFRC has redesigned its supply chain towards a decentralized configuration in 2006, where three Regional Logistics Units (RLUs) were established to support the distribution. The RLUs are placed in strategic locations around the world (in Panama, Dubai and Kuala Lumpur), and centrally managed by a team based in Geneva. They act as intermediaries between the field, suppliers, NSs and the IFRC’s Geneva headquarters (Gatignon et al., 2010). Each RLU has to provide the logistics services within the geographical area of reference, and it “has preparedness capacity to deliver a range of relief items” (Jahre et al. 2009, p.1016). RLUs are in charge of supplies procurement, mobilisation, stocking, warehousing and fleet services, each in its respective geographical location (Gatignon et al., 2010). The decentralised approach proved success as prepositioned stocks are closer to beneficiaries (Jahre et al., 2009) and can be delivered in 24-48 hours after the disaster (Salvadò et al., 2016), also local sourcing and competences are favoured due to the presence of skilled staff at regional level (Jahre et al., 2009).

Humanitarian supply chain follow different strategies regardless the configurations settings, how they fit together and the impact on preparedness and response is an area that needs further research. There is a number of strategies in humanitarian logistics literature, such as, collaboration, flexibility, postponement and speculation (Jahre, 2017). These strategies are mostly on the operational level. The most supply chain strategy adopted is the cluster strategy starting 2005 (OCHA website accessed 27 May 2018). The cluster strategy is based on allocating areas of intervention for each involved humanitarian organization, where the roles and responsibilities are clearly defined and formalised (IASC, 2015). Moreover, a central coordinator is present to manage the interaction and the exchange of information between the different parties. UN OCHA defines this strategy as “clusters are groups of humanitarian organizations, both UN and non-UN, in each of the main sectors of humanitarian action, e.g. water, health and logistics” (OCHA, 2012). The aim of the cluster strategy is to improve “the effectiveness of humanitarian response by ensuring greater predictability and accountability, while at the same time strengthening partnerships between NGOs, international organizations, the International Red Cross and Red Crescent Movement and UN agencies” (IASC 2006, p.1). It is about strengthening the preparedness and the prioritization of the resources thanks to the division of the labour and a clear definition of roles and responsibilities. Thanks to the presence of Humanitarian Coordinators, the approach is applied in different countries (IASC, 2006). For instance, the Humanitarian Coordinator has to ensure coordination and information-sharing amongst different groups and avoid the duplication and overlap among sectors.

The alternative strategy is what we termed the aggregated approach. It refers to the situation in which a central coordinator is not present for managing inter-organisational activities or coordinating the work done by the organizations involved in the disaster response. Looking at the humanitarian supply chain literature it is evident how
coordination represents an important part of the humanitarian response but at the same time how it is a key challenge for the success of humanitarian supply chains (Van Wassenhove 2006, Tomasini and Van Wassenhove 2009, Chandes and Pachè 2009, Yadav and Barve 2015, Varella and Goncalves 2016).

According to Byman et al. (2000) one of the main problems of the humanitarian supply chain is the lack of planning that causes high inefficiencies like the congestion produced by the high volumes of unneeded items. Some humanitarian organizations can focus more on receiving donations from donors, rather than providing help to beneficiaries. As a consequence, they prefer to not share information and to avoid collaboration without considering the benefits that could be generated because to the adoption of a collective strategy. Therefore, given the presence of an environment characterized by the absence of a clear command and control, the lack of profit incentives and the changing priorities, coordination represents a challenge (Tomasini and Van Wassenhove 2009a). The result is a disorganized supply chain due to the limited collaboration, “the lack of recognition of the importance of logistics, the shortage of professionalism of the teams, the lack of use of technology (in particular, this refers to information systems)” (Chandes and Pachè 2009, p.337).

Theoretical Framework
Supply chain capabilities to manage unsolicited donations
Given the complexity of the material convergence phenomenon and the issues generated, it emerges the necessity to identify those approaches, that, if correctly implemented, contribute to the management of material convergence. From the literature, we built on Sabri et al. (2018) work in which eight main supply chain practices were identified; Donations management, Waste management, Material consolidation, Actual needs assessment, Training & Skills, Planning for effective response, Collaboration and Communication. The degree with which these practices suit the preparedness, response and recovery phases of humanitarian supply chain (Kovacs and Spens, 2007) will be explored theoretically and tested in the empirical part of the research.

The first supply chain capability is Material Flow Management. Donations management is linked to Material flow management since the implementation of donations management practices can help in providing guidelines to donors (Holguín-Veras et al., 2014b), and thus, in managing the flow of materials reducing the amount of low priority and non-priority items. Moreover, this is linked to the importance of introducing Waste management and Material consolidation practices to avoid serious congestion problems along the humanitarian supply chain.

The second supply chain capability is Agility which is defined as quickly “respond to sudden and unexpected changes in markets” (Lee 2004, p.4). The possibility to perform accurate actual needs assessment before and during the first stages of a disaster can improve the agility of the humanitarian supply chain. Furthermore, if stronger effort is put to improve the skills of personnel and train them on how to handle the unsolicited donations, the capacity to recognize the needs will improve, and a faster response can be implemented. As such, planning for effective response and relief operations can be implemented faster, and delays will be reduced.

The third supply chain capability selected is Alignment— that is, to “align the differing needs and dynamic roles of many players” (Van Wassenhove 2006, p.486). This can be achieved acting on collaboration and enhancing communication between the humanitarian actors involved (UN and non-UN). Supply chain capabilities are depicted in Table 1.
Supply Chain Configuration-Strategy Matrix

We developed a 2x2 matrix combining supply chain configuration with supply chain management strategy in order to identify potential different profiles. The idea behind the development of the matrix is to understand the mix of capabilities that different configuration and strategy combinations offer to manage unsolicited donations. Moreover, what are the supply chain practices and capabilities most needed in each configuration-strategy combination.

This has resulted in identifying four combinations as depicted in Figure 1: CS1 decentralized configuration and aggregated strategy, CS2: decentralized configuration and cluster strategy, CS3: centralized configuration and aggregated strategy, and CS4: centralized configuration and cluster strategy. Then, each one of the four identified quadrants will be linked to the supply chain capabilities outlined above.

Figure 1 – Supply Chain Configuration – Strategy matrix

First, the level of supply chain practices and resources (i.e. capabilities) utilised in each potential configuration-strategy profile will be explored theoretically and will be given a score on a scale (Low/Medium/High) as follows; i) Low: just one of the supply
chain practices is addressed; ii) Medium: 2 out of 3 supply chain practices are addressed; and iii) High: all the supply chain practices are addressed.

Second, following the same above-outlines score, the resulting theoretical matrix will be tested empirically and afterwards refined based on expert practitioners’ responses, as explained in the following section.

**Methodology**

In this study we applied a Delphi-like approach that enables us to elicit experts’ opinions and analyse these opinions in a structured fashion to test the appropriateness of the developed framework. Prior to commencing the Delphi study, we performed an extensive literature review to identify possible humanitarian supply chain configurations and strategies as depicted in the previous section.

Our Delphi-like approach was composed by multiple rounds and follow-up interviews.

The first step was the development of a structured questionnaire that was dispatched to a group of emergency management experts with a profound knowledge of the humanitarian field, and mainly involved in preparedness and planning phases. The questionnaire addresses the severity of material convergence phenomenon and the importance of the eight supply chain practices in different disaster scenarios. It allows to access the knowledge that comes from different sources since experts belong to different organizations and institutions, have different backgrounds and are located in different geographic areas. It consists of a set of questions aimed at collecting the opinions of experts from all over the world about a phenomenon for which incomplete knowledge is present.

Then, the second step is based on interviews to a selected panel of humanitarian logistics experts in humanitarian aid organisations to refine the findings of the first round of the questionnaire. Moreover, the interviews provide insights on the reasons behind the results obtained and on how further actions can be implemented.

**Findings**

Each one of the four configuration-strategy combinations is analysed and supply chain capabilities are explored in all quadrants. The matrix is updated with the score of the supply chain capabilities (Low/Medium/High) according to the number of practices needed in each quadrant, as depicted in Figure 2. The identification of the most important practices allows to define the configuration and strategy to adopt in each scenario. It is evident how the adoption of the cluster strategy allows dealing larger number of practices. The responses from the interviewees emphasize the usefulness of the cluster approach for achieving a better management of unsolicited donations; since it acts on favouring the collaboration and communication between the actors involved, it enables stronger coordination mechanisms among them.

**CS1** is characterized by a decentralized configuration and aggregate strategy that allows dealing with donations management practices since acceptance guidelines for in-kind donations are formalised. Most of the items are collected in the RLUs, grouped and transported in smaller batches thus generating cost and time savings, hence material consolidation is considered.

**CS1**, similar to the IFRC’s decentralized supply chain, favours the introduction of standardised processes for activities, hence, structured needs assessment is usually performed. Moreover, the importance of improving training & skills of the staff due to the aggregate strategy, for instance defining periodical training sessions. This configuration-strategy combination lacks focus on collaboration and improving the communication due to the aggregate strategy, hence, there is high attention on being prepared for disasters, rather than reacting after a crisis occurs. Indeed, thanks to presence of prepositioned stocks, planning for effective response is improved. As such, **CS1** is very...
agile, yet scores medium in material flow management, and lacks in alignment between the different humanitarian actors. Similar to CS1, CS2 has a decentralised configuration, yet with the cluster strategy more capabilities are developed, specifically collaboration and coordination. In CS2 information and resources are shared among the actors involved, thus guaranteeing flawless communication and messaging. Moreover, communication and coordination with stakeholders are important factors that affect the implementation of disaster waste management programmes.

CS3, the centralised configuration and aggregated strategy, prioritises three supply chain practices. Donations management practices are implemented, but, for sure, they should be improved since organisations do not have clear strategies for the management of unsolicited donations. Regarding the actual needs assessment, it is a practice that was present in the case of the IFRC’s centralized supply chain because it defined a Field Assessment Coordination Team (FACT) in order to assess the needs of beneficiaries and centrally manage the information. Moreover, a well-trained staff was present in order to communicate where, when and what items were needed, thus recognizing the importance of improving the training & skills. CS4 and CS3 share three practices. The difference between them is linked to the adoption of the cluster strategy in CS4 that prioritises collaboration, communication and waste management. Cluster strategy acts as a preventive plan since strategies and plans are defined before a disaster occurs to determine the area of intervention. Thus, there is a focus on planning for effective response recognizing the importance of preparation and pre-positioning of resources.

Figure 1 – Supply chain Configuration, Strategy and Capabilities
The difference between CS2 and CS4 is linked to the possibility to deal with material consolidation practices. In the decentralized configuration, items are grouped in small batches and then delivered to the affected areas. In contrast to the case of centralized configuration, that is not well focused on material consolidation. In this case, the items are just assembled in large batches, thus generating high costs and delivery times. The decision could change from country to country according to factors like the capacity of being prepared or the impact that political and security constraints have on the mobilisation of resources. For instance, in a country that usually faces the same type of disaster, it is preferred the adoption of a decentralized configuration with availability of stocks at regional level. Instead, in cases where the disaster hits a country that is not well prepared, the adoption of a centralized configuration could result easier, since it involves the management of a single warehouse.
Discussion and Conclusion
The high importance of agility (i.e., communication and collaboration) emerges from the analyses of the questionnaire and interviews. Most of the experts recognize the relevance of improving communication among the involved humanitarian actors and to implement a coordinated communication strategy with the aim to keep everyone involved and to spread the same strong message (e.g., cash donations are better than in-kind donations). Moreover, it emerges the importance of planning for effective response and thus of being prepared before a disaster occurs. As highlighted by some experts, an important part of the communication strategy is represented by needs assessment. It is not only linked to the definition of the needs as soon as the disaster arises, but to their identification beforehand the emergency. The analyses suggest that different configuration-strategy combinations can suit different types of disasters. This can help us focus the efforts on developing the needed capabilities that are most relevant to the configuration-strategy-disaster characteristics.

For instance, the combination in CS1 is more suited for addressing unsolicited donations in repetitive regional/local disasters with limited geographical dispersion and high local coping capacity. CS2 is more suited to address disasters where there is short response time, geographically dispersed affected-areas and low local coping capacity with the emergency. Therefore, the implementation of a decentralized configuration will reduce the time needed to manage the emergency and the cluster strategy will improve the capability to cope with the high volumes of items present by enhancing collaboration and communication. CS3 is very agile and there is high alignment, therefore, it can be suited for disasters that need the involvement of a large number of local and international humanitarian actors, this means there is medium-low local coping capacity with the disaster. CS4 combination is suited for disasters that are geographically dispersed or that do not strongly affect the local coping capacity. The adoption of a centralized configuration could result easier in cases where the disaster hits a country that is not well prepared.

This study makes several contributions to humanitarian supply chain literature and practice. Considering how valuable (and often scare) are the resources needed to develop capabilities especially in a humanitarian emergency setting, the study provides guidelines to prioritise the relevant capabilities in potential supply chain configuration-strategy configuration. First, we extend the findings of prior literature to identify proper combinations of supply chain configuration and governance strategies. The matrix provides novel insights to reduce the flow of unsolicited donations and to manage their impact. The analyses presented here guides humanitarian supply chain practitioners on how to better configure humanitarian supply chains and select their strategies, and to identify the most relevant capabilities needed to be developed whilst considering the constraints of the prevalent conditions.

Although all care was put to provide a comprehensive analyses, the present study was limited to the opinions of the members of the 2 expert panels, who mainly belong to international humanitarian organisations. Therefore, an avenue for future research is to further explore this matrix with respondents representing different humanitarian actors. Further, another topic for future research is to deepen the analysis by taking into consideration the situational environment of the disaster-affected location – that is, to link and customise the matrix according to different disaster characteristics.

Abstract

One of the responses to the fight against climate change by the developing world has been the large-scale adoption of solar energy through the installation of photovoltaic farms. The realization of solar energy producing sites involves complex decisions and processes in the selection of sites. The knowhow on this is not available with all the stakeholders supporting (e.g. banks financing the project) the industry value chain. In this paper, we answer how open innovation using satellite imagery based big data analytics can deliver objective assessment of technical, economic, social, and environmental aspects for stakeholders of solar industry value chain.

Keywords: Open innovation, Satellite imagery, Solar industry value chain.

Introduction

Solar energy industry has been touted to be a beacon of hope for a clean-energy future across the world and has received special attention by developing countries such as India which have put in place investments and enabling policies for large scale adoption of renewables to address their rising energy requirements (Kapoor et al., 2014). However, the high initial investment cost associated with solar energy infrastructure is one of the primary barriers that has to be tackled to accelerate its adoption for production of renewable energy (Ansari et al., 2013).

To overcome such barriers, policymakers in the solar photovoltaic sector have constantly fiddled with creating catalytic policies as instruments to induce market growth. Inducing market growth was expected to trigger investments by firms operating in technology adoption and innovation sector (Hoppmann et al., 2013). Even with such elaborate efforts to solve persistent problems, new bottlenecks continued to arise. For instance, unaware of the workings of novel technology-based industries, stakeholders...
who had to invest in the solar photovoltaics value chain (e.g. banks) often viewed the investments as risky and were therefore reluctant to allocate capital (Wilkins, 2002). Acknowledging the importance of the expansion of renewable energy, the policymakers in developing countries like India have been continuously attempting to tackle these bottlenecks using policy interventions which can incentivize investments by the private sector in solar photovoltaics (Jolly & Raven, 2016).

Financing landscape is a bottleneck for solar energy projects and acts as a key barrier to scaling the production of renewable energy in India (Kar, Sharma, & Roy, 2016). One of the key issues contributing to financing landscape bottleneck is the lack of reliable and objective data (e.g. irradiation data over time for different sites, history of performance of commercial solar projects, etc.) in the solar energy industry. Lack of objective data negatively influences the perception of bankers and their risk attitudes towards financing commercial scale solar energy plants (Umamaheswaran & Rajiv, 2015). This negative influence constraints local commercial banks from financing the solar energy projects and thereby pushes the projects to find foreign sources of capital for execution (Sarangi, 2018). The phenomenon aligns with research in the policy landscape of renewable energy projects which suggests that the cost of capital increases with a perception of risk which then significantly influences the business case of a project (Noothout et al., 2016).

Satellite imagery is a unique source of data that has the ability to provide global coverage. The notable transition of the space industry from an open innovation perspective is the move from its controlled nature of national space programmes which shackled satellite data with restrictions or made it expensive to procure to a new era of open-access satellite data (Wulder & Coops, 2014). Examples of this include the 2008 decision of the US Geological Survey (USGS) to provide open and free access to the world’s largest archive of Earth imagery collected by its Landsat satellite series which goes back to the 1970s (Wulder et al., 2012), and Europe’s efforts to make its Sentinel satellite series data openly accessible (Malenovský et al., 2012). These radical shifts in making data available have enabled the exploitation of satellite big data to create socio-economic applications (Kitchin, 2014).

In our paper, we are interested in answering the research question ‘how open innovation using satellite big data analytics can plug information gap for the stakeholders supporting the adoption of solar photovoltaics’. We use a case study of proposed solar photovoltaic site in the Bangalore region to demonstrate how satellite imagery contributed to removing the bottlenecks present in the financing landscape of solar energy projects. We document how satellite imagery helped in independently assessing the technical, economic, social, and environmental viability of projects. The satellite imagery combined with other data sources such as yearly radiation, dew point temperature, wind direction and wind speed were subjected to multi-criteria selection analysis to derive an overall suitability index score for a solar photovoltaic site.

**Data and Analysis**

We utilize the methodological foundations laid down by Eisenhardt (Eisenhardt, 1989) and Yin (Yin, 1994) in case studies. We study and document the assessment of potential photovoltaic sites in the Bangalore region in India to answer the research questions. Despite various normative nature of methodological points, case studies provide grounds to study the effect of information systems on users, organizations or the society (Kaplan
& Duchon, 1988). In our case study research, the open innovation of using satellite data for assessing the potential of photovoltaic sites is based on understanding the contribution of the data to the research question itself (Siggelkow, 2007). Our choice of a single-case study in this paper allows us to answer different form of research questions such as “how”, “what” and “why” through which we are able to analyses the operational challenges in assessment of photovoltaic projects faced by institutional investors in India.

The case study features an assessment of sites for the installation of photovoltaics in the Bangalore region in India. The primary sources of information for the assessment of photovoltaic projects used in this case study are the satellite imagery and data provided by Landsat 8 and Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) satellites. Landsat 8 is a satellite in the Landsat program, which is run by the United States for four decades now. The Landsat represents the world's longest continuously running collection of space-based data which was made open to public access in 2008 (Wulder et al., 2012). Similarly, ASTER is a joint US-Japan satellite flown in 1999 to gather data for creating detailed maps of the Earth’s land surface temperature, reflectance, and elevation. Similar to Landsat’s public access declaration, ASTER’s data products have been made available to open access since 2016. Our case study showcases how such openly available satellite data products can enable their adoption in developing countries who otherwise may not have had the resources or the intellectual property to build such complex systems that can offer information continuity for past several decades.

From the perspective of assessment of the power generation using photovoltaics, a broad range of parameters that encompass climatic conditions, geological features and land access affect the decision making. Table 1 provides a list of key parameters and the source from where the data have been taken for the assessment of photovoltaic projects. The geological and access condition data were sourced from Landsat 8 and ASTER satellites respectively. The climatic conditions data is sourced from both ASTER and Automatic Weather Station (AWS) data, which is again a mix of both satellite-based and ground-based measurement of key weather parameters. The AWS data in the case study was procured from a commercial vendor.

The satellite data provides information extracted for various geological and climatic parameters captured by the sensors onboard the ASTER satellite over the Bangalore region and plotted according to the geographic area of the city. The data from the sensors which have recently been made available openly form the basis of accurately quantifying
the geological and climatic parameters. All the geological and climatic parameter captured within the satellite data over the terrain. The variations include the total radiation received on the ground, height over the terrain of the region above mean sea level (captured through digital elevation model), changes in the slope of the terrain over the region, the airborne water vapor captured as dew point temperature, compass direction that a slope faces captured as aspect, variation of the wind speed, and the wind direction over the Bangalore region. The underlying data is geo-referenced (i.e. tagged with latitude and longitude) and provides accurate mapping of the changes over the Bangalore region for the parameters in question. The geo-referenced satellite data for the Bangalore region is transformed into 70749 segments with area of 2225 m² per segment using a combination of data classifier algorithms including Gaussian Naive Bayes, linear support vector machine, kernel based support vector machine, decision tree, and random tree (Qian, Zhou, Yan, Li, & Han, 2015). Each of the segments have codified identifiers which translates back into a location in Bangalore. We intentionally do not focus on describing the technicalities of using data classifiers to calibrate and derive the baseline data for the attributes recorded in Table 1 from the underlying satellite data. Within the purview of this case study, we believe it is more meaningful to discuss as to how the baseline data post such technicalities is operationalized in the decision-making process to arrive at an assessment of proposed photovoltaic sites rather than describing the standardized computation techniques in satellite image processing. The underlying data from the geo-referenced satellite data as illustrated in The satellite data forms the basis of extracting the quantitative values of parameters listed in Table 1. The geological parameters in the figure such as slope, aspect and height captured against the incident radiation directly affect the interaction between the radiation from the sun and surface of the Earth which in turn affects the output of the photovoltaics (Nguyen & Pearce, 2012). Similarly, local weather variables such as local radiation flux, temperature, wind speed and direction have a bearing on the thermal operating environment, which affect the output of the photovoltaics (Skoplaki & Palyvos, 2009).

Within the list of the parameters recorded in Table 1, no single parameter will be sufficient enough to arrive at a decision on the proposed installation of photovoltaics. The synthesis of wide array of parameters listed in Table 1 pose information processing complexity in the decision making. To address this complexity in decision making, the firm processing the satellite and allied data chose a Multiple Criteria Decision Analysis (MCDA) procedure to derive a decision-making algorithm. Within the MCDA framework, the Analytic Hierarchy Process (AHP) has been utilized to assign weights to each of the parameters listed in Table 1 on the basis of the relative importance to power generation using the photovoltaics. The baseline quantitative data for the AHP process is derived through the satellite data, which captures the data over the Earth’s surface according to the latitude and the longitude. Therefore, the open data from the satellites form the foundation of the MCDA process and aid providing crucial information in identifying a number of functional parameters and assessing their comparative importance for a potential site for the installation of photovoltaics. We intentionally do not detail the AHP process since it has a well-established theoretical (Saaty, 1990) and case study history (Ho, 2008) in management literature. The final computation of the site suitability index based on the AHP process generates end weights which lies between 0 and 1, corresponding to the “worst” and “best” sites, respectively. From a methodological perspective of connecting the AHP to the problem at hand, the Simple Additive Weighting (SAW) is used to arrive at this evaluation criteria. SAW is an established
metamodel for multiple criteria decision analysis (Kaliszewski & Podkopaev, 2016), which in this case study is utilized to aggregate the weights to arrive at an overall site suitability index based on relative importance of each of the functional parameters listed in Table 1.

Results and Discussion

As we discussed in the data and analysis section, the assessment of a potential photovoltaic site cannot be based on the key metric of how much power it produces alone. Factors such as the distance to road access, water access, height and slope of land have a bearing on the initial infrastructure and operating costs of the photovoltaic installation. Therefore, the end analysis using the open satellite data allows to consider comprehensive factors that affect the overall investment and operations rather than produce an assessment based on a prominent output metric. The proposed solar photovoltaic installation sites vary from 2 MW to over 200 MW of energy on the power generation parameter, but their overall site suitability scores range from 0.35 to 0.22 respectively. The limited range of the overall site suitability index against the possible range between 0 to 1 can be attributed to a combination of geological and climatic conditions of the Bangalore region, and the land rights attached to the site (i.e. some latitude and longitudes might turn out to have higher site suitability but the ownership or the right to those lands may not be available to the promoters of the solar photovoltaic installations). Giving due consideration to factors such as topographic, local weather parameters and access to the sites, it is found that several of the high power generating proposed sites have a lower overall site suitability score than their smaller installation counterparts. We have organized the discussion of the results and its implications from the perspective of stakeholders supporting the solar industry value chain.

The assessment conducted by utilizing the open data from satellites has specifically helped loan case officers of banks in Bangalore who now have a basis of relying on the scientific results generated through the data analytics process to make informed decisions. Previously, the case officers who faced bottlenecks due to an insufficient lending experience within their institutions had to engage with external expertise to get such assessments performed. This often led to a practice of clubbing several projects into project volume before submitting to external consulting firms to reduce the per-project cost of assessment. This in-turn caused delay ranging between 3-4 months for the photovoltaic industry loan seekers and at the same time led to increased loan servicing costs which were recovered by offloading to the applicants. The reduced transaction time and costs attained through open innovation using satellite imagery brings more certainty for the industry in planning and operationalizing their roadmap for procurement and installation of photovoltaic modules. This clearly demonstrates that the fundamental value of liberated data is its influence within the transactions between stakeholders supporting the value chain as well as external technology exploitation based on open innovation (Lichtenthaler, 2008). Breaking the shackles of expensive or restricted access to new generation satellite data enables the adoption of the insights generated by the stakeholders supporting the photovoltaic industry value chain. Therefore, the open innovation based on satellite big data allows invoking an independent source of truth, which otherwise might not have been possible owing to the barriers of access.

The firm which has developed the solution discussed in this case study also enabled cloud-based deployment of the final results of the site assessment for the Bangalore
Providing basic training to the loan case officers on how to access and interpret the end results of the data analytics process will build up institutional capacity within the banks. The cloud-based integration of the data analytics platform helps case officers to seamlessly integrate the platform into their daily workflow routines. The combination of open satellite data analytics with the cloud-based deployment clearly lubricates the overall process of exchange of information between the stakeholders. It also provides a foundation to scale-up the use of the end results in the overall lifecycle of the lending and recovery process of the banks. For example, once the assessment of the proposed site is completed and a positive decision to provide credit has been made, the open satellite data with the cloud-based delivery insights can also be used to monitor the use of the credit by the borrowers. The open satellite data in this case allows for the periodic monitoring of the invested asset with the capacity to keep track of changes in construction and its alignment with the projected milestones in the use of the credit by the industry borrowers. Therefore, the applications are not just limited to the initial assessment of the potential photovoltaic sites but there is definite scope for scaling up of use of open satellite data for a deeper deployment in the entire cycle of credit lending and recovery. This represents the horizontal scalability of the underlying innovation.

With the global rise of development of large-scale solar parks, there is an emerging policy and investment decision conflict based on land use that is expected to emerge. (Späth, 2018) has underlined the tension that may emerge between renewable energy development using large-scale on-field photovoltaic generation and the preservation of agricultural land. This conflict may especially be of interest in developing countries since several of them have dense populations. We believe that the case study sheds light on how innovation using novel technologies such as big data analytics based on open data can be leveraged to tackle these emerging problems by providing holistic information to policymakers. The modelling of the utility of land based on the type of land, its current usage, and access to it has been taken into consideration in the site suitability assessment conducted in this case study. There is potential to extend the utility of land use classification model via satellite big data analytics to derive assessments to balance energy policy against the land preservation charter. This extension will provide a basis for decision making by policymakers that will be inclusive and informed of natural environment.

Research indicates that cyclical peddling of policymaking may arise to treat new bottlenecks as impetus is provided for pushing the adoption of novel technology innovations, which may lead to compulsive policy-making (Hoppmann, Huenteler, & Girod, 2014). Adoption of open innovation based technology solutions from lateral sectors (in this case, space industry solutions into energy industry) can alleviate the bottlenecks by removing the information gaps. This in-turn has the potential to avoid compulsive policy-making and ensure effective functioning of stakeholders who support the value chain. Our study indicates that it is important for policymakers to be aware of liberalization of data sources in allied sectors that were previously locked away in the form of lack of access due to sharing restrictions or being too expensive to adopt. Post liberalization of such data sources, the legacy value to the information in such data source may lead to disruptive open innovations which hold the potential to remove previously existing bottlenecks in the processes within the value chain. The case study demonstrates how open data with new sources can lead to taking a comprehensive approach than just taking the obvious or most prominent (e.g. total power) factors into account for decision making.
Our case study explores one of the ways in which open innovation using satellite data can be deployed to create value for stakeholders in an industry value chain by overcoming the legacy barriers for adoption. The results of the case study should provide motivation for practitioners in developing countries to exploit outside-in open innovation based innovation strategy (Bagherzadeh et al., 2019) in building services by combining the liberalized open satellite data and other data sources to support stakeholders in several other industry sectors (e.g., agriculture, infrastructure). We believe there is scope for adoption of products and services using open data from satellites by stakeholders tackling socio-economic or humanitarian challenges such as disaster management, climate change, food security, etc. Open innovation using satellite big data combined with other data sources also have the potential to help support achieving sustainable development goals especially in the context of challenges faced by developing countries.

Within the realm of research based on open innovation, our case study only deals with the pre-installation of the photovoltaics. There is scope to study the effects of open innovation post-installation of the photovoltaics since power monitoring systems are expensive and have a bearing on the operational life of the installation (Triki-Lahiani, Bennani-Ben Abdelghani, & Slama-Belkhodja, 2018). Open innovation based on allied technologies such as Internet of Things (IoT) have the potential to provide solutions to such monitoring problems (López-Vargas, Fuentes, & Vivar, 2018). Moreover, with the emergence of application of novel technologies such as artificial intelligence into the solar photovoltaic industry (Mellit et al., 2009), a larger kaleidoscope of service research on such technologies operating at scale and across the industry value chain on the basis of open data can be explored. From the standpoint of building on top of the existing open satellite data, there are implications to be explored for policymakers and supply chain practitioners based on the implementation of newer technologies such as machine learning. Implementation of these new technologies is expected to deliver better results in various activities within the photovoltaics value chain such as designing higher efficiency solar power plants (Şahin et al., 2014) and large-scale installed capacity monitoring (Assouline, Mohajeri, & Scartezzini, 2017).

**Conclusion**

Satellite big data based open innovation creates a foundation for invoking of an independent source of truth in assessing proposed photovoltaic sites. The tailored assessment conducted using open data has demonstrated the potential for loan case officers of banks in Bangalore to make informed independent decisions for the proposed photovoltaic installations. The proposed solution discussed had a positive bearing on the working of the stakeholders supporting the photovoltaics industry value chain through its ability to reduce the transaction time and costs between the financial institutions and the entrepreneurs. The ripple effect of this catalytic process is the greater certainty for the Indian photovoltaics industry in planning and operationalizing their roadmap for procurement and installation of modules. The utility of satellite big data within the relationship between the bankers and the industry has scope to scale-up by considering the overall lifecycle of the lending and recovery process of the banks. The study demonstrates the potential for using open innovation on the basis of liberated data to resolve bottlenecks in transactions between the stakeholders supporting the photovoltaics industry value chain. The utility of open innovation based on satellite big data analytics with the cloud-based deployment has potential to scale horizontally and vertically within
the solar industry value chain. Exploring such scaling opportunity has the potential to help policymakers solve socio-economic, techno-managerial and environmental challenges in the Indian renewable energy penetration context including management of current power assets, future project planning, management of incentives, deepening of rural electrification and preservation of agricultural land.

Abstract

The proliferation and implementation of technologies that provide data has opened up a myriad of opportunities and previously not exploited sources of and for innovation. The purpose of this paper is to provide an up-to-date review of the literature on data-driven innovation with a specific focus on its opportunities and challenges. A critical analysis is performed with the aim to define a research agenda and the most prominent key actions that could give directions useful for researchers and practitioners.

Keywords: Innovation, Development, Data, Big Data, Artificial Intelligence, Data-driven innovation

Introduction

While innovating in the field of innovations might sound a paradox itself, it is certain that the field is in constant evolution both in practice and in research, reaching however a rather mature status quo. Meanwhile, the proliferation and implementation of technologies that provide data has opened up a myriad of opportunities and previously not exploited sources of and for innovation. Big data, artificial intelligence, Industry 4.0 are only some of the trends that are gradually being implemented and integrated in the operations of the different actors forming the innovation eco-system.

While in practice big data facilitators’ diffusion is ongoing, we question the current status quo of research by raising the question of what, if anything, big data brings to the field of innovation. Finding the right answer might be difficult, especially taking into account the still fuzzy conceptual limits of the big data term, situated at the confluence of social science - where is often more useful- and computer science, a vital component for generating and exploiting it.
It is in this context that we aim to contribute with our research by providing a holistic conceptualisation and an up-to-date review of the literature on data-driven innovation with a specific focus on its opportunities and challenges. A critical analysis is also performed to draw a research agenda and to formulate possible key actions that could give directions for researchers and practitioners.

To the extent of our knowledge, our contribution is the first review to attempt and elucidate the link between data and innovation. Its originality consists in putting a balanced emphasis on both terms, since the existing literature is abundant in analysing them separately.

Method

The field of innovation is abundant in systematic literature reviews, among the most comprehensive ones we mention Keupp et al. (2012) on strategic management of innovation, and Bagno et al. (2017) a review of innovation management models. A series of publications are also available for certain specific topics in relation to innovation, as examples see measurement in the software industry (Édison et al., 2013), product-service systems (Boehm and Thomas, 2013), family firm (Duran et al., 2016), open innovation (), or even more specific barriers to open innovation (Oumlil and Juiz, 2016) to mention just a few.

According to various authors (Budgen and Brereton, 2006; Boehm and Thomas, 2013) a systematic literature review implies three distinguished phases: i) review protocol for defining the objective and scope, ii) a search strategy for encountering relevant literature, and iii) documentation and analysis to answer the question what can be learned from a rigorous analysis. The different authors agreed on the technical details of each phase. Two researchers worked separately and in parallel, but following the same methodology in order to search, select and analyse existing sources of interest for the present contribution. A tabulated spreadsheet template has been used to categorise the selected papers. When finished, the results have been gathered in a unique file while shared and commented among all the authors.

The technical details of the process are visually represented in Figure 1. The authors centred the attention on a unique database, namely Scopus, considered one of the most inclusive databases including all scientific fields. Since 2004, Scopus has delivered a comprehensive overview of the world's scientific research output across all disciplines (Elsevier, 2019). Being the largest abstract and citation database of peer-reviewed literature, and considering the central focus of our task, we do not consider relevant to contemplate other alternatives (Google Scholar, and or discipline-specific databases).

No exact timeframe was set-up and we left open all possible extremes (lower end to nowadays), even including publications from 2019, ongoing. The main reason underlying this decision is that we aim to capture, indifferently of time, all publications focusing on data and innovation, being able to detect possible transformations of terminology or a different understanding attributed to the analysed term. A total of 1018 documents have been identified with the less restricted search terminology. While the focus is on novel approaches, additional search terms have been added resulting in 344 documents. All abstracts have been reviewed in order to make sure that no important source is left out of the review.

A final selection of 30 articles that most fit the purpose of the present review are analysed in detail and presented in the second part of our Results section.
Results

In this section, the results of our review are presented and organised according to relevant aspects including a general overview referred to 344 sources, followed by a more detailed and specific review of a selection of 30 articles that we considered highly relevant for the present review.

The information showed in Figure 2, Figure 3, Figure 4, Figure 5 and Figure 6 are commented globally, allowing for some general highlights. Table 1 contains a summary of the selected sources according to the reviewed items.

Compared to more mature fields, but also to other recent trendy topics (like open innovation, the sharing economy, or gamification in education) research on relating the concepts of data and innovation is (still) embryonic. This finding is somehow surprising since technological advancements and solutions exist, hints on their implementation are also present, and it is believed that exploitation potential is infinite.

In the past decade the body of knowledge has been exponentially growing reaching a total of 344 scientific publication, out of which 114 have been published in 2018 (Figure 2). However significant, the number of scientific articles falls far behind the huge interest raised by the relationship of big data and innovation in real practice.
Figure 2 – Chronological evolution of publications by year

Figure 3 – Classification of publications by discipline

Figure 4 – Classification of publications by type
Figure 5 – Classification of publications by country

Figure 6 – Classification of publications by journal
Further it is interesting to observe, that a classification of the scientific outputs by discipline (Figure 3), shows the predominance of the computer science field (184), followed by social science (112) and business, management and accounting (84) which if summed up equal the amount of the top-ranked field, followed by engineering. These results are illustrative of the fact that possibly the technological component and the (big) data matter is the protagonist and its novelty, complexity and scientific discovery and value makes it worth for researchers to publish their results in specialised journals. In addition, all other disciplines appear to be fields of application, contributing to the body of knowledge by describing the phenomena, envisaging possible uses and benefits, expressing opinion, reflecting on the evolution, presenting some experience, among others.

Out of the 1,018 scientific documents found (Figure 4), outcomes are predominantly in form of articles (539), followed by conference papers (298) and relatively few book chapters (52), with authors’ affiliation (Figure 5) in the US (62), and followed by Germany (40), UK (36), the Netherlands (31), Italy (29) and China (19). When classifying the outcomes by publications, we find a series of well-known and strongly established conference publications and journals (in italic), on the top positions situating Lecture Notes in Business Information Processing, Government Information Quarterly, Lecture Notes in Computer Sciences, followed by Sustainability and Technological Forecasting and Social Change journals. The observation relative to Figure 6 is that the majority of publication appeared in Conference Proceedings which confirms again the field's emergent nature, while also putting in evidence the journals that concentrate the reviewed scientific outcomes.

Due to space limitations the detailed review of selected publications can not be included. It consists in a 30 rows x 6 columns, where each row represents a paper and the columns are paper author/s; topic, focus, aim; theoretical framework used or mentioned; method; source of Big Data; type of innovation. The table is available upon explicit request from the authors.

The status-quo of research in relating big data to innovation can be summarised in the following points:
- Existing work is basically defining the concept and generic
- The approach is predominantly centred on technology, while the field of application and resulting outcome (in the form of innovation) is not explored
- Theories and theoretical frameworks considered as classics in the general field of innovation are neither mentioned or used in the reviewed publications
- Empirical evidence is scarce and anecdotic
- The few empirical papers when giving details on the type of innovations resulting from data are predominantly focused on product innovation; other typologies (service, process, business model, etc.) are missing
- Traditional and established innovation surveys do not include relevant details to capture the existence and relation to data
- Sound and proved argumentations and justifications of the relationships between data and innovation are missing
- The relationship on how data brings value to innovation is not elucidated

**Research agenda**

When drawing a possible research agenda we opt for a two-step approach. First, we select and show the reviewed publications in terms of challenges and opportunities (Table 1) and, second, based on our own interpretation and expertise in the field, we
formulate a resulting research agenda that covers 8 issues which are relevant for the future.

Table 1 – Review of selected publications
As a research agenda to explore the connection of data to innovation, we propose the following areas for research:

1. Generating a common understanding of the Big Data concept
2. Theoretically grounding research on Big Data
3. Overcoming the research-practice gap
4. Conducting valid evaluations (integrating data-sources into innovation surveys and/or conducting independent topic specific evaluations; conducting relevant case studies)
5. Generating data and communicating the benefits of data-driven innovation with valid examples
6. Exploring other innovation types beyond product innovation
7. Connecting and balancing big data and innovation
8. Motivating innovation researchers to collaborate with computer scientists in the framework of international, multidisciplinary collaborative projects

Conclusion

The present contribution aimed to offer a state of the art on data-driven innovation, first by identifying the existing and related scientific publications, reviewing them in terms of aim, theoretical foundations, methodological approaches present in the field as well as uncovering research gaps and setting up future research agenda. Additionally, our contribution could be considered valuable by novice researchers who aim to position and start their research in the field of innovation and big data, in giving them an overview on the field with respect to “what we have” and “what we lack”.

Although some years have already passed since, according to Wamba et al. (2015), the extant literature identified ‘big data’ as the ‘next big thing in innovation’ (Gobble, 2013), this statement remains valid nowadays. Consequently, all pillars in the innovation ecosystem need to co-work and further elucidate what is the roadmap to follow in order to truly achieve making ‘big data’ as the ‘next big thing in innovation’. In this way, there will be a contribution to the body of knowledge on the topic, which is vital in a field still in its early stages. The global question is not if but rather how organisation can benefit from the value of big data.

Abstract

The purpose of this research is to reveal the process of new digital service development, and explore the deployment strategy of digital services, in order to shed more light on the mechanisms of service innovation in the digital age. An in-depth case study is used to identify the digital NSD process and investigate the contingencies of digital NSD. Digital NSD is entrepreneurship intensive and in fast clock-speed. Outsourcing is highly popular and valuable in digital NSD. Digital NSD processes have to be extremely agile to the dynamic context, meeting with ever-changing customers’ needs and fast updated technologies.

Keywords: Digital Services, New Service Development, Service Innovation

Introduction and Purpose

The purpose of this research is to reveal the process of new digital service development, and explore the deployment strategy of digital services, in order to shed more light on the mechanisms of service innovation in the digital age. New service development (NSD) is largely conceived and characterized by previous research as less stable, ad-hoc and informal processes (Santos & Spring, 2013), which are more apparent in the e-services context (Riedl et al., 2011).

The service sector, also known as the tertiary sector, is the third of the three economic sectors, where the others are the secondary sector (referring to manufacturing) and the primary sector (referring to raw materials). The significant role of services in nowadays economy arouses academic researchers’, practitioners’ and entrepreneurs’ interests and surging attention to NSD (Santos & Spring, 2013; Zomerdijk & Voss, 2011). Though NSD stems from new product development (NPD), academic researchers are increasingly exploring and comprehending how NSD is distinctive from NPD (Johnson et al., 2000; Menor et al., 2002; Santos & Spring, 2013; Zomerdijk & Voss, 2011). Moreover, the assortment of services in the tertiary sector also suggests that distinctions exist between the development mechanism of different types of services, such as experiential services, traditional services, and digital services etc. (Menor et al., 2002; Zomerdijk & Voss, 2011). This research mainly focuses on digital services.
Servitization and digitalization, as two megatrends, is bringing about a revolution to the contemporary economy (Häikö & Koivumäki, 2016). Digital services are growing rapidly with the “transformational development of information and communication technologies” (Barrett et al., 2015, p.135). In 2018, the worldwide revenue in the digital services amounted to approximately $18.7bn USD and was predicted to show an annual growth rate (CAGR 2019-2023) of 9.0 % (Statista, 2019). This growth rate shows that digital services are creating new markets.

Digital services, also known as electronic services (e-services), are the service offerings delivered via “electronic network formats”, such as internet and wireless networks (Rust & Kannan, 2003, p. 38). Digital services are different to traditional brick-and-mortar services in terms of barriers to entry, continuous improvement, cost structure, cyclic and iterative development, disintermediation, a high degree of outsourcing, modular architecture, and transparency (Menor et al., 2002; Riedl et al., 2011). As a result, these contingencies create managerial challenges and new research opportunities. For instance, the high clock-speed and short time-to-market nature of digital services renders the management of new service development (NSD) and service innovation challenging (Bowman et al., 2010).

Theoretical Background
NSD research has historically focused on the creation of the service from a marketing or innovation management perspective (Mendes et al., 2017; Papastathopoulou & Hultink, 2012). Whilst less attention has been placed on the systems or processes that are co-created to support the introduction and provision of the service (Mendes et al., 2017). Informing NSD research from the operations management is highly suggested by many scholars (Mendes et al., 2017; Menor et al., 2002; Papastathopoulou & Hultink, 2012).

The definition of a new service is contingent upon the newness of the service offerings or service process, which differentiates between radical innovations (offerings not formerly provided) and incremental innovations (changes to existing offerings) (Johnson et al., 2000). The management of NSD has become a central concern for sustainable development in substantial service industries (Johnson et al., 2000; Menor et al., 2002). Although NSD derives from the plethora of rigorous studies on the NPD. NSD does differ from NPD in plenty of key aspects, due to special characteristics of service (Papastathopoulou & Hultink, 2012). NSD processes are verified to be a lack of formality and rigidity, compared to NPD (Menor & Roth, 2008). NSD remains immature among the least researched and comprehended subjects in the service management literature (Mendes et al., 2017).

NSD is an entrepreneurial process that narrates the value mechanisms and integrates resources and capabilities to define, design, and implement service (Tatikonda & Zeithaml, 2002). According to Johnson et al. (2000), the NSD process cycle consists of four fundamental phases (namely design, analysis, development, and full launch), which is highly iterative and non-linear/cyclic in nature (Bonomi et al., 2013; Menor et al., 2002). The NSD process cycle identifies the essential NSD stages revolving around the design and configuration of the service concept elements and recognizes the operational resources and capabilities in the development process (Santos & Spring, 2013).

The emergence of the Internet and then digital services further complicated the NSD research (Riedl et al., 2011). This is because NSD research is now divided into traditional brick-and-mortar services (such as healthcare, hospitality, financial banking, and transportation) and digital services (such as web-based or Internet-based service) (Bitner et al., 2000; Geum et al., 2016). Substantial researchers necessitate the exploration of NSD in the digital age (Barrett et al, 2015, Riedl et al., 2011).
There are substantial differences between traditional services and digital services, for instance, the transparency of service feedback, improvement status (continuous or discrete) of services, cost structure (fixed and marginal costs), degree of outsourcing, and development speed of new services (Geum et al., 2016; Menor et al., 2002). Digital services are dependent upon the user-interfaces, layout, and the location of menus, regarding the approaches to identify the functional characteristics (Santos, 2003). While traditional services are dependent upon customer participation (Geum et al., 2016). Digital services can be much easier to design and deploy than their physical-service equivalents in NSD processes, since the majority of the service processes happen in the back-office (Menor et al., 2002). Moreover, the interactions between customers and digital services themselves become more transparent, especially in the back-office (Menor et al., 2002; Riedl et al., 2011).

The search and transaction costs and variable costs of service provision and service realisation are reduced via electronic disintermediation (Menor et al., 2002; Riedl et al., 2011). Digital services tend to be decomposed generally contingent upon modular architecture, while traditional services are contingent upon service process (Geum et al., 2016). General delivery or modular components can be easily and rapidly turned over to third-party service suppliers, due to the nature of modularity of digital services (Geum et al., 2016). In turn, outsourcing is highly popular and valuable in digital services sectors (Geum et al., 2016; Menor et al., 2002). Distinctive features of digital services should be considered, when exploring NSD in the digital age.

As a result, these contingencies make the e-service industry more dynamic, uncertain, highly competitive, and a higher risk of imitation (Geum et al., 2016; Menor et al., 2002; Riedl et al., 2011).

**Methodology**

An exploratory case study approach (cf. Eisenhardt, 1989; Yin, 2009) was adopted, as it enables an in-depth understanding of the complex and contemporary phenomenon in the real-life digital context. Although multiple research cases are typically welcomed, which is considered to augment external validity and reduce observer bias (Voss et al., 2002; Yin, 2009). Single case studies can provide in-depth analysis to develop meaningful insights (Beltagui, 2018; Dubois & Gadde, 2014) in this specific digital context, where NSD is considered as complex and dynamic (Papastathopoulou & Hultink, 2012; Santos & Spring, 2013). Moreover, academic researchers can capture complex interactions and a better understanding of the dynamics with a single case (Beltagui, 2018). The study was underpinned by abductive reasoning where the researchers iterated between theory and data (Kovács and Spens, 2005).

Since we investigated the development and deployment of digital services, the unit of analysis is the digital NSD process. The case organization need entail NSD and involve information technology with a network of suppliers and partners that take part in the provision of digital services via the Internet. Case organization in this research mainly provide information services via the Internet (including the activities of web search portals, data processing and hosting activities, as well as other activities primarily supplying information) (UNSD, 2008).

Our research followed a three-phase approach. First, the prototype of the interview protocol was developed based on the extant literature. Then, the protocol was refined with feedback from academics. Second, pilot interviews were conducted with Case Education in March 2018. The further amendment was developed for the protocol to mitigate the ambiguities between academics and practitioners. Third, we investigated the focal organizations between July to September 2018. At the same time, the case study protocol
was kept updated iteratively in light of the emergent data and field notes. The abductive way to develop the protocol was appropriate, as we investigated a nascent phenomenon (Chakkol et al., 2014).

At last, 6 formal semi-structured interviews were conducted and recorded with the focal organization (Table 1). Because of ethical consent, focal organization were anonymized with an alias. The focal organization was visited in person and interviews were conducted face-to-face supplemented with observations. Formal interviews were also triangulated with informal chatting and secondary data such as documentation, which increased the reliability and validity of the results (Voss et al., 2002)

All of the 6 interviews were transcribed verbatim. Each interview and related document were coded and analysed using NVivo. In the coding processes, we followed the guideline of Gioia Methodology (cf. Gioia et al., 2013. Emerging data from the different cases were progressively incorporated into the analysis, allowing for the systematic combining of the transpiring issues and the ongoing development of the interview protocol (Dubois & Gadde, 2002). An iterative approach, moving between the emerging data set and the extant literature, will be adopted in order to make sense of the data and place it in the appropriate theoretical context.

Case study

In September 2018, I got a chance to investigate one of the leading E-commerce companies in China. Platform.Co. is China’s largest online retailer and the biggest Internet companies by revenue. Its unrivalled nationwide fulfillment network provides standard same- and next-day delivery covering a population of more than 1 billion, a level of service and speed that is unmatched globally. As a technology-driven company, Platform.Co. builds reliable and scalable platforms that bring value to partners and customers in sectors such as e-commerce, logistics, Internet finance, cloud computing and smart technology.

Platform. Finance was founded under the name of Platform.Co. and began operating independently in October 2013 in the field of digital finance. Platform. Finance has launched innovative products and services, covering consumer finance, payment, wealth management, crowdfunding, insurance, securities, etc. Platform. Finance aimed to create a trustworthy and inclusive digital financial experience for individual customers.

In November 2018, Platform. Finance was expanded to Platform. Digital, which witnessed the transition from the business model of B2C into B2B2C. At the beginning of the establishment of Platform. Finance, its business model was B2C, which directly provided financial services to individual customers. Then, it began to transform into a “B2B2C model, providing data and technology services to financial institutions” (CEO, Platform. Digital), based on previous experience and accumulated competence with consumers and suppliers.
“The essence of digital technology is to develop cutting-edge technology as the driving force and focus on the unbounded integration of ‘industry x technology’ based on the existing knowledge and data. Digital technology promotes the industrial internalization, digitization and intelligentization, which ultimately achieves lowering the industry costs, improve customer experience, increase industry revenues and upgrade business models.” (CEO, Platform. Digital)

With the core technologies of big data, artificial intelligence (AI) and Internet of thing (IoT), Platform. Digital has completed the “open ecosystem” (CEO, Platform. Co.), the comprehensive arrangement in the fields of digital finance, digital city, digital agriculture, digital marketing and digital campus. Furthermore, Platform. Digital has enhanced the convenience of life by the union of individual customers, business partners and government agencies. The value proposition of Platform. Digital is to implement digital technologies into financial and manufacturing industries, which helps these industries to improve the level of digitization and promote the development of the economy.

The interviewees were mainly in the Natural Language Processing (NLP) Group under the Basic Technology Development Department. NLP is a subfield of computer science, information engineering, and artificial intelligence, concerned with the interactions between computers and human (natural) languages. In particular, NLP solves the problem of how to program computers to process and analyze large amounts of natural language data.

During the period of fieldwork, there were two main projects under the NLP team, focusing on the development of customer service chatbots for different purposes. One targeted on providing the customer service for the presale of investment fund, and the other for the comprehensive aftersales. Customer service chatbot is a smart online robot, developed by the company to reduce the cost of human resources and adapt to the needs of the market. Chatbot can answer frequently asked questions with a satisfied accuracy rate, and replace manual labour to a certain extent. The chatbot is one of the crucial services in Platform. Digital and in delivering intelligent customer service. The service blueprint of the basic customer service request by users is illustrated in the Appendix.

NSD process
In the era of AI, many industries have been subversively developed, and customer service is one of them with AI chatbot. For a long time, customer service has become a bridge between enterprises and customers, and its importance is self-evident. However, there are “many pain points in customer service in the long-term development process” (Product manager, Platform. Digital). For example, from the perspective of enterprises, the cost of customer service investment is very high, but the value return of most jobs is very low; From the perspective of customer service employees, the work is boring, and the career development of customer service is narrow. AI has subverted the development of the customer service, and customer service robots (chatbots) have become really smart.

The NSD process commenced in response to the decision made by the high-level management team in 2017, developing chatbot for the aftersales customer service. A new team was built under the NLP Group to develop customer service robot with the application of AI in-house. A simplified NSD process of Chatbot was depicted in Figure 1. There were mainly five stages of NSD process, namely design, analysis, development, launch, and transition. The activities in the green frame (e.g. idea generation, team building, and interface and function design) belong to the design stage. The activities in the blue frame (e.g. research, analysis, and test) belong to the analysis stage. The activities in the orange frame (e.g. platform and framework building, modular development, transplant and integration, prototype implementation, and iterative development) belong to the development stage. The activities in the pink frame belong to the launch stage. The activities in the purple frame belongs to the transition stage.
This chatbot team consisted of three different positions, namely Management (M), Product (P), and Technology (T). There were different levels of each position ranking from 1 to 10. The staff in a higher level position had higher salaries and more power. Staff in management position tackled with the issues related to the management side, such as leading the scrum meetings, communicating with a higher level of management etc. Though staff in product position and technology position worked on different tasks separately, they communicated to each other frequently during the NSD process of Chatbot.
chatbot. Staff in product position played a role as a communicator between the market and staff in technology position. For instance, the product manager led staff in product position to conduct a research about the total markets, analyse the customer needs to generate a “needs pool” (Assistant of Product Manager, Platform. Digital) and designed the interfaces and specific functions in different context. On the other hand, Staff in technology position (mostly called Algorithm Engineers) built the platform firstly. At the stage of platform and framework building, Staff in technology position didn’t need to have detailed information from staff in product position.

Based on the analysis and design from staff in product position, staff in technology position tried best to meet the requirements of some specific functions of the chatbot, “where a lot of problems emerged and need to be solved” (Senior Algorithm Engineer I, Platform. Digital). Due to the limitation of the AI technologies, staff in technology position could not always meet with the “ideal and surrealistic” needs from staff in product position (Junior Algorithm Engineer, Platform. Digital). A lot of compromise, trade-off and negotiation happened between staff in product position and technology position. In some occasions, the debate even went intensively, where algorithm engineers did not think staff in product position understand the technologies at all.

The stage of the modular development and framework building sometimes happened “in parallel” (Senior Algorithm Engineer II, Platform. Digital). Because some functions could be referenced from open coding resources and only need to be transplanted and integrated with the new platform. After the implementation of the Chatbot where staff in product and technology position came to an agreement on the prototype, the team did the internal alpha test initially, and then the external beta test. Based on results and feedbacks of the tests, “especially keen on the accuracy rate” (Senior Algorithm Engineer III, Platform. Digital), the team followed the iterative and incremental development process, where all the staff in product and technology position went back to the stage of analysis and modular development respectively. And then the whole team followed a similar process again to improve the results of tests. After the high-level management group was satisfied with the final version of the chatbot and approved it, a new type of chatbot was launched as V 1.0.0. Even after the launch of the Chatbot, the whole team still worked on the project, providing maintenance, fixing the bug, catering to the new needs from users, providing solutions to higher management requests. Thus, at the update stage, there were reversed processes going back and forth from the iterative development stage. Among these processes, the versions launched were marked as V 1.1.0 or V 1.1.1 depend on the degree of improvement. Occasionally, if there was a breakthrough of technology or huge changes from high-level management team, the process went back to the initial team building stage even. These kinds of new launches were marked as V 2.0.0 or V 3.0.0 etc.

Findings & Discussions
The LR suggests that there are four different stages in the NSD process, namely design, analysis, development, and launch (Menor et al., 2002). Interestingly, this study identified another additional stage called transition apart from the four traditional NSD stages, which formed a key part of the digital NSD process. In the transition stage, the digital service was kept updating and optimizing iteratively. The NSD process is cyclic and modular in nature, which implies highly iterative and non-linear (Santos & Spring, 2013; Chai et al., 2005; Menor et al., 2002), as shown in Figure 1.

“The mobile application or the official website acted as the core platform, and other subordinate services or functions were gradually developed and modularly added to it.” (Senior Algorithm Engineer III, Platform. Digital).

Moreover, the exemplary NSD process of chatbot in Figure 1 shows cyclic and iterative features between five different NSD stages. For instance, the mobile application
has already launched version 7.4.6 and at least seven launches with dramatic breakthroughs went through the five NSD stages (analysis, design, development, launch, transition) iteratively and non-linearly.

The high clock-speed context of digital services incubated NSD faster with the technology explosion, where new digital services replaced the old offerings more frequently and iteratively. The Digital NSD process is in fast-clock speed. Within only a few months, a new service can be launched.

“We prefer to take a short time to develop a simplified prototype and keep testing and iteratively updating after the official launch, rather than to take a long time for a perfect version.” (Senior Algorithm Engineer I, Platform. Digital).

Because the barriers to entry for new digital services are lower than traditional services due to the lower development cost and opener resources for design. The digital NSD emerges at a much greater rate with radical innovation than traditional services. Entrepreneurial processes are likely to occur in digital NSD, which is much more “entrepreneurship intensive” than traditional NSD (Menor et al, 2002, p.148). The decisions and transformation from the high-level management team played a significant role in the NSD of chatbot.

“Currently, we are in the transition from the business model of B2C into B2B2C, which was proposed by CEO Chen. Actually what we do in our chatbot project is just like we are running start-ups. As we changed our name from Platform. Finance to Platform. Digital. Now we are not only developing customer services chatbot for the financial products, but also providing solutions and services to the other financial institutions. We are transiting form retailers to the digital technology company.” (Product Manager, Platform. Digital)

Outsourcing was highly welcomed at the early beginning of a new service for an organisation in the digital context. At the early stage, the resources and capabilities were quite limited. When the new service became more mature and gained great future potential for profits, the focal organisation could start to develop the resources and capabilities to operate the services in-house. Or the focal organization could also merge the outsourcing partners, where a transition from external partners into internals happened. The in-house operations could help the focal organization have better control and maintain the consistency of quality and build the brand.

Though the NSD itself as a specific dynamic capability helps the organizations better adapt to changes and develop sustainably in a dynamic environment (Gutierrez-Gutierrez et al., 2018). It is still difficult to maintain sustainable competitive advantages in a fast clock-speed context. Further investigation will be conducted.

Conclusions
This study contributes 1) by addressing the lack of NSD research in the digital age, 2) by exploring the development and deployment of digital NSD, 3) by identifying and describing efficient mechanisms for the innovation of digital service.

Digital NSD is much more entrepreneurship intensive than base-line NSD. Second, Digital NSD is in fast clock-speed. Third, outsourcing is highly popular and valuable in digital NSD, as general delivery or modular components can be easily and rapidly turned over to third-party service suppliers. Forth, Digital NSD is more likely to outsource service to a relatively remote site. Fifth, digital services can be much easier designed and deployed than their physical-service equivalents in NSD processes, since the majority of the service processes happen in the back-office. Sixth, a newly burgeoning area of NSD is “electronic disintermediation”, where the traditional manufacturing firms can bypass conventional distribution channels and establish relationships with end customers directly. Seventh, digital NSD processes have to be extremely agile to the dynamic context,
meeting with ever-changing customers’ demands, fast updated technologies, and hyper-aggressive competitors.

Abstract

This paper analyze the impact of team rewards (TR) on NPD success. In particular, we analyzed whether the use of TR affect the success of NPD team projects not only by accomplishing for their work as a team and the performance their perform but also considering the enhancement of the involvement of internal functions and external actors (suppliers and customers) in these projects. Using SEM we observed that TR do not produce a direct effect, but do it through the involvement of SC members in the early stages of NPD. Without involvement, it is not possible to obtain desired NPD success.

Keywords: New product development; Team Reward; Involvement; Supply Chain

Introduction

New product Development (NPD) is a critical concern for manufacturers in an increased global competition. Literature on NPD success has mainly been positioned in the domain of supply chain management (SCM) (Mazzola, Bruccoleri and Perrone; 2015). The most cited references in the field advocate for the involvement of suppliers and customers in NPD process (Flynn et al. 2010) and also to look for complementarities involving internal functions in a collaborative way to achieve NPD success (Homburg and Kuehnl, 2014).
Involving heterogeneous actors in NPD allows firms to enhance the value of knowledge-based resources (Cabrera and Cabrera, 2005). In this sense, evidences has shown that combination of broad and varied information and points of view is positively related to new product performance in terms of cost, time to market and quality (Mishra and Shah, 2009) and also with firm innovation capabilities, and firm performance (Petersen, Handfield and Ragtz, 2005). Nevertheless, some researchers also highlights the costs and challenges of collaborative competences in NPD among SC members (Fawcett et al, 2015), referring to what is known as the “dark side” of collaborative NPD process (Villena, Revilla and Choi, 2011).

As a result, the debate is open, and more research is needed to improve the understanding on how to involve a number of SC agents in the process of developing new products (bringing them closer and involving them), and how to design mechanisms to promote this process (Yang and Wagner, 2017). More specifically, researchers in the field have made a call to analyze organizational issues that promote SC relationship in order to overcome dark-side effects of involving external and internal sources of information and knowledge to achieve NPD success.

With this framework, the aim of this paper is to analyze the impact of team rewards (TR) on NPD success. In this context, an interesting question is whether the use of TR affect the success of NPD team projects not only by accomplishing for their work as a team and the performance their perform but also considering the enhancement of the involvement of internal functions and external actors (suppliers and customers) in these projects.

Overall this study makes three important contributions to the extant literature. First, this study advance in the study of TR on NPD success considering TR as a tool to work in-group involving different and distant actors in the process of NPD. This approach is aligned with the new trends in the field of R & D that recognizes the need for openness and integration of different sources of information and knowledge, providing a clear vision about the importance of adopting integrative strategies as the best way to achieve innovation performance (Crisquuolo et al., 2017). Second, the analysis consider different dimensions of NPD success distinguishing between time to market, technical issues and cost of manufacturing, usually considered in an aggregated way. Third, empirical evidence use an ample database including a more than three hundred of manufacturing
companies from fourteen countries, including developed and developing countries, and from three industry sectors, thus giving more relevance to the results found.

**Theoretical background.**

*Team Reward in New product Development Projects*

A reward system entails the use of the pay system to guide, control and affect the behaviors and efforts of individuals and sub-units toward the achievement of organization’s strategic goals (Gomez-Mejia and Balking, 1992). Total reward is defined as the combination of both the financial and non-financial rewards made to the employees and usually includes basic salary, variable pay, pension benefits, death-in-service benefits, long-term disability benefits, private medical insurance, vacation entitlement, and others (see Jiang et al., 2009).

The group-based incentive plans, such as profit sharing, gainsharing, and team-based reward, may provide an effective means of linking pay to performance in work settings where high-powered individual incentive plans are difficult to implement. Sarin and Mahajan (2001), based on the principles of the organizational control literature proposed to distinguish TR in process-based rewards and outcome-based rewards. Process-based rewards are tied to the accomplishments of procedures, behaviors and other means of achieving desired outcomes, while outcome-based rewards are defined as the degree to which team rewards are tied to the bottom-line profitability of the project. Process controls are exercised during the execution of a task while output controls are exercised after a task is completed. Researchers highlight the both types of rewards may have positive effects on team performance but depends on contingencies of projects.

*Team Rewards and NPD success*

Empirical evidences exploring the relationship between TR and NPD is scant and varied in terms of the measures of TR and performance measures used and mixed in terms of findings. Bonner et al. (2002) considered TR in three ways: financial rewards, internal promotion and recognitions for successful performance. They measure project performance in terms of adherence to budgets and costs, meeting schedule and ask managers to rate for product performance and team functioning performance. They find out no statistical significant relationship between TR and project performance, but all measures were treated in an aggregated way as additive indexes. Chang et al. (2007)
analyzed the effects of joint rewards on NPD performance. The authors distinguished five types of joint reward systems (reward allocation, process-based reward, outcome-based rewards, risk-free of participants, and over-reward incentives) as antecedents of NPD performance. In this case, performance refers to innovation performance in terms of sales, profits and market share, and comparing this measure with regard to competitors, and finally performance in term of the overall profitability. They find out that the overall joint reward system was positive and significantly related to NPD performance. However, only two types of overall reward systems were significant: reward allocation and risk-free to participants, but no significant effect was observed for process-based reward or outcome based rewards.

More recently, Carbonell and Rodriguez-Escudero (2016) analyzed the impact of both process control and process-based rewards (based on procedures and activities) on new product performance and job satisfaction. They find out mixed results since find out a negative association between process-based rewards and quality of new products, a positive association of rewards and the adherence to project schedule and not significant with project budget. The authors also looks for interaction between process control and process-based rewards, but results were not significant to explain project performance, but positive interaction between both tools to explain the quality of new products.

In this paper, we focus on “internal” NPD success measures, considering technical performance, time to market and manufacturing cost (Mishra and Shah, 2009). The adoption of TR is expected to be positively associated with NPD success. Rewarding all team members according with achieving project goals reinforce the perception of workplace justice, avoiding opportunistic behaviors and encouraging cross functional and interfirm collaboration. As a result, the application of TR it is expected that affect team project promoting to work hard to achieve NPD goals.

According with this arguments, we propose the following hypotheses:

- \( H_{1a} \): Team rewards positively impacts on technical performance.
- \( H_{1b} \): Team rewards positively impacts on time to market.
- \( H_{1c} \): Team rewards positively impacts on manufacturing cost.

Team Rewards and the involvement of SC members on NPD
In this section we analyze the effects of adopting TR on the involvement of SC members in early stages of NPD. In particular, we consider bundles of practices in hand of the NPD team, both internal and external, aimed to involve SC members in providing valuable information and ensuring their effective participation in the decision-making process in the early stages of NPD. External involvement (EI) include practices fostering the coordination of decision making and the implication of suppliers and customers in providing valuable information. Internal involvement (II) of manufacturing function encompasses practices concerned with matching design requirements and process capabilities.

The resource based view-RBV (Barney, 1991) suggest that integrating heterogeneous interdependence and complementary source of knowledge is beneficial for all partners involved in NPD processes (Zhao et al., 2011). Related studies have suggested the benefits of adopting bundles of practices aimed to involve complementary sources of information from external and internal SC actors. However, involving internal and external SC members in NPD is a paramount, mainly due to knowledge sharing risk and the hidden cost of coordinate and support relationships with SC actors (Um, Ki-Hyun, and Sang-Man Kim, 2018), which sometimes generates socio-structural resistance by the different members implicated (Fawcett et al., 2015).

In addition, the social capital theory highlight the value of capital as those resources inherent in social relations which facilitate collective action. Related literature stated the positive effects of social capital among the supply chain, promoting cooperative behavior between members, sharing vision, trusting relations, and social ties and reducing the likelihood of conflicts. Nevertheless, some scholars find out the risks and potential negative consequences associated with social capital, which have been recently named as the dark side of social capital (Villena, Revilla and Choi (2011).

From a different perspective, the expectancy theoryconsiders the effort of employees as a function of the perceived value of a reward and the perceived effort-reward probability. As a result, NPD team members will strive more in the search of collaboration of the SC agents if the companies have established a reward system based on the achievement of the objectives of the project especially if these objectives are achievable.

According with this arguments, we propose the following hypothesis:

\[ H_2: \text{Team rewards positively impacts on involvement practices of SC agents} \]

**Involvement of SC members and NPD success.**
Evidences analyzing the process of NPD suggest the benefits of adopting involvement practices with all SC actors in early stages of NPD. Researchers highlight the absorptive capacity of team members, defined as the ability of companies to effectively acquire and exploit both external and internal knowledge to achieve innovation success, as one of the main reasons behind the success in NPD in manufacturing firms (Laursen and Salter, 2006). While firms learn from their external partners, they need to have the internal absorptive capacity to enhance their innovation performance. Hence, Daghfous (2004) highlight the importance of internal mechanisms to learn, to disseminate, and to exploit knowledge to enhance NPD performance.

Thus, practices aimed to involve SC actors are determinant to resolve manufacturing issues in early stages in order to achieve easy manufacturing and improving manufacturability. Johnson and Filippini (2009) comparing collaborative NPD practices such as CI, SI and II across the world on performance, stated that the use of internal involvement is more emphasized than external integration and this was translated into better product performance. In the same way, Ragatz et al. (1997) suggest that the effective integration of suppliers into NPD processes can yield benefits through reduced time to market an improved access to the application of technology. Similarly, involving customers in early stages allows NPD team to know customer assessments in early stages.

According with these arguments, we propose the following hypotheses:

- $H_{3a}$: Involvement positively impacts on technical performance.
- $H_{3b}$: Involvement positively impacts on time to market.
- $H_{3c}$: Involvement positively impacts on manufacturing cost.

**Methodology**

**Sample**

The data used for empirical analysis was collected from the fourth round of the High Performance Manufacturing Project (HPMP), a research project conducted by a team of researchers working in different universities all over the world. The survey was conducted during 2013-2015 in manufacturing plants operating in three industry sectors: machinery, electronics and automotive components (SIC codes: 35, 36 and 37, respectively) and located in different countries: China, Germany, Sweden, Japan, Korea, Spain, Italy, Israel, Brazil, Finland, Austria, Taiwan, United Kingdom and Vietnam). The final data set consists of 309 responses. In table 1 we can observe the profile of the sample for the different countries and for the three industries.

**Measures**
We used 16 items to measure supplier involvement, customer involvement and manufacturing involvement in the NPD process. The items included in the scales have been used by other researchers who have addressed the issue (Mishra and Shah, 2009). The annex shows all these items, to which respondents indicated their agreement/disagreement on a five-point Likert-type scale (from 1 = strongly disagree to 5 = strongly agree). The survey included also other questions related to the country where the companies are located and its activity sector.

We model involvement as a reflective second order construct to capture complementarities arising from the three first order constructs (.suppliers, customer and manufacturing). This second order, involvement construct accounts for multi-lateral interactions and covariances among the first order constructs. The use of second order construct to represent complementarities among first order constructs has been well documented in existing studies (Shah and Ward, 2007).

NPD success is assessed using three commonly used items reflecting time-to-market, technical performance and unit manufacturing cost. NPD project managers were asked to rate the success of the product development project relative to the set goals and objectives on the three measures on a 5-point Likert-type scale (“How successful were the new products in terms of reaching their goals?”).

In order to check for common method variance we used Harmann´s single factor test (Podsakoff & Organ, 1986). This test was conducting using principal component analysis and loading all 20 items (variables of interest) on one factor. The 33.8 % variance explained by a single factor shows that the common method bias is not a major concern in this study (less than 50% cut-off point).

The methodology was developed in two stages. First, the validation of the assessment scale for involvement was settled. The second stage was the assessment of the hypothesized structural relationships of our model. The analysis was conducted using Structural Equation Modeling (SEM) techniques, also with EQS 3.0 software. The seminal works of Baron and Kenny (1986) and Zhao et al. (2010) have inspired the analysis of the mediation role of involvement. Results are summarized in Table 1.

Table 1. Decomposition of the parameters of the research model.

<table>
<thead>
<tr>
<th></th>
<th>Total effect</th>
<th>Indirect effect</th>
<th>Direct effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Team Rewards Involvement</td>
<td>0.614 (4.51)</td>
<td>-</td>
<td>0.614 (4.51) (H1 Accepted)</td>
</tr>
</tbody>
</table>
Technical performance 0.574 (4.19) - 0.574 (4.19) (H2a Accepted)
Time to market 0.494 (3.73) - 0.494 (3.37) (H2b Accepted)
Manufacturing cost 0.453 (3.18) - 0.453 (3.18) (H2c Accepted)

Team Rewards □
Technical performance 0.202 (1.175) 0.352 (2.48) -0.150 (-1.810) (H3a Refused)
Time to market 0.279 (1.622) 0.303 (2.37) -0.024 (-0.267) (H3b Refused)
Manufacturing cost 0.284 (1.512) 0.278 (2.15) 0.006 (0.064) (H3c Refused)

Standardized parameter (t-value).

Findings confirm the first hypothesis that team rewards have a positive impact on involvement; the overall involvement construct is directly influenced by team rewards and the standardised coefficient is 0.614. First hypothesis is then confirmed. In its turn, involvement impact on positive and significantly on the three NPD success items considered, hence the hypotheses H2a, H2b and H2c are also confirmed. One the other hand, neither of the last three hypotheses (H3a, H3b and H3c) can be confirmed.

Conclusions
New product development (NPD) is critical for firm competitive (Brown and Eisenhardt 1995). Studies analyzing NPD success factors have neglected the study of how to involve SC members in early stages of NPD process through the use of motivational practices. The estimations results shed novel evidence. The main finding shows that TR positively affect NPD success in terms of cost, quality and TTM, but, surprisingly, this effect are throughout the involvement of SC members. For NPD projects, linking rewards to the output produced by the team (outcome-based rewards) has a positive influence on SC agents involvement and finally on the internal dimensions on NPD success. Regardless of the type of reward implemented, if team rewards are used to motivate the members of the NPD team, it will be easier to achieve the objectives regarding quality, unit manufacturing cost of products launched and, also, the time to market of new products.

In sum, all the impacts of team rewards on NPD succeed are achieved through the mediation of involvement, which highlights the paramount importance of this construct (involvement). On other words, no effect of TR is achieved without the mediation of involvement.

The relationships of dimensions of competence in the development of new services and the companies’ performance in the development of them

Debora Regina Moehlecke

Abstract

New service development (NSD) had been seen as a result of luck or intuition. However, the need of NSD planning and greater managerial understanding so that companies can achieve the expected performance. Four NSD dimensions were considered: process focus; market acuity; strategy; and culture; plus Information Technology. Exploratory factor analysis and multiple regression analysis were used, it was found that four dimensions can be considered responsible for 30% NSD performance. It is noteworthy that market acuity was found to have more effect on performance. However, NSD strategy could not be evaluated as their variables were eliminated during exploratory factor analysis.

Keywords: New service development performance. Knowledge-intensive service.

Introduction

The service sector is fostered by the evolution of the world economy. The changes that occurred in the last decades of outsourcing of activities and processes contributed to the transition from a manufacturing-based society to services (Chase & Apte, 2007; Sampson, 2000).

The companies that provide services are inserted in an environment of globalization, of constant technological progress and of a dispute for better offers and new clients. This competition scenario therefore demands that they constantly seek to develop new services, whether they are highly innovative or only improvements in those already offered to customers (Brentani, 2001; Noori et al., 1997; Stevens; Dimitriadis, 2005). A new service can be considered as an offer not previously available that results from an addition to the current mix of services as well as from a change made in the delivery process (Menor; Roth, 2007).
The NSD has already been seen as a mere event that was made possible by luck or intuition. Many authors have already studied the difference between developing new services and new products. Some believe that the DSN literature and innovation in service deserve greater attention because of its characteristics (Griffin, 1997; Kelly; Storey, 2000).

The statistics presented may reflect the lack of awareness of the importance of NSD or even have not been raised to the strategic plan and seen as a competitive factor by companies. This leads to the lack of a greater understanding on what can differentiate a company that reaches the success of one that has its service rejected by the market. It was under this approach that Menor and Roth (2007) explored a way to verify NSD success through a competency model spanning five dimensions: i) Focus on the NSD process; (ii) Market acumen; (iii) NSD strategy; iv) NSD culture; and v) Experience in Information Technology (IT).

It is known that financial services companies have been the most analyzed in relation to the NSD (Papastathopoulou & Hultink, 2012), however there are other types of services that also deserve to be mentioned, such as the services intensive in knowledge (SIC), or knowledge-intensive business service (KIBS) that involve activities based heavily on professional knowledge and are needed when there are situations that demand external knowledge (Milles, 2005, Smedlund, Toivonen, 2007). Among the group of this type of companies, it is possible to mention technical consulting firms, civil construction services, software and IT companies, tax and accounting consulting, that produce and transmit knowledge are seen as a source of innovation (Muller, Doloreux, 2009) and are referenced in this study by knowledge-intensive service companies (KISC).

In this way, the following research question is raised: What is the relationship between the competency-building dimensions of new services and the performance of companies in the development of new services?

In order to answer the research question, it was outlined as a general objective: to verify the relationship between the competency-building dimensions of new services and the performance of companies in the development of new services.

To unfold the general objective, the following specific objectives were defined:

a) Confirm the relationship between the five dimensions in the development of new services of knowledge-intensive services companies;

b) Validate the instrument of "competence model" for the development of new services proposed by Menor and Roth (2007);

c) To verify how dimensions contribute together to the performance of knowledge-intensive service companies.

**Hypothesis formulation**

The revealed dimensions are: (1) focus on the NSD process; (2) Market acuity; (3) NSD strategy; (4) NSD culture and (5) experience in Information Technology (IT). Each of them aggregates characteristics of the "best practices" of the companies verified in previous researches and they are identified like resources or organizational routines important for the success of development of a new service. (Jong; Vermeulen, 2003). The five dimensions gave rise to a multidimensional construct called "NSD competence". It is believed that "NSD proficiency shows the expertise that allows a company to provide resources and routines, usually in combination, to reach an end service" (Menor & Roth, 2007, p. 826) as well as "a critical precedent for performance of innovation "(p. 827), that is, it is seen as a precedent of performance in NSD (id, 2007).
Based on the literature presented, the hypothesis related to focus on the NSD process:

**H1: Focus on the NSD process** is positively related to performance in developing new services.

In studies by Oliveira and Roth (2012) the market acuity dimension was considered as an indicator within the market focus competency, which encompasses the company's ability to (1) understand its market and the need of its customers; (2) establish and manage the relationship with its customers and (3) develop new products and services. The results indicate that market acuity and NSD have a positive impact on market focus, which in turn reflects the company's service orientation.

Thus, the hypothesis related to this dimension is formed:

**H2: Market acumen** is positively related to performance in developing new services.

NSD strategy should be able to provide that the offerings of new services are in accordance with the expectations and demands of the clients. (Roth, 2007). In this way, it can be seen as an important agent of impact on the performance of the company (Cooper, Kleinschmidt, 1995, John, Storey, 1998).

Finally, the hypothesis related to this dimension is formed:

**H3: NSD strategy** is positively related to performance in developing new services.

In the conception of Storey and Hughes (2013), the NSD culture is characterized as an entrepreneurial culture, which focuses on the opportunity to generate new services in the external environment, the risk of entrepreneur and the search for the new. All these characteristics are positively related to the number of new services developed by the companies.

Based on this literature, the hypothesis related to this dimension is formed:

**H4: NSD culture** is positively related to performance in developing new services.

The NSD process also benefits from the use of IT as it allows the company to have access to the most accurate and real-time information, such as in the case of reporting and financial data to verify the process, in the development efforts of new services in a company or in decision-making cases where information needs to be available to all. (Fiedler et al., 1996, Froehle et al., 2000).

Finally, the hypothesis related to this dimension is formed:

**H5: IT experience** is positively related to performance in developing new services.

**Methodology**

This research is of a quantitative nature, characterized by the verification of a phenomenon through a technique of collection and statistical analysis (Creswell, 2009) and classified as cross-sectional because it seeks the understanding of a phenomenon in a certain period of time and space and the data are collected only once. (Collis & Hussley, 2006).

The data collection of the present study was performed through the survey method, considered as a method for collecting primary data from individuals of a sample and using a questionnaire elaborated by means of a specific software for such sample. (Hair et al., 2005).

**Research Design**

The next step of the research involved a more operational process of adjustment and verification of the collection instrument, consummation of data collection and statistical tests. Finally, the results were analyzed, thus enabling the verification of which hypotheses were supported and an attempt was made to interpret the
findings in relation to the existing literature. All this process mentioned above is part of the knowledge flow among the main components of a research, according to Hair et al. (2005).

The research design is presented and summarizes all steps involved in the present study: Data collection, Validity and Reliability, Regression Analysis, Results and Discussion.

**Populations and Sample**

The population selected for the validation of the instrument proposed by Menor and Roth (2007) consists of knowledge-intensive service companies. Companies are classified as Miles et al. (1995).

What fostered the choice of the KISCs was their importance in the world economy and for being one of the sectors that has grown the most in the service area. (Miles, 2005; Ostrom et al., 2010). With focus on Brazil, it is evident the great number of jobs generated by companies of this type, only in the activities of Information Technology, there are almost 390,000 people involved; considering technical-professional services this number increases to 871,000 people (IBGE, 2010).

As a source of search for companies, we sought associations, unions and technology parks to which they are integrated in order to ensure that the sample represents the study population with dignity (Collis & Hussley, 2006). Table 1 shows the surveyed entities.

The delimitation of the population of companies to send the research instrument was located in Rio Grande do Sul, Santa Catarina and Paraná. The sample consists of 239 companies related to four types of knowledge-intensive service companies, and the sector is classified as: (1) Advertising activities; (2) Engineering/architecture consultancy activities; (3) Business consulting and (4) IT and related activities. Table 2 shows this relationship.

In the research instrument, the companies were classified according to the number of employees of the company. It can be seen from Table 3 that almost 80% of the sample is from companies of 01-50 employees, which is characteristic of KISC (Miles, 2005).

In order to validate the research instrument in question, the participation of the main actors involved in the development of new business was sought. One representative per company was interviewed from a total of 239 companies. It is believed that the goal of interviewing people who are really involved in the company's business and having a macro view of the market is verified since that more than 85% of the sample was made up of coordinators/supervisors, managers and directors of the chosen organizations, as shown in Table 4. This same caution in the choice of respondents was observed by Menor and Roth (2007) when they detected the right people for the data collection participation.

As it is in the interest of the research to verify if the competence in developing new services contributes to the performance in NSD of the companies, it is necessary that the respondents are involved with the NSD and are aware of the results of the new developments.

**Data collection**

The research instrument was composed of 29 questions, four of which characterize the company, twenty-one questions that cover the five dimensions: (1) focus on the NSD process; (2) market acuity; (3) NSD strategy; (4) NSD culture and (5) Information Technology (IT) experience and four performance-related questions. Table 5 presents the number of questions and types.

Regarding the characterization of the sample, the respondent were: (1) number of employees of the company; (2) the company's sector of activity; (3) company name, and (4) the respondent's position.

Questions related to NSD dimensions and performance have originated from the NSD competency scale elaborated by Menor and Roth (2007) and validated in an environment of financial services companies in the United States (USA).

From the total questions of the "NSD competence” construct, there are an average of four questions for each dimension. All questions were measured using a Likert scale of 1 to 5, with 1 being: Strongly disagree and 5: Strongly agree. The questions were randomly mixed throughout the questionnaire and at no point was the interviewee quoted as referring to the dimensions.

First, the Focus dimension in the NSD process is verified through four questions found in Table 6.

<table>

<tr>
<td>(P1) Our efforts to develop new services / products are composed of formal stages of development activities;</td>
</tr>
<tr>
<td>(P2) Our company employ resource and standardized routines in all new service development projects;</td>
</tr>
<tr>
<td>(P3) Our company employ formalized processes in all new service development projects;</td>
</tr>
<tr>
<td>(P4) All new service development projects are planned according to a planning of predetermined sequence of development activities.</td>
</tr>
</tbody>
</table>

Source: Prepared by Debora Moehlecke

In order to verify the Market Acuity, four questions were also asked as quoted in Table 7.
In order to identify how NSD Strategy contributes to NSD competence, four questions have been considered and are mentioned in Table 8.

**Table 7- Issues in the dimension “Market Acuity”**

Finally, the IT Experience was covered by five questions listed in Table 10. Likewise, the four questions were measured using a Likert scale of 1 to 5, with 1 being: Significantly low/below expected and 5: Significantly high/Meeting expectations. They were inserted in the text at random between the questions of performance/competence. Table 11 addresses the questions considered.

*Data collection*
Data were collected through a survey applied to the people involved in the development of new services. It was sent 990 emails in the first stage with only 39 companies answers. Then, it was decided to hire a company and two people, properly trained and guided about the purpose of the research, conducted 200 interviews. The chosen method of approach was to send emails to all those who had already been sent by the author in the first stage. After this stage, it was contracted professionals called the companies and identified themselves, questioning if they had received the presentation email with the link of the electronic questionnaire and whether the survey had already been answered. If not, I was asked if I would like to do it over the phone.

Descriptive statistics
Descriptive statistics were used to demonstrate the means and standard deviation of each of the 21 variables selected by Menor and Roth (2007) in their study and now applied to the KICS of the study. Data analysis was performed through statistical procedures using SPSS software version 19.0.

Conclusion
Given the importance of the service sector to the world economy and the rise of the number of knowledge-intensive services companies, it sought to understand in this study how these companies are developing their new offerings and how they can improve what is already being done, acting strongly on what has the greatest effect on the performance of an NSD program.

The main objective of this paper was to verify the relationship between the competency dimensions in the development of new services and the performance of the
companies in development of new services. To achieve what was foreseen, some specific objectives were stipulated.

It is believed that the purpose was reached, since through the multiple regression analysis, it was possible to verify the relationship of the competence-forming dimensions in the development of new services and the performance in NSD. It was found that, with the exception of the NSD strategy that was discarded from the analysis through the exploratory factorial analysis, all dimensions have a positive influence on the NSD success of knowledge-intensive service companies.

The first specific objective sought to confirm the relationship between the five dimensions in the development of new services of Knowledge Intensive Business Service (KIBS). It shows that all variables are positively related to the significance level of 0.01, not considering the NSD Strategy dimension, since it was previously excluded.

The second objective included the validation of an instrument of competency model for NSD. It is believed that it was possible to test and validate this instrument on the competence of companies in developing new services.

Finally, the third objective was to verify how the dimensions contribute together to the performance of KIBSs. It shows that the four factors can be considered responsible for 30% of NSD performance and this result, although positive, indicates that there are other dimensions that also contribute to the success of a development project, a new service and that they can be explored at other times, thus enriching NSD research.

Focusing on knowledge-intensive service companies, it is believed that this paper contributes to the studies of this segment that is so prosperous these days. The analyzed dimensions that have been shown to have an impact on the development of new services can be used for further analysis in other companies with the same profile as the ones examined.

The importance of the KIBS in being in tune with the market and its customers is highlighted as managerial implications in order to seek information about their business environment and be prepared to respond quickly to changes in the competitive environment. This all represents the Market Acuity that has been listed as the greatest effect dimension in NSD Performance and can be achieved through information gathering through market research, and participation in fairs and events.

Likewise, the use of IT to share information among all those involved in the NSD deserves evidence. There are many data exchange tools that facilitate communication and allow activities to be performed more quickly, clearly, and securely.

More importantly, the results show that, although the NSD Process Focus is necessary, companies need to be careful about very formal stages of development because they can bureaucratize and hamper the progress of the project. By employing standardized resources and routines, unnecessary effort and time can be expended and the loss of momentum needed in this business environment can occur.

Although these contributions may be relevant, both for the Academy and for the business community, it is understood that this research presented some limitations. First, the research tool was applied to some types of KIBS, with a predominance of IT service companies and related activities. Therefore, this study used the sample to generalize the NSD profile of KIBSs in the Southern region of Brazil. It is known that other results could be found if the focus were, for example, on companies that provide technical tests and analyzes or surveys of area development of health.
Finally, this paper aims to stimulate further studies on the development of new services in Brazil and in emerging countries and was done with much dedication to serve as a reference for future research.

Abstract

32 secondary cases on Design for Additive Manufacturing (DfAM) and expert interviews were used to identify motivations, required competencies and performance impact of AM. Findings suggest that weight reduction motivation coupled with topology optimization competency helped in reducing weight and the number of parts. Material choice competency helped in reducing weight or in improving part functionality or quality. Weight reduction also required design simulation. Choice of appropriate AM process parameters was needed to reduce production time. 8 case studies indicated a collaborative process between DfAM partners.

Keywords: Design for AM, motivation, competencies, performance impact

Introduction

Additive manufacturing (AM) technologies produce objects from computer-aided design (CAD) model data, usually adding layer upon layer, in contrast to conventional subtractive manufacturing methods that involve the removal of material from an initial stock (Gibson et al., 2010). AM provides new benefits that cannot be obtained with conventional production technologies like injection moulding, machining or casting. The capability to extend design freedom is one of AM’s most important advantages (Levy et al., 2003). Trying to produce a part, originally
designed for conventional manufacturing using AM may not be beneficial and some of the benefits of AM can be obtained only if the parts are designed or redesigned for AM. These benefits can be user-fit requirements, improved functionality, parts consolidation and aesthetics (Campbell et al., 2012; Maidin and Campbell, 2011).

To take full advantage of AM, use of specialized computer-aided design software is required. Moreover, structured design tools and procedures are also necessary (Friesike et al., 2018). At the same time, product designers also need to be educated to take full advantage of the benefits which AM offers. Thus, the conventional knowledge, methods, and skills for component design have to be rethought, as product designers currently working in industry are trained to design for traditional manufacturing technologies like injection moulding, casting, machining etc. (Flores Ituarte et al., 2016).

In AM, designers should be encouraged to ignore the “design for manufacturing” limitations (Campbell et al., 2012). Furthermore, the conventional product design process is often conducted in a sequential manner considering a limited amount of discipline related variables but not evaluating across the entire product lifecycle (Mottonen et al., 2009). Boothroyd and Dewhurst (1996) pioneered design for excellence with their concept of design for assembly (DfA) which minimises the number of parts (Gershenson and Lai, 2008). DfA later expanded into design for manufacturing (DfM) including broader manufacturing aspects. Now, DfM is further referred to as DfX where X stands for considerations such as manufacturing, assembly, testability, reliability, disassembly, and cost (Gehin et al., 2008). DfX reduces time-to-market and cost as well as increases product quality (Gungor and M. Gupta, 1999).

Design for AM (DfAM) and DfM may have some similarities. However, manufacturing firms, utilizing conventional manufacturing may need to develop unique competencies to design products for AM. Currently, DfAM exercises in companies are primarily driven as individual exercises without developing a strategic perspective. This results in a scattered approach without full understanding of the competencies which need to be developed to achieve the specific performance objectives. Additionally, the performance impact of DfAM is not obvious as there are still multiple challenges associated with AM that include a limited choice of materials, design rules for different AM technology categories as well as post-processing requirements to make AM technology fit for end use. In the view of the challenges, there is a need to understand the motivations of the manufacturing firms to design or redesign parts for AM, the competencies which are needed to excel in DfAM and the performance benefits that companies are expected to obtain. Thus, the objective of this research is to address the following research questions:

1) What motivates manufacturing companies to design or redesign parts that are suitable for additive manufacturing (AM)?
2) What competencies are needed to excel in Design for AM (DfAM) and how do those differ from traditional design for manufacturing (DfM)?
3) What performance benefits can companies expect in adopting DfAM?

**Literature Review**

The literature review included scholarly journals from multiple databases by using these search strings: "design for additive manufacturing" OR "design for 3D Printing" OR
"design for manufacturing" OR "design for X". Using these search strings, 18 articles were chosen for further review.

We can understand DfAM as a new sub-category within the overarching DfX paradigm, which is in line with DfM but applied to AM technologies. The interesting fact is that DfAM is currently gaining momentum, as AM technology has become a reality as a manufacturing solution (Schmidt et al., 2017). In this regard, there is a need to predict that parts can be built using AM equipment, withstand the forces and other environmental conditions as well as achieve the necessary quality requirements (Gibson et al., 2010). This has fuelled interest in DfAM. Ideally, DfAM must consider: (i) novel design opportunities related to AM technologies including design rules, (ii) material and process constraints related to the different technology categories and (iii) a product lifecycle perspective including supply chain aspects, cost accounting and delivery time (Thompson et al., 2016).

AM and the understanding of DfAM provide new opportunities related to the design of complex geometries, which allows enhancing products by reducing its weight and improving its performance. For example, this is reflected in a number of cases to produce complex hydraulic manifolds (Chekurov and Lantela, 2017) or optimized heat exchangers (Chekurov et al., 2018). DfAM opportunities also relate to part-consolidation, which is the process of simplifying product assemblies by means of consolidating its parts into a minimal set of elements while maintaining its functionality (Flores Ituarte et al., 2019).

AM provides opportunities to reduce product development costs, production costs, costs over the entire value chain or provides some combination of these benefits (Thompson et al., 2016). The opportunities for DfAM are not only limited to enhancing products. Thus, in industrial settings AM allows to digitalising the manufacturing process to gain productivity, especially when there is a need for mass-customisation of assembly elements in an automotive gripper (Flores Ituarte et al., 2018).

Remixing i.e. the creation of new models on the foundation of existing design elements can also be a relevant possibility for DfAM resulting in better design process outcomes in terms of quantity and diversity of designs (Friesike et al., 2018). There are also opportunities for the application of machine learning to provide feasible conceptual design solutions for inexperienced designers by recommending appropriate AM design features (Yao et al., 2017).

However, new possibilities often necessitate new competences. While designing or re-designing a new component for AM, product designers have to ignore limitations from conventional DfM. They need to use their creativity to create product designs which are both functionally improved and geometrically complex in order to benefit from AM (Campbell et al., 2012). In DfaM, the design competences, engineering software tools, manufacturing process rules, and methodologies can become substantially different in comparison to traditional DfM.

To develop DfAM excellence, a methodical approach to formulate design rules with modularity for AM in mind is needed (Jee and Witherell, 2017; Adam and Zimmer, 2015). Competencies needed for DfAM include the ability to use finite element analysis combined with design automation, which can accommodate complex functionally graded materials and topology optimized structures while predicting material layout and part performance in accordance with desired outcomes (Boddeti et al., 2018; Vaughan and Crawford, 2013).
Choosing the appropriate material and processing technology combinations for the particular design is often challenging (Kretzschmar et al., 2018). Different AM technologies have different operating principles, processing characteristics, and compatible material types. The consideration of process-specific variables during the design process is critical for DfAM as those have impact on achievable mechanical properties as well as operational implications in terms of manufacturing time. A supporting competency to decide whether AM is feasible or not included the ability to estimate AM part costs based on few parameters early in the design process (Baldinger et al., 2016). Chiu and Lin, (2016) also demonstrated how DfAM and Design for Supply Chain need to be considered together for customized products.

In summary, this review showed a wide area of opportunities to benefit from AM integration. However, such benefits can only be realised if new competences are developed. Moreover, the opportunities related to DfAM differ from industry to industry and also for different applicants within the same industry. Consequently, performance benefit of DfAM implementation is expected to be different from company to company. We fill this research gap by providing a comprehensive understanding of the motivations, the competencies, with which firms can excel in DfAM as well as the performance benefits, which firms can expect from DfAM.

**Research Methodology**

The first stage was to analyse the DfAM case studies published by AM service providers, equipment manufacturers, and specialised trade journals. The included cases document DfAM cases of successful AM implementation describing how companies benefited from the technology. Table 1 shows the overview of the included cases, the columns represent the industrial sector. Whereas, the rows show the DfAM service providers involved in the cases. In the second stage, semi-structured interviews with AM experts were conducted. For this paper, we could conduct 2 such expert interviews – one with an industrial products manufacturer as an user of AM and another from an AM service provider.

</table>
Out of 65 case studies, 32 cases explicitly covered DfAM aspects. These 32 cases were included as secondary data, from where 5 cases were related to aerospace, 5 cases related to automotive, 14 cases were related to industrial product companies, 3 from consumer products (toys and jewellery), 2 from bike manufacturing and 1 from telecommunication while there was no information about the industry for 2 cases. In summary, 7 of the 32 cases were for production tools like jigs, fixtures or grippers while the remaining were for parts or components of end products.

In summary, the literature review is followed by the collection of relevant secondary data of DfAM cases to conduct cross-case analysis of the motivations, competencies and performance improvements. The semi-structured interviews helped in understanding the competencies required to achieve benefits from DfAM implementation, the role of collaboration between partners and to specify the differences between DfAM and DfX. Data from the secondary cases and the interviews were analysed using text-mining techniques using Nvivo software.

Findings
Analysys of secondary DfAM cases

The findings from the secondary data and included case studies show that the primary motivations for companies to implement DfAM were (i) weight reduction, (ii) development and production of complex parts, (iii) product customization and (iv) reduction of development and go-to-market times. The key competencies identified for DfAM are choice of appropriate materials and related technologies, topology optimization, conducting design simulations and determination of appropriate process parameters. 8 case studies explicitly indicated that a collaborative process between specialized service bureaus offering DfAM and end customers is needed. As the motivations for conducting the DfAM showed the intentions for the companies, the companies were able to achieve performance improvements directly associated with the motivations but also got some additional or secondary performance improvements. The predominant performance improvements obtained were weight reduction, development time reduction, reduction in production time, customization, fewer parts and reduction in manufacturing costs. Thus for example, where weight reduction was the primary motivation, apart from achieving that, reduction in number of parts, improved functionality and development time reduction were also obtained in some cases.

We also conducted analysis by industrial sectors and found that for aerospace companies, the primary motivation for DfAM was weight reduction, the most frequently mentioned competency was topology optimization and the performance improvements obtained were weight reduction, reduction in production time, material consumption reduction and reduction in the number of parts. For automotive companies, the primary motivation was weight reduction and customization opportunities, the most frequently mentioned competencies were topology optimization and application of 3D geometry at slice level instead of at the STL (Standard Tessellation Language) file level where the performance improvements obtained were in weight reduction and improvement of product functionality and performance. Use of slice-based technology helped in keeping to keep the files light, by postponing the calculations of the full design until the slicing step.

For industrial product companies, motivations were difficulty in machining the original part, development, and production of a complex part, customization of parts, reduction in development lead-time and weight reduction. The competencies mentioned were choice of appropriate materials and determination of the optimal process parameters.
The most frequent performance improvements obtained were weight reduction, enabling customization, reduction in development time

The text analysis of the motivations, competencies, and performances in terms of coding similarity across the secondary data reveal the following relationships:

- The motivation of weight reduction coupled with competency of topology optimization results in performance improvement in terms of weight reduction.
- Choice of materials as a competency results either in weight reduction, improved functionality or improved quality of the part while design automation and topology optimization are also needed to achieve weight reduction.
- Similarly, the choice of appropriate AM process parameters is needed to achieve reduction in production time while automating design process results in cost reduction.
- Application of 3D geometry at slice level results in improved product functionality and performance.

Analysis of the 8 cases which specifically mentioned collaboration between different partners revealed that the AM service providers provided expertise in choice of optimal process parameters and in improving the design. In turn the service providers learnt a lot about the needs and challenges faced by the customers.

**Insights from interviews**

The expert from industrial products industry mentioned that the competencies needed for design from AM from their perspective are topology optimization, choice or development of appropriate materials, developing multi-functional parts and simulation as for complex geometries, as it is quite difficult to simulate the performance. He mentioned “Material considerations are extremely important because we design our component with a minimum 15 years of life time. We need to make sure that this 3D printing material they can really stand this.” This also validates our findings from the secondary cases.

To develop design for AM competencies, we learnt from our expert that their company organizes workshops where they co-developed a design rules catalog for engineer teams and R&D teams covering four different AM technologies. They also conduct two-day trainings with an external partner. The industrial product companies reported benefits in terms of weight reduction, reduction in development time and production time, reduction in manufacturing costs and in number of parts. He also mentioned that improvement can be in terms of product efficiency improvement through merging of functionalities in the product and the ability to customize products according to customers’ needs in low volume.

Companies use design for AM for designing or redesigning parts as well as tools. The industrial products company where our expert works has designed press tools, which can be 3D printed, which reduced the costs of producing the tools and also ensured that the tools are more precise. They are also co-developing generic grippers in collaboration with another company, which also needs grippers in their production process, to cover a wider range of sizes for the components, which the grippers can pick.

An expert from a service provider pointed to a balance between having an open mindset towards AM while keeping a realistic eye to the limitations of AM as a key competence beyond the required skills of design skills such as CAD/CAM and other...
software skills. A drawback with AM adoption can be if managers excessively try to exploit the speed and cost benefits of AM leaving too little time and budget to improve the product using the possibilities of AM.

**Research Implications/Limitations**
AM promises the creation of unique parts and products with functionality that was hitherto impossible using conventional manufacturing technologies. However, product designers need to rethink their restrictive design mindsets to explore the full potential of AM. This also requires the development of unique competencies and stronger collaboration with internal and external partners. Limitations of the study are that we have used 32 publicly available secondary case studies but managed to conduct only 2 expert interviews at the time of writing the paper. We plan to include more case studies across service providers in our database and conduct more interviews. It should also be noted that all the secondary case studies did not report the motivations, competencies and the performances.

**Conclusion**
Analysis of the secondary DfAM cases and the interviews with experts revealed that companies design or redesign both parts and production tools for AM. Though some similarities exist in terms of motivations, competencies and performance impact of DfAM across sectors, there are also some differences. We could also identify some specific linkages between motivations, competencies and performances. Hence, companies having similar motivations and desire for particular performance improvements should develop the required competencies or engage service providers which can provide those competencies.

This research has been exploratory in nature. For future research, potential theoretical perspectives such as contingency theory, design science and knowledge management can be used to analyse the secondary cases and the interviews to compare the cases across industries, across service providers and across applications eg. parts and production tools. Future research should also be directed in developing a competency framework for DfAM, analysing how service providers and customers can collaborate to develop those competencies and for empirically validating the relationship between motivation, competencies and performance impact of DfAM using survey data.

(Leipzig University of Applied Sciences,  
Faculty of Business Administration and Industrial Engineering)

Abstract

Constructors of special plants are often developing new plants from the scratch without the economic knowledge of old offers flowing into them. Although rules on technical feasibility or the like are typically taken into account, no conclusions are drawn from the success of historical offers systematically. The paper is going to examine possibilities on how to improve sales representative work using data driven technology. Innovative planning processes are supposed to help design and offer new plants based on knowledge extraction and insights from historic data.

Keywords: Analytics, Big Data, Business Process Management

Purpose

Companies in plant construction and mechanical engineering plan and manufacture customized products. Quotations are created individually based on customer specifications. There are many different possibilities in degrees of freedom for the design of a system’s structure, when planning and using technical components. Due to the high diversity, sales representatives are principally involved in configuration work. In addition to the effort in the planning procedure, calculation of costs as well as lead time and production time must be taken into account. From the IT point of view, planning processes uses appropriate databases for technical components and materials as well as software-tools for quoting. Special manufacturing software is used to evaluate automatically the plant design via rule-based verification to check the feasibility of system requirements.

It is possible that specific requirements in certain areas recur over time, however, currently it can only be identified based on the experience gained by the plant designer. That means the new quotations might lead to increased diversity in plant design based on the employee's planning capabilities and inclinations. Requirements are reconsidered and thus reconfigured. There is also a lack of systematic feedback to the extent that a system configuration has proven to be successful – in the interest of the customer as well as timely and ultimately profitable completion by the system manufacturer. Some companies try to counter diversity with strict standardization. On the other hand, however, standardization slows down technical developments and is very costly.
Quotations accepted by customers culminate in an order and trigger all necessary manufacturing and value-added processes in the factories. A project order generates a large quantity of information in the processing phase and precisely reflects the actual production processes and material requirements. Relevant information is generated during order processing as a data record by various planning systems and is stored for a long period of time.

This provides a basis for a reflected consideration of all past business processes and can be used as a foundation of experience for future planning during the quotation process. In the long term, data-driven project planning information can help to integrate the successful planning and strategies of the past into new quotes and, in addition to process optimization, can also offer better chances of acceptance to order.

Investigation

Nowadays almost every bigger industrial enterprise is storing a lot of business and process data by the use of well established enterprise systems, such as ERP. Core requirement for such systems is to store data confident and secure in table structures in a Database Management System (DBMS). The management is going to ask questions about how to make use of these already stored data to accelerate and improve plant offering processes. Comprehensive and complex analysis is needed to answer these questions by use of plant information of past orders. A process mining is required to use event data to extract process-related information (van der Aalst, 2016). For optimization of planning processes through of configuration proposals, extensive knowledge of the data landscape of the manufacturer is required. The focus is on identification and processing of relevant data from the planning systems. With lot of different kind of data in bigger size and structure, analysts are confronted with huge virtual data rooms and the need of systematic information discovering process, such as ETL (Extraction, Transformation and Loading) and mathematical basements like pattern recognition algorithms to carry out how data can be used to solve future business problems. By compressing and enriching the data, the opportunity to implement new Business Intelligence (BI) analytic tools in business operations is created. The paper is showing selected work of preparation mechanisms and giving ideas of how to examine data from different sources and complexity.

The underlying structure of the investigation is shown in Figure 1. It shows an abstraction model referring to plant building processes. This model defines any project as a plant. Each of them is going to be separated into panels. Plant sizes variate between 5 and 20 panels depending on the customer needs. In the next level panels contain appliances and material which are varying in amount up until hundreds of pieces. They have lot of detailed information about article number, assembly lines, costs and origin data. The quantity increases the more functionality is requested by customer requirements. The whole functionality has to be fitted into an external case with space limitations. Configuration options are high because of so many possibilities to combine different functionality in different panels.

In summary a plant carries out a finite set of functions. That provides a starting point for doing research on the possibilities of a comprehensive description of plant functionality based on all the stored information about already realized projects from the past. The paper shows the investigation and results about the ability to analyze and extract functional groups out of data and gives ideas on use cases where proposal preparations increase the value in planning situations for manufacturer in sales representative work. The following sections describes the necessary steps from data extraction to finally present transformed data in an innovative planning process.
**Process of Extract, Transform, Load and Display**

“ETL was born on the first day that a programmer constructed a program that takes records from a certain persistent file and populates or enriches another file with this information. Since then, any kind of data processing software that reshapes or filters records, calculates new values, and populates another data store than the original one is a form of an ETL program” (Vassiliadis, 2009). ETL is part of a design process and the architectural fundament where data is gathered, cleaned and transformed. The automated exposition of information and knowledge out of business data is a holder of value. By the use of information technology, data from different sources with different structure is collected, transformed and finally loaded into a highly compact data room where analysis can start to figure and show reality out of historical data in charts and graphs. The process is consolidated as Extract, Transform, Load and Display process (ETLD). For the development phase the Big Data Integration needs specific technology and tools to handle data right before it can be consumable for effective decision making (Bansal, 2015 | Kandogan, 2013).
Figure 2 – ETLD Process

Figure 2 is going to show the data flow from different sources to a final centralized storage, so called Data Warehouse (DW), where the analyst benefits on the results of having well structured data with the ability to extract insights and expert knowledge for re-use in operations and generating reports and graphs. The steps in between as main part of ETL are usually extensive but a very important work to establish a Data Staging Area (DSA), where the meaning and understanding of information is extracted out of raw data sets. The main goal for the engineer is to design a DW in a meaningfully powerful software environment. During the research the analytic tool KNIME (Konstanz Information Miner) was used to load large data sets from different kind of sources and to start developing and doing analysis on data collections (Berthold, 2018). One big advantage by the use of open-source client software KNIME Analytics Platform that it is a useful tool for analysis even without or less programming skills. The individual steps of calculation can be done by drag and drop of nodes by using a graphical interface and all the work can be separated into different workflows. It is a modular and highly scalable processing platform. The software has been placed in the leader category in Gartner’s 2018 Magic Quadrant for Data Science and Machine Learning Platforms (Gartner, 2018).

Data extraction
“Data provisioning constitutes the prerequisite for any Business Intelligence (BI) project” (Grossmann, 2015). The first step is to collect data from storage locations like legacy systems, files under any format, web pages or various kinds of documents (Vassiliadis, 2009). The many of different data sources has its distinct set of characteristics that need to be managed. Extraction processes needs to be effectively, while the integrated systems have different platforms, such as varying DBMS, several operating systems or a variation of communication protocols (Shaker, 2011). All the information about orders (actual costs, plant configurations, parts lists, purchasing and logistic details, production sequence) in a period of the last two to three years is a basement for extensive data analysis. The pool of information should reflect the current possible plant configurations as good as possible to avoid planning with outdated functionalities. During ERP research data from already processed orders has to be identified. Every information about costs, design conditions, material and production sequence of each order is important and required to maximize the ability of analysis. After the selection every relevant source of raw data is saved separately into file systems like CSV. The possibilities on how and where to store the input data depends on the system environment and restrictions of the company.
**Data transformation**

Data preprocessing can be seen as a collection of calculation tasks. All the single data sets have to be cleaned and examined in detail. Unnecessary information is filtered out and many additional computational steps like grouping, pivoting and sorting take place. After these preparation steps, related data has to be joined with each other. Therefore identifiers like the order number is necessary to enable connection. Figure 3 is showing an example of joining two lists from different sources and afterwards grouping the result by project ID while calculating the sum of single material price and storing ID and description of material in an array. A collection of data is created, which reflect the original data in compact form and represent project insights in summary. In order to increase information content, key figures are processed to enrich the analysis with more contextual knowledge like the sum of material costs for each panel or the quantities of material input for specific functional solutions in plants.

**Data loading**

The developed data landscape is stored permanently in a data warehouse (DW). Data records for data mining procedures are retrieved from this storage, which leads to the development of planning instructions. Searching and understanding the structure of planning processes is the main task during the analysis. It needs a deep understanding about the manufacturing process in general and product line information in particular. The structured data sets are holder of value about plants, panels and material from already closed orders as a historic summary based on ERP data. They include technical insights of each plant, configurations and listings of components of value. The data now can be evaluated in different abstraction levels as shown in Figure 1. The higher the degree of abstraction, the better analysis is going to build on.

**Display**

After preprocessing and storing the possible interesting data, various algorithms can be used to analyze large data sets to find coherence, rules or similarities in context of appliances, configurations, panels and plants. Afterwards the collected information is taken as valid basement for proposal needs in future planning processes. The findings are transferred and displayed in new services for a business intelligence environment.

- **Prediction and Classification**

  In many applications of Data Mining data sets are compared with each other to divide them in sensuous groups. This division can be determined by Distance and
Similarity (Cleve, 2014). On this occasion the similarity between data sets is assignable by calculated distances.

- Distance \( \text{dist}(x, y) \)
- Similarity \( \text{simil}(x, y) \)

To determine the distance of data points a distance function is required. During the research the Euclidean Distance is used. Therefore in advance the interesting nominal data (plant characteristic with specific value) have to be transformed into metric normalized data. Most algorithms for pattern recognition require normalized data (Shmueli, 2017). Similarity between two data sets is greater the smaller the distance between them. If the distances of all several data points takes the value down to zero, similarity becomes identical.

Similarity between two data-points (1):
\[
\text{simil}(x, y) = f(\text{dist}(x, y))
\]

Euclidean Distance (2):
\[
\text{dist}_E(x, y) = \sqrt{\sum_{i}(x_i - y_i)^2}
\]

One possibility for a planning note is the detection of similarities in the plant configuration. To be able to generate these suggestions, the planner specifies various project characteristics by entering customer requirements or research criteria (starting point of each analysis for proposals). Within existing project collections, records are searched for these characteristics. An algorithm computes the Euclidean distances between the planner's entered characteristics and the prepared project data from the data set. This procedure is referred to as Similarity Search (see Figure 4) and replicates similarities, which are then proposed (displayed) to the planner.

Figure 4 - Similarity Search in given realm of experience

Table 1 is showing an inquiry of a customer in a way of a summary of functions to fulfill the requirements to a specific panel. The closest panel configuration is shown with a distance of zero. It does not matter how many functions are requested. Important for the analysis is always the most possible fulfillment.

Results of a search ideally provide information about the planning structure (design data, parts lists, material scope) and production costs. If tracked, the ability to improve the insights by showing building and delivery times. This process speeds up the quotation planning process and increases the accuracy of pre planning of the offered content. Even processes during the execution benefit from the higher accuracy in the offer phase. Different planning steps can be partly automated in the future by the knowledge extraction.

- **Relationships Among Records (Item Sets)**
  Another possibility of providing project planning support is the usage of association rules explored out of a frequent item set mining process. If individual items showing up together in many transactions, an association between them is going to identify. These learning over transactional databases is also called as affinity analysis or market basket analysis (Cleve, 2016 | Shmueli, 2017). Association rules are often used by online retailers to give customers recommendations in topics of “frequently bought together”.

  With usage of the Apriori algorithm it is possible to discover the appearance of frequent itemsets out of large transactions (Agrawal, 1993). “Determining what qualifies as a frequent item set is related to the concept of support. The support of a rule is simply the number of transactions that include both the antecedent and consequent item sets” (Shmueli, 2017). The analysis is discovered with the fast calculating algorithm of Borgelt, called “Item Set Finder” (Borgelt, 2002). KNIME has an implementation of this algorithm as a workflow node. For the needs in planning situations the analysis helps to show up associations between appliances and material, where it comes to specific functional requirements.

*Figure 5 – Extraction of Item Set*
If a plant planning process is thought as a fulfillment of functionality (functional groups), item sets can be extracted out of already processed solutions from the past and displayed during new planning situations. Therefore, the Apriori algorithm is used to determine the frequency of occurrence of material combinations. Figure 5 is showing a simple example what the algorithm is calculating out of given data records (x, y, ...). Any Function (A, B, ...) represents a list of material as a data record, which is contained in past orders. If a new customer query with subsets of information (items) is given, proposals of design solutions appearing during the planning. In Figure 6 a given item selection is taken as input parameter and the analysis is given back all possible solutions in terms of functionality (Function A or Function B includes both items).

Once the possibilities of searching and recognition for patterns are developed, a graphical interface is needed and some form of interactions with the user to benefit from the intelligent search algorithms. Figure 7 shows a possible setup of such a use case. After passing the functional requirements into a summary list for each individual panel, the algorithms in behind take the information and discover the most similar planned panels with detailed business and plant configuration insights.

Nowadays the rapid technical evolution of internet technologies gives reason to believe in web application development in analytical based processes. During the research different web application frameworks like Ruby on Rails and React where included into technical implementation. The biggest advantage is the use of a powerful Back-End Server to solve large machine-learning problems, while the Front-End Client (User) only needs to
Discussion and Conclusions
The present result motivates to focus in a fully automated offer planning process in plant production situations if the management is looking for standardized solutions. The possibilities to extract already planned solutions of plant designs are high by the use of data-driven technology. Every successful solution in planning situations can be tracked, analyzed and showed. In future scenarios there must be a way to serve a configuration tool directly to the customer to ask for their needs as a function based query process. Therefore the customer is guided to all possible solutions – a kind of “soft” standardization. This increases a higher planning comfort to both, the manufacturer and the customer while the inquiry of needs is based on a more structured planning process in less time.

If it is possible to implement an automated configuration process based on criteria from customers and historical data, it should also be possible to highlight information about current factory workload, availability and delivery times for required material and much more (even external) scenarios with the ability to use analytical insights in all departments of the factory to improve the business process in general.

Midsize and large companies with plant manufacturing background are encouraged to discover their data lakes. Doing research on data-driven process management gives many possibilities to return information from already worked out solutions into future operations, especially in planning processes. The velocity and power of intelligence software environments help companies to improve their needs in digitization and Industry 4.0 context.

Abstract

This paper develops a conceptual model for finding key factors for new product development (NPD) evaluation. It builds on the work of the most cited and published authors on innovation management, but transfers attention from advertising aspects and efficiency, to factors identified within the NPD process such as new product project definition, a firm’s resources, organisation-product fit, and commercial entity, that would lead to success. This paper exhibits a summary of the results, that is based on these authors’ work with their corresponding correlation coefficient between the factors and outcome measures. Further, analytic hierarchy process (AHP) was used to evaluate results.

Keywords: New product development (NPD), New product project, Project evaluation.
Introduction

In recent years innovation has become an important element of economic growth in industrialised countries and is also considered as an essential component of an organisation's processes which are needed for long-term prosperity and survival.

A key function which contributes to the innovation process is new product development (NPD) (Harris & Trainor, 2009). Two critical questions need to be addressed by managers of any new tangible product project when selecting the most promising new products; what determines the success or failure of new products, and what differentiates between a new product’s success and failure? (Cooper & Kleinschmidt, 1987). Although many organisations allocate a substantial amount of financial, human capital and other resources to ensuring the effectiveness of the innovation function, projects can still fail. Failure is not necessarily caused by the lack of commitment of managers and other employees, but, conceivably, by a lack of understanding of the key drivers of NPD (Pisano, 2012).

The purpose of this paper therefore, is the creation of a procedure to determine the key factors for NPD success, to aid the evaluation of NPD projects within the manufacturing industry. The creation of a new conceptual model is the foundation of the process.

The first time that a conceptual model was used for uncovering key factors of NPD was in Cooper’s 1979 study, Project New Prod I (Cooper, 1979). Cooper argued that conceptual models aid in the determination of new product outcomes and allow for deeper recognition of factors that might influence NPD performance.

Additionally, this paper frames the factors and sub-factors of NPD based on rational planning and problem-solving perspectives of research. The focus of the rational planning of research is to determine the factors that affect the financial performance of the new product project. The problem-solving stream looks at the implications of development teams, suppliers and team leaders, which influence the NPD process. This stream was based on a Japanese development discipline, which has at its core a cognitive theoretical orientation, which embraces flexible and different problem-solving methods first applied in Japanese project teams (Song & Noh, 2006).

These two streams of research complement the novel theoretical framework that this paper’s conceptual model uses, which is a resource-based view (RBV) of organisations. RBV aims at determining the influence of a firm’s resources such as, people, product development, product testing and launch on the financial performance of the NPD projects. All assets, capabilities, processes, and organisational attributes such as information and knowledge are considered as resources, which are needed for the development of strategies that enable firms to be effective and efficient in their creation of a new product project (Calantone et al., 2006).

Thieme (2007) ranked the leading authors’ work in the field of innovation by the number of publications across 14 leading journals on technology and innovation management, marketing, and management, between 1990 and 2004.

This paper’s conceptual model focuses on work of the leading authors recognised by Thieme, and was derived by critically evaluating the work of Robert Cooper and Elko Kleinschmidt (ranked by Thieme as 2nd and 5th respectively), Michael Song, (ranked 1st), and Roger Calantone (ranked 3rd).
Conceptual models

Cooper’s 1979 conceptual model, known as project New Prod I, was used to evaluate the impact of different factors on the outcome of the new product projects. In this model Cooper organised the factors under different categories, such as the nature of the project, its environmental category and “commercial entity”. Cooper suggested that the success or failure of a new product project is based directly on the relationship of its “commercial entity” with the market; other categories mainly influence the commercial entity directly, therefore affecting the overall outcome indirectly. (Cooper, 1979)

Song and Parry (1997) expanded on Cooper’s project New Prod I conceptual model by creating eight hypotheses that considered the direct and indirect relationships of the factors underlying Cooper’s three categories:

H1 The positive effect of competitive potency level on ‘Market and competitor intelligence’ but negatively affects ‘New product competitive advantages’ and ‘Degree of new product successful out-come’.
H2 The positive affect of firm’s marketing skills and resources on ‘Market and competitive intelligence’ and ‘Proficiency of marketing activities’.
H3 The positive impact of firm’s technical skills and resources on ‘Market and competitive intelligence’ and ‘Proficiency of technical activities’.
H6 Market activity proficiency positively affects ‘product competitive advantage’.
H7 Technical activity proficiency positively affects ‘Market activity proficiency’ and ‘Product competitive advantage’.
H8 Positive affect of the product competitive advantage on ‘the new product success’.

Cooper and Kleinschmidt’s (1987) conceptual model was based on Cooper’s previous research and empirical evidence, and demonstrated the relationship of the environmental factors with the new product strategies and implementation. They defined new product strategies as the new product itself, namely, product design, product advantages, and the launch of the new product into the market. The product strategy is the outcome of the new product process from the idea generation to product launch. The relationship between environmental factors and new product strategy is that the latter is executed within the organisation’s environment.

Song et al (2003) proposed a conceptual model, which examines the relationship of project management characteristics, consisting of factors such as project management style, project manager skills and senior management support, with structural and process dimensions that has factors such as cross-functional integration and planning proficiency.

Calantone and other’s (2008) conceptual model combines the key factors of NPD recognised Cooper and Kleinschmidt’s and Song et al., by determining the direct and indirect impact of proactive strategic orientation of an organisation and organisational structure on the successful outcome of the NPD process. Calantone et al (2008) explain the proactive strategic orientation of an organisation as the aggressive action and
strategies of an organisation, and the organisational structure as the work allocation and administrative aspects that directs activities, resources and coordination of these aspects of the NPD process. They also considered environmental turbulence such as market, competition and technological changes as a moderating factor for the relationship of the interorganisational aspects that is not under managerial control. The impact that environmental turbulent has on the relationship of the factors may influence the outcome of the NPD project.

Methods

In 1979, Cooper examined which factors lead to success or failure and collected data from 177 manufacturing companies from a variety of industries in Canada. He collected data by telephone initially, and then a questionnaire followed by mail. The first part of the asked each organisation to choose two of their new products, one successful and one unsuccessful product. This was followed by a more detailed questionnaire in which a list of 77 statements, formed from the factors of the conceptual model, were presented to the managers, who then were asked to agree or disagree with the statements on a scale of 0 to 10. Cooper used two statistical measures for evaluating the relationship of these variables; the analysis of variance (ANOVA) and the correlation coefficient. (Cooper, 1979)

In 1997 Song and Parry started by creating a questionnaire and inviting 28 new product teams; 16 from Japan and 12 from the United states. They pre-tested their questionnaire thoroughly by sending samples to four Japanese organisations. Finally, 792 companies, traded on the Japanese stock exchanges in Tokyo, Osaka and Nagoya, were surveyed.

From the survey, Song and Parry recognised that 611 companies had introduced manufactured goods to the market since 1990. They then selected randomly, 500 manufacturing organisations from these, and sent-out personalised letters with two copies of questionnaires in each and they received 788 usable questionnaires from 404 of the companies. Multi-item scales were then used to measure all constructs, which are the factors and sub-factors mentioned in their eight hypotheses. Performance measures, such as profitability and sales volume, were used for determining the success of the new product in its market. (Song & Parry 1997)

Cooper and Kleinschmidt’s 1987 project, New Prod II, determined which aspects of new product projects affect which success measures and whether there are different dimensions of success. The study focused on two major problems; the extent to which the success of the new product project can be measured, and the perspectives by which it can be measured, and whether such independent measurements exist, and; what the different aspects of identifying the success of the new product project are, and whether there are there similarities between them.

To do so, Cooper and Kleinschmidt gathered 200 new product project cases from 125 various manufacturing organisations. Out of the 200 cases, 120 were successful projects and 80 were not. They conducted interviews with managers and project leaders assigned to these projects. The interview was conducted around 5 important aspects; the nature of the product and the advantages that it offers; the product’s target market and the attractiveness of the market; the risk related to the purchase of the product by the consumer; the product organisation fit or synergy, that is, does the new product project fit with the firm’s resources, skills and experience, and; the organisational commitment to the new product project and how well defined were the protocols for engaging for its
development. Between seven and ten questions were formulated for each aspect, resulting in a total of forty questions, with responses based on a scale of 0-10, in order to understand fully the nature of the new product project. (Cooper & Kleinschmidt, 1987)

In comparison, Song et al’s 2003 study focused on data received on 64 and 128 new product projects from Japanese and Korean OEMs respectively. These products were tangible and were from industries producing for example, semiconductors, electronics, computer, instrumental, audio-visual and communication products. Each product manager selected four relevant new product projects, which were representative of the firm’s newest technologies and operational methods. Again, the questionnaire responses were on a scale of 0 to 10 and some verification of the data garnered was conducted from company records. They tested their hypotheses in two stages, a measurement model and a path model. (Song et. al, 2003)

Calantone et al’s 2008 study was conducted on 346 manufacturing organisations from the Fortune 500 list. The questionnaires were sent to managers of new product projects or managers of special business units. The response rate for this research was 58%, were from 41 different industries and comprising of products produced within the last 5 years. To analyse the results, they used a two-step approach for the separation of the measurement model from the structural model. (Calantone et.al 2008)

Results

Cooper’s environmental category was divided into three factors; the market, the firm’s resources and the nature of the project. Cooper concluded that the category had no major impact on the outcome of the projects, contradicting the importance that he initially put on this category in his conceptual model and could be said in most screening models as well. However, firm’s resources had the most impact on the outcome of the new product projects. Four of the most influential sub-factors were sales force or resources and skills distribution, the personnel and skills of the marketing research division, skill of management and the resources and skills of the promotion and advertisement division. (Cooper, 1979)

“Proficiencies of processes” according to Cooper’s analysis is the most important and noteworthy major factor on outcome of the three other controllable variables. The three most significant sub-factors of this factor were market lunch, prototyping with consumer input and test marketing–trial selling. Therefore, it could be said that the most influential sub-factor that has an impact on the success or failure is the marketing aspect of the new product project process. This aspect was further supported by information acquired factor with three most influential sub-factors were knowledge of consumer price sensitivity, understanding the buyer’s behaviour and knowledge of consumer needs and wants, and the technical aspects needed for the new product. From these most influential sub-factors, it could be concluded that having greater knowledge of the consumer based on their price preferences, behaviour, wants and needs according to Cooper’s finding have a significant impact on the success or failure of the new product project. (Cooper, 1979)

Moreover, Song and Parry’s 1997 work examined that in the case of new product selection; evaluating competitive environment, marketing and technical synergies are important. Furthermore, cross-functional integration is highly important for the successful development of the new product project and its overall success in the market. They confirm Cooper’s 1979 study that impact of marketing and competitive intelligence, market activity proficiency and product competitive advantage on the project management aspect of the new product project programme. However, in Japanese firm
the market activity proficiency, which directly affects new product competitive advantage and new product success positively, is less important. (Song & Parry 1997)

Cooper & Kleinschmidt’s 1987 shown that product cases when went through the 10 performance measures, three critical dimensions effecting the outcome and performance of the new product project that were: Financial performance, Opportunity window and Market impacts. Furthermore, according to them, some of the new product project characteristics were not affecting the any of the three performance measures, these were low priced, financial synergy in terms of resources, market size, purchasing nature by the consumer and new product design. (Cooper & Kleinschmidt, 1987)

On the other hand, Song and other’s 2003 study, examined three sub-factors of the planning that contributes to the survival of the new product project within the market, which were detailed planning, all team member contributing to the planning process and autonomy and flexibility of the project teams. Detailed planning could increase the efficiency of the development process that in turn could impact the efficiency and overall performance of the new product within the market. (Song et. al, 2003)

However, Calantone and other’s observed that environmental turbulent, which consists of technological uncertainty and market turbulence, acts as moderator for their model. However, they assessed that only a moderate relationship exists between innovativeness and market intelligence on the outcome of the new product project. Hence, during low-turbulent environment market intelligence had a positive impact on the successful outcome rather than the relationship between innovativeness and success that occurs during highly-turbulent environments. Furthermore, a positive relationship between proactive strategy with innovativeness and marketing intelligence has been observed by their model. (Calantone et.al 2008)

**Summary table and analysis**

Table 1 illustrates the summary of the results obtain by the authors with their corresponding correlation coefficient between these factors and performance measures of financial, market share and window of opportunity performance outcomes. The factors and sub-factors have been organised based on Cooper’s 1979 categorisation of the key factors. However, the firm’s strategy factor has been added based on Calantone et. al, 2008 study.

Moreover, the table exhibits analytic hierarchy process (AHP) that was comprised of the correlation coefficients of sub-factors adjusted by the ranking of the authors according to Jeff Thiem’s 2007 study. The table illustrates the mean of AHP results for each key factor. The formula that the AHP used is shown in Equation 1:

\[
WK_i = \frac{\sum_{j=1}^{n} R_j K_{ij}}{\sum_{j=1}^{n} R_j} \quad \text{(Equation 1)}
\]

Whereas Weighted Key sub-factors (WK) represents the correlation coefficients of sub-factors adjusted by the ranking of the authors. (R) represents the ranking of the authors that this paper assumed by a scale of 1 to 10. Finally, (K) represents the correlation coefficients of each sub-factor.

</table>
The proposed conceptual model

The AHP analysis, establishes the information acquired as the underlying key factor, which has a mean (r) of 0.21. The most influential sub-factor of this factor is a knowledge of consumer needs, wants and technical aspects needed for the new product with r equaling 0.42.

Other significant factors were a firm’s resources and organisation-product fit, proficiency of processes, commercial entity, firm’s strategy and project definition with mean (r) equalling to 0.2, 0.18, 0.16, 0.12 and 0.11 respectively.

Thus, based on the results obtained, Figure 1 represents the basis of this paper’s conceptual model.

![Figure 1: The proposed Conceptual model structure](image-url)
According to the conceptual model, a successful outcome of a new product project is directly influenced by the commercial entity factor (with its corresponding sub-factors). This factor is the output of a transformation process, which in this case were proficient NPD processes. For the NPD processes to be proficient, the model determined that a Firm’s resources and organisational-product fit has a direct impact on this factor.

Furthermore, the inputs of this transformation process were considered as being the project definition and the firm’s strategy, and that both factors influence each other. Finally, the information acquired was assumed as a factor at the beginning of the process, and directly influences the project definition and a firm’s strategy. Moreover, it links to other factors in the model by collecting and sharing information for each stage of the NPD process. The factor was considered as the underlying key factor, as it effects the successful outcome of an NPD project.

Future of the research

This research will continue with the application of a quantitative approach to test the factors and sub-factors found of the proposed conceptual model. The results attained from this scrutiny will validate or reject current factors or identify new key factors and sub-factors for the proposed conceptual model.

Abstract

Among the various models for innovation, there is a constant shock between the technological incentive and the market demand approaches, with a controversial strategy choice, there also occurring a growing interest for mixing them. Seeking to fill in this knowledge gap, a systematic literature review, combining bibliometrics, networks and content analysis, was applied, exploring the determinants of the market orientation strategy choice, in a 105-publication sample. Highlighting a continuous mixed organizational alignment, between technological incentive and market demand approaches, seeking to take advantage from both, but with an inclination toward one or the other, depending on some organizational perspectives.

Keywords: Strategies to market innovations, Technological incentive, Market demand, Systematic literature review.

Introduction

Innovations can be brought to market through two different approaches, Technological Incentive Strategy (TIS) or Market Demand Strategy (MDS) (Peters et al. 2012). The TIS, is technology-oriented, whereby the company pushes the potential customer to the market, through the areas of research and development, operating the sales team, without necessarily considering the customers’ needs (Baumers et al. 2016). Conversely, in the MDS (Horbach et al. 2012), a company can create innovations, understanding the market needs. The choice between these two strategies determines the company Strategy to Market Innovations (SMI), directly connected to the process by which a company produces new products and is organized, playing an important role in companies’ success (Dosi 1982).

These two strategies are well covered in the literature, but there is a research gap regarding the processes of choosing between them and a growing interest in mixing them (Costantini et
al. 2015), in which innovations are first designed through a technological bias, while demand allows innovations to adapt to market needs, to facilitate their adoption and diffusion (Stefano et al. 2012). This line of mix strategies can be found, for example, in the Lean Startup approach (Blank 2013), in which there are alternating cycles of innovation pushed to the market, and validation with the customers, for constantly improving the product or service developed. The choice of the SMI has several important consequences, because the improper choice can negatively affect the company’s results, reducing overall sales, conducting to customers’ dissatisfaction and leading to the discontinuation of projects with low return over investment (Brem & Voigt 2009).

Thus, this paper proposes to answer three main research questions: What factors determine the choice between the strategies to market innovations? How do companies position themselves in relation to these strategies to market innovations, considering their market segment, the company’s structure and business model? And What conduct companies choose of strategies to market innovations? In this scenario, this work aimed to investigate the determinants for choosing SMI (Bernstein & Singh 2006). To address these issues, the methodological approach was the systematic literature review, combining bibliometrics, networks and content analysis. The sampling used as a reference was collected from the Web of Science, Scopus and Elsevier, being composed for 105 papers. This study seeks to identify and to analyse the most relevant papers and authors, from the context of TIS and MDS, besides their perspectives for the SMI, highlighting the determinants of choosing SMI.

This research has six main sections. Section one introduces this research, also justifying its relevance. Section two presents the theoretical background. Section three details the methodology. Section four presents this research results. Section five discusses the results, and section six concludes this research.

Theoretical Background

One of the major challenges for the study of Technological Incentive (TI) and Market Demand (MD) is the lack of consistency and uniformity in the understanding and use of terminologies. Many terms emerged to describe the internal process of TI, such as technology push and science push (Schmoch 2007), while the process of innovation from MD have already been termed as: market pull, marketing pull, need pull, demand pull and communication pull (Chidamber & Kon 1994; Oncioiu 2013). Leading to a scenario of greater difficulty in understanding and use these terminologies, damaging this subject research and practice. The TI and MD are especially present in interdisciplinary areas, involving the use of multiple contexts, such as project management as in Aritua et al. (2009) and supply chain management as in Hinkelman (2005). This research considered all the studies concerning the subjects, regardless of the term used.

Market Orientation

Market orientation concept can be considered the result of the deep discussion about the marketing concept implementation (Kohli & Jaworski 1990). In the literature, we could also find near concepts of market orientation such as customer orientation (Berthon et al. 2004) and marketing orientation (Payne 1988). Shapiro (1988) discussed the three previous concepts, and concluded that they were so close that there could hardly be any distinction between them. Day (1992) and Kohli and Jaworski (1990), summarized the construction of the market orientation strategy as a customers’ information collection (market demand) and the competitor, disseminated throughout the company and exploited to satisfy the market current needs. The relationship between the market orientation strategy and the business performance was confirmed in different studies, such as Deshpande et al. (1993) and Kohli and Jaworski (1990).
The market orientation division into two complementary approaches, reactive (close to MD) and proactive (close to TI), introduced by Schumpeter (1934). Slater and Narver (1998) suggested that in a turbulent market environment, focusing on the customer latent needs can lead to better results than focusing on the existing customer needs. Thus, in the reactive market orientation, also known as customer obligated (Day 1992) and customer led (Narver et al. 2004), the company places its effort in discovering the current situation and expresses its customer’s needs. In contrast, the proactive market orientation focuses on the customers’ latent needs, needs which the customers can still ignore. Thus, depending on how a company intends to adopt the TI and the MD, the company can position itself more reactively or proactively, in a given market (Narver et al. 2004).

Technological Incentive (TI)
The first TI in large-scale is connected to the increase of the industrial activities and of Research and Development (R&D), after the II World War (Schmoch 2007). The first favourable argument about this paradigm predicted the basic science knowledge progression applied to the commercial product development research. Then, Dosi (1982) attributed the importance of this line of reasoning to some innovation process characteristics: science growing importance in the innovation process, increasing complexity requiring a long-term view, strong apparent correlations between R&D with the innovative production and innovation process inherent uncertainty. One of the main technology incentives arguments is a criticism in which it does not consider prices and other economic conditions changes, which affect the innovations profitability. Another criticism is that the emphasis on a one-way progression in the innovation process stages is incompatible with the subsequent development, which gives importance to feedbacks and interactions (Freeman & Louçã 2001).

Subsequent researches offered a less deterministic version of TI, while still giving importance to the role of science and technology. Some researchers argued that the availability of exploitable technological opportunities plays a role in determining the innovations rate and direction, and that it may depend on the field science strength (Rosenberg 1974). Companies must invest in scientific knowledge to develop their capacity to absorb knowledge, by exploiting emerging opportunities of the state of the art elsewhere (Freeman 1982). Other researchers support issues regarding the relationship between the technological system and the importance of knowledge flows among the different company’s fields (Rosenberg 1974). Finally, there is a line that characterizes this model of innovation as a linear model, advocating the sequential characteristic of the technological incentive (Rothwell 1994). The concept of TI that emerged and was widely used in the mid-20st century was slowly side-lined to the detriment of a counter-flow perspective, to observe market needs and to act reactively to meet those needs.

Market Demand (MD)
In the 1950s and 1960s, several studies argued that MD drives the innovations rate and direction. The changes in market conditions create opportunities for companies to invest in innovations to meet customers’ unmet needs. This demand guides companies to work on certain problems (Rosenberg 1969). Price changes, geographic variation in demand, as well as the identification of latent demand and potential new markets, affect the size of the reward in successful innovation investments, thus increasing the importance of considering the market for strategies outlined by a company.

Critics of this paradigm of market demand highlight three main points. Academically, the definition of demand, in general, was considered a very broad concept to be useful (Mowery & Rosenberg 1979; Chidamber & Kon 1994). Another criticism line explains that the change in market vision, as well as the technological one, is incremental and does not cause radical
changes, making the most relevant innovations impossible (Mowery & Rosenberg 1979). A third reasoning addresses the assumptions of the company's capacity arguments, expressing scepticism about: (1) how companies can identify the undisclosed needs of a near-infinite set of possible human needs; (2) the extent to which companies in general have access to a stock of techniques large enough to meet the variety of needs one might expect to emerge, and (3) to what extent companies can venture into existing routines, to meet non-satisfied demands. However, the concept of MD is widely used in the literature and applied to companies (Schmoch 2007).

Methodology

We applied a systematic literature review to identify and to synthesize the current literature in Technological Incentive (TI) and Market Demand (MD), as different market orientation strategies, answering this study research questions. The systematic literature review was conducted in three main steps, as suggested by Dybå & Dingsøyr (2008):

- (1) Criterions for including and excluding studies, research strategy - ensuring the sample quality, we only considered publications that underwent review process, filtering the results by articles or conferences publications from the Web of Science (WoS) database. Chosen because the database covers the results of greater relevance journals (journals with Journal Citation Report - JCR) from other databases. We also not exclude high impact studies from journals without JCR, also considering, the Scopus and the Elsevier ScienceDirect databases (Fleury et al. 2016).
  This research encompasses all the different nomenclatures for TI (technology push, science push) and MD (market-pull, marketing-pull, need pull, demand pull, communication pull), finding 543 papers in the databases (200 WoS, 257 Scopus and 86 Elsevier ScienceDirect), resulting in 326 papers after eliminating duplicity;
- (2) Sample filtering criteria to select the most relevant studies – only the studies with relationship with this research subject were selected (Karlsson, 2010), 105 papers.
- (3) Studies models’ analysis – data analysis includes bibliometrics, networks and content analysis (Fleury et al. 2016), in three steps. Step one the bibliometric analyses were applied identifying the main subject trends and journals, also highlighting the publications evolution over time. Step two the networks analyses were carried out, using the software VOSviewer 1.6.5. Always using the sample of 105 papers. The first two steps can provide an updated broad overview of existing research, which can be used as a starting point for academics who want to research this area of knowledge. Step three, perform the content analyses, only the most relevant articles were selected, according to their impact factor. The calculation of the impact factor considers the average number of citations (Cm) and the impact factor of the journal, JCR, also being applied a Pareto’ analysis, resulting in 12% of the papers (13 papers) representing more than 80% of the total sample representativeness, as done in Takey and Carvalho (2016). The content analysis applied systematic procedures to standardization and synthesis the content, with the purpose of answering the research questions (Bardin 2011).

 equation (1):
\[ Fi = Cm \times (JCR + 1) \]

Results

Bibliometric and Network Analysis

The journals Research Policy, Technovation and International Journal of Technology Management are the main journals publishing papers about TI and MD together, with each one published six papers. Figure 1 evidences the papers evolution over the years.
The network analysis allows the evaluation of subjects’ trends and relationships. In Figure 2 the lines connect the most cited keywords and the line thickness evidences the relationship strength between them. The most cited keywords were: market pull, technology push, industrial management and innovation, respectively, evidencing the intersection of market pull and technology push with the industrial management and innovation. With innovation and innovation process more related to the TI approach, being aligned with the study of Stefano et al. (2012), what can occur for the TI be more based on the companies’ ability to manage the internal production for new innovative products and services, while MD is more related to companies’ external factors, such as governmental environmental policies, patents, eco-innovation and environmental technologies, evidencing that companies that use MD strategy are more susceptible to external influences, such as customer brand perception and regulations.

In Figure 3, the lines connect the papers that share bibliographic references and the line thickness determines the sharing intensity. It is possible to highlight three clusters. Cluster 1 - focus on reduction of impacts on the environment, innovations related to sustainability and eco-innovation, with a great correlation between Horbach et al. (2012) and Rehfeld et al. (2007), that shares one of the authors and are related to eco-innovation in Germany. Cluster 2 - characterized by literature review studies. Cluster 3 - dealing with the biotechnology field.
This network assists the papers interpretation in the content analysis, useful to find similarities in the determining factors for choosing the market orientation strategy.

Content Analysis
To answer: What are the factors that determine the choice between the strategies to market innovations? The content analysis focus on: the main factors that affect the choice of a Technological Incentive (TI), Market Demand (MD) or a mix of the approaches; the implications for the market orientation strategy; and how each market segments has to adapt itself, in this context.

It was highlight that the topic of strategy choice is still controversial in the literature. On one side, Brem and Voigt (2009), based on their innovation theoretical and conceptual models consider that the two strategies (TI and MD) are equally important for all kinds of companies. Their model supposes that none of the strategies is better and that the adoption of only one of them can sink the company competitiveness in the long term. On the other side, Pearson (1990) proposes that the use of only one predominant strategy. In this scenario, raises some determining factors for a company choose between the three approaches mentioned.

Factors for Technological Incentive (TI)
According to Kivimaa and Kern (2016) the use of technological innovation systems in the context of sustainability, allow the creation of market from the new market demand creation. This new market creation can be done by demonstrating projects, creating bridges between markets or massifying a market. In the context of agricultural innovations, the concept of open innovation has been shown as a potentiator of the TI model (Caetano & Amaral 2011). The open innovation allows that companies and government create cooperation and collaboration for knowledge and responsibilities sharing, allowing the achievement of shared benefits.

Environmental Management Systems (EMSs) allow the introduction of clean technologies that reduce costs by reducing the lack of information (Horbach et al. 2012). In addition to companies’ systems, some factors, such as employee empowerment, senior management commitment and mapping process can make possible the creation of new processes and products that generate less pollution, being important factors of eco-innovation (Stefano et al. 2012).

Factors for Market Demand (MD)
For Rehfeld et al. (2007) the concern with customer satisfaction is the main factor that a company must consider in a MD strategy. With large manufacturing companies focusing on
market demand to ensure that their products fit the market, reducing their risk (Walsh et al. 2002).

In the scenarios such as green products, consumers can prioritize sustainability credentials as a primary factor and put price and performance in the background. This way in segments such as the development of sustainable products it is necessary to have a well-aligned policy with the market (Kivimaa & Kern 2016). With a contrary approach, Horbach et al. (2012) believe that there is still little demand stimulation since eco-friendly products are still often very expensive. Making the costs and final price highly relevant to the eco-innovations.

Factors for the mixed approach
Majority of studies, in the field, search for innovation through a mixed approach, where technology appears to be the central point of the innovation, while demand allows the adaption of the innovation for the market needs, facilitating its adoption and diffusion (Stefano et al. 2012). The mixed approach process is a natural flow that occurs in cycles, as in the robotics industry (Schmoch 2007). The early cycles are driven by technology and produce innovations that generate what the Gartner company calls a cycle of enthusiasm. Often due to the lack of adherence of the technology to the market, there is a disillusionment, and it opens the door to a cycle more oriented to market demand. This cycle adapts the technology created for market demands, through the creation of various services and products. Then these services and products go through a consolidation phase.

Another relevant factor that affects the approaches is government policies that may end up favouring one approach or other (Nemet 2009). These policies can reduce the private costs of producing innovation, which ultimately stimulate technology, or can implement measures that reward private initiative for successful innovations (market demand).

Discussion
To answer: How do companies position themselves in relation to these strategies to market innovations, considering their market segment, the company’s structure and business model? And What conduct companies choose of strategies to market innovations? It was evidenced that in addition to the internal factors (technical competencies, organizational structure, top management vision) and external factors (public policies, price of the service or product, consumer needs) that were determinant in choosing the market orientation, it was possible to identify that the business model, the organizational structure and the market segment where the company operates, are also variables with great influence in the choice of strategy adoption by the company.

The business model and organizational structure influences the company marketing orientation, because companies in established or saturated markets are usually oriented to a well-known market, while companies that operate in poorly defined markets search to be guided by new technologies (Costantini et al. 2015; Stefano et al. 2012). Large companies tend to search for incremental innovations, favouring the marketing demand approach, searching to respond to present market demands, whereas small companies are usually driven by technological innovations, searching to respond for future market demands, creating new technologies (Walsh et al., 2002; Nemet 2009).

Companies whose competitive advantage is in the internal knowledge management skills tend to focus on technological development, while organizations whose competitive advantage is in the marketing and sales fields tend to respond to market needs (Horbach et al. 2012). Companies oriented to create products and services to other companies tend to search innovation in new technologies, while companies that sell to end customers tend to respond to the demands of their market (Brem & Voigt 2009). See Figure 4.
Considering the studied publications, it is possible to affirm that there is an alignment between the strategies and the market segments. With the TI strategy more associated with the segments of agriculture and industry software (B2B). While the MD strategy is more associated with conventional biofuels, software industry (B2C), wind power and large manufacturing companies. With the mixed strategies appearing more in segments such as advanced biofuels, food, robotics and biotechnology.

For the biofuels market, investment in R&D accelerate the transition from conventional fuel technologies (from edible raw material) to advanced fuels (from non-edible raw material) and the technical capability allied to technological knowledge are recognized as very important for the production and diffusion of eco-innovation, highlighting the importance of the technological incentive. At the same time, obtaining market incentives for the consumption of biofuels in a national scale, external investments and costs specific advantages are relevant factors for a market-oriented policy (Costantini et al. 2015).

For the creation of new functional foods, is important to balance consumer needs with technical realities, ensuring the incorporation of opportunities for advancement in technology, gaining competitive advantage (Van Kleef et al. 2002), balancing what can be done (customer perspective) with what could be done (scientific/technological perspective). Small manufacturing companies, in order to achieve disruptive innovation, use both TI and MD, with the process influenced for the optimization of the Time-to-Market (Walsh et al. 2002).

**Conclusion**

This study searched to fill the literature gap about the choice between the different approaches to market positioning (Technological Incentive - TI, Market Demand - MD and mixed approach). Conducting a systematic literature review to analyse the existing literature in these subjects, through a multi-method approach (bibliometrics, networks and content analysis). The literature evidenced that most of the articles that deal with one approach do not discuss the others.

The bibliometric analysis highlights the growing importance of the subjects. The networks analysis points to a greater intersection of TI with the internal issues to the organization of industrial management and innovation while the MD is more related to the external issues sustainability and government policies. Both bibliometric and network analysis contributes to theory by updating the body of knowledge on TI and MD, helping academics who want to
start looking into those concepts, to better understand which areas of study each of these topics are being further developed, if any different area can be used as reference (e.g. industrial management researchers may find relevant findings in studies on biotechnology and areas that use similar approach for SMI) and which authors can be used as a starting point for exploring the theme.

Based on the content analysis, this study compared the factors that determined the company’s strategy. Evidencing a tendency for a mixed company alignment between the strategies of TI and MD, taking advantage of both, but with a more inclination towards one or other approach, depending on the: companies’ structure, business model or companies’ segment. The TI strategy aligns with emerging markets, in organizations with internal technological bias skills in search for radical innovations, in small and medium-sized companies and B2B businesses. The MD strategy is more associated with consolidated markets, with companies focusing on marketing and sales and incremental innovations, large companies and B2C businesses. The main objective of the TI approach is the constant relocation of the company as a technological leader in the field, while the MD allows less exposure to risks.

The findings of this research bring contributions to the literature, greater clarifying the differences between the main approaches of market position, consolidating how each company has had greater success defining its market strategy orientation. Also contributing with practitioners (strategic and marketing managers) by bringing an understanding of how better position themselves in front of the market due to organizational internal and external factors, maximizing the organizational results, improving the sales and increasing the customers’ satisfaction.

This paper presents limitations regarding the number of scientific bases and the combination of keywords, presented in the method section. This research also has implications for future researchers, highlighting some authors recommendations: study the importance of greater analysis in the mixed approach models in the initial stages of product conceptualization and its impacts in the development of the product (Van Kleef et al. 2002), and the opportunity to carry out studies on open innovation and its impacts to the market demand model (Caetano & Amaral 2011).

The structure, nature and significance of alliances in innovation networks – the case of new product development in biotechnology

Keywords: Innovation, Alliance Networks, New Product Development

Topic(s):
9. Innovation, Product and Service Development
4. Empirical Modelling and Simulation
1. Behavioural Operations

Word count: 983

Purpose

Scholars recognize the transition from exploratory innovation to commercial exploitation as a learning process (March, 1991; Yamakawa, Yang, & Lin, 2011). One unique characteristic of the commercialization pathway that the innovation literature has not rigorously assessed is the relational nature of different components in the ecosystem (Powell, White, Koput, & Owen-Smith, 2005). Powell et al. (1996) network approach finds that centrally connected exploratory R&D alliances are necessary to achieve “valued organizational outcomes”. Rothaermel and Deeds (2004) exploration–exploitation framework of organizational learning suggests a causal relationship between venture alliances, that new product development depends on the type of the alliance, and that it is moderated negatively by firm size.

We build on these and other works to establish a structural model of learning networks via organizational alliance/ties (Figure 1), and their relative impact on new product development in the biotechnology sector.
The confluence of these associative learning networks via organizational ties raises the following hypotheses:

**Hypothesis 1:** The system of new product development linking explorative R&D alliances to products on market is persistent in the biotechnology industry.

**Hypothesis 2:** The new product development path leading from explorative R&D alliances to products on market is moderated by tie centrality and tie age.

**Design**

We test these hypotheses on a sample of dedicated biotechnology firms in the years 1988-2018, using a pooled, within-firm, averaged time series analysis. We identified firms dedicated to human therapeutics listed in the Cortellis Database. The companies in our data pool were collected from four segments:

- Generic Pharmaceuticals
- Specialty and Advanced Pharmaceuticals
- Biopharmaceuticals
- Biotherapeutic Drugs

This process yielded a sample of 300 biotechnology firms centred in a range of nations. We tested the model using a structural equation model built using AMOS.

**Control Measures**

We employed several control variables that may impact upon the new product development system (Figure 1). We control for firm structure with the usual array of...
variables used in previous studies. We control for the nature of the alliance/tie network with the following variables:
- age of a firm’s alliance/ties in months – longer preferred
- degree centrality - how well a firm is connected,
- closeness centrality - reciprocal sum of degree distance to each other firm
- exploration centrality - how well a firm is connected in the exploration network
- exploitation centrality - how well a firm is connected in the exploitation network

Findings

The results of our analysis are depicted in the measurement model below (Figure 2). Our results reveal a good model fit for the sampled data, with NFI, CFI and RFI > 0.96, and RMSEA < 0.026 with a 90 percent confidence interval of (0.000, 0.094). We also conduct Lagrange multiplier tests to find that no alternative specification of the parameters would have led to a model that better represented the data. There is strong support for Hypothesis 1 that there is a robust persistent system structure of new product development linking explorative R&D ties to products on market in the biotechnology industry (as originally suggested by Rothaermel and Deeds (2004)). However unlike Rothaermel and Deeds we find little evidence that the entire new product development path is moderated by firm size, and by contrast firm age has a negative influence on exploiting potential products. We build on these works by finding the conflagration explorative tie age has on the new product development path.

![Figure 2](image-url)

**Figure 2** Measurement model for commercialisation of biotechnology alliances

We find partial support for Hypothesis 2 that the new product development path is moderated by tie centrality and tie age. In deference to Powell et al. (1996) we find that centrally connected exploratory ties are necessary to achieve “valued organizational outcomes”. But rather than manifest in firm size growth, we find this influence extends through the entire network, to eventually have a negative impact on products on market.
We extend on Powell’s various works by finding that exploitive tie centrality has a similar impact on the new product development path, but that the age of these ties is insignificant.

**Contribution**

The current study is in an attempt to better understand the commercialization pathway for innovation in the biotechnology sector. The analysis revealed that in addition to firm structural controls, the nature of network alliance/ties challenges and improves on the findings of previous inter-organizational innovation networks studies. Our theoretic contribution is to confirm that while multi stage collaboration is necessary in order to bring commercial reality to the discoveries, it is the centrality and age nature of these alliance/ties that enables effective delivery of products to market. The contribution we make to practice is to proffer a utopian commercialization pathway for discoveries in the biotechnology industry, namely one that encompasses; clusters of specific centralised expertise/learning at defined stages of development, and deemphasises the focus on large, old U.S. based firms that offer poor equity deals.

An approach for identifying collaborative business opportunities for networked organizations: application to connected and autonomous vehicles

Alexandros Zafeiriadis (A.Zafeiriadis@warwick.ac.uk)
Warwick Manufacturing Group, University of Warwick, Coventry CV4 7AL, UK

Ahmet Onur Agca
Warwick Manufacturing Group, University of Warwick, Coventry CV4 7AL, UK

Abstract

This paper presents the results of a study conducted with a network of organizations involved in the connected and autonomous vehicle’s technology as an emerging trend, which aimed at developing an approach for the identification of collaborative business opportunities by deploying coopetition theory, design thinking principles, and business model theory. The purpose of this paper is twofold. Firstly, it tries to develop an approach that will enable organisations to identify collaborative business opportunities and, secondly, provides insights into the challenges and requirements for the realization of full scaled solutions for the connected and autonomous vehicles.

Keywords: design thinking, coopetition, connected and autonomous vehicles

Introduction

Emerging technologies and innovations are creating a new landscape of competition with disruptive business models being introduced into traditional industries. Therefore, it is suggested that firms should be strategically prepared to respond to emerging trends. A common strategy for that involves the transformation from separate product and service offering toward more complex value propositions that will enable firms to harness market opportunities to sustain and grow their market position. However, high uncertainty for the final offering, products’ short life cycles, technology convergence and R&D expenditure intensity are just some of the reasons of why vertically-integrated resources and capabilities are never enough for a standalone firm when new industries are formed (Bengtsson and Kock, 2014). Hence, these product-service value propositions can only be realised where different actors collectively create and deliver value by integrating their resources and capabilities to overcome technological and commercial challenges.

Connected and autonomous vehicles (CAVs) are about to become a reality and, thus, automotive manufacturers have made considerable investments to make the technology more viable, affordable and safer focusing on safety case development, environmental impacts, traffic operations and infrastructure design (Talebian and Mishra, 2018). Through that, it is evident that the traditional value creation chain is shifting to an
ecosystem of multiple partners who contribute to the technological readiness and will be part of the value propositions for the emerging opportunities around CAVs. Thus, an approach that identifies collaborative business opportunities seems relevant to move forward.

This study views coopetition as an entrepreneurial process that can cope with uncertainty, explore and exploit opportunities and develop innovative solutions within a collaborative environment. Therefore, the aim of this study is twofold. Firstly, it tries to develop an approach that will enable organisations to identify collaborative business opportunities under the coopetition theory by utilising design thinking principles and the business model canvas. Secondly, empirical data is analysed to provide insights into the challenges and requirements for the realisation of full scaled solutions for the connected and autonomous vehicles.

Context

Coopetition
Coopetition - the simultaneous competition and cooperation among firms- is discussed in strategic management as an alternative for rival organisations to complement their competencies through collaboration (Bengtsson, Kock and Lundgren-Henriksson, 2018; Gnyawali and Ryan Charleton, 2018; Hoffmann et al., 2018). In their review of coopetition research, Bengtsson and Kock (2014:182) provide an inclusive definition of coopetition, which is seen as ‘a paradoxical relationship between two or more actors simultaneously involved in cooperative and competitive interactions, regardless of whether their relationship is horizontal or vertical’. This definition outlines that coopetition includes relationships in both the inter-organizational and the intra-organizational level of analysis. In this paper, we discuss coopetition as the simultaneously collaborative and competitive relationship among firms in the value chain of connected and autonomous vehicles that constitute an emerging technological innovation.

Coopetition fit for opportunities and innovation
As noted earlier, high technology industries seem to face unique challenges and opportunities that require the collective contribution of different actors to be resolved and exploited, respectively. Thus, the strategic choice of coopetition seems more conductive in those industries. Scholars have emphasized coopetition strategies as the main triggers in innovation efforts as firms have used them for the development of new products (Bouncken, Clauß and Fredrich, 2016), and innovative business models (Velu, 2016). Moreover, evidence show that coopetition enriches the process of generating value-creation opportunities (Ye and Yamamoto, 2018), is a mechanism for learning and sharing knowledge (Bouncken and Kraus, 2013), and it can protect innovation projects from imitation through novelty in the business concepts and competencies (Ritala, 2012; Ritala and Hurmelinna-Laukkanen, 2013). Empirical evidence shows that being involved in coopeting relationships is essential not only to acquire new technological knowledge and skills, but it can also support the creation and access of other capabilities exploiting the existing ones (Quintana-García and Benavides-Velasco, 2004). It seems relevant to outline that radical innovations are suitable to be exploited in the setting of where more
than two firms are involved in coopetition (Yami and Nemeh, 2014). On the other hand, strategic innovations on their own can lead to increased cooperation and competition (Roy and Yami, 2009). All of the above evidence suggests that coopetition can be beneficial during the innovation process and can determine ways to move forward for the post-launch phase. Hence, it is important to be considered for connected and autonomous vehicles where new collaborative value propositions are likely to be offered in the future.

**Coopetition and uncertainty**

Coopetition strategies have been seen as mechanisms to cope with uncertainty (Bouncken and Frefrich, 2012). While innovation is strongly linked with uncertainty, and coopetition is a source of opportunities for enhancing innovation efforts, it is a beneficial practice under other conditions as well (Ritala, 2012). For example, the application of coopetition is relevant when industry develops swiftly, and its future is unpredictable. Firms involved in coopetition can harness multiple benefits under those conditions such as a risk of failure and cost sharing and increase their market performance (Ritala, Golnam and Wegmann, 2014). Moreover, competitors that operate in similar domains possess similar resources or complementary resources, and insights about the business environment, hence, they can better determine what these new offerings and new markets will be decreasing uncertainty. Ritala, Golnam and Wegmann (2014) suggest that in the creation of industries and offerings, coopetition is beneficial due to positive network externalities. These network externalities refer to offerings where the value that is delivered to the customer from a product or service depends on the number of other customers utilising the same product or service (Wang and Xie, 2008). For example, the mobility benefits of CAVs are expected to increase as the adoption of the technology increases in the market; therefore, competing firms are in critical roles to form a common basis for utilizing resources that work together.

**Design thinking**

Design thinking has different definitions as the technique has been developed simultaneously by different groups and organisations. Gruber et al. (2015, p.2) describe design thinking as a ‘human-centered approach to innovation that puts observation and discovery of often highly nuanced, even tacit needs right at the forefront of the innovation process. It considers not just the technological system constraints but the socio-cultural system context’. Design thinking can be practised at multiple levels by people with different capabilities since it depends on an argumentative process in which the people involved can perceive a problem and explore potential solutions gradually.

Dunne and Martin (2006) argue that management solutions use inductive and deductive logic and are acquired from a list of proposed potential solutions. Design thinking aims to think outside these predetermined answers, and to use abductive logic to attempt to see what could be. Hence, design thinking is appropriate for dealing with uncertainty when there is not available information that can solve ambiguous problems. In that sense, it fits the innovation process for connected and autonomous vehicles as within a business perspective it combines the generation of new ideas with their analysis and evaluation of how they apply in a holistic sense (Vinnakota and Narayana, 2014).
Business models
A business model has been seen as a platform between strategy and practice, describing the mechanisms of value creation and capture for organisations (e.g. Amit and Zott, 2001; Chesbrough and Rosenbloom, 2002; Teece, 2010). Essentially, a business model is a story that explains how an organisation works. To that end, business models and coopetition are linked since, in both, value creation and capture are central elements (Nalebuff and Brandenburger, 1997). Business model tools can be used to support the innovation process. Utilising the business model canvas, developed by Osterwalder and Pigneur (2011), is an effective way to understand a firm's business model by reducing complexity through a holistic analysis. Having developed a logical and tangible perspective of an organisation is important for facilitating discussion, debate and exploration of potential innovations in existing business models and promote the creation of new value through the joint resource utilisation of coopeting firms (Ritala, Golnam and Wegmann, 2014).

Approach/methodology
The 4-stages approach is based on co-creation design thinking using closed-loop processes to enable the generation of ideas based on customer aspirations and to translate them into product features and services. In particular, for emerging industries and new technologies, such as CAVs, new insights, innovations and new capabilities can be realised rapidly. The method used in this project was made up of the following four phases: discovery; design; define and ideation, and delivery phase and consisted of the following elements:

- The utilisation of the business model canvas to map organisational elements, resources, capabilities and the relationship of each organisation with its customers, suppliers and partners using semi-structured interviews with each participant organization. The business model canvas permits to visualize the main elements and was used as a guide in the ideation process (Bocken et al., 2014).
- The analysis of the business model elements and the expectations for participant organisations about the connected and autonomous vehicles were utilized to design the workshop that was introduced in the define and ideation phase. This involved the visualisation of all relevant information in enabling information and knowledge transfer among the coopeting organisations informing each organisation about relevant resources, capabilities and the perception for the technology solutions around the CAV.
- Following the background work and based on resulting syntheses, a workshop was organized following these specific activities
  o Activity 1 was dedicated to helping participant organisations to understand the business model elements of their coopetitors and complement on resources and capabilities for the connected and autonomous vehicles. This facilitated a draft of the key points of the business models to assist the innovation process.
  o Activity 2 was dedicated to the development of insights about what could be enabled by the technology in the future. Hence, following a user-centred approach, participants were positioned on the role of the customers to visualise the CAVs as part of their day in the future and match their aspirations with product and service offerings.
Activity 3 consisted of framing the problem of commuting and finding out how CAV can provide a solution to these problems. This allowed participant organizations to work for a common goal and connect product and services related to CAVs with actual problems.

Activity 4 was dedicated to the analysis of the ideas for products and services of the previous activities to allow clustering them and combine them in relevant business opportunities.

Activity 5 involved the discussion around which business opportunities seems more appealing from each organisation's perspective and voting for the most favourable. The participants evaluated the concepts that reached a consensus and then selected the ones as more likely to be further developed.

Activity 6 was dedicated to exploring how competing organisations will co-create value for the most favourable business opportunities. This involved the allocation of relevant resources and capabilities of each organization to enable the development of the business opportunities scenarios.

Activity 7 was dedicated to the identification of barriers for the realization of these scenarios considering the technical robustness and the fit with to the users. Then, mitigating actions to these barriers were defined.

In the last phase, the documentation of the solutions and recommendations for next steps in a report allowed participating organisations to provide their feedback.

An abductive research process was followed since it is a way of working that enables data collection and theory development to take place simultaneously and fits the purpose of study that targets on a specific problem in the automotive industry (Saunders et al., 2015). Moreover, there is a clear link of abductive reasoning with the design thinking process.

![The abductive process adopted by Kovács and Spens, 2005](image)

The research was built towards the development of an approach that will enable the effective exploration and exploitation of collaborative business opportunities for
connected and autonomous vehicles. A case study is the most appropriate research method since it moves away from just closing theoretical gaps through basic research and explores theory to provide a solution to a problem. To enhance the research, interviews and a workshop were selected as the most appropriate data collection tools.

Figure 2 - The interview process

All interviews were conducted via face2face meetings to secure that participant organisations were adequately informed, and their input was captured, providing them with the chance to follow-up on issues if needed. Organisations that collaborate in an established project and will be involved in the formation of commercial solutions for the connected and autonomous vehicle were interviewed. Through that, the necessary technological and market knowledge was secured, as well as, the fit of coopetition theory. Table 1 provides a full list of companies and their relevant role.

Findings

As illustrated in Figure 3, a new approach based on design thinking was developed, called the 4-stages modified design thinking process. The modified approach provides a strategic approach to identifying the most advantageous co-creation opportunities for an emerging industry where the final offering is still uncertain.

Figure 3 - 4-stages design thinking process

The process utilized a modified version of the business model canvas to inform coopeting organisations on the resources and capabilities of each organisation, eliminating the inaccuracies on information gathering and transfer. This is achieved by...
enabling organizations to provide feedback on the information gathered through the interviews. Moreover, the business model canvas provided an effective way for knowledge and information sharing enhancing the cooperation and allowed matching ideas for co-creation with relevant resources and capabilities of each organization (Osterwalder and Pigneur, 2011; Bouncken and Kraus, 2013).

Design thinking worked as a mean to dissolve competing relationships in the ideation stage by positioning participants in the role of the customer where details of user's lives led to new and more profound insights for offerings enabled by the connected and autonomous vehicles that were translated into products and services. A second impact during the ideation stage was observed by focusing on exploring the problem of commuting itself and, then, based on the new understandings; ideas were generated for products, services and business models to solve these problems. Dorst (2015) has argued that problem framing is one of the key design practices that make the method more likely to yield better solutions than conventional approaches to problem-solving. This stage was enhanced by having participants with different backgrounds from academics, product managers, business developers to technology specialists as different perspectives on the examined issues were combined.

Participant organizations had to collaborate in order to achieve a consensus about the most beneficial business opportunities and match their resources and capabilities to these scenarios. To achieve this, organizations had to define which technology will be used for the connectivity side. Despite that, opportunistic behaviour can be seen on determining the mix of technologies as organisations compete following their individual strategies, consensus on the resources and capabilities that are required for the realization of the final three business opportunity scenarios was found. In that sense, coopetition seems to be seen as a strategic choice for the CAVs among the networked organizations (Roy and Yami, 2009). Figure (4) describes the results of following the developed approach.

![Diagram](image_url)

**Figure 4: Results of the approach**

Using a design thinking approach enabled discussions and observations that have not been identified focusing solely on the development of the technology. Hence, further insights were formed for the difficulties of commercialising CAV-enabled products and services. Except of the technological development, which is the base level in the suggested framework, data ownership and sharing issues, and incentivization were
identified as two challenges that organizations should overcome to realise the final offering of connected and autonomous vehicles. To that end, the collaborative efforts should be targeting on understanding how the customers will adopt the technology and how to demonstrate these benefits through the offerings. Moreover, the huge amounts of data that will be generated and collected as the connected vehicle interacts and exchanges data with other vehicles and the infrastructure should be classified in order to build a joint agreement about its usage and ownership. Finally, specific attention should be given around the security of the systems and the formation of an adaptive regulatory environment for the CAV technologies, products and services, with the involvement of both organisations and governments to clarify the path in all levels of commercial readiness. Figure 5 illustrates the framework for CAV commercial readiness.

Figure 5- Framework for CAV products and services commercialization

Conclusion
To summarize, this study provides an approach for the identification of collaborative business opportunities utilizing coopetition theory, design thinking principles and the business model canvas. The case study results indicate that all three topics can be combined through the approach to enhance networked organizations in the innovation process of emerging technologies focusing on connected and autonomous vehicles. Moreover, it illustrates how competition and design thinking are valuable to provide new insights on emerging trends as they can be used for the identification of challenges and requirements that were not considered before. Finally, it provides a framework for the commercial readiness of the CAVs as the outcome of the empirical analysis. Through that, it shows that an intermediate level is required from technology development to full-scale solutions.

How do firms manage network learning to develop solutions in global engineering services?

Thanh Tran (danytran810@gmail.com)
Birmingham Business School, University of Birmingham

YuFeng Zhang
Birmingham Business School, University of Birmingham

John Bryson
Birmingham Business School, University of Birmingham

Abstract
Global engineering services firms develop solutions through network learning with customers, suppliers and intra-firm engineering units, but the connection and contribution of these processes are unclear in the current literature. This paper aims to explore how firms integrate inter- and intra-firm network learning for solution development. Through the multiple case study method, it explores that firms develop solutions through an integrated inter- and intra-firm network learning process, rather than independent ones as having developed in previous studies. The integrated process is facilitated by a set of knowledge boundary spanning and governance mechanisms.

Keywords: Network learning, Solution development, Global engineering services

1. Introduction
Global engineering services (GES) firms, who provide through life-cycle project-based services to support customer businesses on a global scale, are increasingly adopting network learning for solution development to compete effectively in the changing global market (Brady and Davies, 2004; ISG, 2016; Salonen et al., 2018). Network learning is an intra- and inter-firm process that enhances firm performance through knowledge creation and reuse (March, 1991; Brady and Davies, 2004; Kotlarsky et al., 2014). Studies on network learning have found that GES firms manage network learning to acquire and develop knowledge together with customers, suppliers, and intra-firm engineering units to develop engineering solutions (Brady and Davies, 2004; Kotlarsky et al., 2014; Galbraith, 2014; Salonen et al., 2018). However, their connection and contribution to the process of engineering solution development are unclear in the current literature.

Specifically, there are two separated streams of research contributing to inter-firm and intra-firm network learning as independent processes. The marketing literature has highlighted that network learning with customers and suppliers in business networks is key to solution development (Jaakkola and Hakanen, 2013). The operations management literature has pointed out that network learning with intra-firm engineering units is the main contributor to solution efficiency, flexibility and innovation (Kotlarsky et al., 2014; Zhang et al., 2016). In this paper, we argue that network learning with
customers, suppliers and intra-firm engineering units altogether contribute to GES solution development in an integrated all-encompassing process. We will reveal the linkage between inter-firm and intra-firm network learning that contributes to engineering solution development. In brief, the main research question of our research is: **How do GES firms manage inter-firm and intra-firm network learning to develop engineering solutions in global operations?**

This paper will explore the activities and their interactions of network learning with customers, suppliers and intra-firm engineering units that contribute to GES solution development. From the perspective of learning and knowledge management, this paper will construct an integrated framework of network learning by reviewing the literature in GES solution development and network learning. This preliminary framework guides the analysis of different learning episodes from three cases. The analysis shows that GES firms manage network learning with customers, suppliers, and intra-firm engineering units within an integrated process to develop solutions. This process is facilitated by a set of knowledge boundary spanning and governance mechanisms to address knowledge boundaries between customers, suppliers, and engineering units. As the key contribution, this paper clarifies the linkage between network learning with customers, suppliers, and intra-firm engineering units to facilitate solution development in GES. This paper proposes a conceptual framework to improve our understanding of integrated network learning and offer managerial implications for facilitating solution development in GES operations.

2. **The theoretical foundation**

2.1 Global engineering services (GES)

Global engineering services (GES) refer to “the application of engineering knowledge (including engineering technologies, skills, and expertise) possessed by an engineering services firm in effective problem-solving for the benefit of customers in a global context” (Zhang et al., 2016, p.81). They include three interrelated stages: corporate technology planning, technology development, and product development (ISG, 2013). Corporate technology planning is a complex and valuable activity, directing the operations of the other stages. Technology and product development are more operational, involving engineering research, design and development, and manufacturing engineering. These operations can be distributed in many countries to enhance operational efficiency and effectiveness (Zhang et al., 2016).

GES are delivered in different types of projects at firm facilities or customer sites (Malhotra & Morris, 2009). Customers are integrated into projects for the purposes of customisation (Jaakkola & Hakanen, 2013). GES firms employ diverse teams of engineers with different backgrounds, skills and experiences, and integrate them into specialised engineering units for GES operations (Malhotra & Morris, 2009). Suppliers are also involved into GES projects to co-create the solutions required by customers, providing complementary knowledge for GES operations (Jaakkola & Hakanen, 2013).

2.2 Solution development in GES

GES projects generate customised solutions which are developed continuously to meet changing customer demands (Tuli et al., 2007). Engineering solutions involve product life-cycle development for the benefits of customers (Kujala et al., 2010). They include process-oriented and output-oriented solutions (Breidbach and Malgio, 2016). Process-oriented engineering solutions are created only when engineers are deeply embedded within the customer organisational context to co-create engineering solutions...
through the eyes of the customers (Tuli et al., 2007). Output-oriented solutions are mostly created separately from the customer organisational context and rely on service provider specialised expertise, involving the delivery of artefacts as the mechanisms for service (Galbraith, 2014).

GES firms develop solutions either by enhancing their operational performance (Brady and Davies, 2004; Kotlarsky et al., 2014) or creating novel solutions (Galbraith, 2014; Zhang et al., 2016). An efficiency-focused solution development strategy enhances the operational abilities that help GES firms outperform their rivals through implementing their engineering tasks with fewer resources (Brady and Davies, 2004, Kotlarsky et al., 2014). An innovation-focused strategy highlights the operational abilities that help GES firms create new engineering solutions for customers (Galbraith, 2014, Zhang et al., 2016). Firms can also focus on a flexible strategy which emphasizes the operational abilities that help GES firms quickly respond and adapt to changing customer needs either for efficiency or innovation (Johnstone et al., 2009; Zhang et al., 2016).

2.3 Network learning for solution development in GES

Network learning has been increasingly recognized as a key strategy for solution development in GES (Brady and Davies, 2004, Zhang et al., 2016; Salonen et al., 2018). The concept of network learning has been studied within the field of organizational learning (Crossan et al., 1995, Knight, 2002). Knight and Pie (2002;2005) are among the influential authors who studied network learning as the fourth level of organisational learning which refers to the learning of organizations as a group. Network learning occurs when there are changes in network shared cognition and practices. Knight (2002) argues that network learning, whether inter-firm or intra-firm network learning, can only be captured within a network learning episode in which learning goals, actors and activities are specified. To understand how firms manage network learning, the context, content, and process of network learning should be clarified (Knight and Pie, 2005). The network learning context refers to various facets of the outer and inner contexts that drive and affect the network learning process and the network learning content. Network learning content refers to learning outcomes within a network learning episode. Network learning process refers to network practices and interactions through which network-level changes occur (Knight & Pie, 2005). Network learning faces challenges regarding knowledge boundaries between network learning actors that require knowledge boundary spanning mechanisms to facilitate knowledge transfer, translation and transformation (Dyer and Nobeoka, 2000; Carlile, 2004). In this view, network learning with customers, suppliers, and intra-firm engineering units for solution development in GES can be studied in aspects of network learning drivers, outcomes, processes and supporting mechanisms.

GES firms practise network learning with customers due to changing customer demands (Tuli et al., 2007). Under pressures from markets and regulators, customers are constantly changing their demands for innovative and more efficient solutions (ISG, 2016). Customers can demand a better service (Brady & Davies, 2004), a new product (Galbraith, 2014), or new technologies (Johnstone et al., 2009). Network learning with customers, on the one hand, is to create engineering solutions that customers demand. On the other hand, it is to capture solution knowledge co-created with customers for future exploitation (Brady and Davies, 2004; Salonen et al., 2018). Network learning processes with customers therefore include knowledge creation with customers (Brady and Davies, 2004; Jaakkola and Hakanen, 2013) and knowledge reuse for innovation with a group of customers to transform existing solutions into better ones (Majchrzak et
al., 2004; Galbraith, 2014). These processes are supported by boundary spanners and governance mechanisms such as boundary spanning tools, learning coordination, knowledge governance and technological mechanisms to facilitate knowledge sharing, creation and reuse (Breidbach & Maglio, 2016; Zhang et al., 2016).

GES firms collaborate with various sub-tier suppliers and technology partners to create solutions that customers require (Windahl & Lakemond, 2006; Coghlan & Coughlan, 2014). Under the contexts of changing technologies and changing demands, firms need to collaborate with various suppliers to have complementary capabilities facilitating customer-driven innovation (Meijboom et al., 2007). By integrating suppliers into solution networks and adopting network learning with suppliers, GES firms use suppliers’ capabilities and are thus able to fulfil changing customer demands (Windahl & Lakemond, 2006; Jaakkola & Hakanen, 2013). Past research indicated that GES firms practised network learning with sub-tier suppliers to co-create knowledge for operations improvement (Coghlan & Coughlan, 2014) and with technological partners to reuse knowledge for innovation (Majchrzak et al., 2004; Windahl & Lakemond, 2006). Various boundary spanners and governance mechanisms are adopted to facilitate knowledge sharing and network learning (Coghlan & Coughlan, 2014; Salonen et al., 2018).

Intra-firm engineering units are involved in network learning to enhance GES efficiency, flexibility, and innovation (Kotlarsky et al., 2014; Zhang et al., 2016). Moore & Birkinshaw (1998) argue that the competitive advantage of GES firms is determined by their capability to bridge the knowledge gaps between internationally dispersed engineering units. GES network learning with engineering units enables knowledge sharing between engineering units (Hansen, 2002) and helps transfer intangible knowledge across dispersed engineering units (Malhotra & Morris, 2009; Kotlarsky et al., 2014). Research on network learning with intra-firm engineering units shows that GES firms reuse knowledge across different project teams for solution development (Brady and Davies, 2004; Kotlarsky et al., 2014) and create new solutions within autonomous research projects involving various engineering functions and research engineers (Hoegl & Schulze, 2005; Galbraith, 2014). In the adoption of network learning with intra-firm engineering units, GES firms face challenges caused by dispersed intangible engineering knowledge and complexity knowledge boundaries between different engineering units (Dyer and Nobeoka, 2000; Carlile, 2004). They must use different knowledge boundary spanners and governance mechanisms to facilitate knowledge sharing for network learning (Moore and Birkinshaw, 1998; Kotlarsky et al., 2014; Zhang et al., 2016).

2.4. The preliminary framework

The literature review suggests that GES firms adopt network learning with customers, suppliers, and intra-firm engineering units to develop more efficient and innovative solutions in GES (Brady and Davies, 2004; Jaakkola & Hakanen, 2013; Zhang et al., 2016). However, the connection and contribution of these processes to solution development remain unclear in existing studies. They have been developed within an either inter-firm or intra-firm network learning context. These processes are fragmented and inconsistent in the current literature. Figure 1 indicates the current relations between network learning with customers, suppliers, and intra-firm engineering units that contribute to solution development. The figure offers a preliminary framework to investigate an integrated network learning process for solution development in GES. With this integrated process, GES firms adopt network learning with customers to address the changing customer demands, with suppliers to
exploit complementary capabilities, and with intra-firm engineering units to leverage dispersed engineering units’ knowledge. Network learning with customers, suppliers, and intra-firm engineering units all involve knowledge reuse and knowledge creation, supported by a set of knowledge boundary spanners and governance mechanisms.

Figure 1 – The preliminary framework

3. Methodology

The inconsistency of current literature and the complexity of GES firms’ operations suggested the appropriateness of using case studies for theory building of integrated network learning for solution development in GES (Ketokivi & Choi, 2014; Miller & Tsang, 2010). A multiple case study method was adopted to address the diversity of GES firms and their complex network learning practices, which enhances the external validity of our research findings (Eisenhardt, 1989; Miller & Tsang, 2010). The preliminary framework guides case selection, data collection and analysis.

**Case selection** - three GES firms were intentionally selected for the purpose of theoretical replication (Yin, 2018), i.e. Case A, B and C (see Table 1). Case A provides process-oriented IT solutions; Case B offers aerospace engineering solutions; and Case C produces bio-simulation solutions for drug development. They are networked engineering service firms, having relationships with numerous customers and suppliers, and being different in industries, sizes, and solution development strategies. These differences offer opportunities to enhance the emerging constructs of the theoretical framework (Eisenhardt, 1989).

**Data collection** - interviews were the main method used to capture empirical data. They were complemented and triangulated by documentary studies, archival records, direct and participatory observations (Yin, 2018). A semi-structured interview protocol was developed based on the preliminary framework, focusing on the key themes such as network learning drivers and outcomes, knowledge reuse and creation processes, and facilitating mechanisms for knowledge sharing. A total of 31 interviews were conducted across the three case companies in the period from September 2016 to November 2017, with the average duration of around one hour per interview. Informants were intentionally selected (Eisenhardt & Graebner, 2007) to include respondents at different management levels, and with different engineering functions and geographical locations in the UK and South East Asia. They were corporate level managers, business managers,
site managers and engineers who were engaged in network learning for solution development. There were seven informants from Case A, five from Case B and nineteen from Case C. The lead author had an opportunity to stay in the head office of Case C for one week and therefore had opportunities to reach a large number of informants. In the Case A and B, it was challenging to reach new and existing informants in terms of time and space because they were located at different sites in different countries and had tight working schedules. About one-fifth of the informants were interviewed multiple times through various communication channels such as face to face meetings, phone calls, Skype and WebEx sessions. After each interview, the data were transcribed, resulting in a total of 436 pages of text which were then input into Nvivo software for data analysis. In addition, over 20 company documents, 11 company archives, and more than 30 public company reports were used as another data source for triangulation (Yin, 2018).

**Data analysis**- single and cross-case analysis were conducted to explore the linkage between inter-firm and intra-firm network learning and to explain their contributions to solution development. Single case analysis was based on three network learning episodes with customers, suppliers, and intra-firm engineering units to explore their network learning drivers, processes and mechanisms, and outcomes. It allowed for the identification of the connection and contribution of these network learning episodes to each other and to solution development in GES. Interview transcriptions were coded and analysed according to predefined preliminary framework emphasizing network learning drivers, outcomes, and processes. The coding processes were assisted by NVivo – version 11 in organizing and integrating nodes into categories such as network learning drivers, outcomes, processes, and mechanisms. Pattern matching techniques were adopted for single and cross-case analysis (Yin, 2018). Network learning episodes were compared in terms of context, content and process. Such techniques enabled to clarify the connection and contribution of network learning episodes and induce an
emerging theoretical framework of integrated network learning for solution development in GES.

4. Case analysis

Single case studies showed that firms managed network learning with customers, suppliers, and intra-firm engineering units in an integrated process, rather than managing them independently, to develop solutions in GES. Firms used inter-firm network learning to capture new knowledge and information for intra-firm knowledge reuse that enhance solution operation performance and intra-firm knowledge creation and solution innovation. These integrated network learning processes were facilitated by a set of knowledge boundary spanning mechanisms that enhance knowledge sharing and network learning across internal and external boundaries. Table 2 presents key results from single case analysis.

<pre><code>                                                                                     | • Knowledge reuse for innovation between engineering sites and customers to capture customers’ problems for technology innovation. |
                                                                                     | • Knowledge creation across engineering sites for new technology generation. |
                                                                                     | • Knowledge reuse for innovation between engineering sites and technology partners to capture suppliers’ knowledge for technology transformation. |
</code></pre>
Cross case analysis indicates two patterns of integrated network learning: network learning for novel and efficient solutions (Figure 2 & 3). Case B and C developed novel solutions by re-using knowledge for innovation with external customers and suppliers to capture customers’ requirements and complementary supplier knowledge for intra-firm knowledge creation. Inter-firm network learning employed centralised management teams and formal governance mechanisms to facilitate external knowledge sharing, while intra-firm network learning relied on decentralised project teams and informal coordination and governance mechanisms to facilitate knowledge creation.

Figure 2 – Integrated network learning for novel solutions
Case A and B enhanced solution efficiency by co-creating knowledge with suppliers and customers that was reused across intra-firm engineering units. They adopted centralised functional teams and formal governance mechanisms to address knowledge boundaries across customers and engineering units. Decentralised functional teams and informal governance mechanisms were more effective to facilitate local knowledge creation with suppliers.

Knowledge creation with suppliers to capture suppliers’ updated knowledge
- Decentralised functional teams.
- Informal coordination and governance mechanisms (e.g. workshops, clusters)

Knowledge co-creation with customers to develop new knowledge
- Centralised functional teams.
- Global information management systems
- Formal coordination and governance mechanisms (e.g. standards, projects, modularisation, requirements)

Knowledge reuse across intra-firm engineering units for efficient solutions in GES
- Centralised functional teams.
- Global information management systems
- Formal coordination and governance mechanisms (e.g. projects, standards, HRM policies)
- Digital and machine learning technologies

Figure 3 – Integrated network learning for efficient solutions

5. Conclusion

The paper provided a deeper insight into how firms integrate inter-firm and intra-firm network learning for solution development. It showed that firms integrated inter-firm and intra-firm network learning to develop solutions in GES through a set of interrelated knowledge capture and development processes and knowledge boundary spanning mechanisms. The analysis also indicated two patterns of integrated network learning, network learning for novel and efficient solutions.

The case study clarifies the linkage of inter-firm and intra-firm network learning processes for novel and more efficient solutions in GES which remained unclear in the operations management literature (Moore and Birkinshaw, 1998; Kotlarsky et al., 2014; Zhang et al., 2016) and the industrial marketing management literature (Jaakkola and Hakanen, 2013; Breidbach and Maglio, 2016; Salonen et al., 2018). The developed integrating frameworks also offer managerial implications for effective implementation. Managers can adopt various mechanisms to facilitate knowledge sharing, reuse and creation across internal and external boundaries that enhance solution performance. Future research is expected to further develop network learning processes through customers’ and suppliers’ viewpoints, validate them with large scale empirical data, and transfer them to other industrial settings.

Abstract  

The design of business models for sustainability has gained increased attention recently. A common understanding of the principles and requirements for the development sustainability-oriented business model is sought. Literature has endeavoured into a profound analysis of design tools for business models. Results show methodological gaps that could be potentially addressed by further development. Within such context, the aim of this work is to contribute towards exploring how a dynamic approach to sustainability-oriented business modelling may overcome such gaps. The proposed approach uses a systemic design perspective derived from the combination between the original Business Model Canvas and System Dynamics modelling.  

*Keywords:* business models for sustainability, dynamic business modelling, system dynamics.  

Introduction  

The emerging field of business models for sustainability (BMfS) have been steadily gaining attention from scholars and practitioners, with scientific conferences and journals encouraging the development of the debate on their design, use and innovation processes (Foss & Saebi, 2017). Recent studies highlighting the relevance of BMfS explored the state-of-the-art in the field, bringing out principles, criteria, and tools related to BMfS development, as well as design requirements, methodological gaps and shortcomings of the extant modelling approaches (Breuer et al., 2018; Lüdeke-Freund et al., 2019; Dentchev et al., 2018). 

The research process presented in this paper begins with the review of the literature on BMfS design tools. This review is combined with an examination of existing approaches which make use of a systemic design approach to model BMfS. Thus, it offers a wide overview on the state of the art wherefrom to draw insights towards identifying methodological shortcomings and for ultimately comparing findings.
Given the multi-dimensional and complex nature of sustainability (Laasch, 2018), the process of designing business models to represent sustainable value adequate becomes a challenge (Biloslavo, Bagnoli, & Edgar, 2018). Furthermore, the extant modelling and design methods for business models are limited and rarely geared towards sustainable value (Evans et al., 2017).

As business models ultimately establish and define several of the relationships among actors across a value network in constantly changing (dynamic) setup, simulation is required in order to reveal accurate systemic decision-making (Täuscher & Abdelkafi, 2017). Drawing on these findings and with a view to overcoming the main critical issues affecting the development of BMfS, this paper aims at conceptualizing and investigating a systemic approach for designing BMfS wherein sustainable value elements (i.e., environmental, social and economic/financial) may coexist and interact forming causal feedback structures able to frame value generation processes.

Research Design

Within such context, a four-step design approach has been defined, as shown in the schematic representation of Figure 1. The process starts with a review of the literature on business models (BM) design tools (step 1). This particular review is combined with an investigation into existing approaches that makes clear use of a systemic design perspective to derive business models, with a particular emphasis on tools for sustainability-oriented modelling. This step offers a wide overview on the state of the art. From there, methodological shortcomings in the currently available tools are identified (step 2).

Building on this literature review, an approach named Dynamic Business Modelling for Sustainability (DBMfS) is conceptualized as a lean systemic method to model and explore the process of creating sustainable value (step 3). Finally, a critical analysis was performed in order to understand the main potential areas for improvement in the proposed approach, as a way to inform next steps in this research stream (step 4).

Results and Discussion

As emerged from the literature review, current design tools and approaches for developing BMfS seem to generally display three main severe limitations, namely (i) the main outputs (i.e., innovation ideas) originated from business modelling activities are not followed up; (ii) there is a persistent lack of implementation of BMfS and (iii) business models implemented by companies typically fail when exposed to the market (Geissdoerfer et al., 2018). This is mainly caused by the complex and dynamic nature of BMfS and its implementation (Abdelkafi & Täuscher, 2016; Demil & Lecocq, 2010; Evans et al., 2017). Namely, such a dynamic complexity characterizes BMfS as living structures, with a wealth of interactions and complementarities that can be framed through feedback loops (Abdelkafi & Täuscher, 2016; Hjorth & Bagheri, 2006; Sterman, 2000), thus capturing sustainability from a systemic perspective (Abdelkafi & Täuscher, 2016; Boons et al., 2013; Lozano, 2018).

There seems to be an underlying requirement that underpins the logic of these design tools and approaches for BMfS: innovation must be focused on producing social and/or
environmental benefits. This focus prescribes a shift of value proposition to explicitly address and encompass the society and the environment (Bocken et al., 2014; Stubbs & Cocklin, 2008). Furthermore, Breuer et al. (2018) emphasize the need to expand traditional organizational boundaries in alignment with a systemic perspective. The underlying rationale of this expansion is to integrate a multitude of stakeholders and make better use of resources, both internal and external, such as knowledge and information.

By considering a wider perspective of sustainable value creation, with multiple stakeholders, companies not only considerably reduce risks, but also mitigate the effects of potential tensions across the stakeholder network. Collaborative modelling techniques are proved to be effective for engaging multiple stakeholders into one shared and common perspective (Rouwette, 2011). As a complement to this idea of active stakeholder engagement and management, scholars and practitioners consider the BMfS to be an extremely useful tool for examining the sustainability and viability of a business, supported by a selected set of key performance measures. More rigorous empirical approaches for collecting data and measuring performance should then reflect the potential differences between planned and actual business models, and potential unrealized activities (Dentchev et al., 2018).

The approach proposed in this paper builds upon the combination of the (i) modified Sustainable Business Model Canvas (Osterwalder & Pigneur, 2010) proposed by Bocken et al. (2018) and the (ii) System Dynamics (SD) modelling approach (Cosenz, 2017; Cosenz & Noto, 2018). Figure 2 displays a generic schematic representation of the proposed design approach. The methodological support provided by SD has proven to be effective in modelling and analyzing business systems characterized by dynamic complexity and unpredictability, as well as in experimenting with the models to design and test strategies for performance management, sustainable development, and change (Morecroft, 2007, 2013; Torres et al., 2017; Sterman, 2000; Bianchi, 2016; Videira et al., 2010).

![Figure 2 – Schematic representation of the Dynamic Business Modelling for Sustainability (DBMfS)](image-url)
The proposed DBMfS expands the model’s dimension of *key partners* by contemplating other relevant stakeholders (Bocken et al., 2015; Bocken et al., 2018). Additionally, the perspectives of customer relations, distribution channels and key activities are then unified in the *key processes* dimension. Furthermore, the core concept of value proposition is divided into sub-categories which individually addresses (i) *value drivers*, i.e. those critical factors influencing key processes and therefore providing mechanisms for achieving competitive edges, (ii) *outputs*, i.e. short-term results achieved by the company and, finally, (iii) *outcomes*, i.e. long-term results that displays broader impact within and beyond the reach of where the company actually operates. These outcomes are further sub-categorized into (a) *social value*, (b) *economic value* and (c) *environmental value* in order to frame the sustainable value dimensions better. Each sub-category in the value proposition embraces a set of indicators to measure the firm’s performance according to the multidimensional perspective of sustainable value (Evans et al., 2017; Dentchev et al., 2018; Bocken, 2015; Bocken et al., 2018).

With a view to addressing design limitations and conform with the requirements for business model development (Bocken et al., 2014; Breuer et al., 2018; Dentchev et al., 2018), the methodological structure provided by System Dynamics modelling approach allows for the charting and quantification of the causal links among elements of the business model, in close alignment with a systemic and endogenous perspective. The attributes proving the effectiveness of this simulation method for the design of BMfS are also associated with the rationale geared towards understanding how results emerge from different inputs in a complex setting that is particularly full of causal loops (Davis et al., 2007; Torres et al., 2017). These elements are compliant with the pragmatic approach required by the research on design of BMfS (Bocken et al., 2014; Breuer et al., 2018; Dentchev et al., 2018). With this, the proposed DBMfS, based on a SD approach, may offer profounder understanding of how specific conditions may affect business performance.

**Conclusion**

This approach contributes to sustainable business model research by conceptualizing a systemic and holistic design tool which frames environmental, social and economic drivers of value generation into a unique business model causal feedback structure.

For researchers, the study offers new streams of research for simulation-based and dynamic business modelling tools to be enhanced and developed. For practitioners, the conceptualization of the DBMfS approach adds value to how a company's business model can be properly understood, adapted and changed over time in order to create sustainable value, with its three distinguished components. The study also shows how decision-makers can make use of the DBMfS to develop scenarios and "what-if" analysis.

For policy-makers, the proposed DBMfS might potentially aid the development of targeted sustainability-related policies based on the substance of value created by specific initiatives. Different industrial sectors or types of organizations might respond differently to sustainability inputs in terms of performance, thus supporting the development of context-specific policies for the development of BMfS.

Several topics for future research can be explored. In order to fully explore the potential put forth by the proposed approach, next research efforts could focus on (i) developing a quantitative approach based on the concept of the DBMfS in order to simulate the different scenarios for the business models; (ii) designing an empirical data collection protocol to test the efficacy of the DBMfS, and (iii) defining and structuring...
the types of data that are required in order to fully develop the quantitative frame of the DBMfS.

Abstract

In the fast changing global business, New Product Development (NPD) has emerged as an integral part of business strategy. For a firm to maintain its position in market and to gain a sustainable competitive advantage new product is an important driver to innovate. Implementation of NPD is a challenging task and is affected by numerous factors therefore choosing a right combination of variables or factors or enablers may result in a design of a unique theme for making a successful new product and also provide an opportunity to cater the needs of environmental sustainability.

Keywords: Determinants/Factors, Interpretive Structural Modeling, and New Product Development

Introduction

New product development basically includes all activities connected with transforming the substantial ideas into a tangible product for market affirmation. The objective of product development process is to convert the market opportunity and a set of assumptions regarding product technology into a product available for sale (Krishnan and Ulrich, 2001). In business success, New Product Development is considered as one of the most crucial areas for the competence of the firm (Guo, 2008). According to the best practices surveys conducted by Product Development & Management Association (PDMA) it is deduced that even organizations had carried out a number of new methods and techniques to improve the process of new product development, the success rates of new product remains to be steady at around 60%. The probability of increasing the success rate of new products is invariably a key motivation in carrying out research in new product development by developing the new practices.

The aim of this paper is to develop the relationships among the combined identified factors of NPD and circular economy by using interpretive structural modeling (ISM) and classify these factors depending upon their driving and dependence power. ISM is a well established methodology for identifying relationships among specific items which
define a problem or an issue (Thakkar, 2008). The opinions from group of experts are used in developing the relationship matrix, which was later used in the development of the ISM model. The factors are derived theoretically from various literature sources, and experts’ discussion. Some factors are extracted from the work of those who have explored product development (PD) in general or have addressed a particular factor in detail.

**Literature Review**

Factors, which aid organizations to implement PD, have been identified from various authors who have researched and written directly on this issue. Studies have highlighted few critical factors influencing NPD of firms viz., product meets customer needs; company resources, launch proficiency, senior management support, cross functional integration, organizational culture and many more as discussed in the literature review. From the results of the Cooper’s and Kleinschmidt’s initial work at the project level up to the end of the 1970s, concerning the NPD process the two observations can be made from the two aspects that have been had a notable positive impact on the success of new products. These are 1) the efficiency of activities performed at each stage of product development particularly in development, market observations, and launch in the market and 2) employing market information during the entire NPD process which is later confirmed by Cooper (1979a, 1980a) and Atuahene-Gima (1995). A strong market orientation, undertaking the marketing tasks in a quality fashion, doing the predevelopment activities well, and having sharp, early product definition before product development begins have all been found to be correlated with success. Aligned with this type of approach, another study to explore the practices has identified two major factors namely customers’ needs, wants, and specifications for the product, customers’ price sensitivity to implement product development (Mishra et al., 1996). In addition to market information and customer orientation it is observed that firm management plays a crucial role for subjective and long term performance measurement as governed by senior management support. It is essential when resistance to change is encountered (McAdam and Leonard 2004). Second, the momentum behind new product ideas is stronger if senior management is directly involved during the front end activities of NPD (Murphy and kumar, 1997; Lauto et al., 2013)

For a firm to achieve pioneering advantage (or first-mover advantage) which is defined as the capability of a firm to obtain an advantage over its competitors by the early introduction of a new product category they have to keep pace with the ever changing market (Suarez and Lanzolla, 2005). The necessary resources people, money, facilities to achieve the stated new product objectives; R&D budgets were adequate; and the needed people-with free time were in place. Reengineering and reorganizing new product processes and structures is an unending endeavor, as management seeks to improve new product success rates, yet reduce development cycle time.

A recent study based on 233 empirical studies done by authors Evanschitzky et al. (2012), has proposed thirty three factors, amongst them, cross-functional integration and culture have been identified as top most factors (Evanschitzky et al., 2012). According to this survey, there is no cross-functional transformation available. Merely coordinating, collaborating, or even integrating the two functions does not transfer differentiated assets between them. A creative culture encourages a firm’s employees to use their innovative talent to produce and refine a steady stream of ideas (Murphy and Kumar, 1997; Kim and Wilemon, 2002). A creative culture also reinforces a firm’s
market orientation by promoting consistency, efficiency, and productivity in the front end (Langerak et al., 2004).

The above factors are then compared with the factors of circular economy and their combined effect is taken in our study. The study by Sousa-Zomer et al. (2018) highlighted that for successful implementation of circular business model collaboration, involvement of different organization functions and integration between the outside factors and the business model are important. Another study by Kirchherr et al. (2018) regarding barriers of circular economy from the European Union explained the main factors as non awareness of customer, status of uncertainty of the companies, stringent laws and regulation, lack of proven technologies to adopt new processes. The behavioral study model by Singh et al. (2018) explored circular economy readiness in manufacturing MSMEs in India found environmental commitment, green economic incentives and social pressure as important components affecting other factors as well. Limitations and challenges for achieving circular economy is discussed by Ghisellini et al. (2016) in his study of the last two decades of literature review of circular economy at the micro, meso and macro level.

Based on the literature review, the authors have identified nine factors to PD initiatives in the organization based on circular economic perspective. These factors have been considered for the analysis in the paper.

**Research Methodology**

ISM is a well-established methodology for identifying relationships among specific items, which define a problem or an issue (Sage, 1977). ISM methodology is an interactive learning process whereby a set of different directly and indirectly related elements are structured into a comprehensive systematic model. The model so developed by ISM portrays the structure of a complex issue, a system of a field of study,
in a carefully designed pattern employing graphics as well as words. ISM methodology helps to impose order and direction on the complexity of relationships among elements of a system.

**Steps of ISM Methodology**

**Structural self-interaction matrix (SSIM)**

Group of experts, from industries and the academics were consulted in identifying the nature of contextual relationships among the factors. For analyzing the factors in developing SSIM, the following four symbols have been used to denote the direction of relationship between factors (i and j):

- V - factor i will help to achieve factor j;
- A - factor j will help to achieve factor i;
- X - factors i and j will help to achieve each other; and
- O - factors i and j are unrelated

Reachability matrix
The SSIM has been converted into a binary matrix, called the initial reachability matrix by substituting V, A, X and O by 1 and 0 as per the case. The substitution of 1s and 0s are as per the following rules:

- if the (i, j) entry in the SSIM is V, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry becomes 0;
- if the (i, j) entry in the SSIM is A, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry becomes 1;
- if the (i, j) entry in the SSIM is X, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry also becomes 1; and
- if the (i, j) entry in the SSIM is 0, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0.

Level partitions
From the final reachability matrix, the reachability and antecedent set for each factor is found. The reachability set consists of the element itself and the other elements which it may help achieve, whereas the antecedent set consists of the element itself and the other elements which may help in achieving it. Thereafter, the intersection of these sets is derived for all the factors. The factors for which the reachability and the intersection sets are the same occupy the top level in the ISM hierarchy. The top-level element in the hierarchy would not help achieve any other element above its own level. Once the top-level element is identified it is separated out from the other elements. Then, the same process is repeated to find out the elements in the next level. This process is continued until the level of each element is found. These levels help in building the diagraph and the final model.

Figure 3 - ISM based model

Fuzzy MICMAC Analysis
Only binary relation is considered in the conventional MICMAC analysis. To increase the sensitivity of MICMAC analysis here we are using fuzzy set theory. There is an introduction of an additional input for the possibility of interaction among the elements
in FUZZY MICMAC. By this the strength of relationships can be improved instead of just establishing a relationship among the elements through previous method.

**Binary direct relationship matrix (BDRM)**

It is constructed by examining the direct relationship among the factors. The diagonal entries of the table 3 are converted to zero and hence BDRM is derived.

**Development of linguistic assessment direct reachability matrix (LADRM)**

The gradual assessment of the membership of elements in the set, explained with the help of membership function whose values lie in the real unit interval [0, 1]. A triangular fuzzy number “A” is presented as a triplet (l,m,r). The membership function is defined as

\[
\mu_A(z) = \begin{cases} 
0 & x < l \\
\frac{x-l}{m-l} & l \leq x \leq m \\
\frac{m-x}{r-m} & m \leq x \leq r \\
0 & x > r 
\end{cases}
\]  

(1)

The relationship among the factors is obtained by taking the opinion of the same industry experts and then superimposed on the BDRM to get the linguistic assessment direct reachability matrix LADRM. Since, the matrix operation can’t be performed on fuzzy numbers therefore to obtain the crisp values we have used the equation of best non-fuzzy performance value. By this method we have obtained the fuzzy direct reachability matrix (FDRM).

**Fuzzy MICMAC Stabilized Matrix**

The FDRM is taken as input to obtain the Fuzzy MICMAC Stabilized Matrix. The matrix is multiplied repeatedly until the hierarchies of the driver power and dependence stabilize. Fuzzy matrix multiplication is followed by the equation.

\[
P = Q, R = \max_k [(\min(q_{ik}, r_{kj})) \text{ where } Q = [q_{ik}] \text{ and } B = [r_{kj}]]
\]

Dependence power

|     | 0   | 1.5 | 1.5 | 1.5 | 2   | 2   | 2.9 | 3.1 | 2.9 |

Classification of factors
All factors have been classified, based on their driving power and dependence power, into four categories as autonomous factors, dependent factors, linkage factors, and independent factors.

Figure 2- Cluster of PD factors
It is observed that factor 1 has a driving power of 5.6 and a dependence power of 0 and therefore, it is positioned at a place which corresponds to a driving power of 5.6 and a dependence power of 0 as shown in Fig. 2. The objective behind the classification of factors is to analyze the driving power and dependence power of the factors. In this classification of factors, the first cluster is of autonomous factors that have a weak driving power and weak dependence power. The second cluster consists of dependent factors that have weak driving power and strong dependence power. The dependant
factors are relatively disconnected from the system. In the present case, there are no dependent factors. The third cluster consists of linkage factors that have strong driving and dependence power. Any action on these factors will have an effect on the other factors and also a feedback effect on themselves. In this case, there are no linkage factors. The fourth cluster includes independent factors that have strong driving power and weak dependence power. In this case, factors 1 and 3 are in the category of independent factors. The driving power and dependence power diagram for factors is shown in Figure 2.

**Results and Discussion**

The levels of factors are important in understanding of successful NP implementation. Product meeting customer needs and company resources are the most important factors due to its high driving power and low dependence among all the identified PD factors. These factors are positioned at the lowest level in the hierarchy of the ISM-based model. The factor, organization culture, is at the highest level in the ISM-based model due to its high dependence power and low driving power. Those factors which are at the fourth and third levels in the model with highest driving power are known as ‘strategic factors’. These factors play a key role in product development and also creating an environment for the budding ideas. These factors require greater attention from the top management. The driving power and dependence power diagram gives some valuable insights about the relative importance and interdependencies of the factors. The driving power and dependence diagram (Fig. 2) indicates that there is no dependence factor in the process of successful product development. Dependence factors are weak drivers but high dependence. The absence of dependent and linkage factors in this study indicates that all the identified factors influence the process of successful product development. Therefore, it is suggested that management should pay serious attention to all PD factors.

The proposed approach gives managers a better understanding of the determinants/factors that have most influence on others (driving determinants/factors) and are therefore crucial. These are the ones which forms the basis for the rest of the factors and due to this should be taken into account at first. Those measures which are most influenced by others (dependent determinants/factors) and whose performances are always relative to the driving factors. This kind of information is strategic for managers who can use it to identify which performance measures they should concentrate on and how they can manage the trade-offs between measures. The relationship between new product development and the state of the economy has long been acknowledged. People are purchasing products keeping in mind about the time frame after which the product will become obsolete instead of using it to the last penny. But now the government policies in industrialized countries like Britain have sought to separate economic growth from the environmental contexts. This requires an alteration from a linear model to a circular economic model. In circular economy the focus is on minimizing the throughput of materials and energy by optimizing products longevity, reuse of products, reconditioning the products and their components and recycling.

**Conclusion and Future directions**

The levels of factors are important in the PD implementation process. It can also be observed from Fig. 2 that three factors, namely product meeting customer needs (factor 2), company resources (factor 3), and launch strategy (factor 4) have high driving power and less dependence power. Therefore, these factors can be treated as key PD factors.
On the basis of above discussion, we can conclude that all the nine factors are important in varying degree for the purpose of successful implementation of PD. In this research only nine PD factors have been used to develop the ISM model, but more PD factors can be included to develop the relationship among them using the ISM methodology. Further, in this research, the relationship model among the identified PD factors has not been statistically validated.

Abstract

Although attention to sustainability-oriented innovation (SOI) continues to grow significantly, less is known about the capabilities that firms need to develop in order to advance their approach. In this study, we conducted a qualitative study of firms’ approaches to SOI, the barriers they face, and the specific capabilities required to become a sustainable innovator. Our findings revealed that the majority of firms operated in an operational optimization as the basic context in the SOI approach. The specific capabilities required capture SOI idea, a proactive strategy, a process to commercialize or implement SOI, stakeholder management, governance, and continual learning.

Keywords: sustainability-oriented innovation, capability, qualitative

Introduction

In recent years, sustainability-oriented innovation (SOI) is generating considerable attention among researchers and practitioners in order to develop sustainable competitive advantage (Adams et al., 2016; Varadarajan, 2017; Watson et al., 2018). SOI is concerned with organizational innovation that is not only for profit, but also involves environmental and social sustainability benefits in their innovation (Hansen and Große-Dunker, 2013; Adams et al., 2016). SOI is crucially important in practice in the era of growing discussion over global warming and climate change. For example, a study from Unilever shows that one-third of consumers prefer to buy a brand that they believe has a commitment to sustainability (Unilever, 2017). Sustainability is also being considered as a key driver for innovation (Nidumolu et al. 2009).

Despite the growing attention in this area, the debate tends to focus on the model or typologies of firms' behavior or approaches towards SOI (e.g. Aragón-Correa et al., 2008; Elkington, 2012; Klewitz and Hansen, 2014; Adams et al., 2016). These typologies are useful to map the level of maturity of firms in adopting and developing SOI. However, less is known about the specific capabilities required to attain the greater degree of maturity among these typologies. Francis & Bessant (2005) in the context of innovation management capabilities argued that specific capabilities are required in the course of
firm's growth. Likewise, this applies to the firm's journey to become more sustainable in their innovation. A gap in literature is observed by seminal reviews of Klewitz & Hansen (2014) and Adams et al. (2016) in terms of understanding the capabilities required to develop SOI. In the future research direction, both highlighted that the identification of capabilities required to be a sustainable innovator, will be an important contribution to literature. Similarly, Dangelico, Pujari, & Pontrandolfo (2017) suggested that the study of SOI from a capability perspective is still rare in the existing literature, and empirical research with a sound theoretical underlying is required.

To follow up on this opportunity, our study aims to understand firms’ readiness to develop their SOI capabilities. The specific research questions are: (a) How do firms approach SOI? (b) What are the barriers these firms are facing to becoming a more sustainable innovator? and (c) What specific SOI capabilities are required to be a more sustainable innovator? To address these questions, we conducted an empirical qualitative investigation in context of Indonesian firms in multiple sector scenarios. The important contribution of this study to the SOI literature is the findings on specific capabilities required for developing SOI, which are outlined by previous researchers as important areas of interest (Klewitz and Hansen, 2014; Adams et al., 2016; Dangelico, Pujari and Pontrandolfo, 2017).

**Research context**

This empirical study focuses on manufacturing firms in Indonesia. The manufacturing sector is considered for this study due to their considerable impact on the economic, natural and social environment of a country. More specifically, we emphasise on two manufacturing industries that are of top priority for Indonesia from 2015 to 2035 based on regulation No. 14 of 2015 (Government of Indonesia, 2015) namely (a) food and beverages industry, and (b) textile, leather, footwear, and multifarious industry. Also, some other top priority industries which have high entry barriers such as pharmaceuticals, cosmetics, and medical devices, automotive industry, and electronics and ICT industry are included to the research sample which in this study is referred to as (c) other industries.

Indonesia is an interesting context for SOI research. In the reviews of Klewitz & Hansen (2014), Adams et al. (2016), or Watson et al. (2018) the emerging economies context is under-represented, with none of the studies discussed Indonesia. As one of the fourth largest major economies in the world after China, India, and the US, it represents a large market size. Indonesia, with its rapid economic growth, has not yet shown good performance in innovation and sustainability. This is reflected in its Global Innovation Index ranking, 85th of 126 (Cornell University, INSEAD and WIPO, 2018) and Country Sustainability Index ranking, 48th of 65 (RobecoSAM, 2018). From the policy side, recently Indonesia has shown a great desire to be able to significantly enhance its innovation and sustainability conditions as reflected from its official document of Master Plan Indonesia 2011-2025 (Indonesia Ministry for Economic Affairs, 2011) and The National Medium-Term Development Plan (RPJMN 2015-2019) (Bappenas Indonesia, 2014).

**Methodology**

The nature of this research is exploratory, considering the fact that the research on SOI from a capability perspective is still lacking (Dangelico, Pujari and Pontrandolfo, 2017) and very few empirical data comes from an emerging economies context (Klewitz and Hansen, 2014; Adams et al., 2016; Watson et al., 2018). This nature is best approached using a qualitative approach to address the phenomena effectively. Data for this study was
collected through semi-structured interviews with key participants that are firm owners or managers, given their knowledge of innovation and sustainability in their company.

The instrument for this study uses an interview schedule which has been tested and subtly refined following the pilot study that we did in the first half of 2018. The initial part of the instrument contained questions about general information of the firm. Then they were asked their opinion about the innovation, sustainability, and capabilities that might be required for SOI with questions mainly adapted from literature, including Bansal and Roth, 2000; Tidd and Bessant, 2009; Bos-brouwers, 2010a; Adams et al., 2016.

The sampling strategy used is purposeful sampling (Patton, 1990). In constructing samples, we try to elaborate views from the sample with diverse characteristics in terms of industry and size. This strategy provides advantages in the form of a detailed description of voice from diverse characteristics of the sample. Industrial classification is based on industry grouping according to regulation No. 14 of 2015 (Government of Indonesia, 2015). Firm size refers to the Enterprise Survey (The World Bank, 2015) where a small firm is defined as a firm with 5 to 19 employees, a medium 20 to 99, and large more than 100 employees. Potential participants were identified through several means, including: (a) Business incubation centre of one of the public universities in Indonesia that partners with business sectors, (b) One of the state-owned enterprises in Indonesia that also partners with businesses across Indonesia, (c) Chain or snowballing, (d) Personal contacts, and (e) Advertisement. Samples were spread across six provinces (Banten, Jakarta, West Java, Yogyakarta, East Java, and Lampung) in Indonesia.

In total, thirty-three interviews were conducted, each for average fifty minutes duration, involving 25 different firms. These 25 firms were cross-size and cross-industry. Eight small, eight medium, and nine large firms. Ten firms from industry I (food and beverage), eleven from industry II (textile, leather, footwear and multifarious), and four from industry III (other sectors including pharmacy, cosmetics, and medical devices industry or transportation industry or electronics and ICT industry). The oldest firm was established in 1950 dan youngest was 2015. We conducted site visit to most of the firms (sixteen of twenty-five). Interviewees’ position varies including CEO, VP operations, R&D manager, marketing manager, and HR & legal manager. All interviewees gave their consent for the interview to be recorded. All interviews were conducted in 2018 and early 2019. To improve the rigorousness and reliability of our data, we also talked to people outside the company, and collected archival documentation.

Collected data were subjected to thematic analysis. Thematic analysis is a logical way to search for themes or patterns across datasets, and leads to rich descriptions, explanations, and theorisation (Braun and Clarke, 2006; Saunders, Lewis and Thornhill, 2016). To ensure analytical rigor, we followed and combined approaches from Braun and Clarke (2006) and Gioia, Corley and Hamilton (2012). Braun and Clarke’s approach is useful in helping with the thinking process during data analysis, which is then visually displayed in the form of a thematic map. The Gioia approach is very useful in showing links between data and themes in a systematic and transparent way. In this paper, data analysis followed five key phases: preparation and familiarization, generate initial codes, finding the themes, develop the data structure, and producing the report. The computer-aided qualitative data analysis package NVivo 12 and spreadsheet MS Excel are used to assist the analysis. We use MS Visio to help visualization.

Specific for the SOI approach, to complement the thematic analysis, we follow the technique of Watson et al. (2018) in which scoring was determined to identify firms’ SOI approach by a certain number as a threshold. The difference is that Watson et al. applied this assessment to filter the quality of the paper in their review. In this study, SOI approach is identified from the data based on three criteria as outlined in Adams et al. (2016: 185)
including the innovation's relationship to the firm, innovation outcome, and innovation objective. We set a score of 5 (out of a maximum possible 9) as a threshold where companies with a lower average to average (0 to 5) categorize operating in operational optimization, and companies with a score above average (6 to 9) are categorized as a company that moves beyond operational optimization.

Findings
The SOI approach reflects a firms’ approach to the innovation in their organization. Two approaches identified from participants: (1) operational optimization and (2) beyond operational optimization. We find that most of the firms (19 of 25) are in the context of operational optimization and there are some that move beyond operational optimization. A summary of the results and examples of quotes is shown in table 1.

Firms in operational optimization context basically innovate with the characteristics of incremental improvement, harm reduction, and compliance/efficiency. Incremental improvements in the food and beverage industry are manifested in the form of changes in packaging, modification of recipes, and diversification of similar products. Firm A, for example, made an innovation incrementally in packaging. Firm A succeeded at first by packaging the traditional Indonesian food "rendang." “Rendang” was voted as one of the most delicious food in the world based on a readers’ choice of Cable News Network poll (Nurmufida et al., 2017). Firm I introduced a number of similar new variants using fish caught by local fishermen.

process innovation. It is as carried out by firm E which aims to educate the public about the benefits of mushrooms for health and inject the spirit of entrepreneurship to students around them. Firm E is located near the university. Firm O, which operates in the leather industry, has a different method. This company is one of a few Indonesian leather companies that are able to export their products abroad. The main market is the Netherlands, Australia, Japan, and the Indonesian market, with a production capacity of 42,000 bags and 2,400 pairs of shoes per year. Despite having a global reputation, when we conducted a site visit, we were quite surprised because the location of both the workshop and the showroom were in a simple village. Their presence there is intentional because according to the owner they are anti-mainstream and believe that good products will be sought by people, wherever they are located. Especially now that there are digital maps like Google Maps or Waze. Because of its contribution to bringing local products to the world market, even though the location is in a village, this company has been visited several times by the first and second lady.

**SOI barriers**

Based on the analysis, the barriers to developing SOI are divided into two factors, namely internal and external. Findings related to the barriers are presented using a thematic map. Internal barriers include capital, human resources, and organizational priority. Capital is associated with a large investment need to develop sustainability elements of innovation, for example to purchase assets such as land, buildings, or machinery. This obstacle, for example, was expressed by participants from Firm A, “innovation is always limited by funds” and Firm P, “…don't have special funds that we can set aside.” The human resources barrier was emphasized by quite a lot of interviewees, for example the participant from Firm F, "I think it depends on the man". The organizational barrier is the view that SOI is not an organizational priority, as stated by participants from firm B, “It’s actually not a main priority.”

External barriers include raw materials, technological, governmental, and macroeconomic. Raw materials are related to their availability and price. This is, for example, as expressed by participants from Firm L, “the condition of resource availability at that time”. Technological, similar to raw materials, deals with availability and price. For example, as expressed by participants from Firm B, “it’s expensive and the technology may not yet exist.” Barriers from government as explained by participants from Firm H, “must be supported by the government, because it requires large area”. Macroeconomic is related to consumer purchasing power and economic conditions. This is for example as expressed by participants from Firm C, “is because of decline in purchasing power”.

**SOI capabilities**

The SOI specific capabilities reflect the specific capabilities needed by the firms to become a sustainable innovator. Two key groups of capabilities are observed here: (1) substantive, and (2) dynamic. We see a pattern that substantive capabilities are owned by all firms while dynamic capabilities are owned by firms that approach SOI in a more sophisticated manner. Figure 1 shows the process of developing thematic maps based on data. Figure 2 shows data structure for SOI capabilities.

Substantive capabilities reflect the firms’ fundamental ability to create their products. There are three visible elements of all companies, both those that are in operational optimization and beyond operational optimization context, namely: (1) production, (2) marketing, and (3) environmental and social. Production refers to the company’s technical capabilities in producing products.
All our interviews show that all firms have deep technical capabilities in producing their products. Marketing capabilities, which reflect the firms’ abilities to market and sell their products. This was also found in all participants we interviewed. Because of the importance of this marketing ability, participants from firm H said that “no need to think hard for operating, the thing we should think more about is marketing”. For the capability related to environmental and social, we found that it is included substantive capabilities, not dynamic. This is because all firms in the sample are registered firms, which when registered are required to have the ability to manage waste that has the potential to pollute the environment. As for the social aspect, in the Indonesian context there is also an unwritten rule that the company must employ workers from the immediate surrounding environment. 

SOI dynamic capabilities reflect the company's ability to adapt, integrate, and reconfigure their ability to respond to contemporary sustainability challenges (Teece, 2007; Adams et al., 2016). We explore this capability, especially from firms that are more mature in their SOI level. We found that there are six specific capabilities that need to be possessed, namely generating a SOI idea, creating a proactive strategy, having a process to commercialize/implement SOI, managing stakeholders, governance, and continual learning. We group them into three dimensions: sensing, seizing, and transforming (Teece, 2007).
· We assemble the production machines ourselves... Start from raw materials to production machines that we make it ourselves.
· They (academic) have the knowledge, we have the practical ones, we're practitioners
· It is starting from the production side.

· They have the knowledge, we have the practical ones, we're practitioners
· It is starting from the production side.

· A company with a bad marketing will crash
· The synergy actually strengthens marketing capabilities and market reach.
· Especially through social media such as Instagram, we had membership card, the we had discounts continuously, sometimes we had a sales off.

· The environmental impact analysis must be verified
· Everything tested on environmental analysis test
· We usually give charity when feast day
· There are about 30% the employees are local resident

· We assemble the production machines ourselves...
· Start from raw materials to production machines that we make it ourselves.

· Then, I had an idea to make local rice as a souvenir of this city.
· When I contacted them, they had never made it.
· I introduced myself and introduced the products.
· We took the initiative to work with educational institution.

· We don’t buy licenses, we develop the products ourselves
· I experimented until I found the perfect recipe
· Partnering... there are 250 farmers
· I often interviewed by journalist
· A program in collaboration with the Ministry of Communication

· There are representatives of us... who manage it.
· We even have directors’ decrees about rewards for innovation
· One employee normally carry out training – 16 hours per year

Figure 2 – Data structure of SOI capabilities
Sensing reflects the company’s ability to detect opportunities for SOI. In this study we found that sensing included the generation of SOI ideas and proactive strategies to follow up. We found that the role of owner in scanning and detection is highly dominant for SMEs. Seizing reflects the firms’ ability to address sensed opportunities by generating innovations that contain elements of sustainability. Transforming reflects the company's ability to maintain its SOI. Governance, for example, is practiced through the mechanism of rewards and recognition for internal stakeholders who play a role in giving ideas (as practiced by Firm L) or forming teams and mechanisms so that relationships with suppliers from the surrounding environment can be lasting (as practiced by Firm C). Continual learning in Firm C, Firm E and Firm O still emphasize the role of entrepreneurs, while company L formally facilitates learning by employees, with learning requirements for each employee of at least a certain number of hours each year.

**Discussion**

This study investigates firms’ approaches towards SOI, the barriers to SOI, and the specific capabilities needed to become a sustainable innovator. This study contributes to the SOI literature by empirically investigating the capabilities required for developing SOI, which are outlined by previous researchers as important areas of interest (Klewitz and Hansen, 2014; Adams et al., 2016).

Our findings indicate that most of the companies in our sample (19 of 25) approach SOI using operational optimization as a basic context in Adams et al.’s (2016) model. This result is not surprising considering Indonesia is considered an emerging economy, which typically has high economic growth but still experiences severe sustainability challenges (OECD, 2012). Some practices that appear in operational optimization come in slight changes in product design (Alston et al., 1999), or changes in aspects of waste handling (Dangelico and Pujari, 2010). The nature of this change is incremental and focuses on the intra-organizational. Among the unique things that we found in the Indonesian context is creativity to modify production machines, as part of process innovation, so as to reduce resource use, provide higher efficiency, or produce better quality products.

Firms operating beyond operational optimization have approaches that are more inter-organizational in nature and have a wider impact. Among the practices that we found are product innovation by offering products that are healthier, consumed by the public, or raising local cultures. As a process, we have found SOI practices that have mutual partnerships with suppliers from the surrounding environment. This practice is beyond just local sourcing (Rodgers, 2010) because there are elements of training, effort to maintain quality, and work together for mutual benefit.

The fact that most firms are still limited to complying with regulations might be attributed to various barriers both internally and externally. Internally, these barriers can take the form of financial or capital factors (Skjøndal Bar, 2015) due to limited company funds to finance R&D as well purchase assets and materials for SOI. The other internal barrier that we found was the priorities of the organization, where SOI was not considered a priority because the demand was unclear (Laukkanen and Patala, 2014) while the investment was high. This can be due to a lack of understanding that current sustainability is a driver of innovation that has the strategic potential to increase profitability and competitive advantage (Porter and Kramer, 2006). Externally, creating an eco-friendly product usually requires relatively expensive raw materials that are not necessarily available in the market. To produce such a product, new machines are needed, which in general are also different from the standard product that is produced currently. From the government side, obstacles to developing SOI originated from the government because there were no clear and attractive incentives or facilities (van Hemel and Cramer, 2002).
The government is expected to be able to create incentives and support with attractive facilities and can also prioritize local products compared to imported products so as to make producers more passionate about developing SOI.

Although facing a number of barriers, firms operating at a higher level of SOI have specific capabilities above baseline substantive capabilities (production, marketing, environmental and social) that help them become more sustainable innovators. The first two specific capabilities are SOI idea creating and having a proactive strategy to follow up on the idea. In theory, these dynamic capabilities (Teece and Pisano, 1994; Teece, 2007) are categorized as SOI sensing, which refers to sensitivity and proactivity towards SOI ideas. SOI sensing relies on the role of the owner or entrepreneur or the strength of the firm's R & D. The next specific capability is the process of commercializing or implementing SOI (Tidd and Bessant, 2009; Adams et al., 2016), and stakeholder management (Watson et al., 2018) which when referring to the theory can be categorized as SOI seizing. The process for following up on SOI ideas takes the form of intensive experimentation, sampling, and market testing. We found that larger companies maximize their relationship with research institutions at this stage and have formal procedures in developing new products or processes. The last two capabilities are governance and continual learning (Tidd and Bessant, 2009) which in the theory are categorized as transforming. Governance and continual learning in smaller companies relies on the role of entrepreneurs, while larger companies rely on formal procedures and programs.

**Conclusion**

The firms in Indonesian context have significant room for improvement, considering that they are still limited to complying with regulations. Our study indicates that with various advantages and disadvantages in the context, there are firms that are able to operate beyond the basic context of operational optimization. This means, for companies small, medium and large, they have the same opportunity to develop their capabilities for SOI by focusing on SOI specific capabilities. For policy makers, the desire of the Indonesian government to build an innovative and sustainable economy (Indonesia Ministry for Economic Affairs, 2011; Bappenas Indonesia, 2014) can be realized in policies that support the business community in developing SOI specific capabilities as discussed in this study.

This study certainly has several limitations. First, this study focuses on manufacturing sectors, more specifically, two priority industries in Indonesia (Government of Indonesia, 2015), namely food and beverages industry, and textile, leather, footwear, and multifarious industries, plus other priority industries (pharmacy, cosmetics, and industrial medical devices or transportation industry or electronics and ICT industry) so the results of the study apply only to these industries. Further studies can be conducted in different industries. Second, this study was conducted in the Indonesian context, so the results are limited to that context. However, the results of this study may be applied in other emerging economies, keeping in mind their similar characteristics.

Abstract
This study attempts to answer the question why certain buying firms tend to leverage suppliers’ input better than the others in creating innovations. Using theory of planned behaviour and embeddedness, this paper seeks to shed a light on this by investigating the moderating role of buying firms’ employee’s intent to learn in facilitating efforts in mobilising input from the buying firm’s supply network. The results suggested that the strong moderation of employee’s intent to learn, meaningful work and work-life balance with the two dimensions of embeddedness such as between degree centrality and betweenness centrality on the buying firm’s innovation creation.

Keywords: planned behaviour theory, innovation, supplier network, structural embeddedness, text mining.

Introduction
It is obvious that the supply network is an importance source of innovations for buying firms. There have been a number of studies investigating the link between the buying firm’s reliance on suppliers for innovation creation (Narasimhan and Narayanan, 2013) and there have been a constant stream of research investigating the place of suppliers in buyers’ innovation creation (Wagner 2012; Henke and Zhang, 2010; Wagner and Bode, 2014). However, there is lack of research investigating this from the perspective of a supplier network, which is characterised by interactions and different actors, resources and processes (Bellamy et al., 2014), influence on buying firms innovation performance. A innovation research from the supply network view, however, is still relatively rare. The main reason for this is the difficulty in obtaining a real-life supply network data, therefore, the majority of such studies analysed firm level ego networks (e.g., Kim et al., 2011). In addition, a study by Lawson and Potter (2012) explains how closeness with supplier can uncover protectiveness in knowledge transfer across firms. However, learning intent scale used in the study reflects only the knowledge capture but didn’t say anything about employee’s learning intent. Buying firms extraction of knowledge depends on employees’ intention to invent. There are also studies that support the well-being of
employees and firm’s innovation (Bryson et al., 2009). However, it is still not clear how employees’ intention to learn within a firm helps to derive innovation from supplier.

The literature review revealed three major gaps. Firstly, there is a scarcity of studies integrating planned behaviour theory with embeddedness theory for explaining how a buying firm leverages contributions from external organizations in its supply network towards its own innovation. Secondly, “intent to learn” construct was mostly done through a survey instrument, which many not be sufficient in reflecting “collective intent to learn”. It is obvious that using anonymous platforms, such as a social media review, to measure a construct of this nature would alleviate this issue, however, not widely used in academic literature. It is well established that higher levels of engagement will lead to higher profitability. Thirdly, there is a contradictory argument that innovative culture will lead to lack of attention in work-life balance and causes time-based stress, depletion of resources, including psychological and physical energy (Sok et al., 2014).

Given the above background, we seek to answer the question why a certain buying firms tend to leverage suppliers’ input better than the others in creating innovations by considering the firm’s employees’ collective intent to learn as a moderator.

**Literature Review**

This paper uses multiple theoretical lens (i) social network theory and (ii) planned behaviour theory the answer the above research question.

*Embeddedness of a Buying Firm in its Supply Network and its Innovation Creation*

The social network theory is based on the idea of embeddedness (Kim et al., 2011). Embeddedness refers to non-economic factors, motivating various economic exchanges (Moran, 2005; Barden and Mitchell, 2007; Cowan et al., 2007; Kim, 2014). One notable example of embeddedness is “a social tie” (Koufteros et al., 2007; Dong et al., 2015), since economic activities are often embedded in them (Uzzi and Lancaster, 2003). The link between a firms’ performance and its embeddedness has been scrutinised by the scholars to find out how the embeddedness would explain how different levels of embeddedness are related to the variations in the firm’s performance (Adler and Kwon, 2002; Kim, 2014).

Firm’s embeddedness has been investigated from two distinctive perspectives, which are (i) configurations of social ties and (ii) quality of social ties, (Gulati, 1998; Uzzi and Lancaster, 2003; Moran; 2005; Autry and Griffis, 2008; Dong et al., 2015; Kim and Henderson, 2015). As such, even though there are some variations of conceptualisation of the embeddedness (Tsai and Ghoshal, 1998; Min et al., 2008; Kim, 2014), two salient forms of embeddedness are (1) relational and (2) structural (Granovetter, 1985, 1992; Uzzi, 1996, 1997; Gulati, 1998; Rowley et al., 2000). Relational embeddedness refers to the strength of dyadic ties (Granovetter, 1992; Moran, 2005; Kim, 2014) that is an extent to which a firm develops close and personal relationships with other members in its network (Barden and Mitchell; 2007; Autry and Griffis, 2008; Landoli et al., 2012; Dong et al., 2015). On the other hand, structural embeddedness, which is the main focus of the investigation of this paper, refers to configuration of linkages/relationships among actors (Nahapiet and Ghoshal, 1998; Gulati and Gargiulo, 1999; Moran, 2005; Barden and Mitchell, 2007; Dong et al., 2015).

Accumulation of knowledge assets for a firm’s innovation creation has two main sources, those are (1) internal knowledge generation and (2) knowledge with an external origin (Cooper and
Edgett, 2007; Bellamy et al., 2014). For a buying firm, its supply network is an important external source for its knowledge assets (Autry and Griffis, 2008; Bellamy et al., 2014) such as knowledge and resources held by its supplier. Such resources can provide a firm with external information necessary for idea generations as well as improving its process (Tsai, 2001) as well as an opportunity to combine their knowledge for innovation creation (Ahuja, 2000). Therefore, a buying firm’s structural embeddedness in its supply network indicates its ability to access the knowledge and information held by its imminent suppliers and beyond (Uzzi, 1996; Tsai, 2001; Cowan et al., 2007; Greve, 2009; Bellamy et al., 2014). The implications of different aspects of a buying firm’s structural embeddedness on its innovation creation has been investigated mainly from the perspective of the buying firm’s centrality in its network. The centrality of a buying firm reflects its relative importance in its supply network (Kim, 2011; Dong et al., 2015).

A company occupies in a central location, it will get access to information and knowledge more easily helping them to create knowledge assets for its innovation creation (Tsai 2001; Bell, 2005; Greve, 2009; Autry and Griffis, 2008; Bellamy et al., 2014). Moreover, the level of centrality of a buying firm would signal its reputation to its suppliers (Borgatti and Foster 2003), alleviating their fear of failing to protect their knowledge as a result of a buyer opportunism (Mayer, 2006) and would result in more information sharing activities.

**Buying Firms’ Employees’ Intent to Learn**
A theoretical aspect to exploit employee’s learning intent in leveraging supplier input for its own innovation creation is the Planned Behaviour Theory, which is used to understand individual behaviour and it is a function of attitude, subjective norms and control (Ryan, 2010). Using the above analogy, in our case, employees’ intent to learn depends of three dimensions such as meaningful work, subjective wellbeing and work life balance.

Meaningful work capture individual’s attitude towards work using four dimensions such as developing the inner self, unity with others, expressing full potential and service to others (Lips-Wiersma et al., 2012). A study by Pradhan and Jena (2019) unfolded the lack of studies that explored the role of meaningful work on the relationship between transformational leadership and innovative work behaviour. Since meaningful work construct is relatively a new term and its usage is limited in the literature. However, subjective wellbeing is a psychological factor that is defined as individual’s cognitive and affective evaluation of the experience in terms of pleasant emotions, negative mood and life satisfaction (Wang et al., 2017). An individual’s subjective wellbeing depends on complex array of contextual factors including individual determinants, socio-demographic, economic, situational and institutional factors (Binder, 2013). Self-esteem or other personality traits are examples of individual determinants, likewise gender, age, education or marital status are examples of socio demographies. Similarly, income or unemployment corresponds to economic status, health and social relationship corresponds to situational factors (Binder, 2013). In addition, it is rare to find the integration of planned behavior theories within and external organization’s contribution to innovation. A study by Binder (2013) states the individual’s preferences are dynamic and the measurement of affective experience is very difficult in practice to capture that reflect the preference changes of individuals over time. To overcome this global corporations are relying on anonymous platforms to measure the satisfaction of employees and fixing them on a swift basis to improve engagement. The companies are keen to do this because it is well know that higher levels of engagement will lead to higher profitability and improved employee’s commitment (Bonnici, 2018).
Employees are juggling with multiple commitments at work and home where the successful people are good at balancing the two. Conceptually, offering work life balance through flexible working hours will enable employees to perform better and stay in a single company for a longer duration. However, in practices employers are not ready to do so until they see a bottom line economic advantage (James, 2014). However, there are a few evidences that illustrates flexible working hours benefits all staff irrespective of caring staff. Besides this generalist view of benefits, there are several dis-benefits such as increased workloads, understaffing, heightened fear of job loss, dramatic change in labour and demands. In addition, from the organisation’s perspective continuous innovation to meet consumer demand and pressure to increase work-life balance of employees to retain them and satisfy customers are the tricky challenges posing those (Malhotra et al., 2016).

**Conceptual Model and Hypotheses**

In this paper, we seek to investigate the impact of a buying firm’s structural embeddedness in its supply network in its innovation creation and how an endogenous organisational factor “employee’s intent to learn” of the employee of a buying firm would moderate this relationship.

First, we investigate the link three centrality dimensions of a buying firm’s structural embeddedness and its innovation output measured in the number of patents it holds.

The first dimension, degree centrality refers to the number of direct links an organisation maintains with others in its network (Provan et al., 2007). Degree centrality can be interpreted as the amount of knowledge, resource and information coming into the buying firm (Provan et al., 2007; Borgatti and Li, 2009). The following is, therefore, hypothesised:

\[ H_1: \text{Buying firm’s degree centrality in its supply network is positively related to the number of patents it has} \]

The second dimension, betweenness centrality refers to how often the node lies on the shortest path between all combinations of pairs of other nodes (Borgatti and Li, 2009; Kim, et al., 2011). An organisation with high level of betweenness can act as a gatekeeper to other members in its network (Borgatti and Everett, 2006, Provan et al., 2007; Borgatti and Li, 2009; Kim, et al., 2011). In supply network, this means a firm with high-level of betweenness centrality would act as a hub for material (Kim, et al., 2011) and information flows (Bellamy et al., 2014) enables it performance benefits such as access to novel information. The following is, therefore, hypothesised:

\[ H_2: \text{Buying firm’s betweenness centrality in its supply network is positively related to the number of patents it has. The following is, therefore, hypothesised:} \]

The third dimension, closeness centrality refers to how close an organisation is to all other members in its network including those without direct connections (Provan et al., 2007; Kim, et al., 2011). A buying firm can acquire knowledge indirectly through spill-over from its tier 1 suppliers, with its origin back to its interactions with the supplier’s own tier 1 suppliers (Gulati and Garguilo, 1990). Considering this, a buying firm with higher closeness centrality can access information, knowledge and resources from indirect suppliers beyond tier 1 more easily, therefore, it is related to the network effectiveness of knowledge access (Bellamy et al., 2014).
H3: Buying firm’s closeness centrality in its supply network is positively related to the number of patents it has. The following is, therefore, hypothesised:

As per planned behaviour theory, the influence of three dimensions of employees’ intent to learn from suppliers is discussed in the following section. Typically, our intention is to explore to what extent the three dimensions enables employees to better exploit supplier inputs for its own innovation creation. A study by Pantea (2018), it is obvious that the relationship between supplier input and the buying firm’s innovation creation would be stronger if employees’ collectively perceive their works more meaningful. This is because, Meaningful work refers to a place with autonomy, less-tension, spirituality and reduced level of absenteeism.

H1a: As perception of meaningful work among employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H2a: As perception of meaningful work among employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger
H3a: As perception of meaningful work among employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger

Studies explored the rationale for the positive relationship between subjective wellbeing and better work performance, knowledge sharing and achievements (Russell, 2008; Wang et al., 2017). Previous studies have found that satisfaction degree and positive emotions helps individual to remember and boost creative problem solving (Koveshnikov et al., 2014; Hashim and Tan, 2015). Other than performance, positive emotions, such as feeling of joy and pleasure, one among the subjective wellbeing factors will enhance individuals to share tacit and explicit knowledge (Henttonen et al., 2016). The following is, therefore, hypothesised:

H1b: As perceived well-being of employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H2b: As perceived well-being of employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger
H3b: As perceived well-being of employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger

Very few studies attempted to understand the relationship between work life balance and organization culture represented as innovative and supportive culture (Sok et al., 2014). There is a contradictory arguments that innovative culture values behaviours teamwork including solution-oriented, communicative and quick in terms of decision making. The overall understanding is innovative culture will lead to lack of attention in work-life balance and causes time-based stress, depletion of resources, including psychological and physical energy (Sok et al., 2014). However, this is not applicable to all contexts and needs to be investigated further. Based on the above arguments we propose the following sub hypothesis to test the moderation of three dimensions of employees learning intent. The following is, therefore, hypothesised:

H1c: As perceived work life balance of employees of a buying firm increases, the association between its degree centrality and the number of patents becomes stronger
H2c: As perceived work life balance of employees of a buying firm increases, the association between its closeness centrality and the number of patents becomes stronger

H3c: As perceived work life balance of employees of a buying firm increases, the association between its betweenness centrality and the number of patents becomes stronger

Methodology
This paper investigates if of a buying firm’s employees’ intent to learn would moderate the relationship between the structural embeddedness of a buying firm in its supply network and its innovation output. For this, we used the data of 182 companies from the S&P 500 list by discarding non-manufacturing sectors such as financials and real estate as well as those companies with excessive amount of missing data.

Data
The data set for this study was built using following databases. For the embeddedness of a buying firm, the list of its suppliers was collected from Bloomberg SPLC database and Factset. As for a firm’s innovation performance, the number of patents held by a buying firm was collected using Orbis database. For the intent to learn, employee reviews of their current and previous companies for 182 S&P 500 companies posted in Glassdoor between 2015 and 2017 were collected (475,910 sets of a positive and a negative review). Glassdoor is a social media website, where current and past employees can rate various aspects of their companies such as leadership, work environments and pays (Associate Press, 2013). Glassdoor is the oldest (founded in 2004) and the largest online resources in terms of the number of firms covered and the reviews (Ji et al., 2017).

Measures
In this study, we use social network analysis (SNA) to measure different dimensions of structural embeddedness of a buying firm. Considering a matrix $A_{ij}$, with a set of nodes and a set of edges, degree centrality is defined as the number of edges tied to a node. It is usually interpreted as the size of a node’s direct network. Closeness centrality, in contrast, considers the node’s wider network by measuring the distance of a node to all others in within the network. Moreover, betweenness centrality captures the importance of a node for the network by measuring the number of shortest path that rely on that node (for a more detailed overview on network measures, please be referred to Borgatti et al., 2018).

Table 1: Description of network measures.

Intents to learn
In order to measure employees’ intent to learn of a buying firm, content analysis was used to code the textual reviews from the social media site, Glassdoor. Content analysis is "a research technique for making replicable and valid inferences from texts (or other meaningful matter) to the contexts of their use," (Krippendorff, 2013; p.24). As mentioned earlier, a user can leave
two separate textual review about a company, one for the positive and another one for the negative and these unistructural parts of the reviews were coded using content analysis. Due to the sheer volume of the textual data (475,910 sets of a positive and a negative review and around 17 million words), a computer-aided content analysis (CATA) was selected over manual coding. For this, WordStat 8 from Provalis Research was used. Due to the lack of a pre-made dictionary, a set of new dictionaries for the positive and negative were created from scratch using the dictionary building method suggested by Sodhi and Son (2010). Using these dictionaries, the percentages of positive and negative reviews containing specific words or phrases from the total reviews of a specific company were calculated and then, standardised. The difference between the positive and the negative was used to measure each dimension of employees’ intent to learn. The assumption is that the greater the difference is the more positive employees’ intent to learn.

Innovation Output

In order to measure the innovation performance of a buying firm, the number of patents the firm was used. Use of the number of patents to measure a firm’s innovation output has been wildly used by the previous studies (for an example, see: Tsu, 2009; Bellamy et al., 2014; Isaksson et al., 2016).

Analysis and Results

We conducted hierarchical regression analyses using SPSS version 25 to test our hypotheses. Our main models examined if the level of 3 centrality dimensions of a buying firm is related to its innovation output (the number of patents). The results of the analyses provided support for H1 (degree centrality => patents, $\beta = 0.31$, $p < 0.01$) and H2 (betweenness centrality => patents, $\beta = 0.27$, $p < 0.01$). H3, where the relationship between closeness and the innovation output was postulated, was not supported. In the interaction models, the results supported that wellbeing and work life balance positively moderate the relationship between two centrality dimensions (degree centrality and betweenness) and the buying firm’s innovation, the number of patents.

Conclusion and Discussion

To the best of the authors’ knowledge, this paper is one of the first to combine social network theory and planned behaviour theory to uncover the role of an organisational factor, employee’s intent to learn, in leveraging input from its supply network for its own innovation creation.

Our results for the first set of hypotheses are in line with the findings of Bellamy et al., (2014) that the structural embeddedness a buying firm is related to its innovation creation since it determines (1) the amount of knowledge held by its direct suppliers and (2) how easily it can access it. Also, our results suggested that if a buying firm has high level of betweenness, this means the firm acts as hub (Borgatti and Everett, 2006, Provan et al., 2007; Borgatti and Li, 2009; Kim, et al., 2011) and would enable them to acquire novel information by playing a gate keeper role. On the other hand, H3 for close centrality was not supported suggesting that the value of the indirect ties in a supply network for innovation creation may not be that significant as previously thought. Or findings on the second set of hypotheses on the moderating roles of employee’s intent to learn suggested that their subjective wellbeing as well as work life balance do matter in fully utilising suppliers’ contribution in its own innovation creation. However, our findings suggested that ‘meaningful work’ does not increase the efficacy of supplier inputs and uncovering the reasons behind this require further research.

Abstract

This study aims to recognize the idiosyncrasies of not-for-profit performing arts organizations (PAOs) and how they can provide products/services to improve and benefit a community and the broad public interests. We consider innovation as a strategic weapon in addressing PAOs’ increasing need for improvement in their operating structures and performance outcomes.

Drawing on the theory of dynamic capabilities and based on a literature review, four major internal capabilities have been identified that can theoretically increase PAOs’ level of product and service innovation, as well as their performance factors: Environmental Intelligence, Internal Integration, Core Operational Capabilities, External Partnerships and Collaborations.

Keywords: Not-for-profits, Innovation, Performance

Introduction

The not-for-profit (NFP) organizations have received little attention despite the fact that they are quite different in terms of their resources, motivations, governance structures, and operating practices, as compared to for-profits (Rodríguez et al., 2016). To address this gap, this study aims to expand our field’s discourse to recognize the idiosyncrasies of NFP PAOs and how they can survive and achieve their goal, i.e., providing products and services to improve and benefit a community and the broad public interests.

NFP PAOs are tax-exempt organizations with special institutionalized governance, financial and operational structures, which are undergoing a gradual process of change and restructuration (Glynn and Lounsbury, 2005), due to public resource scarcities, self-dependency and transparency urges, and diversity of stakeholders’ expectations. Innovation is known to be one of the best strategic weapons for PAOs to cope with such changes in their institutional environment and to improve their effectiveness and performance (Tepavac, 2010).

Arts management literature has broadly considered innovation in NFP PAOs from a purely “artistic” perspective (DiMaggio and Stenberg, 1985; Voss, Montoya-Weiss and Voss, 2006) and only few studies have taken other aspects of innovation into account (Camarero and Garrido, 2008b; Castro-Martinez, Recasens and Jiménez-Sáez, 2013).
This study contributes to the literature by taking a holistic operational perspective and defining PAO innovation as any incremental movement towards change along two dimensions: product and service.

In addition, drawing on the theory of dynamic capabilities (Eisenhardt and Martin, 2000; Wu, Melnyk and Flynn, 2010; Hitt, Xu and Carnes, 2016) and based on a systematic review of the literatures on NFP organizations and arts management, we identify a set of PAOs’ internal capabilities as the major drivers of product and service innovations and examine how the innovation enhancements affect PAOs’ financial, social, and artistic performance.

Performing Arts Organizations
With the recent decrease in PAOs’ governmental funding and graying of their audiences which are also shrinking in number, they have been experiencing a state of great turmoil and change over the past three decades (DiMaggio and Mukhtar, 2004).

Besides, PAOs are facing new struggles to compete with entertainment sector. At the same time, they need to absorb and retain new audiences by means of diversifying their target segments, reaching out to the public, and deepening their relationship with serious art audiences (Bakhshi and Throsby, 2009). Given these conditions, we could say that PAOs are currently operating within a moderately volatile environment in which their existing competencies are deemed as ineffective (Glynn and Lounsbury, 2005) and therefore, they are under an increasing pressure to develop new capabilities for survival (Scheff and Kotler, 1996a; Hume et al., 2006; Tepavac, 2010).

In doing so, and in order to become economically sustainable, PAOs attempt to pursue strategies that are already adapted and proved to be successful in the for-profit sectors; most importantly amongst those are effectiveness and efficiency (Weinstein and Bukovinsky, 2009). They also attempt to become more accountable to their funders and supporters by concentrating on issues like public value creation, social inclusion, and diversity. These, in turn, have heated the debate over two conflicting logics in PAOs: the art logic symbolizing the perspective of artists in commitment to producing “the works of art, for the sake of art itself” and the managerial/market logic promoted by funding bodies and supporting associations’ tendency toward formalization, accountability, and effectiveness (Glynn and Lounsbury, 2005).

Innovation in PAOs
Similar to other creative businesses, innovation is a crucial and essential part of PAOs’ existence from administrative and governance processes to their operations, products, and services. A concise view to innovation in cultural organizations, as part of the NFP sector, often considers it as incremental and continuous improvements either in terms of enhancing the audience experience, service delivery, and interaction methods through adoption of new technologies from for-profit sectors, or as managerial changes aimed at enlarging the customer base (Camarero and Garrido, 2008b). Empirical studies in arts management and public policy, on the other hand, have often been focused on artistic innovation in PAOs, that is the degree of novelty in the content or artform of the artistic products (Castañer and Campos, 2002).

To provide a broader and encompassing conceptualization, we integrate the arts management and operations management perspectives and define PAO innovation, in terms of what these organizations have to offer, as “any incremental or radical change, compared to the PAO’s past situation, detected throughout the entire value chain of design, production, and supporting of its products and services”. Given these specifics,
PAO innovation can be classified into two categories: Product and Service Innovation. It should be noted, however, that these categories are not necessarily mutually exclusive.

**Product Innovation**
Product innovation refers to the incremental or radical changes in either or both the content and artform aspects of PAOs’ cultural products. Innovation in content refers to the degree of originality, novelty, or rarity of the presented artworks. Taking orchestra field as an example, programming more recent or less performed pieces is considered a product innovation, in terms of the content. Although cognitive boundaries of content and artform are blurred, basically due to their interactions, artform innovation could be simply defined as novel approaches to presenting known works of art, as well as incorporating new technologies, artistic techniques and mediums in the performance process (Brown, 2004).

**Service Innovation**
Our conceptualization of service innovation includes two types of change: delivery innovation and new service development. Delivery innovation refers to changes in (i) the peripheral services which facilitate and accommodate the delivery process of the main service/product—the show, or (ii) the touchpoints, delivery process, and medium through which the main product is delivered (Hume, 2008; Menor, 2015). Scheduling versatility, improving accessibility and facilities, adding supplementary services (e.g., culinary and beverages, parking, accommodations, backstage meetings), and touring, as well as diversifying venues and concert locations are examples of incremental service delivery innovations. New service development, on the other hand, is attributed to development of new services, which often do not contain a show element and are basically aimed at fulfilling educational, cultural, and social needs of the society or the attenders.

**Drivers of PAO Innovation**
According to the theory of dynamic capabilities, to gain and retain competitive advantage, organizations need to have the capabilities required to detect and adapt to the abrupt changes in their market and environment (Teece, Pisano and Shuen, 1997). In moderately volatile environments, such as that of PAOs’, organization’s dynamic capabilities are mostly reflected in the operational ‘best practices’ they follow to generate, combine, and reconfigure their internal/external resources, so that they can innovate and provide new products and services (Eisenhardt and Martin, 2000; den Hertog, van der Aa and de Jong, 2010; Hitt, Xu and Carnes, 2016). Specifically, while few PAOs with adequate financial resources and artistic merits might take the leap to implement breakthrough innovations and implement highly ambitious projects to stay ahead of the game; many others gradually mimic the best practices and create new capabilities to stay in the game. They draw on their artistic and technical qualities and their social capital to reconfigure their operations with more recently-generated internal and external routines/resources or create incremental innovations in various aspects of their products and services.

In this study, based on a systematic review of the NFP organizations, professional services, and arts management literatures, we put forth a bundle of capabilities (Figure 1) which significantly drive innovation in PAOs, as discussed in the following sections.
**Environmental Intelligence Capability**

We define PAO’s environmental intelligence capability along two major dimensions: accumulation and assimilation. Accumulation refers to the PAOs’ routines and processes to acquire and collect information regarding every element of their broader environment. Assimilation, on the other hand, is the PAOs’ ability to disseminate the information, generate a knowledge-base, and integrate it into the design, programming, production, and delivery of their products and services.

The positive relation between an inward flow of information from the environment toward the organization and innovation, new service development, and new product development has been theorized and tested in NFP sector (Camarero and Garrido, 2008b, 2008a; Weerawardena and Sullivan Mort, 2012; Sanzo-Perez, Álvarez-González and Rey-García, 2015). Particularly, innovation in PAOs is highly dependent on how their external conditions compare to their internal resources and strengths (Voss, Sirdeshmukh and Voss, 2008), which necessitates a certain level of environmental intelligence.

Nowadays, the ideas of diversity and social relevance necessitate the individual PAOs to incorporate their regional culture and local artists into their artworks. Moreover, PAOs as risk-averse organizations need to be aware of the reaction of different audience segments to the new artworks. This makes PAOs acquire and analyze both global and local data regarding the audiences’ expectations and feedbacks from peer organizations and local PAOs.

- **P1a**: The PAO’s environmental intelligence is positively related to its level of product innovation.

In addition, a thorough understanding of the local opportunities and potential partnerships aids PAOs in selecting and defining their innovative service delivery. Being aware of the challenges and necessities regarding the incorporation of services and business models similar to other NFP organizations could both eliminate waste and risks and elevate the success propensity. New service development programs also heavily depend on the in-depth knowledge of the PAOs about liabilities, needs, and characteristics of the hosting communities.

- **P1b**: The PAO’s environmental intelligence is positively related to its level of service innovation.

**Internal Integration Capability**

Internal integration generally refers to both formal and informal collaborative behavior, information exchange, and joint decision-making within an organization (Gittell, 2006; Lin and Chen, 2008; Fu, 2015; Liu, Chen and Tao, 2015). The positive relationship...
between internal integration and innovation and new product development in both for-profit and NFP sectors has been well established in the literature (Tatikonda and Montoya-Weiss, 2001; Agarwal, Krishna Erramilli and Dev, 2003; Hult et al., 2008; Fu, 2015).

Accordingly, in this study, we define PAOs’ internal integration capability along two dimensions: design and implementation. Integration in design pertains to the inclusion of all departments and members, and their knowledge and expertise regarding the planning and programming of the products and services. Integration in implementation, on the other hand, focuses on coordinating the interactions between various processes and departments as well as allocating and integrating the resources to ensure that the planned quality, speed, and smoothness of the processes are met and the balance between the routine operations and innovative processes is maintained.

PAOs strive for creating synergies through creating organizational memory, collaboration, and coordination via a pattern of simultaneous decentralization and formalization to address their environmental complexities in design and implementation. The formation of cross-departmental committees for coordination between different constituents of the internal operations is a practical initiative for PAOs to instill internal integration. Another approach is to engage artists and other members in the decision-making processes (Tepavac, 2010).

Moreover, product and service innovations significantly add to the level of intensity and simultaneity of routines in PAOs, which, in turn, increases the multitude of logics, conflicting interests and priorities, as well as the number of experts engaged in design and implementation processes. These together lead to inefficiencies in communication, resource allocation, and conflict resolution processes both within and between teams and departments. In this vein, it could be hypothesized that higher rates of successful product and service innovation coincide with higher rates of internal integration. Thus:

• P2a,b: The PAO’s internal integration is positively related to its levels of both product and service innovation.

Core Operational Capability
We define core operational capability (COC) as a differentiated set of “skills, processes, and routines for incrementally refining and reinforcing existing operations processes” (Wu, Melnyk and Flynn, 2010, pp. 727-728). This encompasses two dimensions for PAOs: (i) artistic component, which refers to the overall collective level of artistry and technical ability of the PAO as the result of its persistence and frequent experiences in performing demanding programs and pieces; and (ii) technical component, which pertains to the PAO’s competencies in terms of improving their logistics for stage, rehearsals and backstage, auditorium facilitations, as well as its commitment to improve acoustic, sound, and visual systems in venue (Boyle, 2007; Tepavac, 2010).

Tepavac (2010) puts the artistic excellence as the footstone of her model of innovation in PAOs, as all five cases she had studied were high on the main technical and artistic abilities. In the same vein, we suggest that the COC acts as a driver of resource accumulation in PAOs, which in turn enables them to innovate in other aspects of their products and services by first, elevating their chances to attract other artists and partners; second, allowing them to spend their resources on experimentation and exploration on various aspects of their products and services (i.e., innovativeness); and third, by gaining legitimacy and the required financial resources (through winning peer reviewed grant applications due to perceived artistic excellence).

• P3a,b: The PAO’s core operational capability is positively related to its levels of both product and service innovation.
**Partnership and Collaboration Capability**

The academic literature on service innovation highlights the necessity of partnerships in new service development and delivery where each partner facilitates a different component of the whole designed service (den Hertog, van der Aa and de Jong, 2010). Although taking part in coalitions of value-creation is of critical importance, the competency to coordinate and manage such interactions is also crucial since they can detract from organizational performance in the absence of coordination and cooperation capabilities or other misalignments between organizations (Eisenhardt and Martin, 2000; G. B. Voss and Voss, 2000; Teece, 2007; Tepavac, 2010; Weinstein, 2010).

In this study, we define partnership and collaboration capability (PC) as PAOs’ and their members’ experience and competency in absorbing for-profit or NFP, artistic or non-artistic business partners, as well as their success in leveraging frequent and long-term well-coordinated inter-organizational collaborations at low transactional costs.

There are multiple evidences of positive impact of partnership and collaboration on innovation, performance, and resource absorption in the NFP sector. (Jaskyte and Lee, 2006; Hartley, Sørensen and Torfing, 2013; Sanzo et al., 2015; Wade-Berg and Robinson-Dooley, 2015).

Presenting innovative works, either in terms of content or artform entails deployment of knowledge and capability sources which even large organizations lack in isolation, especially when it comes to interdisciplinary approaches to artform (Scheff and Kotler, 1996b). On the other hand, service innovation either necessitates knowledge, expertise, assets, and capabilities in the fields which basically fall outside the area of PAOs’ business (e.g., adopting technologies, educational and other public projects) or entails combining unrelated types of service with the main products (e.g., out of venue concerts, supplementary services, accommodations, tours, tourism programs). That is why recently there has been an intense growth in the number of innovative partnerships between PAOs and for-profit technology or service providers or with other arts and culture organizations (Backer, 2002; Ostrower, 2003; Bakhshi and Throsby, 2009). In addition, the academic literature provides cases supporting a positive relationship between investment in close partnership relationships and successful innovative outcomes (Tepavac, 2010; Castro-Martínez, Recasens and Jiménez-Sáez, 2013).

- **P4a,b:** The PAO’s partnership and collaboration capability is positively related to its levels of both product and service innovation.

**PAO Performance**

While, the PAOs’ performance – like other NFP organizations – has been traditionally measured in terms of effectiveness rather than efficiency (Turbi de and Laurin, 2009), Kaplan and Norton’s Balanced Score Card (BSC) offers an effective tool for measuring the outcomes of these organizations (Weinstein and Bukovsky, 2009). Similar to their approach, we focus on artistic (parallel to internal operations), social (parallel to customer and general public), and financial performance as the main measures of PAOs’ operational outcomes.

Financial performance of a PAO is defined as its overall success in ensuing earned unearned financial resources and maintaining a feasible balance of their revenues and expenses (Herman, 1990).

In this study, we define the artistic performance of a PAO as the overall level of artistic merits and contributions that a PAO makes to the art community or the industry, as perceived by experts, peers, and artists (Glynn, 2000; Glynn and Lounsbury, 2005; Preece, 2005; Sorjonen, 2011). A high level of artistic performance or excellence is
amongst the most important factors in absorbing and retaining artistic talents and partners by PAOs (Scapolan and Montanari, 2013). It also has a significant effect on their survival, reputation, and legitimacy. Particularly, the experts’ opinions directly affect the funding agencies’ decisions, since fund applications are normally reviewed by peer artists. Therefore, artistic performance can play a significant role in increasing both earned and unearned revenues of PAOs (Gainer and Padanyi, 2002; Padanyi and Gainer, 2003; Preece, 2005):

- **P5:** Artistic performance of a PAO is positively related to its financial performance.

Social performance refers to a mix of advantages that PAOs can create for both the community they reside in as well as their audiences (Preece, 2005). In general, it can be defined as the overall success of a PAO in absorbing and retaining the continuous attendance and attention of the audiences in its public events and paid services, together with its commitment to presenting products and services to a broader and more diverse population in the society. This dimension of performance is well reflected in audience satisfaction and retention, which directly affects the PAOs’ earned revenues (Gainer and Padanyi, 2002, 2005; Hume et al., 2006; Camarero and Garrido, 2008b; Hume and Sullivan Mort, 2010; Vakharia and Janardhan, 2017) as well as their public value (G. B. Voss and Voss, 2000; Z. G. Voss and Voss, 2000). The earned revenues usually account for thirty to fifty percent of the PAOs’ total income (Weinstein and Bukovinsky, 2009; Orchestra Canada, 2017). Besides, although public value creation may not directly generate revenue for the PAOs, it can immensely affect their unearned revenues since the funding agencies, private donors, and corporate sponsors are increasingly concerned about this issue. Therefore,

- **P6:** Social performance of a PAO is positively related to its financial performance.

### Innovation and Performance

Based on the dynamic capabilities theory as well as the literature on innovation in manufacturing and service sectors, innovation and new product/service development are one of the most effective approaches for organizations to gain competitive advantage and improve their operational and/or financial performance in the face of environmental uncertainties (Eisenhardt and Martin, 2000; Agarwal, Krishna Erramilli and Dev, 2003; Wu, Melnyk and Flynn, 2010; Hitt, Xu and Carnes, 2016). Particularly, the NFP organizations require innovation to deal with the uncertainties and increasing pressures to develop their products and processes in social services (Voss, Montoya-Weiss and Voss, 2006; Camarero and Garrido, 2008b; Weerawardena and Sullivan Mort, 2012; Sanzo-Perez, Álvarez-González and Rey-García, 2015).

The combination of higher levels of artistic quality and more frequent performances of modern pieces can elevate the appreciation of the artists, critics, and experts in the peer organizations, as well as the community and funding agencies. Moreover, productions that entail novel formal aspects can positively influence the artistic merits of the organization (Gainer and Padanyi, 2002). While currently only a small segment of the subscribers and general audience (i.e., arts-enthusiasts) are primarily focused on the pure artistic values of the presented works (Hume et al., 2006), research in the field has not been able to refute the general public’s appreciation for the artistic merits of the artworks and PAOs are recently advised to accept the public artistic sensitivities (Gainer and Padanyi, 2002; Tepavac, 2010), as product innovations could also absorb the attention of non-expert audiences. This is, in particular, justifiable where formal sophistication and simultaneity of different streams of meaning embodied in artforms and other sources (e.g., musical, visual, and textual codes) absorb the new generations, specially the
millennials, more effectively; hence, extends the experiential aspects and appeal of the presented products (Brown, 2004; Bakhshi and Throsby, 2009). Therefore,

- P7a: Product innovation in a PAO is positively related to its artistic performance.
- P7b: Product innovation in a PAO is positively related to its social performance.

Service innovations, on the other hand, are aimed at absorbing the attention of the otherwise disconnected segments of the society by accentuating services or aspects of the service which favor the social development and public roles of the PAOs over their artistic merits. Besides, service innovations are implemented to heighten and deepen the PAOs’ relationship with the general audience, particularly the entertainment-seekers, by enhancing the accessibility and experiential aspects of the artistic encounters (Hume et al., 2006; Hume, 2008). The effect of new service development on performance, effectiveness, and competitiveness in for-profit sector is established in the literature (Menor and Roth, 2008). In PAOs, the experiential aspects of the new service offerings as well as addressing the expectations of different audience segments promote the social performance; hence promote their financial performance (Andreasen and Belk, 1980; Scheff and Kotler, 1996a; Hume and Sullivan Mort, 2010; Menor, 2015).

- P8a: Service innovation in a PAO is positively related to its social performance.

In addition, service innovations are basically designed to widen the audience-base and ensure customer retention in terms of irregular audiences. Keeping higher numbers of community members in touch with art would be a contribution to the art and can result in the appreciation of arts community. Moreover, it could add to the propensity of the audiences to become serious audiences or even art practitioners. As a matter of fact, children and youth participating in public/paid educational and outreach programs are more likely to become future artists. The activities aiming to increase and retain the audience-base can also positively enhance the learning curve of the organizations in both artistic (i.e., stimulation of the appreciation of the community for art) and operational aspects, especially in the long-run.

- P8b: Service innovation in a PAO is positively related to its artistic performance.

Abstract

This work aims at proposing an innovation model for the women's fashion industry, which intends to understand the behaviour of styles and trends spread by companies. The model discusses the fashion styles that remain in fashion in a continuous or discontinuous manner and the polarization of styles around feminine and androgynous concepts. The methodology adopted was hypothetical deductive. In order to verify the hypotheses, an exploratory data analysis was developed by means of descriptive statistic. The results showed there are fashion styles that remain continuously fashionable and there are polarizations periods of style grouped.

Keywords: Innovation, Fashion, Style

Introduction with a situation problem

Consumers recognize innovation in the fashion industry through the style imprinted in its products. Style is identified by the designs and colors of different clothing elements (clothes, shoes, and accessories). The combination of these elements also characterizes the formation of a style (Cappetta et al. 2006). These styles express concepts linked with cultural, social, and economic settings (Sabino, 2007).

The design of a product associated to its form limits the comprehension of its meaning. According to Kontic (2007), fashion design fits into a distinct category of knowledge, being on the edge of the productive process and product development. Therefore, design is the result of the process of developing a new product (Roper et al. 2016). However, the technological capacity of a firm determines design (Utterback and Albernathy, 1975; Tran, 2010). The consumer identifies design through shapes and colors of the products, while style is recognized by trends, meaning inclinations and repetitions through a period of time.

Since consumers identify style as the main element of innovation in fashion, understanding its behavior is fundamental for innovation processes by companies. Therefore, this research aims mainly to present a trend and style innovation model for
the women’s fashion industry. The model focuses on style, which is determined and widespread by high-end prêt-à-porter companies.

Industrially manufactured clothing is called prêt-à-porter. This market segment can be divided into high-end, mid-end low-end prêt-à-porter. These different areas are distinguished by the consumer public and the price of the pieces. The high-end prêt-à-porter products are more expensive and an elite set of consumers. In the mid-to low-end ranges of prêt-à-porter, the pieces become cheaper and reach mass consumption (Cappetta et al., 2006). The model in this research focuses on high-end prêt-à-porter as these are created by the style and trendsetting companies.

The high segmentation in the fashion industry increases the companies’ need to develop strategies to gain space in the consumer market. Innovation is one of these strategies. Innovation is incremental and directed to the product. Incremental innovation consists of small product modifications and improvements (Davila et al., 2008; Rogers and Schoemaker, 1971). In particular, design has an impact on the competitiveness of companies and industry standards (Utterback and Albernathy, 1975; Baldwin et al. Hippel, 2006).

This research investigates trend and current styles as an indicator of behavior by innovation in contemporary fashion. The idea is to identify which trends are permanently in fashion. Rationalizing the process systematically reduces uncertainties regarding new style releases. Moreover, some contemporary fashion styles (after 1990) show conceptual similarity, which allows grouped around the same concept.

The main motivations for this study are two aspects: there is room in the literature for more studies regarding the proposed theme, and there is a need in the fashion industry for a study about trends and style behavior. There are currently several articles in the literature referring to the subject. A bibliometric analyses was used to measure of the quantity and diversity of the topics in articles about fashion. Notwithstanding, for the specific objectives of this research, only a few of the articles are relevant and pertinent, which demonstrates that there is room for further literature in this field.

The innovation models for the fashion industry referred to in this research are from different perspectives. This gives rise to questions as to which elements are fundamental for the construction of an innovation model. The innovation model for product development, by Markevicute and Blazenaite (2011), focuses on analyzing the processes for new product production, from the generation of ideas to their dissemination. The innovation models regarding fashion trends (Jones, 2004; Caldas, 2005; Sarma et al., 2010) aim at understanding institutions and the elements that generate the styles and trends, as well as their diffusion channels. The model for fashion cycles shows fashion innovation through market behavior (Pesendorf, 1995). Lastly, innovation models for style behavior, by Cappetta et al. (2006) contribute by uniting style behavior to its period.

The main question that these models raise is: If fashion is fundamentally product, style and design changes through time, should an innovation model have these elements as variables? Only the Cappetta et al. (2006) model takes this approach. So, it is relevant and pertinent to develop a model using these attributes.

To understand their contribution, it is necessary to establish some definitions concepts about fashion, design, style and trend. Fashion is an intangible phenomenon, with trends, styles and design changes introduced at pre-determined time intervals (Lipovetsky, 1989; Caldas, 2005; Markevicute and Blazenaite, 2011). Fashion represents what is current, in evidence.

Contemporary fashion (21st century) is determined by fashion institutions, for example: (i) prêt-à-porter, (ii) high fashion, (iii) style bureaus, (iv) media, (v) young
subcultures/street style, (vi) social elite, wealthy people, artists, and celebrities, (vii) individuals in general (Caldas, 2005).

Design represents the form and aesthetics present in products. In fashion, design is identified by the form, volume, and silhouette of products. Design is a component of style. Style is the combination of apparel elements (clothes and accessories) that can be identified by form (design) and color. Styles express concepts recognized in cultural, social, and economic patterns. That is why styles characterize specific time periods (Sabino, 2007).

An example of style is romantic attire. At the beginning of the 19th century, more precisely between 1820 and 1840, this style of clothing was distinguishable by: a thin waist, light-colored dresses (solid print or with flowers), puffed sleeves, voluminous skirts, ruffles and bows (Laver, 2006). In other times, when clothing had similar elements to those used in the romantic period, these are classified as being of the romantic style.

In addition to styles associated with a time period, there are styles characteristic to certain companies. For example, at the house of Chanel, cardigan-style jackets (button-down, long-sleeved wool coats) are present in every collection. New product versions are introduced in each collection; however, the original design characteristics are preserved. Lacoste is another example of a company that has its iconic pieces in every collection. Its polo shirts are a brand iconic piece because they were released at the creation of the company and reinforce the concept that the brand has a casual, sports style (Vincent-Ricard, 1989).

Trends are inclinations and repetitions of certain behaviors and styles. Trends are determined by fashion companies and they always looking to introduce something new. Determining trends through the components of the production chain tends to reduce the risk in developing a product collection. In the case of textile/clothing production, this is composed of threads, weaving and manufacturing, among others (Caldas, 2005).

Of the innovation models for the fashion industry, the Pesendorf (1995) use his model to define the process of the generation and obsolescence of style, and how consumer behavior influences it. The latest releases are the most desired by consumers. Products of older style and design become obsolete. Consumer behavior confirms this proposition.

For Pesendorf (1995), there are two influences on consumer behavior: the bandwagon and the snob effects. The bandwagon effect in product demand is stimulated by elite consumer behavior. Elite consumption directs other customers’ consumption. The moment favored products reach mass consumption, the snob effect occurs. Elite consumers then discard these products and the fashion’s companies releases new products.

Regarding the release and diffusion of trends and styles, Caldas’s (2005) and Jones’s (2004) models show that fashion trends come from opposing directions. The trickle-down model reinforces the idea that elite-directed consumption conditions mass consumption. The bubble-up model shows the opposite, where trends are defined by an “underground culture”. However, in both models, trends reach the elite first and, then, are made available for mass consumption.

Cappetta et al. (2006) agree with Pesendorf (1995) independent to the process of trend appearance, elite consumption conditions mass consumption (bandwagon effect). From the moment a trend is absorbed by mass consumption, the style is rejected by the elite consumer and becomes obsolete (snob effect).

Plurality in style and trend formation and determination varies according to each period. Cappetta et al. (2006) present the hypothesis of convergence and divergence of
style. In convergence periods, styles are more similar and tend to assume the same shape and color patterns. In the divergence periods with effervescence of styles, there is the release of several styles, all different. The authors’ argument is grounded in a specific fashion period – from 1984 to 2002.

The central feature of the proposed model is to evaluate whether there are fashion styles that remain in fashion in a continuous or discontinuous manner. The model also discusses the polarization of styles around feminine and androgynous concepts.

The proposed model assumes the concept that style innovation depends of the technology employed in product manufacturing, once the design is a style element. Style is determined by dominant companies in the chain production and, then, reproduced by companies of lesser importance.

Dominant companies are those that reach elite consumption first, and have brands that can be identified by the public. How companies become established in this position depends on market behavior and company strategies. A company may successfully launch a new style at one period of time, then be unsuccessful at the next.

The proposed model also assumes that the style diffusion process happens through the trickle-down model, in which the determination of trends and styles comes from chain-production dominant companies. While it is accepted that other fashion institutions may determine styles and trends, they still need dominant companies to produce and release them to the elite consumer market. As elite consumption conditions mass consumption, the bandwagon and snob effects are considered real.

The proposed model does not intend to investigate internal processes in detail; it assumes that the innovation process goes from idea generation to product dissemination in the market. In this regard, there is no contribution to the literature. The contribution of the model lies in helping to forward an understanding of contemporary style and trend behavior.

According to Jones (2004), styles can be classified as classic and ephemeral. Styles that are considered classic are those that are present in different times through fashion history. These styles are re-edited, their original version is modified but keep their basic essence. Classic styles remain in fashion for a longer time. Ephemeral styles have a short period in fashion.

A commonly accepted concept in fashion history studies is that predominant styles practiced in a time period are the opposite to those practiced in the next. For example, in the 1960s and early 1970s, there was a counter-cultural revolution where young people started to question the values imposed by society. In fashion, this was reflected in miniskirts, geometric dresses, with psychedelic colors, and the hippie style. The 1980s are culturally the opposite, reflecting the body and work cult of that time. Women’s fashion clothing was more comfortable and adaptable to the job market (more ample and loose shapes) (Jones, 2004).

In contemporary fashion, there are both the coexistence of classic and ephemeral styles and the idea of the continuity of styles instead of ruptures. Fashion, from the 1990s, starts to admit a higher number of styles and trends. Furthermore, it disrupts the idea that styles and trends are specific to each decade. Styles stay in fashion for longer periods of time, with small changes to the design and colors. Conceptual aspects of each style and their cultural and socioeconomic identification patterns follow the same references.

The aim of this model is to understand trend behavior in contemporary fashion. If the coexistence of conceptually opposite and similar styles has occurred in fashion, then, it is possible that trends aggregate styles around common behavioral concepts. Trend
behavior reveals the fashion development pattern, explaining which behavioral aspects are and tend to stay current.

The research aims to investigate how contemporary fashion trends indicate aspects of current fashion behavior. The idea is to identify which trends have been constantly in fashion. Rationalizing the process a system of thought would reduce uncertainties related to launching new styles.

The first question in this research considers if styles remain in fashion in a continuous or discontinuous way. Understanding style behavior is to understand the way trends are developed. So, the first question in the research is: In contemporary fashion (from the 1990s), are there styles that remain in fashion continuously, while others do not (go out of fashion)? The hypotheses developed to help answer this question are the following:

- H1: There are styles that remain in fashion continuously, while others do not.
- H0: There are no styles that remain continuously in fashion; there is a pattern of discontinuity for all styles.

The second question in the research considers style merging. Each style has specific characteristics in terms of concept and design, although there are also similarities between styles. In this research, only women’s fashion is investigated. The main differentiation in styles considered in this research is in gender identification. Some styles, depending on their design and clothing composition, seem more feminine while others seem more androgynous. Styles that focus around gender identification may lead to an understanding of whether there are some periods where styles become polarized, and others where they do not.

Polarization means that, during a specific time period, the relative frequency of styles grouped that suggest androgyny. In other moments, the relative frequency of styles grouped suggest femininity. Depolarization means that there are no specific periods with polarization, that the relative frequency of agglomerations is constant throughout the period.

As such, the second question of the research is: Are there periods in which there is polarization of style grouped? The hypotheses to answering this question are as follows:

- H1: There are periods in which there is polarization of style combination around gender identity.
- H0: There are no periods in which there is polarization of style combination around gender identity.

The graphic representation of the proposed model, shown in Figure 1, demonstrates the beginning of the style-generating process which occurs in companies that dominate the production chain. From the moment in which the generated style starts to be disseminated, it assumes different behavioral trends (continuous and discontinued) that allow polarizations around gender identity (androgyny and femininity).
Methodology

In order to test the validity of the model the empiric research was made. The research has a phenomenological, qualitative, and longitudinal approach and the methodology adopted was hypothetical and deductive. For hypothesis verification, an exploratory data analysis was used through the descriptive statistics.

The data collection sources were Vogue America issues from 1991–2013, and 230 issues were used. Vogue’s View editorials were used as the analysis unit. Vogue’s View editorials were chosen because Vogue America magazine addresses other topics related to fashion like: architecture, decoration, cosmetics, and behavior.

The data collection methods in phenomenological research (qualitative) are a series of interpretive techniques to describe and understand the meaning of a given phenomenon. To classify a method as phenomenological, and, therefore, adequate to qualitative research, depends on its intended use (Collis and Hussey, 2005).

Some styles are explained in the editorials, while others are only referred to. New styles are mentioned in the editorials and explained. Commonly-used fashion styles are just cited for the data collection, the editorials were read, and the photographs that referred to the cited style were analyzed.

The process of labeling each style consisted of describing its components, as collected in the explanation of the editorials. A list of the styles mentioned follows below:

- **Ethnic**: characterized by clothes that were inspired from Russian, Chinese, Indian, and African cultures;
- **Grunge**: characterized by loose T-shirts, plaid flannel and cotton shirts, ripped up jeans, wool caps and boots;
- **Hippie**: characterized by casual looks, long skirts, smocked tops, low waisted, straight or bell-bottom jeans;
- **Casual**: characterized by light fabric loose clothing (cotton and jersey), or materials appropriate for informal situations (wools, knits, and jeans). Accessories are simple and unobtrusive;
- **Dandy/Edwardian**: characterized by high-neck shirts, tight pants, body-hugging vests, and boots. The style implies androgyny;
- **Minimalist**: characterized by clothing (skirts, dresses, shirts and pants) that are straight fitted, with no volume. Clothing is a solid color (no color mixing) and accessories are simple and discreet;
- **Romantic**: characterized by dresses and skirts that have volume. Clothing has floral or solid patterns, with ruffles, lace and embroideries;
▪ Animal print: characterized by clothes with animal skin patterns. Suggests sensuality and femininity;
▪ Total black: characterized by the use of the color black in every piece of clothing;
▪ Total white: characterized by the use of the color white in every piece of clothing;
▪ Black-white: characterized by the combined use of the colors black and white. The color change is in one piece, for example, black pants and white shirt;
▪ Doll: characterized by clothes adequate to young women and city life romantic. Clothing features: short, tight skirts, shoulder to shoulder tops, empire waist-lines (waist comes right below the bust);
▪ Ethical: characterized by ecologically correct clothing;
▪ Futuristic: characterized by its use of plastic and synthetic fabrics, bright and bold colors;
▪ Kitsch: characterized as a tacky, corny style, with bright and fluorescent colors. The accessories are big and flamboyant;
▪ Georgette: characterized as a style of clothing inspired by 1920s’ fashion. Garments are satin (fabric) dresses, with lace and low necklines. Accessories are pearl necklaces and earrings, and pointy shoes;
▪ Lady-like: characterized by clothing including knee-length, A-line skirts (tighter at the waist and broader at the hem), or pencil (tight, high waisted) skirts. Light fabric (chiffon, silk crepe), buttoned-down, cuffed shirts;
▪ Men’s wear: characterized by garments made up of: pinstriped suits (jacket and pants), shirts (buttoned-down, cuffed, with collar), trench coat (straight fit or military style) and boots;
▪ Radical chic: characterized by garments that are voluminous and no shoulder straps. Lace details. Metal accessories (jewelry) are large and heavy;
▪ Classic chic tailleur: characterized by composed of tailor-made suits (skirts, shirts and jackets) adorned by metallic buttons and worn with large jewelry;
▪ Work appearance: characterized by suits (jacket with straight pants or skirt) and normally in dark colors. Pieces are straight cut, with no volume or flamboyant details, being more suitable for the work environment.

Style combination according to gender identity can be classified in three ways: androgynous, feminine, and neutral. In fashion, androgynous styles highlight the absence of femininity. As this study is about women’s fashion, it is important to briefly discuss gender differentiation in clothing. The identification of gender specific (masculine and feminine) clothing has occurred since the beginning of fashion, in the 14th century (Lipovetsky, 1989). Twentieth century fashion broke these barriers and incorporated masculine pieces into feminine clothing. When this happens, clothing is no longer essentially feminine and becomes androgynous. Androgynous styles are: dandy/Edwardian, minimalist, menswear, classic chic tailleur, work appearance.

Feminine styles, on the other hand, are the opposite, highlighting aspects such as feminine sensuality and fragility. Styles suitable for the workplace do not fall into this classification. Thus, feminine styles are: romantic, animal print, doll, georgette, lady like, and radical chic. Not all styles can be classified according to gender identity, in which case, the neutral classification was adopted. Neutral styles are those that have no elements identifiable to either femininity or androgyny. The neutral styles are: ethnic, grunge, hippie, casual, total black, total white, black-white, ethic, futuristic, and kitsch.
**Result**

In the research were identified twenty one different styles. The results showed there are fashion styles that remain continuously fashionable. A polygonal graph shows a stacked view of the relative frequencies of all styles. In graph 1, the horizontal axis shows the years, and the vertical axis, relative frequency. The legend indicates each of the twenty-one styles.

![Graph 1: Stacked areas of relative frequencies](source: Prepared by the authors)

Style classification by gender identity is defined by the conceptual content of each style. Even though this research focuses on women’s fashion, there are styles with greater identification to the concept of femininity, and others with greater identification to the concept of androgyny and, finally, neutral styles, which are those that do not fit into either of the above categories. The styles corresponding to each category are:

- **Androgynous styles**: dandy/Edwardian, minimalist, menswear, classic chic tailleur, work appearance;
- **Feminine styles**: romantic, animal print, doll, georgette, lady like, radical chic;
- **Neutral styles**: ethnic, grunge, hippie, casual, total black, total white, black-white, ethical, futuristic, kitsch.

The graphical distribution of the combination around of frequency results is presented in Graph 2. It is possible to see the polarization of the androgynous style in the period 1991–2000. The feminine gender identity predominated in the 2001–2013 period, indicating a possible polarization in this time periods.
Conclusion

The proposed model is initially grounded on fashion styles generated by the dominating chain production companies. The diffusion of generated styles leads to the formation of continuous and discontinuous behavior trends. The fact that fashion is a social phenomenon reverberates in style behavior. As fashion product consumption is an elite consumer differentiation factor, the style adhesion by the masses provokes the obsolescence of these products. Thus, style behavior is influenced by consumer receptivity to the generated products.

There are other factors that also influence product consumption in general, such as demographics, regions, and socioeconomics. However, as the model was aimed at high-end prêt-à-porter companies, which release and market their products in different parts of the world, these factors were not explored. The proposed model considered only social factors as influences to consumer behavior.

Further, when analyzed through descriptive statistical methods, the collected data was able to prove the coexistence hypotheses of continuous and discontinuous styles. The existence of polarizations around androgynous styles in the 1990s, and feminine styles in the 2000s can also be proved.

The positive aspects of the proposed model dwell in three factors. First, the presentation of a model with theoretical coverage relating the behavior of companies, innovation processes, and consumer behavior when faced with innovative product releases is original and unprecedented. Second, using statistical methods for understanding style behavior and trend generation allows clear and proper identification of the characteristics of contemporary fashion and the polarization of gender identity styles in different periods of time. Third, the research classifies and compiles existing innovation models for the fashion industry.

This model’s limitations are present in the collection and classification of styles. The sole source used for the collection of styles was Vogue America, a magazine read throughout the world, but directed to the American market. Even though fashion is globalized and the same styles generated by high-end prêt-à-porter companies are diffused by world media, there are specific characteristics of the American market that foster greater preference of some styles over others. This happens in all markets.
Moreover, without any doubt, the style classification process was conceived by this author herself. While the whole classification followed pre-established criteria, still the styles went through one sole evaluation during the classification process.

Abstract
The potential of digital innovations is clearly recognized. However, its implementation within manufacturing companies seems to be more difficult. Considering that digital innovation within manufacturing companies are a combination of digital and physical assets, it seems plausible that the consideration of information systems related governance mechanism may support the digital innovation management within manufacturing companies. We derive six propositions which give insights into which dimensions are relevant for digital innovation management in manufacturing companies.

Keywords: Digital Innovation Management, Digital Technologies

Introduction
The diffusion of digital technologies into the manufacturing industry creates new opportunities. These opportunities may arise from improvements in efficiency and effectiveness (i.e. smart factory) or through the offerings of new products, services or even business models. The combination of digital technologies such as sensors, actors and cloud computing with non-digital products and services provide significant opportunities but capturing the value of the digital transformation has proven to be challenging to firms in traditional industries (Henfridsson et al., 2018; Svahn and Henfridsson, 2012). Whereas the innovation potential of digital technologies is widely recognized, few studies address the management of digital innovations (Abrell et al., 2016). We aim to enhance the understanding of how to manage digital innovations in manufacturing companies. To do so, we relate to IS literature and derive insights from software development projects and compare these with the activities and challenges of eleven Industrial Internet of Things (IIoT) projects of three manufacturing companies.

Digital Transformation
Digital transformation describes how companies need to change their processes and the company’s way to compete in the digital age. There exist different terms describing the changes, such as information age, industrial internet or industry 4.0. The information age started with the third industrial revolution, also known as the digital or ICT revolution, at the end of the twentieth century (e.g., Castells, 2011; Dosi and Galambos, 2013). The technologies, mainly
ICT, lay new foundations for companies, economies and societies. In addition, Musso (2013) concludes that the information age has sped up the transition from manufacturing to services, highlighting the influence of the technological changes on business models.

In industrial companies, these changes are labelled as industrial internet, industrial internet of things (IIoT) or Industry 4.0. The main approach of the industrial internet or industrial internet of things (IIoT) is to bring software and machines together (Bruner, 2013). The term stems from the US and was first introduced by General Electric. IIoT enfold initiatives belonging to a higher degree of intelligence with the power of advanced computing, analytics, low-cost sensing, and new levels of Internet connectivity (Posada et al., 2015). Posada et al. (2015) highlight three key elements of IIoT: (1) intelligent machines, (2) advanced analytics and (3) people at work.

Industry 4.0 belongs to a similar initiative, mainly pushed from Germany. The core elements of Industry 4.0 are embedded systems, smart objects, cyber physical systems (CPS), the concept of a Smart Factory, robust networks, cloud computing, and IT-security (Bauer et al., 2014). The coexistence of the physical and virtual worlds, with the use of emerging ICT, opens possibilities such as “enhanced human-machine cooperation (including human interaction with robots and intelligent machines), connected machine networks that follow paradigms of Internet connectivity and social networks, improved human-in-the-loop interaction between the cyber and physical worlds, networked and decentralized value chain transnational scenarios, and emergence of product-service networks based in intelligent, smart products, and associated services” (Posada et al., 2015, p.27).

Whereas Industry 4.0, IoT, IIoT and digital manufacturing focus on the changes of digital technologies in industrial companies, the term digital transformation is industry independent and analysed based on the perspective of different research streams. Vial (2019) defines, based on a comprehensive literature review, digital transformation as “a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies”.

Although avoiding the term “digital technologies” in his definition, Vial (2019) highlights that that most of the digital technologies mentioned in the literature review fit with the popular SMACIT acronym, referring to technologies related to social, mobile, analytics, cloud, and the internet of things. Furthermore, it’s the combination of technologies that are particularly relevant in the context of digital transformation (Bharadwaj et al., 2013). For example, the use of social media on the mobile phone may be the prerequisite for gathering and storing big data and to perform analytics.

Others, in addition, highlight the merge of the physical and digital world, enabled through IoT sensor and actuators and connectivity technologies (Fleisch et al., 2014; Yoo et al., 2010). Summarizing, the traditional processes of manufacturing companies focusing on physical products is challenged with the requirements to integrate digital aspects. How to cope with these new requirements is a challenging task for manufacturing companies. Hence, to get an understanding of the different requirements manufacturing companies are facing while developing digitally enhanced products, services or processes, we summarize the key aspects of the traditional innovation management and information systems (IS) related innovation management.

Traditional Innovation Management: Insights from Business Management

Managing innovation has traditionally focused on new product development (NPD) activities. Prerequisites for the development of products are the engagement in a bundle of activities that include the management and transformation of resources and information in order to create products that meet or create market demand (Wheelwright and Clark, 1992). Typically, in innovation management, four types of innovation exist: process, product, service and business model innovation (e.g., Teece, 2010). Considering key determinants of the traditional
innovation management, Damanpour (1991) highlights in his meta-analysis several factors that have a positive correlation with innovation: specialization, functional differentiation, professionalism, managerial attitude toward change, technical knowledge resources, administrative intensity, slack resources, and external and internal communication.

Johansson and Kullström (2018) argue that an innovation management, which has been dominated by structure and control, mirrors the circumstances where goals and objectives have been clear. Instead, innovation activities nowadays are increasingly confronted with fuzzy objectives and complex processes and traditional methods have been found lacking (Kapsali, 2013). Therefore, there is a need to find methods that suit more complex projects.

Innovation management: Insights from IS literature

Traditionally IS innovation research has focused on the adoption, diffusion, implementation, acceptance, and assimilation of IT in organizations (Fielt and Gregor, 2016). However, there is a growing interest on the paradoxes and dilemmas that digitization creates for organizations developing, deploying, and managing digital innovation (Nambisan et al., 2017). As Nambisan (2017) states: “This transition from innovation to digital innovation comes as a golden opportunity to be seized upon by information systems (IS) researchers. IS researchers have, for the last four decades, been at the forefront in observing the dawn and consecutive wakes of digitization in organizations and, broadly, in society, and explaining its repercussions.” Similar to the definitions in business research, IS scholars define digital innovation as the creation of (and consequent change in) market offerings, business processes, or models that result from the use of digital technology. Stated differently, in digital innovation, digital technologies and associated digitizing processes form the base for new ideas. Thus, digital innovation management refers to the practices, processes, and principles that underlie the effective orchestration of digital innovation (Nambisan, 2017).

Svahn and Henfridsson (2012) conclude that product innovation and IT innovation literature provide a different outlook on innovation. While product innovation cultivates firm-centricity and exercise of formal control, IT innovation builds upon network-centricity and the creation of digital options. Network-centricity introduces uncertainty that counteracts the traditionally exercised formal control over the product innovation process. The authors conclude that more research is needed on these seemingly opposing logics (Svahn and Henfridsson, 2012).

Digital Innovation Management: Research Framework

Different researchers argue that there is a need for new theories in this age of digital innovation and digital transformation (Hinings et al., 2018; Svahn and Henfridsson, 2012; Yoo et al., 2012). More specifically, Nambisan et al. (2017) say that “[t]here is a critical need for novel theorizing on digital innovation management” that deals more adequately with the rapidly changing nature of innovation processes in a digital world. Although the innovation process itself is crucial to understand, the management is important as well.

As the proportion of software within innovations of manufacturing companies is rapidly growing, manufacturing companies can profit from understanding the requirements to successfully manage IT innovations. However, as Svahn and Henfridsson (2012) highlight, there are differences between the management of product and IT innovations and hence, there is a need to get an understanding on how to incorporate both aspects.

To do so, we rely on the concept on IT governance. As Leonhardt et al. (2018) summarizes, newer research on IT governance mainly enfoils the governance mechanisms related to structure, process and relational mechanisms.

One key aspect to IT governance is the decision-making structure, implemented to define the locus of authority for IT activities (Sambamurthy and Zmud, 1999). Choices range from centralized to decentralized or hybrid decision-making. More specifically, a central decision architecture grants all decision rights to the IT organization, a decentralized one delegates
decision-making authority to the business units (Brown and Magill, 1994). Thus, we conclude that the *locus of authority* and its role in digital innovation management needs further research attention.

Horizontal coordination mechanism enfold informal and formal designs that focus on the interaction of individuals and the coordination of activities across units (Mintzberg, 1979). The mechanism aim at facilitating interaction and problem-solving across different departments (Brown, 1999). The formal coordination mechanism refer to steering committees or cross-unit integrators. Examples of cross-unit integrators are Chief Digital Officers.

Since digital innovation requires the combination of diverse knowledge across different departments (Yoo et al., 2010), interdepartmental dynamics and the respective *horizontal coordination mechanism* may be at the core of digital innovation management.

Although Yoo et al. (2010) focus on the internal cooperation relevant to acquire knowledge, Hildebrandt et al. (2015) highlight the growing importance of cooperation with external partners. More specifically, acquiring and integrating complementary and heterogeneous external knowledge on digital technologies is an important prerequisite for digital innovation (Hildebrandt et al., 2015). Thus, we add *internal cooperation* and *external cooperation* as two further dimension as being potentially relevant to understand digital innovation management.

As it is our goal to understand digital innovation management, we focus on the analysis of the innovation process itself and the four governance mechanisms as summarized in Figure 1.

![Digital Innovation Management](image)

**Figure 1 - Research Framework**

**Research methodology**
We grounded our observations in data from a multi-case study with three multinational companies from the machine industry that face the diffusion of digital technologies. Each of the companies belong to a wider company network and reports to headquarters. In addition, company B acts as a national headquarter for further subsidiaries. Overall, we have analyzed eleven IIoT initiatives that are the unit of analysis for the study at hand. Because of the emergent nature of this topic, we apply an exploratory research approach. In addition, we analyze existing literature focusing on digital innovation and its management and derive a framework that guides our research (Eisenhardt, 1989). The goal is to match theory and reality in a nonlinear, path-dependent process that systematically combines empirical observations and insights from extant literature (Storbacka, 2011).

The exploratory research lasted from January 2016 to September 2017, with follow-up interviews in 2019. We accompanied the companies throughout the development process and conducted 12 to 16 meetings within each of the participating companies. The companies were part of a joint working group. Hence, there are activities that the companies conducted jointly (i.e. successful practice visits) or applied the same methods (i.e. evaluation of market trends). Other activities are company specific. The data gathering occurred through meetings within each of the three companies. During the meetings, we observed the activities and conducted
interviews. We wrote minutes for each meeting (observation and interviews), and compared them with literature.

We used Miles and Huberman’s (1994) four-step approach to analyze the collected data. First, we developed a contact summary sheet in which the main themes of each interview were recorded. One researcher identified the main themes, while the other two researchers checked these themes using the interview minutes. The themes covered, for example, the content of different IIoT initiatives and the measures to implement them. Second, a complete theme list was developed based on the contact summary sheet. Third, all interviews were coded using selective coding (Strauss and Corbin, 1990) to categorize the answers into the main themes. One researcher was responsible for coding the interview minutes, while the other researcher checked the coding. In the event of disagreement, the point was discussed until agreement was reached. If no agreement was reached, the point was referred to the interviewees for clarification. This procedure ensured a high level of inter-rater reliability (Voss et al., 2002).

Fourth, we wrote the case study and performed a final validity check, which was done by presenting the results to the interviewees and to the top management of the respective company.

Case study analysis

The three manufacturing companies developed nine IIoT ideas that focus on offering new services to the customers. Three initiatives focus on the digitalization of internal processes (i.e. digital working instructions, dynamic planning and production system (smart factory) and global service). Overall, the activities of the innovation process can be described according to the six generic dimensions: idea generation, idea selection (I), idea concretization, idea selection (II), development and dissemination. Table 1 and Table 2 summarize the main activities, separated into activities that each company conducted similar as well as company specific activities.

Table 1: Insights from the innovation process of 11 IIoT initiatives (I)

We conducted follow up interviews in 2019 to derive the level of diffusion. Whereas company A achieved to implement three pilot tests with customers (Case A1, A2 and A3), company B is also able to cooperate with pilot customers for case B1. Only company C had to stop all of its activities.
Based on the research framework derived, next to the process, we focused on the governance mechanism. Whereas in some cases, the governance mechanism have been similar for the studied company, other mechanism differed depending on the initiative. Table 3 highlights the insights of the governance mechanism.

Table 2: Insights from the innovation process of 11 IIoT initiatives (II)

**Discussion**

The specific activities of company A and B at the beginning of the innovation process highlight the need to coordinate with other subsidiaries or activities conducted throughout the company. At company A, during the idea concretization phase, headquarters was involved to align the subsidiary activities with companywide initiatives. Although each of the four cases at company A was presented to headquarters, the “pay per use” initiative needed further alignment as the potential service offering influenced process steps covered from other subsidiaries and was clearly in the locus of authority of headquarters.

The interdisciplinary project team is a central part in traditional as well as digital innovation management and was present in each of the studied initiatives. Interdisciplinarity seems to be important, not only for the knowledge needed for the development of digital innovation but also for the strengthening of internal cooperation and thus the implementation of the digital innovation throughout the company. More specifically, the interdisciplinary teams helped to improve the attention throughout the company and, in addition, to integrate knowledge from other functions. In the case of company B, internal cooperation was strengthened through a mix of focused project developments and larger group meetings that involved up to forty employees from different functions and subsidiaries. Although company B’s project team consisted of internal members, there was a continuous possibility to take in additional knowledge from the network. Company A and B continuously harmonized their activities with other ongoing projects and hence, allowed to take in additional knowledge from the network. Thus, the insights suggest that besides the internal cooperation, digital innovation management is strengthened through collaboration with the company wide network.
**P1:** Internal cooperation through interdisciplinary project teams supports the knowledge intake from different functions and the knowledge diffusion throughout the company and hence, the digital innovation management.

**P2:** Cooperation throughout the company wide network supports the knowledge intake and hence, the digital innovation management.

---

### Table 3: Insights from governance mechanism of 11 IIoT initiatives

With focus on external cooperation, the eleven initiatives differed. The development activities of the four initiatives of company A are conducted internally or in cooperation with the company wide network. Company C had an even stronger focus on the knowledge of internal members. Only company B did involve external partners, exemplifying the agile development philosophy through an early involvement of customers and suppliers. Based on the follow up interviews, the management of company B highlighted that the early collaboration with partners (customers and (technology) suppliers) helped for the internal and external focused innovations. The digital transformation representative of company A confirmed, as he states: “We should have integrated the customer right in the beginning”.

**P3:** External cooperation with partners (customer, supplier, experts) is important for digital innovation management.

The initiatives of company A have been orchestrated by a specifically assigned digital transformation leader. His role was to coordinate the different initiatives and to integrate the various activities throughout the company. In addition, the CEO had a central role, showing the
importance of the digital innovations and fostering its implementation activities. Company B assigned one initiative to the leader of strategic projects (guaranteed machine availability) and the internal focused projects to the COO. Whereas the leader of strategic projects continuously involved employees from different functions and subsidiaries and actively strengthened the informal knowledge transfer, the COO did not install similar coordination mechanisms. At company C, one initiative (Global Service) was assigned to the head of global services. Even though there was a high involvement of the CEO in company C, horizontal coordination mechanisms were missing for the other initiatives.

**P4: Formal and informal coordination mechanism are important to consider for the digital innovation management.**

The analysis of the locus of authority within the cases leads to different insights. In company A, the initiatives are highly linked to headquarters as the offerings of the services lies in the responsibility of headquarters. Being aware of this, the company tried to involve headquarters early and continuously. The locus of authority within company B changed during the innovation process. Whereas in the beginning, the company had the authority to decide, there was a development stop ordered from headquarters. Only after the company achieved a buy-out a restart of the innovation processes were possible. After that, Swiss headquarters was officially assigned to be the locus of authority and, in the case of case B1, successfully continued the project. Similarly, based on headquarters orders, company C was not allowed to invest in the development of digital innovations as headquarters wanted to integrate the initiatives network. Since they were driven from the Swiss site alone, headquarters did not allow continuing with the initiatives before analyzing which other sites from the company wide network needs to be integrated into the development process.

Each of the analyzed initiatives had issues with the locus of authority. It seems that the primary prerequisite is to have it defined and second, to handle changing locus of authority and to adapt the management of digital innovation.

**P5: The definition of the locus of authority is a requirement for digital innovation management. If new requirements lead to a change in the locus of authority, digital innovation management needs to be adapted.**

Only one of the studied initiatives (B1) did integrate the agile development philosophy. The follow up interviews with the leader of the strategic development projects supported the importance of this philosophy, while contrasting the success of the digital innovation (B1) with the two other projects (B2 and B3). Similarly, company A highlights retrospectively that an earlier involvement of customer needs (and pains) and a more agile development process would have helped to speed up the development process.

**P6: An agile innovation process with an early involvement of customers and suppliers as well as iterative phases supports digital innovation management.**

**Conclusion**

The analysis of the management of eleven IoT initiatives exemplifies the difficulties of managing digital innovations within manufacturing companies. We add to literature as we compare the micro-level activities of the development of the IoT initiatives with the relevant dimensions derived from the IS literature on digital innovation and its management. First, we show that a linear development process, as implemented from the manufacturing companies, does not respect the complexity of digital innovations. As suggested from the IS literature on digital innovation, an iterative and agile approach helps to get a better understanding of the
underlying interdependencies. Another influencing factor is the interdisciplinary of teams, which need to be visible throughout the company and act as intermediaries between their functions and the project team (internal cooperation). Third, external cooperation is not only needed in the idea generation phase but during all the development stages. The development of digital innovations is complex and often, there is a lack of knowledge and experience which needs to be incorporated from external partners. Forth, in addition to internal and external cooperation, the cooperation within the company wide network is another important dimension for knowledge intake and diffusion. Fifth, changing locus of authority led to project stops and hence, exemplified its importance. The sixth dimension, horizontal coordination mechanism, shows the need to have defined responsibilities, which covers the interdisciplinary nature of digital innovations.

The exploratory research approach and the comparison with insights from IS literature allows to expand our understanding of digital innovation management. All derived dimensions need to be considered to successfully manage digital innovations within manufacturing companies. Limitations occurs as the development activities are still ongoing. In addition, more cases are needed in order to understand if one of the derived dimensions do have stronger impacts on digital innovation management than others.

Nevertheless, the derived proposition provide a starting point for further research. For example, the locus of authority needs further research attention as despite the clear finding of its importance, it remains open, how subsidiaries need to operate within the realm of headquarters.

Abstract

Developing Product-Service Systems (PSS) is uniquely challenging in terms of both the offering and the development process due to the combination of product and service components. This paper investigates the applicability of agile and scrum method, having originate in the software industry, to the development of PSS to address these challenges in practice. Based on a combination of agile and servitization literature, this paper offers a conceptual framework detailing the applicability of four agile elements (application, management, technical, personnel), and nine scrum elements in three groups (events, artefacts, roles). This research contributes to the servitization literature by extending the knowledge on PSS development and deriving suitable management practices.

Keywords: Agile, Scrum, Product-Service System, Project Management

Introduction

Manufacturers are increasingly seeking to servitize their business through the provision of Product-Service Systems (PSS), compound offerings of products and services. This trend promises the provider high gains including closer customer contact, stable revenue streams, and higher profit margins (Isaksson et al., 2009). However, by far not all manufacturers experimenting with the concept of PSS are able to harvest these benefits. Indeed, the history of servitization shows many examples of PSS development projects, which fail already during the development and never even reach the market. In response, a stream emerged in the academic servitization literature, which discusses in particular the challenges of PSS development.

Core challenges for manufacturing firms in the development of PSS often arise because of the radical nature of the final offering (Baines et al., 2017), the systemic complexity of parallel development of the product and service (Trevisan and Brissaud, 2017), and the difficulty of project execution (Morelli, 2006). Here challenges can arise in the course of defining and testing intangible service elements, as many services are
produced and consumed simultaneously (Lankhorst, 2012). In addition, manufacturers often have to manage the systemic complexity of developing not only the product and the service distinctly, but as a system. Here manufacturers often lack knowledge regarding the diverse interfaces in this systemic integration (Trevisan and Brissaud, 2017). Lastly, uncertainty arising from the unpredictability of the competitors’ actions, the precise customer needs, or other macro-economic changes can impede the development (Kreye, 2017). In short, the development of PSS is often characterized through high uncertainty and complexity (Ramírez Hernández et al., 2018).

While contributions in the servitization literature investigated the challenges of PSS development, no suitable solution has been identified up to date. The PSS development methodologies offered today (Dingsøyr et al., 2012; Vasantha et al., 2012a) are still strongly oriented on the traditional stage gate approach (Aurich et al., 2006; Vasantha et al., 2012b; Weber et al., 2004). Academic literature has however reflected upon uncertainty management in new product or service development. As such, Rice et al (2008) proposed the use of more “agile” methods under circumstances of high uncertainty, and more “staged” methods, under circumstances of low uncertainty. Short development cycles through testing of assumptions about uncertain conditions and incorporating these learnings into the development project to plan the next short iteration are used to navigate these uncertainty conditions. Moreover, Boehm and Turner have investigated the concept of agile further and identified the basis of agile, i.e. when agile works most successful. They distinguish four elements: Application, Management, Technical and Personnel, and discussed their variance for the optimal application in agile. These four elements of agile represent a guidance for where to apply agile.

Further, the concept of agile manifests itself in several methods, of which scrum is one of the most mature and widely applied (Dingsøyr et al., 2012). It is divided into three groups; events, artefacts and roles, with three elements each (Cooper and Sommer, 2016a; Schwaber and Sutherland, 2017). The events include the sprint planning and sprint, the daily scrum, and the review and retrospective meeting. The artefacts contain the product backlog, the sprint backlog, and the increment. The roles are distinguished into the product owner, the scrum master, and the scrum team. These nine elements of scrum provide guidance on how to apply agile.

While the body of knowledge about agile (and its manifestation in scrum) has grown substantially in the field of software, its application outside this realm is still nascent. Specifically, the applicability of agile and scrum in contexts such as PSS development is promising, yet underexplored. Accordingly, we ask the following research question to close this gap:

Which elements of agile and the scrum methodology are applicable to the development of Product-Service Systems?

Based on the analysis of existing servitization and agile literature, we offer a conceptual framework detailing the above-mentioned four elements of agile and nine elements of scrum, in terms of their applicability in PSS development. While describing these elements of agile and scrum is not in itself a new contribution to the literature, assessing their application and adaptation to the PSS development context contributes to theory building in the field of servitization and agile.

Research Design
To answer the research question, we conducted an exploratory literature review based on contributions in the field of agile and servitization. The aim of the literature review was
to create a rich understanding of the state-of-the-art literature and to comprehend the applicability of agile and scrum to the PSS development context. The literature review is based on contributions identified through a keyword search in the search databases including Scopus and Web of Science.

The review of the agile literature included search strings derived from the following keywords: “agile” (Boehm and Turner, 2003; Dingsøyr et al., 2012; Moran, 2015), “agile development” (Conforto et al., 2014; Nerur and Balijepally, 2007), “scrum” (Dybå and Dingsøyr, 2008; Schwaber and Sutherland, 2017), “agile service development” (Cocca et al., 2015; Lankhorst, 2012), “agile product development” (Cooper and Sommer, 2018; Karlström and Runeson, 2006). Similarly, the review of the servitization literature was conducted using keywords “Product-Service System” or “PSS” (Beuren et al., 2013; Mont, 2002; Tukker, 2004), “integrated solution” (Storbacka, 2011), “bundled services” (Schmenner, 2009), “servitization” (Baines et al., 2017; Díaz-Garrido et al., 2018), “PSS development” (Aurich et al., 2006; Wallin et al., 2015; Wuest and Wellsandt, 2016), and “new service development” (Papastathopoulou and Hultink, 2012; Santos and Spring, 2013). Based on the initial findings, we refined and combined the keywords further in the course of the literature review.

The literature review revealed the need to differentiate between the application of agile as a concept and its manifestation in a specific method (Boehm and Turner, 2004). Agile as a concept provides guidelines of a general setting under which agile is best applied. Boehm and Turner, (2004) summarized a framework which distinguished four elements as the general basis of agile: Application, Management, Technical and Personnel. The Application of agile details that it unfolds its full potential in volatile conditions through rapid value creation in small teams. The Management relies strongly on intense customer involvement in the project, with qualitative control mechanisms and strong utilization of tacit, interpersonal knowledge. The Technical element details simple designs, which are easily refactorable in short increments with test cycles, as well as prioritized requirements, which are evolving continuously. Lastly, agile relies strongly on Personnel who are 100% dedicated to the project, working co-located and with a culture of empowerment. These four elements of agile constitute the overall applicability of agile to a certain setting and thus form the basis for our discussion in the PSS development context.

The manifestation of agile finds its way into several methods in practice. One of the most applied and researched methods is scrum, which describes an iterative development process with incremental value delivery. Although scrum is often modified to fit the particular situation, for the purpose of the present research we will refer to the original form derived from the software development (Schwaber and Sutherland, 2017). It distinguishes events, artefacts and roles, with three elements each (Cooper and Sommer, 2016a; Schwaber and Sutherland, 2017). The events include the sprint planning and sprint, the daily scrum, and the review and retrospective meeting. The sprint planning is an event in which the work packages for the upcoming development are planned. The sprint represents the subsequent intense development period of usually 1-4 weeks duration, in which the previously defined work packages are created. The daily scrum represents a stand-up meeting on each day of the sprint, in which each team member reflects on the progress of the developments, as well as potential problems. After the sprint a review and retrospective meeting is held, in which the team reflects upon the developed work, as well as the process through which it was developed.

The artefacts are the product backlog, the sprint backlog, and the increment. The product backlog represents the prioritized list of requirements, which is continually updated to incorporate the learnings of each sprint. The sprint backlog is the amount of
work chosen by the development team to be executed in the course of one sprint. Unlike the product backlog, the sprint backlog requirements do not change during the sprint. The increment is the outcome of the development work in the course of one sprint. It is used in the review and retrospective meeting to test and seek feedback from customers and stakeholders. Based on this feedback, the product backlog is re-prioritized.

The roles include the product owner, the scrum master, and the scrum team. The product owner is the person responsible to update and manage the product backlog to achieve the desired product. The scrum master is the process owner and facilitates the team in the application of scrum, as well as the removal of impediments of the development project. Lastly, the scrum team is responsible for the actual development and consists of a cross-functional, fully dedicated team.

While the application through reduction of uncertainty promises a beneficial application of agile and scrum in PSS, it is however important to note that PSS also differ from the origin of agile in pure software development. While software is intangible, infinitely divisible, and easily refactorable, this is not true for PSS. Particularly the product element of PSS is tangible, most likely not infinitely divisible, and, once produced, only refactorable under additional costs. The service element on the other hand is intangible and often easily refactorable (or adjustable to the customer conditions), but can only fully be tested in the field as it is produced and consumed simultaneously. As such, it remains to be investigated which elements of agile and scrum can be applied to PSS development to address the strong challenges during the development.

Conceptual Framework: Applicability of Agile and Scrum in PSS Development

To answer our research question, we utilize a conceptual framework combining the four bases of agile defined by Boehm and Turner (2003) with the nine elements from the events, artefacts and roles described by (Cooper and Sommer, 2016a; Schwaber and Sutherland, 2017). We apply this framework to assess the suitability and adaptation of agile and scrum in the specific context of PSS development.

Agile Elements

(1) The Application
The first basis of agile, the Application, is highly similar to the original description, as regularly also in PSS development, volatile conditions have to be managed and customer needs addressed. In addition, PSS often possess systemic complexity between the product and the service part, which implies that scrum needs to be scaled to coordinate the separate developments of several components (e.g. service and product components) in parallel through e.g. “scrum-of-scrum” (Dingsøyr et al., 2018). Overall, no adaptation to the element of Application to PSS development is needed.

(2) The Management
For the basis of Management, small adaptations have to be considered in the PSS context. The development of PSS may be highly customer focused and involve a close collaboration or even co-creation with the customer (Kristensson et al., 2008; Vargo and Lusch, 2008). It also often relies strongly on communication and team collaboration (Wolfenstetter et al., 2015). However, large and traditional enterprises moving towards servitizing their business through offering PSS are likely unable to abandon their legacy plan-based and KPI-driven development and solely rely on qualitative control mechanisms and tacit, interpersonal knowledge (Boehm and Turner, 2005). This organizational resistance to agile may be overcome through change management
practices. As such, the agile basis of Management is generally applicable to PSS development, calls however often for additional change management practices.

(3) The Technical
The Technical basis of agile partly conflicts with the characteristics of PSS. Some PSS can possess a high systemic complexity, which arises from the combination of (tangible) product and (intangible, process-focused) service elements. This combination creates high interdependencies to ensure operability of the Product-Service System. As such, the service has to be tailored to the product characteristics, and the product design should consider the service-ability (Trevisan and Brissaud, 2017). Due to this strong limitation, literature proposes a more structured approach such as the application of e.g. the Scaled Agile Framework (SAFe) (Leffingwell et al., 2013), to coordinate the integrated development. In addition, the product element is not as easily refactorable as pure software code due to its tangibility (Conforto et al., 2014) and thus, limits the optimal operation of agile as suggested by the Technical basis. However, PSS generally complies with the struggle of volatile requirements and the need for testing the developed increments (Morelli, 2006; Wolfenstetter et al., 2015) mentioned for the Technical basis. Concluding, while some parts of PSS development characteristics comply this Technical basis, others call for strong adjustments.

(4) The Personnel
Lastly, the agile basis of Personnel is again partially applicable to PSS development. While PSS development thrives on cross-functional teams with high customer engagement (Wolfenstetter et al., 2015), traditional manufacturers regularly struggle with full staffing of the employees on the project. In addition, large organizations are often regionally spread out, which hampers the ability to develop with co-located team members (Conforto et al., 2014). Furthermore, traditional manufacturers may struggle with the transition from a hierarchical towards a flat and empowered culture (Paasivaara et al., 2018). As such, in principle PSS development complies with the Personnel basis of agile; in practice however, manufacturers may need to adapt agile to operate within the existing structures of the organization.

Scrum Elements
(1) Sprint and Sprint Planning
The first event consists of the sprint planning and sprint. The agile literature has already investigated the applicability of the sprint planning and sprint to new service development as well as to new product development in separation. In new service development, the service may be developed through planned, time-boxed iterations and short feedback cycles with the customer (Cocca et al., 2015; Lamberth-Cocca and Meiren, 2017; Lankhorst, 2012). In new product development however, the sprint planning and sprint is not as easily applied. Due to the tangibility of the product, many teams struggle to decompose the physical product into several fully-functional sub-products which are developed in sequential, periodic sprint cycles. As such, not every sprint planning and sprint may be able to create a functional sub-product that can be demonstrated to the customer as originally defined. Rather, several sprint planning and sprints may be required to deliver the concept, the CAD-model or drawing, the testable component, an integrated prototype, and finally the product (Cooper and Sommer, 2016b). In addition, the systemic complexity of integrating product and service elements calls for a more structured approach to coordinate the interrelation between them (Morelli, 2006; Wolfenstetter et al., 2015). To answer these limitations of PSS development to a pure sprint planning and sprint, literature proposes a more linear agile process, called the Agile-Stage-Gate hybrid (Cooper and Sommer, 2016a). Here the linear development
mode and the periodic control of the stage gate process are merged with agile sprints in between the gates.

(2) The Daily Scrum
The second event, the daily scrum, is intended to foster a short, intense exchange of the most critical information regarding the development project (Paasivaara et al., 2012). PSS development frequently also builds upon intense collaboration between the team members to coordinate the systemic complexity (Trevisan and Brissaud, 2017). The daily scrum is thus easily transferrable to the PSS development context and may even enhance the collaboration.

(3) The Retrospective and Review Meeting
The third event of scrum is called the retrospective and review meeting. Here lessons learned are implemented already in the course of the development project. In contrast, in traditional PSS development literature, the revision of the PSS developed and a reflection on the underlying process is conducted after finalizing the PSS (Aurich et al., 2006; Vasantha et al., 2012b). Thus, the lessons-learned are implemented in the subsequent development project. Given the often high degree of uncertainty in PSS development, fast learning and adaptation is not only transferrable, but also strongly recommendable.

(4) The Product Backlog
The first artefact of scrum is the product backlog and comprises a prioritized list of features the final offering should have. It represents the counterpart to the detailed requirement specifications in PSS development (Aurich et al., 2006). However, the product backlog of scrum is a tool which acknowledges the degree of uncertainty connected to the requirements and is thus constantly updated (Schwaber and Sutherland, 2017). Due to the uncertainty in the context of PSS development (Morelli, 2006), the application of ongoing adaptable requirements can be recommended. As the most important items of the product backlog assure the most important items for the creation of customer value (Schwaber and Sutherland, 2017), the application of the product backlog (in combination with iterations collecting customer feedback) enhances customer satisfaction (Cooper and Sommer, 2018). Since PSS often aim to create strong long-term customer relationships (Beuren et al., 2013; Visnjic et al., 2016), the application of the product backlog may not only reduce uncertainty, but also strengthen the customer relationship (and satisfaction).

(5) The Sprint Backlog
The second artefact is the sprint backlog. The sprint backlog is the selection of the most important requirements to be developed in one sprint and remains unchanged in the course of this sprint. At its core, the sprint backlog provides the team with the necessary structure and implies a small plan-based approach: after planning the requirements, the actual development is carried out. Traditional PSS development methodologies follow this logic (just at a larger scale) (Aurich et al., 2006; Vasantha et al., 2012b). Accordingly, if the structure of periodic sprints is to be used, the sprint backlog should be easily transferrable to PSS development.

(6) The Increment
The third artefact is the Increment. This is the complete, functional, testable and releasable outcome of a sprint (Schwaber and Sutherland, 2017). Although in the context of new service development, the increment could be easily applied (Cocca et al., 2015; Lamberth-Cocca and Meiren, 2017; Lankhorst, 2012), in the context of new product development the original definition of the increment is troublesome (Cooper and Sommer, 2018; Karlström and Runeson, 2006). As elaborated before, the physicality of the product hampers the development complete and functional product increment (Karlström and Runeson, 2006). Research from the use of scrum in product development...
proposes here a redefinition of the increment towards “a complete and testable deliverable”, which can thus also be applied in the context of PSS development (Cooper and Sommer, 2016b).

(7) The Product Owner

The first role is the product owner. The product owner is responsible for the prioritization of the product backlog and the stakeholder management to ensure management support (Schwaber and Sutherland, 2017). In PSS development, this role requires a strong understanding of both the product and the service elements, as the product owner must continually re-prioritize the requirements for the entire project. While the role as such is easily applicable to PSS development, in practice it may require senior experts to execute this role (Dikert et al., 2016).

(8) The Scrum Master

The second role is the scrum master. The scrum master is responsible for the correct execution of the scrum methodology and the removal of obstacles the development team may encounter (Schwaber and Sutherland, 2017). In the context of PSS development, organizational resistance can arise as both, the PSS offering (Visnjic et al., 2016) and the scrum process (Dikert et al., 2016), may be novel to the organization. Therefore focus should be laid on a properly trained scrum master with strong stakeholder management capabilities (Boehm and Turner, 2005). Overall, the scrum master should be easily applied to any PSS development project.

(9) The Scrum Team

The scrum team is defined as the last role of the scrum methodology. Here, in the original definition the team should be fully dedicated, co-located, empowered and cross-functional (Schwaber and Sutherland, 2017). As mentioned in the Personnel element, full dedication, co-location and empowerment can be challenging for traditional manufacturers. The scrum methodology specifies however, that the full potential of scrum can only be reached if the elements are kept as defined – specifically the fully dedicated and co-located team (Boehm and Turner, 2005). Weakening of this requirement would strongly impact the team’s ability to learn and adapt fast. Accordingly, an adaptation for this challenge could be to apply scrum only to highly critical projects of PSS development with high uncertainty. In short, the application of the scrum team in its original sense poses challenges to traditional manufacturers, but should not be compromised when applied in the PSS context.

Figure 1 summarizes our conceptual framework. In sum, the concept of agile is generally applicable to the PSS development context. While some elements are fully or through smaller adaptations directly transferable to PSS development, the Technical element requires major adaptation in the PSS context. The same accounts for the application of agile through the method scrum. Some elements are easily transferrable to the PSS development context, while others need major adaptations.
Implications and Conclusion

In this paper, we investigate the question of which elements of agile and scrum are applicable to the development of Product-Service Systems. Through an exploratory literature review, we derive a conceptual framework based on the literature streams of agile and servitization. This framework distinguishes four elements of agile, and nine elements of scrum, which are each discussed in the context of PSS development. While the concept of agile and scrum have already been discussed in depth in the software development literature, we investigate the expansion of its application areas to the context of PSS, which has not been discussed previously.

This framework contributes to the servitization literature by discussing a theoretically founded, alternative development approach of PSS through the application of agile and scrum. Through uniting the bases of agile with a method of implementation, scrum, we help solving the challenges during the development of PSS due to its often volatile and uncertain conditions.

This framework contributes to the servitization literature by discussing a theoretically founded, alternative development approach of PSS through the application of agile and scrum. Through uniting the bases of agile with a method of implementation, scrum, we help solving the challenges during the development of PSS due to its often volatile and uncertain conditions.

This paper also contributes to the agile literature by expanding its areas of application. Through the theoretical discussion of the application of agile and scrum in PSS development, we test its functionality from the original realm of software. We reveal its strengths and limitations in the context of PSS, and expand the discussion through the proposition of potential adaptations needed for this application.

For managers, this research holds several implications. The proposed framework raises awareness to the distinct circumstances of PSS development. It provides managers further with a guideline on when to apply agile management methods, and how scrum can be utilized in the context of PSS development. It also gives suggestions on how to adapt scrum specifically to the PSS development setting.

This research bases on the retrospective and conceptual analysis of academic literature, which represents a major limitation for the validity of the framework. Further research is planned to advance the insights from this framework through case-study research.

The influence of intrapreneurship on the introduction of process innovations for administrative processes in context of digitization projects

Sebastian Kasselmann (skasselmann@ipri-institute.com)
IPRI – International Performance Research Institute gGmbH, Stuttgart, Germany

Abstract

Industry 4.0 and the digital transformation of economy and society are currently dominant topics. Process innovations aim to optimise existing processes in the company. Administrative process innovations in particular, such as robotic process automation, represent radical organisational change. Intrapreneurship is an opportunity to promote innovations. My dissertation therefore considers the following research question: How does intrapreneurship influence the introduction of administrative process innovations in the context of digitisation projects? New insights are expected for executives and experts regarding the design of organisational structures to promote intrapreneurship.

Keywords: intrapreneurship, administrative process innovation, project management

Derivation of the research question

Industry 4.0 and the digital transformation of economy and society are currently dominant topics. Both concepts lead to fundamental changes. Under these framework conditions, process innovations, such as the digitalisation of production and the digital transformation of controlling (e.g. through the introduction of SAP S4/Hana), can enable promising solutions in international competition for industry in Germany (Gassmann/Schweitzer, 2018; Malanowski/Brandt, 2014). Administrative process innovations in particular, such as the introduction of shared service centres or robotic process automation, represent radical organisational change that can generate considerable savings potential (Svatopluk et al., 2018; Dietrich et al., 2014; Beck et al., 2008). Furthermore, competitiveness requires continuous process innovation. Process innovations pursue the goal of optimising existing processes in the company, for example to be able to produce a product more cost-effectively or with higher quality by using new raw materials. Formally, this innovation represents at least a further development of the original process and contributes to increasing entrepreneurial success from the earnings perspective. Companies must enable organisational structures that promote the introduction of process innovations (Grübner, 2007; Eversheim, 2003; Wettengl, 1999). In the following, only projects that pursue the goal of introducing process innovations are considered (Gerpott, 2005; Antoncic/Hisrich, 2001).

Intrapreneurship is often attributed the role of innovation driver within a company (Heim, 2015; Völker et al., 2011; Haid, 2004). This term is used to describe the entrepreneurial spirit of employees in established companies or existing organisations (Hauschildt/Salomo, 2011; Hisrich, 1986). Intrapreneurship is a people-oriented...
approach in which employees are seen as a decisive factor for entrepreneurial behaviour within a given organisation (Schießl, 2015; Becker, 2008; Pinchot, 1985). This means that an employee in an established organisational environment is motivated on his own initiative and perseveres despite internal resistance to implement innovative ideas within the organisation. It can be assumed that at least 16% of the members of an organisation are intrapreneurs. According to a study by Engelen and Weinekötter, there are four different groups of employees within a company: blind activists with high entrepreneurial activity and low entrepreneurial potential, stabilisers with low activity and low potential, passive intrapreneurs with low activity but high potential, and active intrapreneurs with both high activity and high potential. Both active and passive intrapreneurs are relevant for this study (Engelen/Weinekötter, 2015). Employees act as promoters in the introduction of innovations. Promoters are people who actively promote an innovation process (Witte, 1973).

Implementation in the form of project management links the social (human) with the technical subsystem on the one hand, and the organisational structures on the other. The future management of process innovations must consider the increased requirements during the implementation; time, budget, and quality requirements are essential here (Lischka, 2011). It is still unclear what influence intrapreneurs have on the introduction of process innovations.

The following question is derived from the problem: How does intrapreneurship influence the introduction of process innovations (with a focus on administrative processes)? To answer this question, the following sub-questions (Figure 1) must be addressed:

1. What are the characteristics of process innovations with a focus on administrative processes in the context of digitisation projects?
2. What characteristics and behaviours do intrapreneurs exhibit when introducing administrative process innovations?
3. Which essential factors (people, technology, and organisation) influence the introduction of process innovations?
4. What implications for research and practice can be derived from this?

![Figure 1: Context of the research question and sub-questions](image)

The first sub-question deals with the properties and characteristics of process innovations. These are to be operationalised with regard to the different properties and characteristics.

The second sub-question serves to investigate the characteristics and behaviours of intrapreneurs in the introduction of process innovation, which also needs to be operationalised.
The third sub-question focuses on the interrelationship (moderator, mediator) between intrapreneurs and the essential factors (technology, organisation, and personnel) for the introduction of process innovations.

The fourth sub-question concerns recommendations for action for research and practice. Implications for corporate management are to be derived with regard to the identified influencing factors for increasing competitiveness.

The aim of this research project is to prove that intrapreneurship influences the introduction of process innovations.

**Proof of the scientific relevance of the research question**

The research question focuses on the influence of intrapreneurship on the introduction of process innovations. The following presents the current state of research on intrapreneurship and process innovations. Subsequently, the research question is justified based on the research gap identified in the literature.

**Classification of intrapreneurship**

To date, research in the field of intrapreneurship has focused on the framework conditions for the occurrence of intrapreneurship in companies. The characteristics, influencing factors, and prerequisites for intrapreneurship in the company have been identified. At the organisational level, intrapreneurship is often subsumed under corporate entrepreneurship (Lumpkin et al., 2009; Green et al., 2008). Intrapreneurship can be classified using a comparative classification scheme. For this purpose, a distinction is made between the employment relationship and the behaviour of the individual on the basis of two characteristics (Wennekers, 2006). First, the employment relationship may be either self-employed or salaried. Second, behaviour is divided into three dimensions: entrepreneurial behaviour, which is dedicated to the new economic focus (for example, the new business models); leading behaviour, which pursues the coordination and organisation of existing resource combinations; and non-leading behaviour. The intrapreneur shows the same behaviour as the entrepreneur; the difference is in the employment status (Wennekers/Thurik, 1999).

**Classification of process innovation**

The concept of innovation is not defined uniformly in the literature, but is always understood as the creation of something new (Stummer/Günther, 2013). In most cases, process innovations are described as redesigning or improving the performance of a company. Their aim is to increase productivity and efficiency, which is usually accompanied by quality improvements and cost reductions (Perl, 2007). One can refer to different business processes: material processes (for example, manufacturing a product) and informational processes (for example, exchanging and processing information). The present work exclusively considers administrative processes, in the sense of informational processes (Vahs/Brem, 2015). For this purpose, it is of fundamental importance to design the organisation in companies, which differs in terms of process and organisational structure. The process organisation structures the activities in the company, while the organisational structure bundles competencies into an organisational chart. The administrative processes (including administrative activities) are reflected in the cross-sectional functions of the organisational structure (Spath et al., 2017). Examples include the introduction of shared service centres and the integration of robotic process automation in accounting and controlling. Although process innovations have a considerable influence on the success of a company, both research and practice focus on product innovations.
Scientific approaches to the influence of intrapreneurship on process innovation

In general, the development of an innovation takes place in different phases (see Figure 2). This PhD project focuses on the realisation and usage phase. In this phase, the innovation is introduced by a project team, and adapted in the three areas of organisation, technology, and human resources. The realisation and utilisation phase extends from adaptation to actual implementation and the subsequent test run. From a formal point of view, the test run continues into the usage phase. This is indispensable for the measurability of the success of an introduction. Adaptation in particular usually takes place through the interaction of several people within a company.

As a rule, innovations are implemented in the company with the help of project management, which is the cross-sectional discipline of general business administration that ensures the professional handling and achievement of objectives in projects (Krings, 2012). This consists of different employees with different roles. Witte's promoter model distinguishes three basic types: the professional promoter, who brings competence and creativity into the project as resources; the process promoter, who brings in social connections; and the power promoter, who provides financial resources. Promoters are people who actively and innovatively promote an innovation process. When introducing process innovations, project management has the greatest influence on personal characteristics, leadership, and tactics. It is also possible to institutionalise cooperation between promoters within the framework of project management. The promoter model considers the different roles in the implementation of an innovation. During innovation, there are usually factual and personnel barriers that disrupt the process flow. Different promoters counteract these different barriers (Hauschildt/Salomo, 2011).

So far, research has not investigated how intrapreneurship affects the introduction of process innovations. In this context, the question is how intrapreneurs can act as...
promoters for the introduction of process innovations due to their intrinsic motivation to act entrepreneurially (see Figure 3).

Measurability of the influence of intrapreneurship on the introduction of process innovations

The interaction between people, technology, and organisation within a company (socio-technical system) is a complex entity (Preisendörfer, 2016). It can be mapped using system theory as a complexity-reducing modelling approach. A model is used to simplify the representation of a real system (see Figure 4) with the aim of identifying cause-effect relationships.

Projects can be monitored and controlled by means of project management and controlling. The methods used for this purpose ‘serve the purpose of comparing the planned with reality in order to then derive project changes from it if necessary’. In the classical literature, the triangle of time, cost, and result or quality is used to measure the success of a project. In accordance with DIN EN ISO 9000:2015-11, the term ‘quality’ refers to the ‘degree to which a set of inherent characteristics meets requirements’. The task is to achieve the project goal by a fixed date and with a certain amount of resources made available at the beginning of the project. Project controlling focuses on monitoring schedules, reviewing and planning the resources to be deployed, and controlling the degree of completion. Performance measurement is based on operational and strategic aspects (multidimensional criteria) (Bösch, 2007). The qualitative recording of introduction processes in terms of duration, dynamics, complexity, and uncertainty is problematic. The introduction of process innovations requires the control and motivation of the project team and proof of performance (Pleschak/Sabisch, 1996). The failure of an introduction is often the result of a misdirection of resources.

Figure 4: System theory (Haberfellner, 2015)

The research question encompasses three research fields: intrapreneurship (element for increasing company profits), process innovation (securing economic performance), and project controlling (measurability of project output). Gawke et al. and Newman et al. postulate that intrapreneurship has an effect on corporate performance and on the organisation. They provide an impetus for the research question chosen here, since to date no study has investigated project performance in the introduction of process innovations in the context of intrapreneurship research (Newman et al., 2018; Gawke et al., 2017).

Proof of the practical relevance of the research question

Innovation management plays an important role in companies. The focus is not on the actual implementation of innovations, but on their development in general. However, less importance is attached to process innovations, although they are a partial goal to achieve cost and quality leadership (Haneda/Ito, 2018). Moreover, studies show that process innovations increase competitiveness. According to a ZEW study, process innovations increase the efficiency of companies by 3.2%. This success is measured by the reduction of the average costs per unit or per process. The ZEW study further indicates that approximately 28% of companies in the manufacturing sector initiate process innovations every year. From a business perspective, companies should promote intrapreneurs by
creating structures that make intrapreneurship within the company possible in the first place (Rammer et al., 2017).

In the present feasibility study, interviews were conducted with managing directors and executives from the mechanical and plant engineering industry and the manufacturing sector. The aim of these interviews was to discuss the practical relevance of the research question. The surveyed companies expect high potential in the identification of intrapreneurs for the introduction of new processes in management accounting. However, the influence varies with the degree of the process’s innovation. Companies are aware of the potential of intrapreneurship, but hesitate to promote this approach.

**Proof of the degree of innovation of the research question**

Although many studies have already dealt with the topic of intrapreneurship, its influence on the introduction of process innovations has not yet been explicitly addressed. There is a lack of research measuring the potential of intrapreneurs in the effective and efficient introduction of process innovations. The present study is the first to combine the introduction of process innovations with the topic of intrapreneurship. To measure project success, this study proposes a project scorecard adapted to the specifics of intrapreneurship in addition to general quantitative key figures and qualitative statements. The degree of innovation of this dissertation project can be justified from both a scientific and a practical perspective (see Table 1).

**Research design to answer the research question**

This project can be divided into three dimensions with different objectives. To answer the research question, a suitable research design is required that is empirical and application oriented. Hence, the research design consists of descriptive, model designing, and model sampling phases (Horváth, 2007).

Qualitative phase
First, the relationships under investigation (Figure 1) are operationalised (Schnell et al., 2014). To this end, the research field is defined: the theory of social networks (network theory) provides the framework for the present dissertation (Schwaiger/Meyer, 2011). Social networks are associations of concrete and abstract actors connected by relationships. At the heart of this framework is the explanation of the impact of individual action on the network. The theory has been used since the 1930s in the analysis of social networks and in organisational research. The actor network theory is an extension of the network theory (Latour, 2007). It can be used to explain the relationships between the members of the project team and their influence as a network on the project outcome. The conceptual frame of reference for the influence of intrapreneurship on the introduction of process innovations within project management is validated by a literature analysis and expert discussions. The theory-based explanatory model is based on these findings. Therefore, an extensive literature analysis is used to derive hypotheses that explain the relationship between the properties of an intrapreneur and his or her influence on the introduction of process innovations as a function of the moderators in the SEM. After deriving the hypotheses and developing the explanatory model, the research question is analysed by means of a questionnaire study (see quantitative phase).

**Quantitative phase**

The quantitative phase includes data collection and evaluation. First, data will be collected by means of a questionnaire and project controlling. The questionnaire will be answered by all members of the project team, including x-Intrapreneurs. The project success will be determined by data from project controlling and by an interview (using the critical incident technique) with the project manager. Since project teams consisting of different employees are critical when innovations are introduced, it is necessary to measure the relevant facts in the company at employee level (Homburg et al., 2012).

Jong et al. (2015) uses a multi-item measuring instrument for the evaluation of individual entrepreneurial behaviour, which allows firm statements to be made about this behaviour. Three questions are asked on each of the three dimensions of innovation, proactivity, and risk-taking, and employees must rate these on a 7-point Likert scale. The average across all dimensions provides information about the degree of individual corporate entrepreneurship (=intrapreneur) (Jong et al., 2015). The project success is determined on the basis of the relative deviations between planned and actual values of the project planning. The ‘iron triangle’, which consists of budget, time, and quality key figures, serves as a key performance indicator (see Figure 5).

The data is then evaluated. In this study, a structural equation model (SEM) is expected to be used for this purpose (see Figure 6). This can explain real, complex facts (explanatory models), but the user must have a clear idea of the context of those facts.
The model serves to illustrate the relationships between intrapreneurship and the introduction of process innovations. Furthermore, the model explains the influence of the moderator variables. Subsequently, statements about correlations between different variables are possible, which can be confirmed by empirical testing (Weiber/Mühlhaus, 2014).

![Figure 6: Provisional structural equation model](image_url)

**Interpretation phase**

After evaluating the preceding steps, the collected results are discussed in practice and subsequently converted into recommendations for action. In practice, these should help to recognise the phenomenon of intrapreneurship in peripheral areas of innovation management and to exploit its positive effects. These recommendations are again validated in practice based on 10 interviews with representatives of three large, three small, and three medium-sized enterprises as well as one representative from the scientific community. As a result, a catalogue of recommendations is created for the design of the technology as well as for the organisation and personnel management for the introduction of process innovations by intrapreneurs.

**Feasibility of the research design**

As described in the previous section, the research design requires an empirical examination of hypotheses to answer the research question. For this purpose, primary data are collected by means of a questionnaire study and used as an empirical basis. To ensure the quality of research, care is taken to meet the requirements of objectivity, reliability, validity, and generalisability of the results (see Figure 7).

![Figure 7: Ensuring the quality of research](image_url)

**Conclusion**

As discussed in this paper, it is relevant for companies to know whether an intrapreneur in the project team has a positive effect on the project outcome. This analysis aims at identifying practical implications for project management in order to optimize the composition of projects with regard to the characteristics of intrapreneurship.

Two major conclusions can be drawn from this paper. First, intrapreneurs influence project success in some way. The intrinsic motivation is likely to ensure that the project...
will probably fulfill the KPI. All team members will be examined for their intrapreneur score by answering a questionnaire. Idea: A high score leads to a lower exceeding of the Δ-KPI. Second, all intrapreneurs must be identified role-specifically, i.e. the role in the project must also be clearly measured by using questionnaires. This information will later be relevant for project management, as it can be used, for example, to derive meaningful incentive systems for employee management.

As an outlook, the next steps of this research are described briefly. Based on the findings of this paper, the theoretical framework is used to derive research hypotheses. Next, data is gathered using a questionnaire design. The hypotheses are evaluated using a SEM. Finally, interviews are conducted and practical implications are derived.

Abstract

Digital process innovation—defined as the use of digital technology for process innovation—has recently become a new orientation of manufacturing companies to solve operational problems; however, the actual impact of digital process innovation is still unclear. In this research, we study the actual effect of digital process innovation on organizational performance. We further examine whether the impact of digital process innovation is strengthened if manufacturing firms increase their absorptive capability and their slack resource. This research provides valuable insights into how to effectively implement the strategy of digital process innovation.

Keywords: Digital process innovation, Absorptive capacity, Slack resource

Introduction

Operational problems, such as high-volume inventory, continuously increasing operational cost, operational inefficiency, are usually the concerns of the conventional manufacturing process (e.g., Boston Consulting Group, 2014; Kearney, 2016). Recently, digital process innovation—defined as the use of digital technology for process innovation—has become a new orientation of manufacturing companies to solve such kind of operational problems and has demonstrated its effectiveness. Taking GE Company (d’Aveni, 2015) as an example, it adopted digital technology in the production mode transformation of an engine from the assembly of twenty separate cast parts into direct production of one piece. This saves 75% of the operational cost. Nevertheless, there are some other concerns towards the effect of digitized operational processes. For instance, more energy is required in three-dimensional printing than in the traditional injection molding (Chen et al., 2015). Thus, the actual impact of digital process innovation is still unclear.
In this research, we study the actual impact of digital process innovation on organizational performance. We further investigate operational factors that may exert significant bearing on digital process innovation to enhance a firm’s performance. Specifically, we examine that the impact of digital process innovation is strengthened if manufacturing firms increase their knowledge absorptive capability and their slack resource.

**Theoretical Background and Hypothesis Development**

Digital process innovation enables firms to promptly and accurately identify customer requirements and preferences and to offer customized even new products that, in turn, better meet customer individual requirements (Armenakis and Harris, 2009; Ye et al., 2007; Judge et al., 2009). This may result in increasing firms’ performance. Hence, we hypothesize that the adoption of digital process innovation can improve a firm’s performance, as shown below.

**Hypothesis 1:** Digital process innovation enhances organizational performance.

Operational absorptive capacity is referred to the capability of an organization’s operational units to obtain, assimilate and exploit knowledge from external source (Patel et al., 2012). In a company, when its operating unit has absorptive capacity, the unit is more likely to have the ability and flexibility to obtain, assimilate and exploit the information provided by external parties and required for the implementation of digital process innovation, leading to higher organizational performance. Therefore, we hypothesize:

**Hypothesis 2:** Absorptive capacity of a firm positively moderates the relationship between digital process innovation and organizational performance.

Slack resource is defined as the buffer resource, in excess of the minimum necessary resources for a firm’s daily operation, for coping with environmental uncertainty (Nohria and Gulati 1996). Companies with slack resource are likely to have buffer resource as safeguard to present the risk imposed while implementing digital process innovation, leading to enhanced organizational performance. Thus, we have the following hypothesis.

**Hypothesis 3:** Slack resource of a firm positively moderates the relationship between digital process innovation and organizational performance.

**Methodology**

We conducted a longitudinal event study to test the effect of digital process innovation on organizational performance. We focus on manufacturing companies that are publicly listed firms in the Mainland China. Driven by the recent China’s policies such as Made in China 2025 and internet plus manufacturing action (China Daily, 2016), many manufacturing companies have gradually adopted and even have fully implemented the strategy of digital process innovation. Hence, manufacturing companies in the Mainland China are the most proper setting to conduct this study.

We consider digital process innovation as a firm’s official launch of digital innovation initiative for its manufacturing process. Accordingly, we collected the
announcements about the adoption of digital process innovation from Factiva and Wisenews using keywords, for example digital platform, digital channel, digital manufacturing, intelligent manufacturing, additive manufacturing, and three-dimensional or 3D printing. Return on asset is regarded as the performance outcome of the firm. R&D intensity as a proxy for absorptive capability while slack resource is based on inventory level.

Finally, we obtained the relevant announcements from a sample of 168 firms. For these sampled firms, we collected data on return on asset, absorptive capacity and slack resource from the China Stock Market and Accounting Research databases.

Data Analysis and Results
We employed the approach of longitudinal event study to test the causal relationship between digital process innovation strategy and organizational performance. The results show that digital process innovation has a long-term effect on the performance of manufacturing companies. Subsequently, we conducted the ordinary least squares regression to examine the potential moderating effects of absorptive capacity and slack resource on the association among digital process innovation strategy and firm performance. The findings demonstrate that absorptive capacity and slack resource strengthen the effect of digital process innovation on firm’s performance.

Discussion and Conclusion
This research reveals the real impact of digital process innovation on organizational performance in the manufacturing domain and explores the factors to enhance such impact. Specifically, it fills up the gap how to effectively implement the strategy of digital process innovation. This research also provides useful guideline for effective implementation of digital process innovation by considering a firm’s internal absorptive capacity and slack resource.

Abstract

Multi-sided platforms (MSPs) have to evolve over time to remain competitive and to survive on the long term. The evolvability of MSPs can be supported by a modular service architecture. The purpose of this paper is to study how MSPs evolve over time and how service modularity principles can be applied to support platform evolvability. To gain these insights, the study adopts an exploratory case-study methodology. Results highlight different forms of platform evolution and their effects on the main information processing capabilities of MSPs. Subsequently, modularity principles are proposed to support these forms of evolution.

Keywords: Multi-sided platform, Platform evolution, Modularity, Architecture

Introduction

The importance of multi-sided platform (MSP) companies has grown significantly the last 10-15 years (Parker et al., 2016). Well-known examples are Uber, Airbnb and eBay, but also credit card firms such as Visa and MasterCard can be considered as MSP companies. The services offered by these companies, denoted as MSP services, are matchmaking services that create value by linking distinct customer groups, where associates of at least one group prefer to enter into transactions with the associates of the other group (Hagiu and Wright, 2015). Essential for MSP services is the underlying service platform, which is the system with specific information processing capabilities operated by the MSP company that link customers and enable the transactions to be made among them.

Although MSPs services are often considered in the literature as rather static, it is increasingly recognized that MSP services need to evolve (Staykova and Damsgaard, 2017). In their early days, MSP companies generally start with establishing a primary core exchange platform between two customer groups. Then, over time, successful MSP companies tend to evolve and scale by layering new interactions on top of the initial core exchange (Parker et al., 2016). MSPs companies primarily evolve over time to safeguard their market survival when
facing internal and/or external challenges (Tiwana 2014). Adding new features, functionality and interactions to the service platform can help to increase its usefulness, attract more users and remain competitive and value adding in the long term. Hence, being able to evolve over time is an important ability for MSP companies to survive in the long term (Parker et al., 2016; Staykova and Damsgaard, 2017).

The evolvability of MSP services is impacted by the underlying service architecture, where an important design decision is whether to develop an integral or modular service architecture. An integral architecture has advantages especially when the service needs to be developed quickly and to serve a single purpose, often in the early days of a platform. However, in the long run, the literature argues that successful MSP services require a more modular architecture, especially stemming from the inherent need to evolve over time (Parker et al., 2016; Staykova and Damsgaard, 2017). Adopting a more modular architecture allows to easily adding new service components with new functionality (Baldwin and Woodard, 2009; Parker et al., 2016).

Although MSP services gained significant attention in the literature and the potential of a modular architecture is recognized, studies focussing on the implementations and the underlying service architectures are scarce. As Brax et al. (2017) argue, research on modular service architectures is scant in the context of MSP services and attention is needed due to the specific characteristics of this service type. In addition to this, although it is recognized that MSP services need to evolve, MSP evolution remains an ill-defined and rather abstract concept in the literature (Staykova and Damsgaard, 2017). This makes it unclear how MSP services evolve exactly over time. Understanding how MSP services evolve over time is important as this can help to design appropriate modular service architectures that support their evolvability.

Based on these gaps in knowledge, this paper aims to study how MSP services evolve over time and how service modularity principles can be applied to support platform evolvability. This objective is formulated in the following research questions: *How can service modularity principles be applied in the design of MSP services to support MSP evolvability?* To answer this question, the following guiding sub-questions will be answered: (1) What are the main information processing capabilities that constitute the service platform of MSP services? (2) What forms of evolution can be distinguished in MSP services that impact the service platform? (3) What modularity principles be applied in the design of the service platform of MSP services?

By answering these questions, this paper adds to the literature on MSP service evolution and architecture. Specifically, it makes the following contributions. First, the paper contributes by discussing various forms of MSP service evolution and their impact on the underlying service platform that creates the core exchange. Second, the paper contributes by proposing a modular functional framework of the main information processing capabilities that create the core exchange of MSPs to support MSP evolvability.

**Theoretical background**

**Multi sided platform services**

MSP services create value by linking two or more distinct customer groups, where the members of one customer group have a specific interest concerning the members of the other group (Stabell and Fjeldstad, 1998, Parker et al., 2016). Specifically, MSPs exist because they support or enable exchanges to be made between the customers of both sides. These exchanges are often denoted as the core exchanges of the platform (Parker et al., 2016) and would probably not occur without the MSP service. Hence, MSPs create value for both customer sides by minimizing transaction costs (Stabell and Fjeldstad, 1998). The value of MSPs for customers of one specific side often depends on the number of customers on the other side with whom
they can interact, which is referred to as ‘positive network externalities’ (Hagiu and Wright, 2015). Hence, it is important for MSPs to continuously attract new customers on both sides, which can be realized by adding new features (Parker et al., 2016).

**Key platform elements to create core exchanges**

The goal of an MSP company is to repeat and optimize the value creating core exchange enabled by the service platform. To establish/create the core exchange, MSPs generally encompass the following basic key elements (Parker et al., 2016), which are visualized in Figure 1.

![Figure 1 – Key platform elements creating the core exchange](image)

**The Value unit** - The value unit is the key product or service where the core exchange is all about. Based on supplementary information interactions, the platform participants may decide to exchange the value unit. This can occur either through or outside the platform. As an example, in the case of Uber, the value unit is a taxi ride provided by a driver who is matched with the customer by the platform.

**Platform participants** - Core exchanges are always between participants of both sides of the platform, often denoted as the producers and the consumers on the platform. The participants can have one-to-one exchanges, but also multiple-to-one, one-to-multiple or multiple-to-multiple. In the case of Uber, the taxi drivers are the producers on the platform and the customers are the consumers on the platform.

**Supplementary interactions** - Every core exchange enabled by an MSP generally involves two types of supporting interactions. (1) *Information*; every core exchange starts with information interactions between the participants (both sides) and the platform, which enables the participants involved to decide whether, and how, to engage in a further exchange. Information exchanges always takes place through the platform and is therefore one of the fundamental characteristics of a platform business. Uber, as an example, continuously gathers and monitors information from their drivers (e.g. location and availability) and consumers (e.g. locations and destinations). (2) *Currency*; when goods or services are exchanged between platform participants, payment often needs to take place, which can also go through the platform or outside the platform.

**The platform filter** – The platform filter, often a computer algorithm, is used by the platform to determine the best exchanges of *Value units* between the involved platform participants. The platform filter has a significant impact on the ‘quality’ of the exchanges to be made and therewith the value created by the platform for the participants. Input for the algorithms, amongst others, can be the supplementary collected information from participants of both sides and often involves advanced data analytics. In the case of Uber, the platform filter is an algorithm that matches a customer request with a driver.
**MSP evolution and evolvability**

MSP evolution is a rather ill-defined concept in the literature and is studied under different labels, such as platform development (Ruutu et al., 2017), platform expansion (Hagiu, 2006) or the shift of platform boundaries (Gawer, 2015). Besides the use of different labels, there is also difference on what is seen as platform evolution. While some papers see platform evolution more as the growing size of the platform (e.g. in terms of the number of participants affiliated) (Evans and Schmalensee, 2016), other studies see platform evolution more as a change in functionalities offered, increasing an MSPs value proposition to existing and upcoming participants (Edelman, 2015). Within the latter branch of literature, various functional changes are discussed. Some authors argue that just new features and functionalities can be added (Hagiu, 2006; Staykova and Damsgaard, 2017), although it is unclear/unspecified how this relates to the core exchanges provided by the MSP. Others, such as Parker et al. (2016) argue that the value unit exchanged between platform participants can change or that variants can be added. In addition, it is argued that new categories of platform participants, either producers or consumers, can join the platform (Parker et al., 2016). Some papers discuss mergers and acquisitions (also named platform envelopment) as a way to evolve or the creation of additional stand-alone platforms, such as UberEats (Staykova and Damsgaard, 2017).

According to Tiwana (2014), platform evolvability means that MSPs have the capacity or ability to do things in the future that they were not necessarily originally designed to do. To enable this, the architecture, and especially the interfaces, of a platform should be stable over time (Baldwin and Woodard, 2009). This property allows an MSP to be extensible in the near term and exhibit emergent behaviour in the longer term (Parker et al., 2016; Tiwana, 2014).

**Modular service system architecture**

All types of human-made systems, including services, have architectures (Baldwin and Woodard, 2009; Eppinger and Browning, 2012). The concept of ‘service architecture’ is defined by Simon (1962) as “the way/structure in which service system functionalities are decomposed into individual functional elements (e.g. activities and tasks) that together delivers the overall services provided by the system”. The creation of an architecture is the result of a design process and drives service attributes, functioning and overall system behaviour (Eppinger and Browning, 2012). As the service architecture has serious impact on service performance and value, both in the short and long term, a well-designed architecture can support the long-term viability of a service (Eppinger and Browning, 2012).

**Integral vs modular architectures**

Architectures can be characterized on a continuum as being more integral or modular. Where an integral architecture includes a complex (non one-to-one) mapping from functional elements to system components, a modular architecture follows a one-to-one mapping from functional elements to system components (Ulrich, 1995). Moreover, a modular architecture involves a decomposition logic that aims to divide the service system into delineated subsystems that each fulfil a specific function whereby the dependencies within these subsystems are relatively high and those between subsystems low (Baldwin and Clark, 2000; Salvador et al., 2002). Therewith, a system with a modular architecture is composed of modules that are designed independently but still function as an integrated whole (Staykova and Damsgaard, 2015).

**Interfaces**

A critical factor that makes modular architectures so effective is that when systems are cleanly partitioned into subsystems and components, they can work as a whole by connecting and communicating through well-defined interfaces. Interfaces, in general, prescribe how two or more components in a modular system mutually interact (Salvador, 2007). More specifically,
interfaces are the set of rules and guidelines governing the flexible arrangement, interconnection, and interdependence of service system components (De Blok et al., 2014, p. 30). Interfaces manage the connections and inter-dependencies across various types of components that comprise the system and are typically standardized. Therewith, interfaces enable the substitution and exchange of these components and allow that such components can be designed independently (Parker et al., 2016). As argued by Tiwana (2014), essential in the evolvability of MSP services is stable yet versatile interfaces that ensure autonomy between the different service platform modules. This makes the architecture rich in “real options”, and permit its mutation into derivative service platforms.

Decomposition logic
A crucial question in system modularization is how to identify the individual parts of a system or service offering and how to determine which of these parts – alone or together – can be designed as modules (Salvador et al., 2002). This question relates to the decomposition logic, which is the explication of the design choices involved in decomposing a service offering/system into modules (van der Laan et al., 2016).

Methodology
This study adopts an exploratory case-study research methodology (Voss et al., 2002), which is deemed the most suitable as the theory development related to MSP evolution and modular architecture is in its early stages. In particular, the case studies methodology can support identifying key variables and their relationships (Yin, 2009) and allows one to explore unknown phenomena in their natural setting, thereby generating meaningful understanding (Voss et al., 2002). Further, this methodology is appropriate for studying emerging phenomenon in depth, such as MSP architecture and evolution.

Case selection and background
Although the research intents to cover multiple cases from different industries, this paper presents the results of a single case study. To scope the research, we focus on MSPs that provide on-demand matchmaking of the core exchange by the platform, when requested by a customer. That means, the platform participants provide the required input information, and the platform makes the actual match between platform producers and consumers to exchange the value unit (e.g. as in Uber). This is different from platforms where participants themselves make a match out of a list of candidates proposed by the platform (e.g. as in eBay or Airbnb). The unit of analysis is the set of information processing capabilities of the MSP that creates the core exchange.

The selected case for this study is an energy flexibility aggregator. Nowadays, due to the fast introduction of uncontrollable wind and solar energy, energy systems face serious challenges concerning the system balance of energy production and consumption. Energy flexibility aggregators, in general, aim to provide solutions to these problems by steering energy consumption of for example large amounts of household appliances, electrical vehicles (EVs) and industries on the request of Network operators and Energy retailers. In so doing, aggregators function as MSPs, filling an intermediary networking service between ‘Flexibility suppliers’ and ‘Flexibility consumers’.

Data collection and analysis
The main form of data collection was through semi-structured interviews with case managers. A semi-structured interview protocol was developed to guide the data collection. In total, 6 semi-structured interviews were held. Each interview lasted between 35 and 90 minutes. Other sources of evidence were also gathered (Yin, 2009) for triangulation purposes. These include
company presentations, (informal) group discussions, telephone calls and company documents (e.g. PowerPoints, flyers, service contracts, websites, service applications, news items and commercials).

The data were coded and subsequently analysed following an inductive approach. The codes that emerged from the data were grouped into codes related to platform functions, architecture and evolution. All the interviews were coded by the main researcher.

Results
This section describes the results of the study. First the main information processing capabilities of MSPs are described and following the forms of evolutions found in MSPs.

MSP main information processing capabilities
The study’s results show that MSPs encompass the following four essential Information Processing Capabilities (IPC) to realize/establish a core exchange between platform producers and consumers.

1. Inbound information management - This IPC describes the activities in which all kinds of information are gathered from both the Production side and Consumption side participants. This information is necessary input for making the match between Production side and Consumption side participants to create the core exchange. Besides gathering information from the platform participants, the platforms generally also gather various kinds of data from other external sources that can be used by the platform to support the matchmaking. All the data gathered is generally transformed into useful input for the Data analytics and Platform matchmaking functions, described below.

<table>
<thead>
<tr>
<th>Table 1: Information gathered in the Energy flexibility case</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Production side info</strong></td>
</tr>
<tr>
<td>Technical specs of flex device (EVs/HPs), location in the grid, customer preferences concerning charge EV/using HP</td>
</tr>
</tbody>
</table>

2. Data analytics - The Data analytics main function is processing and analysing all gathered data and transforming it into relevant information and insights that can support matchmaking and establish the best possible core exchanges. For example, in the energy flexibility case, various kinds of forecasts are made related to both the production and consumption side of the platform. Concerning the production side, for example the expected heat demand for the heat pumps, the expected upcoming wind profiles, and the expected number of connected EVs per location is forecasted. Ultimately, this is input for predicting the expected available flexibility at the production side of the platform. Concerning the consumption side, forecasts are made about the expected energy market prices and the expected flexibility demand. Output of all these forecasts are input for the matchmaking function.

3. Platform matchmaking - Platform matchmaking is about making the best possible match, in terms of the Value unit(s) exchanged, between platform producers and consumers. Matchmaking is based on specific information from both Production and Consumption side participants and the information processed by the Data analytics capability.

In the case of energy flexibility, two types of matchmaking take place, i.e. Tactical matchmaking and Operational matchmaking. In ‘tactical matchmaking’, the aggregator offers certain aggregated amounts of flexibility (what he is able to provide in a certain time period) as bids to the flexibility requesting party. These bids are based on the forecasts on the expected
upcoming available flexibility. Then, when bids are accepted, the flexibility requesting party can send a flexibility request to the aggregator when a certain amount of flexibility is needed. At that moment, **Operational matchmaking** takes place, in which it is determined what flex devices of the production side will be used to offer the flexibility requested (e.g. the charging of which specific cars will be used to what specific extent). Not all cases use both **Tactical matchmaking** and **Operational matchmaking**. Most cases do not offer specific bids upfront, and only use **Operational matchmaking** when the service is requested.

4. **Outbound information management** - **Outbound information management** involves all outgoing information from the platform, such as communication of matchmaking information to the Production side and **Consumption side participants** of the platform, but also communication of information related to the matchmaking to external stakeholders. For example, requests of money transfers from banks.

In the energy flexibility case, examples of outgoing information to the production side are the actual control signals to all scheduled flexible energy devices to steer energy production or consumption, based on the outcome of the platform matchmaking function.

**Forms of MSP evolution**
The results show four different ways in which platforms evolve over time (Figure 2). In the analysis, the focus was on the forms of platform evolution that have an impact on the functions of the platform. Geographical spread and growth, as an example, is therefore not considered as a form of platform evolution and therefore not taken into account.

![Figure 2: Forms of platform evolution and their impact](image)

1. **Technical evolution: Improved internal functioning** - This form of evolution effects how the core exchange is created/realized by the platform. However, it has no direct functional consequences for the platform customers as it does not impact or change the core exchange or the value unit exchanged. Specific service processes, tasks, components or interfaces are updated and replaced for improved versions, but without changing functionality.

Some examples from the Energy flexibility case are the replacement of a specific matchmaking algorithm by an improved version or adding an improved forecasting sub-module in the Data analytics module.

2. **Additional service features for customers on top of the core exchange** - This form of evolution describes the addition of new features and functionality offered by the platform for the customers, however, without impacting or changing the core exchange or the value unit exchanged.

One example from the Energy flexibility case is the creation of an information dashboard for their flexibility suppliers (platform producers), on which all kinds of customer specific energy information is shown (e.g. info on energy productions/consumption, provided flex, financial gains, etc.). As another example, the case also improved the manner in which EV drivers could set their charging preferences, using an app.
3. New type of participants added to the platform sides - This form of evolution involves adding new types of platform participants to the production and/or consumption sides of the platform. Therewith, it impacts the core exchange and the value unit exchanged by the MSP. Besides, this form of evolution has a significant impact on all the platforms internal information processing capabilities, as new information streams needs to be gathered and processed (i.e. incoming information, new forecasts/data analytics, changes in matchmaking algorithms and new outgoing information).

Concerning the productions side, the energy flexibility case started with EV drivers as their main producers, but over time also enabled wind turbines and households with HPs to provide flexibility. In addition, at the consumption side, the platform started supplying only to the TSO, but now also experiments with providing flexibility to the DSO (having other flexibility requirements).

4. Variance of the Value unit exchanged - This form of evolution is about enabling exchanging variances of the initial Value unit by the platform. Derived from the initial Value unit, variances that differ slightly are also exchanged between the similar platform participants. This form of evolution also has a significant impact on the platform’s internal information processing capabilities, as new information streams needs to be gathered and processed (i.e. incoming information about the new value unit, changes in the matchmaking algorithms and new outgoing information about the new matches).

In the energy flexibility case, the flexibility aggregator initially only offered Frequency Restoration Reserve. However, it now also offers Frequency Containment Reserve, which is slightly different. Both are services based on flexibility, but with different time durations and technical requirements (in terms of kW, kW/h and kWh) to provide. In the end, this effects how electricity devices should be controlled at the production side of the platform.

Discussion & conclusions

Modular functional architecture of MSPs internal IPCs

This section discusses the main theoretical contribution by answering the main research question, which was formulated as follows: How to design a modular functional architecture of MSPs that supports platform evolvability around the core exchange?

Based on the results of this study (i.e. MSPs main IPCs and forms of evolution and their impact on the IPCs) we developed and proposed the following modular functional architecture with associated interfaces (Figure 3). The design is developed in such a way that it satisfies the ‘Independence design axiom’ proposed by Suh (1998). This axiom argues that all functional requirements of a design should be maintained independent of each other. More specifically, it is argued that when two or more functional requirements exist, the design solution must be such that every single functional requirement can be satisfied without disturbing another functional requirement. For this reason, all main IPCs, that needs to be present to enable the core exchange of the MSP, can be seen as independent capabilities. Moreover, both the Inbound information management and the Outbound information management IPCs are split in this design into three separate IPCs, as they all fulfil different functional requirements. Then, to support evolvability, all main IPCs can be supplemented with additional, rather independently operating modules. These modules have standardized interfaces to interact with the other IPCs of the MSP.

A clear data flow can be seen through the platforms IPCs, indicated by the arrows that also represent the interfaces. Information is gathered from multiple sides, processed internally, and then resulting in multiple outgoing information streams to the platform participants and external stakeholders. No clear logical starting point exists in the information flows, something which is characterizing for MSPs in general.
Figure 3: Modular functional design of MSPs main IPCs

Theoretical contributions
This study makes two contributions to the literature on MSP evolution and architecture. First, the paper contributes by discussing various forms of MSP evolution around the core exchange enabled by MSPs. So far, MSP evolution remained an ill-defined and rather abstract concept in the literature (Staykova and Damsgaard, 2017), making it unclear how MSPs evolve exactly over time. Understanding MSP evolution is important as this can help to design appropriate modular service architectures supporting evolvability. Second, the paper contributes by proposing a modular functional design of the main IPCs that create the core exchange of MSPs with the aim to support evolvability. So far, the literature on MSPs recognized the potential of modular architectures to support evolvability (Parker et al., 2016), however, studies focussing on their implementations and the underlying service architectures are scarce. In addition, argued by Brax et al. (2017), research on modular service architectures of MSPs is limited and requires attention due to the specific characteristics of this service type.

Managerial implications
Beyond the theoretical contributions, this study also has practical implications for MSP service development. The results of this study (i.e. the design a modular functional architecture of MSPs) can be used by both existing and starting business aiming to developing an MSP. The proposed functional architecture can be used as a generic modular blueprint of the main IPCs to be developed, for example by further specifying the specific information processes of the platform to be developed or reengineered. In the end, this can help practitioners to design modular architectures that can evolve over time supporting the long-term viability of their service.

Suggestions for future research
Our exploratory study, and its associated limitations, gives rise to several possibilities for future research. First, while this study focussed on one specific type of MSPs (i.e. on-demand automated matchmaking by the platform), it can be interesting to study other types of MSPs as well. Second, we suggest to study the long-term effects of applying service modularity principles to support platform evolvability. This can be realized by for example longitudinal case studies and a design science approach.

Abstract
The context of Industry 4.0 has been manifested in the farming sector where the wave of Agriculture 4.0 provides multiple opportunities for the farmers, consumers and extends to the world population and nations. The major obstacle in the adoption of Agriculture 4.0 paradigm is associated with the data sharing concerns. Small and medium farms often fail to follow the evolution and applications of Industry 4.0 (nevertheless the multiple opportunities) due to concerns around the data sharing practices. Data sharing agreements and access control should build an essential path for data management among various entities/agents of the farming systems.

Keywords: Agriculture 4.0; Artificial Intelligence; Data Sharing; Argumentation Reasoning

Introduction
Following the recent advances of the information technology in a broad variety of areas and the availability of data in increased volume, in different forms and from various sources, not only digital and technological sectors have shown interest, but also more traditional sectors like agriculture try to benefit from this disruption of the industrial landscape. The wave of Industry 4.0, due to the evolution of Big Data Analytics and the associated capabilities provides opportunities but also new challenges the traditional farming has to overcome. The evolution of Industry 4.0 in the farming sector, Agriculture 4.0, has been manifested in the field as new Big Data initiatives and applications in various areas (i.e. agriculture) are becoming economically viable. The proliferation of data and the associated applications has evolved due to the lower (comparatively to previous years) costs of sensor solutions, data storage and processing in cloud infrastructures, development and expansion of mobile networks and the
transmission of data sets from fields around the world. Data can improve not only individual farms but also a large group of farms that utilise the information, technology, equipment and benefit from a wide range of services. The data evolution and the transformation of the agrarian operating models should not only focus on value creation for the consumers, but also for the individual farmer and the society through the use of Big Data.

Trying to expand the context of Industry 4.0 to the agricultural sector, as stated by CEMA (CEMA - European Agricultural Machinery, 2017a, p. 1) the “‘Digital Farming is structurally similar to the concept of Industry 4.0’’. In our study, we follow the definition of Industry 4.0 which ‘entails a confluence of technologies ranging from a variety of digital technologies (e.g. 3D printing, Internet of Things, advanced robotics) to new materials (e.g. bio or nano-based) to new processes (e.g. data-driven production, artificial intelligence, synthetic biology) and these technologies will be available in the near future.’ (OECD, 2016, p. 3). Nonetheless, the notable distinguishing parameters in agricultural production processes are somewhat different from industrial processes, as agriculture is heavily determined by natural and biological factors (CEMA - European Agricultural Machinery, 2017a, 2017b), and therefore the ‘physical’ artefact should be strongly considered. The terms ‘Digital Farming’, ‘Farming 4.0’ and ‘Agriculture 4.0’ are often referring to similar contexts and therefore are used interchangeably (Lamborelle, 2016; Weltzien, 2016; Yahya, 2018).

In our study, we follow the definition of ‘Agriculture 4.0’ (CEMA - European Agricultural Machinery, 2017a, p. 1) as the ‘evolution in agriculture and agricultural engineering from Precision Farming to connected, knowledge-based farm production systems’. Applying data-intensive practices and Internet-of-Things (IoT) technologies in the areas of agriculture and farming, due to the increasing benefits arising from the data evolution; can provide a lens for ensuring the transparency of the farming practices and sustainability of the food production processes. The focus of Agriculture 4.0 on digitalised ways of farming can generate renewed interest in transforming the traditional operating and process models to digital data-intensive ones focusing on analytics and decision-making practices. The use of data analytics and associated technologies could create value for the businesses that could harness the innovation opportunities arising from this evolution (Duan et al., 2018; Pape, 2016), but also manage the challenges that come along this change.

There is still an open discussion, and multiple challenges about Agriculture 4.0 and specifically a resistance wave from small farms due to data sharing concerns and access control policies of the data available among the multiple parties. Building on the background of data management and the data quality attributes; this paper proposes techniques from Artificial Intelligence (AI) through an argumentation reasoning approach for bridging the data sharing concerns. This approach focuses on the attributes of agricultural data and defining Data Sharing Agreements (DSAs) around specified attributes.

**Theoretical Background**

*Data in Supply Chain Management*

Nowadays, firms from multiple industries invest on data-driven decision-making and business analytics solutions, for improving their performance and operations (Akter et al., 2016; Feki et al., 2016; Wamba et al., 2015). The use of data in supply chain management as well as raw materials in production and service improvement is
presented the last decade as a solution for enterprises to create value by using their analytical skills in visualising, optimising and transforming their supply chains (Hazen et al., 2016; Waller and Fawcett, 2013). Although data can be used along with the core business focus in different industries, we can observe that the recent data evolution expanded the business scope and disrupted the operating models providing opportunities to work solely on data as the main “raw material”, processing this data, creating new products and services and also reselling and exchanging data (Spanaki et al., 2017, 2016).

The analogy of the data production process to a manufacturing process is prevalent in data management studies (Karafili et al., 2018; Spanaki et al., 2017). There are some significant differences between the data production process and the manufacturing process, but also noticeable similarities between these two (Karafili et al., 2018).

- The manufacturing process involves the processing of raw materials as inputs to that process, the materials are refined, and the result of this process is the output in the form of a manufactured product.
- The data manufacturing (production process) involves the data as raw materials and the input which triggers the process, the data is refined in a data product as the output of this process.

The main difference of these two processes is around the quality of data. Data of bad quality used through the data manufacturing process should be cleaned, and tailored until the quality is improved and the data product qualifies to be sold or marketed (Hazen et al., 2014; Jones-Farmer et al., 2014; Yeganeh et al., 2014).

The data manufacturing framing presented in data management literature of the previous decades could be applied in the context of data processing and production. The major concern though, is the fact that it should be extended in a boundary-less context between firms and the target should be innovative outputs, as these are mostly the results of the data evolution (Spanaki et al., 2017). Data manufacturing analogy was based on the data artefact as a unit of analysis; however, data era requires novel techniques focusing on the processing of data but not solely on their processing mechanism, but also the quality and sharing attributes associated with them (Karafili et al., 2018). Data sharing control was not the major focus of data management in previous decades; as the data were mostly shared within the boundaries of a company or between single databases. Dealing with problems of a sole database or a single company, we imply that the trust and security issues were solved by the individual sharing entities and the associated agreements between interested parties.

The Agrifood Supply Chain
The Agri-Food Supply Chain (ASC) encompasses a set of activities that move agricultural products across the chain from production to consumption; the set of operations includes farming, processing, packaging, warehousing, transportation, distribution, marketing (Iakovou et al., 2014). A number of actors are involved as part of these activities such as research institutions, farmers, an agricultural cooperative, intermediaries, manufacturers, distributors, traders, wholesalers, retailers, and consumers (Jaffee et al., 2008). The sector is highly concentrated on retailers and large agricultural enterprises and small scale farms (UNCTAD, 2016). ASC farmers face many challenges due to high input costs, production inefficiencies, high levels of food waste, and low-profit margins (Anderson and Gundel, 2011). All the different ASC stakeholders are
also affected by the sector-specific challenges related to the increasing need for transparency and sustainability, world’s food insecurity, future resource scarcity, limited agricultural land availability, food waste levels across the chain, and supply chain risks (Driscoll, 2012; Fearne, 1998; UN Food and Agriculture Organization, 2011).

ASC has some unique characteristics compared to other food supply chains and in general other supply chain networks (Luo et al., 2018; Tsolakis et al., 2014). Some of these unique characteristics are the following: short shelf-life, seasonality, quality and quantity variability, compliance with national and international food regulations, specific requirements for transport, handling, and storage due to perishability, need for efficiency and productivity, price variability, dependence on weather conditions (Iakovou et al., 2014). These unique characteristics of the ASC in combination with the challenges faced by the ASC stakeholders hinder the effectiveness, profitability and sustainability of the sector and therefore provide a ground for innovation in the field following the technological advances (Meola, 2016).

Data Access and Usage Control

The research focus of data sharing studies usually is around the protection of the data itself (for used and shared data), as well as the databases where they are stored (Gertz and Jajodia, 2008) or the network used for the transfer of this data (Kaufman, 2009). Due to the increasing connectivity between users, there is a parallel increase of the associated security breaches and attacks. Protecting and securing the environment where the data can transferred/stored/used or even re-used was always and is still remaining a major challenge for all the interested parties (Karafili et al., 2015). Data-centric security solutions have dominant position in the literature (Bayuk, 2009; Kim et al., 2010; Pearson and Casassa-Mont, 2011; Wang et al., 2010; Zhou et al., 2010) and specifically the data protection of the data transfers and transactions. Data-centric security solutions present two main challenges associated with the access and the usage control of the data. Both of them, have been widely studied and the research has developed multiple solutions for solving such problems (Ferraiolo et al., 1992; Lazouski et al., 2012). The existing solutions will be presented briefly at this section to distinguish the proposed approach from previous research paths.

Role-based access control according to Ferraiolo and Kuhn (Ferraiolo et al., 1992) can be presented based on specifying the user roles in the data access controls. Motivated by this direction, we expand this context with a data representation technique for specified user roles with defined usage access and policies for the data. Usage control (UCON) as defined by Park and Sandhu (Park and Sandhu, 2004) is a widely studied concept following different approaches, some of them represent the UCON for controlling the access and usage of digital information emphasizing on the problem of rights delegation (Park and Sandhu, 2002).

An additional approach for sharing and accessing data is the use of sticky policies (Pearson and Casassa-Mont, 2011). Sticky polices are machine readable policies that contain conditions and constraints attached to data that describe how the data should be treated while shared among multiple parties. The sticky policy paradigm, technologies for enterprise privacy enforcement and the exchange of customer data are represented through a privacy control language for specified privacy rights and obligations (Karjoth and Schunter, 2002). The privacy control language presents authorization management
and access control for user consents, obligations and distributed administration, with
extension of the sticky policy paradigm also for the cloud environment (Trabelsi and
Sendor, 2012).
Before creating, sharing and using the data, the data subject, controller and processor
should agree regarding the different rules that describe how the data should be treated,
that are called data sharing agreements (Swarup et al., 2006). The DSAs describe not
only the agreements between the data subject, controller, and processor, but also the
compliance of the different business and regulatory contexts for data sharing. A
language representation of different rules for data sharing agreements (DSAs) as
presented by Matteucci et al. (2010) fails to provide expressivity. This language cannot
permit the representation of complex DSAs, as well as analysis for the DSAs and leaves
unsolved the problem of deciding which rules to apply to the DSAs.
All the above represented approaches, from the data access and usage control, to the
sticky policies and finally the DSAs representation, seem incomplete to provide a
decision background for the rules that should apply to the shared data. Following this
motivation, we propose a combinatory analysis of the rules with a conflict resolution
technique. The proposed analysis is based on abductive (Kakas et al., 1992) and
argumentation based reasoning (Bondarenko et al., 1997; Dung, 1995), as this technique
can facilitate decision making mechanisms under conflicting knowledge (Bandara et al.,

Methodological Approach
The approach presented in this study assumes that data are processed by different
entities. Data Sharing Agreements (DSAs) are established between the entities for data
processing composed of various constraints and rules. An expressive policy analysis
language is used in this case for representing the DSAs. Data quality is the main focus
of the data processing mechanism; therefore the policy language is enriched to capture
various data quality properties like accessibility, timeliness and accuracy. The used
policy language permits the analysis of the various policies and the detection of the
rising conflicts, redundancies or the missing cases. We follow argumentation and
abductive reasoning to build our proposed method to capture and solve conflicts
between context dependent rules. The introduced analysis permits the construction of
precise DSAs that can be applied in various contexts during data processing phase.

General Representation Context
We introduce here the general representation context, where we put a background case
of collecting, processing and sharing data. We show in the coming section how our
methodology for Data Sharing Agreements is used in this scenario for naturally
representing the needs of the various actors involved, and effectively deciding who can
access to what part of the data.
The main actor of our scenario has a data-related activity, and decides to start collecting
data around this specific activity. The collection of the data can be made in different
ways: manually, through IoT devices, drones etc. The way the data is collected can
influence directly the accuracy aspect. The collection of data can occur in different
intervals within the day/time, e.g., every hour/day/month, always. The collection
time/period influences the freshness of the data. This freshness is strictly related also to
the type of data.
• The owner of the data-related activity is called the data owner, and in this case s/he is also the data subject, as part of his data are collected as well, e.g., name of the activity, his personal data, and the data controller as s/he determine the purpose and means of processing the data.

• The data recipients are all actors that want to access/use/share the data owner’s data, the stakeholders involved in the activity or similar activities. Data recipients need to comply with the data controller rules.

• Sometimes the owner of the activity relies on third parties that provide the technical support for collecting the data. In this case owner is the data owner/subject but he can delegate the control of his/her activity data to a third party that is now the data controller.

• The data processor is an entity (public authority, agency, legal person) that is processing the data on behalf of the controller. In our use case, the collected/processed/shared data can be stored in the cloud. Thus the cloud provider is considered the data processor as far as it respects the instructions of the controller. The controller rules that should be respected by the processor can also have a legal nature, e.g., if the controller is in an EU country, the cloud provider should as well be in an EU country and cannot send the data to countries outside the EU and EEA.

• A third party is an entity (public authority, agency, legal person) that is not the data subject, data controller or processor, and that under the direct authority of the controller or processor is authorized to process the data. In our case, a company that is outside of the immediate boundaries of the data owner which is granted access can be considered a third party. Once access is obtained, the third party becomes a data controller and has to comply with the data protection principals.

The Policy Language
The proposed model is based on the policy analysis language (Craven et al., 2009) that is constructed using the Event Calculus. This language represents the required rules and constraints for accessing, using and sharing the data. The policy regulation rules are composed of predicates and domain descriptions, and represent the authorization and obligation rules. The authorization rules have in their structure a specific subject, as well as specified targets, and actions. A brief introduction to the language with some of the main predicate is given below.

\[
\text{req}(Sub, Tar, Act, T) \quad \text{obl}(Sub, Tar, Act, T, T_0, T) \\
\text{permitted}(Sub, Tar, Act, T) \quad \text{denied}(Sub, Tar, Act, T)
\]

The above predicate represents correspondingly: a request made from the subject \( Sub \), at the instant of time \( T \), to perform a certain action \( Act \) at the target \( Tar \); the obligation for a given subject to perform an action during the period of time from \( T \) to \( T_0 \); that a given subject is permitted/denied at time \( T \), to perform a certain action to the target. A domain description predicate is \( \text{holdsAt} \), which means that a given property/predicate is true in a given instance of time.

The used policy language can represent the permission, denial and obligation concepts for the DSAs. In the following examples, we introduce the representation of some DSAs rules from our use case.
Example 1. For our example, we assume that the farmer is the owner of the data and wants to access the data. We use the owner property for stating that a given actor is the owner of the data.

Rule 1: The owner of the data can access his/her data with the original quality they were captured.

(1) \( \text{Access(data, O, permitted)} \leftarrow \text{Owner(O, data)} \).

The conclusion of the rule is presented on the left side of the arrow (\( \leftarrow \)) in this case is \( \text{Access(data, O, permitted)} \), which states that subject O is permitted the access to the data. The preconditions of the rule are presented on the right side of the arrow (\( \rightarrow \)). In the above case, the precondition of the conclusion is composed of just one predicate to be satisfied in order to have the conclusion, and it is \( \text{Owner(O, data)} \), which means that subject O needs to be the owner of the data. In case there is more than one predicate to be satisfied, then the predicates are separated by a comma (,) in case they all need to be satisfied, in order for the conclusion to hold, or by a (\( \lor \)) that represent the logical symbol for OR, in case at least one of the predicates needs to be satisfied in order for the conclusion to hold. In case the conclusion is always true, thus it does not need any precondition to hold, then the right side of the arrow is empty.

Example 2. A third party Research Institute wants to access the data and provide tailored services and information about agricultural production, advances in technology (Agri-Tech) and advice on farming practices and activities.

Rule 2: The research institute can access all the data related to a particular product, and the accuracy and timeliness of the data are high.

The research institute can access all the related data of a particular product that they are interested in, and the data are only the production-related data. In this case, as the subject is a research institute \( \text{ResearchI(R)} \), and its main focus is to conduct a scientific research that in the future would bring benefits to the farmer, the quality of the data is not altered.

(2) \( \text{Access(data, R, permitted)} \leftarrow \text{Interest(R, data), ResearchI(R), Prod(data)} \).

Representation of the Quality and Sharing Aspects

The sharing and usage of data raises issues around the description of other properties related to the quality of the collected data. When working with data quality the entities that are using, sharing, storing the data are called data consumers. In our case, the data consumers are considered the data collectors and the data processors. The data quality is an important factor when we are working with data consumers, where data quality is defined as data that fit the requirements for being used by data consumers (Wang and Strong, 1996).

Accessibility: Also another important aspect of data quality is accessibility. Our DSA representation together with the used policies set data accessibility permissions. The used methodology ensures the data accessibility complies to data owner’s constraints, and other legal internal and external frameworks and regulations.

Accuracy: An important data quality attribute which should be met is the accuracy of the collected data. When data are collected by an human actor, we can put in act a deontic obligation for the actor to use a particular accuracy level when collecting and storing the data. This case can suffer from human errors. On the other hand, when a device is collecting the data, e.g., an IoT device, we can be more specific and ensure the data accuracy by checking the parameters of the various devices.
accuracy(\text{Data}, T) \leftarrow \text{holdsAt(meas(Device, Data), T)},
\text{holdsAt(acceptP(Device), T)}.

In the above case, we state that the data collected are accurate, as the device that collected them is able to measure the data with acceptable parameters, (\text{acceptP}), for ensuring data accuracy.

\textbf{Freshness:} Another important data quality characteristic is data \textbf{freshness} which is the degree data represent reality in the required point in time. The notion of data freshness is part of the \textbf{timeliness} as a data quality aspect. For our scenario we will work only on the data freshness predicate, as it represents the data timeliness depending on the different contexts. Data freshness is a predicate that expresses the last time when a given piece of data has been updated:

\textit{freshness}(\text{Tar}, T)

where \text{Tar} is the targeted data, and \text{T} is the last instant of time when the data were updated.

\textbf{Conclusion}

The study proposes an approach for the data sharing problem in Agriculture 4.0, where data can be accessible by different entities. Through the application of Artificial Intelligence (AI) and Logic Programming, we aim to present through case scenarios new ways to build efficient Data Sharing Agreements (DSAs), thus eliminating data sharing concerns which hinder the wider adoption of Agriculture 4.0 paradigm.

Abstract

Recent advancements in digital technologies and a growing availability of data create new opportunities for firms to increase revenues and improve operational efficiency. To date, there is a gap in research describing transition pathways to digital-intensive models of production and operation companies may choose depending on the industry context, company sizes, technology push and market pull forces. This conceptual paper develops a framework of digitalisation stages in firms: analogue, coordinated transition, digitally fragmented, and a full-fledged digital enterprise. Examples from the industry are used to illustrate the framework.

Keywords: digitalisation, technology push, market pull

Introduction

Digitalisation leads to paradigm shifts in the business sector with far-reaching effects on value chains, business models and company structures. According to Gartner (2019), digitalisation is the application of digital resources to change business models and capture new revenue opportunities. Digital transformations unravel in highly uncertain and rapidly changing technological and socio-economic environments characterised by unpredictable outcomes of investments into digital products and services. Digitalisation is largely seen as a powerful intervention into the core business of companies and associated with organisation-wide modernisation efforts (Valenduc & Vendramin, 2017). Recent advancements in digital technologies like AI and blockchain are expected to bring about major changes for how firms are organised and governed and how decision-making is executed and translated into real actions. In order to harvest opportunities and mitigate the risks of digital disruptions, companies both from traditional sectors (e.g. construction, agriculture) and technology-intensive industries (e.g. telecom) design “strategies that embrace the implications of digital transformations and drive better operational performance” (Hess et al, 2016).

A digital transformation strategy serves as an overarching and a company-wide vision steering an organisation through digitally induced changes and strengthening the ability to react proactively and timely to internal and external shocks caused by organisational, cultural and technological implications of digitalisation. Due to a relative novelty of transformational changes of digitalisation, its complexity, profound and long-lasting impacts on versatile aspects of production and operations, corporate digital transformation strategies and the mechanisms for their initiation and implementation have not been thoroughly studied by the academic community. At the same time, there is an urgent need from the side of the business sector to have conceptual frameworks to support a frictionless evolution towards a new functioning
model of a business organisation supported by an intensive use of digital technologies. This paper addresses main rationales, promises and challenges of digitalisation in firms with a view to providing a classification of different stages of digital transformations. The research findings are based on an extensive literature review of underlying technological and organisational trends and the phenomenon of digital transformation strategies.

**Framework conditions that affect digital intensity of firms**

Digitalisation requires the development of strategies to proactively react to external and internal shocks brought about by technological advancements. A successful market performance is associated with an ability of a firm to manage complexity of production and operations, be it management of a global network of factories or commercialisation of research findings. A current wave of changes in digital technologies unravels on a much deeper level compared to the past developments. Digitalisation contributes to blurring of lines between industries (WEF, 2016), disruptive changes in innovation cycles (Rachinger et al, 2018), new means of value creation, new types of relations and hierarchies among customers, producers and suppliers (Heinonen & Michelsson, 2010; Lee & Berente, 2012). Digital transformations exhibit a tendency for a strong reciprocity between transformed and impacted business activities (Ismail et al, 2017). That is to say that digitalisation of a product or a service will sparkle changes in a whole value chain and should be inevitably aligned and supported with digitalisation or managerial changes of all stages of production and operations. Firms need to integrate digital technologies into their business processes and operations and channel complementary investments into the reorganization of hierarchical structures, skills and business models. This ‘domino effect’ of digital transformations increases the complexity and the uncertainty of actions a firm needs to undertake to fully harvest a potential of technological advancements.

Conception and implementation of digital transformation strategies are affected by a combination of external and internal factors: market pull (changes in client demand, market trends), technology push (advancements in a computational power), type of industry and company size. A study of micro-data from the Statistics Canada Survey of Advanced Technologies (2015) identified that large companies use advanced digital solutions more often in comparison to small and medium enterprises (Galindo-Rueda et al, 2019). Under advanced digital solutions we understand in this context tools based on machine learning, natural language processing, deep learning, blockchain, the semantic web, advanced visualization methods and Big Data. Whereas the application of cloud computing and other infrastructure service technologies have the same levels of proliferation for all company sizes, small and medium enterprises generally have lower capabilities in integrating advanced digital technologies into organisational settings to extract a commercial value. Therefore, company size may be a path-dependent force defining frameworks for a digital transformation.

Clavino et al (2018) proposed a taxonomy of industrial sectors based on the use of digital technologies in production and operations applying a set of indicators designed atop the OECD country-specific data, e.g. investments in technological solutions, human capital required to exploit technologies, and changes in output market (online sales). According to the study findings, ICT, telecommunications, finance are leading in the digital intensity, whereas companies involved in agriculture, mining and real estate are lagging behind. A type of industry, in which companies operate, has an impact on technology intensity of firms and whether they start the adoption of digital solutions early on. Both company sizes and industry types are not decisive factors for digital intensity of firms. Some start-ups and small and medium enterprises have a high capacity in designing new products, services, business models...
leveraging a potential of digital technologies (“digirati” or “digital-born”). While operating in the retail sector which generally does not exhibit high digital intensity, Walmart is gradually becoming a digitally intensive company by using big data analytics to improve customer experience and advance supply chain management. Company sizes and industry types can tilt companies to a direction of digitalisation, but cannot be a decisive force for the success of such transformations.

Changes in company operations that happen under the impact of digital technologies can be seen from the classical theory of the technology push and demand pull (von Hippel, 1976; Mowery & Rosenberg, 1979; Dosi, 1982). The concept of technology push proposes a linear process of innovation, in which research and development are ultimately translated to commercialized outputs (Bush, 1945). The concept of the demand pull, on the contrary, argues that the anticipated customer demand is the main driver of innovation activities, as it provides incentives to conduct research and development in new areas (Schmookler, 1966; Scherer, 1982). Scholars reached a consensus that there is a close interplay between technology push and demand pull which is largely defined by different industry life cycles, characteristics of the end market and broader economic conditions (Mowery & Rosenberg, 1979; Stefano et al, 2012; Balconi et al, 2010). Digitalisation brings new dynamics into this paradigm by strengthening a technological impacts on a broad array of operations in firms and market developments. A technological aspect is becoming more pervasive in defining rationales for corporate strategies and market pull dynamics. Although advancements in digital technologies and a growing availability of data have not fundamentally changed technology push and demand pull forces, the general direction goes to a more heavy-weight technological component.

**Technology push**

Organisations are engaged in an iterative process of exploring the potential of digital technologies for their business needs. Companies start adopting digital solutions to improve operational efficiency and effectiveness (Bilgeri et al, 2017), decrease costs (Valenduc & Vendramin, 2017), improve supply and demand matching (Groen et al, 2017), ensure strategic differentiations from competitors (Andriole, 2017), enhance skills of workers (OECD, 2016) and support strategic planning, problem-solving and decision-making (Carlsson, 2018). Digital technologies contribute to an emergence of new business models, products and services. According to the survey of the Harvard Business Review, 84% out of 783 company senior managers believe that their industries are already being disrupted or will be disrupted by digital technologies by 2020 (Harvard Business Review, 2017). The Internet of Things (IoT) enables companies to design on-demand services creating sizable efficiency gains both for customers and providers. Several examples of such solutions include lighting on demand service of Philips, Power by the Hour service of Rolls-Royce, performance-based contracts of General Electric and on-demand services of Kaeser Kompressoren. Through such services, customers may reduce their financial risks, improve planning of operational costs, pay for highly personalised products and services only when in use and benefit from automatic and constant improvements. Digitalisation enables rapid prototyping, computer modelling and simulations, reducing costs and material use and accelerating innovation cycles. Over-the-air software updates let manufacturers launch a product on the market before it is fully finalised. For

---

1 The survey covered companies active in manufacturing, finances and technology. Organisations with more than 10 000 employees formed 53% of respondents, organisations with 1000-9999 employees accounted for 26% of respondents, organisations with 100-999 employees constituted 21% of respondents. The geographical representation is as follows: North America (35%), Europe/MEA (35%), Asia/Pacific (23%) and South and Central America (35%).
instance, Tesla launched its S model in an alpha version. Through constant software updates and monitoring of the product usage behaviour, Tesla was able to further improve the functionality of the S model on the go without recalling cars for a technical maintenance.

Data-driven services let companies bypass intermediaries and build up direct relationships with their customers, thus strengthening bargaining positions in value chains. New operating models and process innovations powered by digital technologies can also disintermediate relations between suppliers and customers. With the emergence of digital services developed atop existing physical products, firms can engage in closer interactions with their customers and extract value beyond the sale date. Consequently, revenue streams can become less vulnerable to cyclical fluctuations and exhibit positive tendencies for a substantial growth.

Another factor which raises the interest of firms in digital technologies is new opportunities for revenue extraction provided by digital platforms. According to the findings of the World Economic Forum’s Digital Transformation Initiative (DTI), digital platforms have a potential to generate $10 trillion of value for companies till 2025 (WEF, 2017). Platforms introduce new ways for interactions between customers and suppliers, blur boundaries between industries, enable the co-creation of new services with ecosystem partners and raise the scalability of businesses without significant follow-up investments (Tiwana, 2014; de Reuver et al 2018; Von Engelhardt et al, 2017). Technology companies like Amazon and Google leverage their capabilities in data analytics to design digital platforms for connected and autonomous vehicles and telematics. While in the future that may raise competition for car manufactures who are also interested in providing paid digital services, the collection of large volumes of user data already enables Amazon and Google to become active in the auto insurance market, thus reducing market shares of insurance companies. Digital platforms are seen as an important instrument for digital transformations of traditional industries, where they serve not only as a tool to provide valuable additions to the core business, but also as a powerful instrument to further advance key organisational competences and create new business models.

**Market pull**

Changes in economic conditions and in demand have impacts on the profitability of innovations, thus providing incentives for firms to work on certain solutions (Rosenberg, 1969; Freeman, 1979; Brem & Voigt, 2009; Lubik et al, 2012). Companies embark on a digitalisation path to respond to market and competition trends and remain competitive. Customers have developed a different set of expectations towards products and services: e.g. personalised customer experiences, recommendations based on previous purchases and attractive and easy-to-use digital interfaces.

At the same time, a new generation of workforce have a different set of values and motivating factors. They have different perceptions towards working conditions (e.g. flexible working hours, teleworking) and digital competences of companies (e.g. optimisation of workflows through digital tools, convenient digital working environment) (Kaufman & Horton, 2015). Firms need to adapt to changes in demands and expectations of clients and employees by increasing a digital component in their portfolios and operations.

Digitalisation might be a way to mitigate risks to core business activities either by expanding to new markets and business lines or through creating vendor lock-ins by digital extensions to core products. For example, academic publishers like Elsevier and Holtzbrinck Publishing Group face challenges posed by terminations of national paid subscriptions to their content and the emergence of alternative channels and providers of content supply. Publishers are trying to
mitigate these risks by designing digital services atop their proprietary databases and data generated by users. The share of digital content in a total revenue by format raised from 22% in 2000 up to 74% in 2017 for the RELX Group, an owner of Elsevier. For Elsevier this number is even higher: 81% in 2017 (RELX Group, 2017). As a result of such developments, Elsevier has recently changed its status of an academic publisher to a global information analytics company. Digitalisation may offer not only an opportunity to mitigate competitive pressures, but also a chance to transform the core business of a company and capture a higher value.

Digital products and services are characterized by the ‘fluidity’, an ability to “be reproduced, shared, manipulated instantaneously at any scale and no cost” (Paunov & Guellec, 2018). Digital technologies like AI, big data analytics and distributed ledger technology (blockchain) are general purpose technology (GPT) and can be applied across various business lines contributing to productivity gains and efficiency improvements. By leveraging opportunities provided by recent advancements in digital technologies and a growing availability of data, firms can scale up rapidly in the market without significant follow-up investments. A so-called ‘scale-without-mass effect’ lowers costs of a market entry and provide companies with powerful instruments for a market expansion (Brynjolfsson et al, 2008). That may ignite a rapid development of small and medium enterprises that may undermine competitive powers of market incumbents. However, depending on a combination of internal and external factors, it may also result in a reverse trend, a ‘winner-takes-most’ phenomenon, in which a small group of large technology companies establish a monopoly in a market. Such dominant positions are difficult to contest due to network effects of digital products and services, economies of scale and scope, vendor lock-ins and data ownership and access.

A growing availability of vast volumes of data on product delivery and user behaviours provides companies with opportunities to manage their supply chains in a faster and more flexible manner and cause new market dynamics. Amazon is working on predictive shipping model in which the pre-packaging of goods starts before a customer purchases it. The model is underpinned by analyses of customer behaviours, product usage and online searches. Digital solutions have a potential to raise transparency, authenticity, traceability and security of transactions within supply chains (Wang et al, 2019) and improve forecasting of irregular demands thus decreasing costs (Amirkolaii et al, 2017). In previous decades, the proliferation of the Internet disintermediated several industries leading to disruptions for market incumbents. For instance, in tourism industry hotels and airlines started providing their services directly to customers through websites bypassing tourism agencies. Currently, a new value for market disintermediation is seen in distributed ledger technology (blockchain). It is already used to support the implementation of smart contracts across various industries (Kim & Laskovski, 2017) and for disintermediation of energy markets by providing peer-to-peer trading solutions, e.g. owners of photovoltaic batteries have a possibility to seamlessly sell energy to their neighbours (Andoni et al, 2019; PwC, 2017).

Changes in customer needs geared towards an improved digital content, competitive pressures on existing business, changes in supply chain management and new competitive dynamics caused by digital technologies form market trends that stimulate companies to explore a potential of digital technologies for reaching their strategic objectives.

**An interplay between technology push and market pull in the digitalisation context**

Insights on capabilities of digital technologies coupled with information on customer needs and expectations drive the development of new products and services. That should be further
aligned with necessary changes in production and operations management (e.g. reconsideration of supplier relations, new ways of customer engagement), changes in skills (e.g. acquisition of capabilities in data analytics), the development of a new culture (e.g. strengthening of openness and transparency, data curation) and changes in organisational hierarchies (e.g. flatter organisational structures and cross-functional project teams). The most challenging task is to implement necessary reforms in decision-making arrangements: e.g. how to translate intelligence retrieved by digital technologies into a detailed sequence of actions; how to monitor areas of potential breakthroughs and accommodate promises of digital technologies to gain a competitive advantage; how to balance investments into digitalisation programmes with other strategic objectives.

In the context of digitalisation, decision-making process is organised along the alignment of business needs, internal capabilities, technological promises and the external environment (fig. 1). Whether a company will be successful in harnessing the potential of digital technologies depends on the ability to identify promising technological applications and relate them to business needs and internal capabilities with a view of possible effects from an external environment.

**Figure 1. – The nodes of decision-making in the context of digitalisation**

Changes in decision-making arrangements driven by new trends in client demand and the competitive landscape can be the main force behind digitalisation of a company. In situations when a technology push has a dominant role, digitalisation tend to happen in a bottom-up and fragmented manner and is focused on specific project demands. It sparkles changes in process and operations management further leading to changes in organisational structures, skills and culture, later on affecting mechanisms for decision-making. When the influence of the market pull is more significant, the whole process of digitalisation starts from changes in corporate decision-making which is further translated to other stages of production and operation. In this case, digitalisation of a company is characterised by a top-down approach and distinguished by a coordinated nature. A number of firms have launched corporate digitalisation strategies setting out objectives for digital transformations and identifying major barriers and the ways to overcome them.
Digitalisation strategies are aligned with R&D strategies, customer engagement strategies and other key documents incorporating a company’s vision on its future development and measures aimed at achieving objectives. Having a corporate digitalisation strategy is instrumental for ensuring an optimal transition towards digitalised processes, business models, products and services, as it unites stakeholders over a selected list of objectives, channels required resources to priority areas and resolves duplications of efforts and information asymmetry in companies. While project-based digitalisation can bring positive results for short-term objectives, it is not well positioned to push frontiers of digital transformations, as they are constrained by existing bottlenecks of organisational settings that should have been addressed by senior management in the first place.

Figure 2. – A typology of digitalisation in firms

![Figure 2](image)

Figure 2 presents a framework for classification of digital transformations in firms based on a degree of coordination of digitalisation initiatives and the intensity of use of digital technologies. Company sizes, industry types define a starting point of digital transformations of companies, whereas the market pull and technology push can be drivers of a transition to other stages. This figure provides an analytical framework of macro-forces affecting digital transformations in firms, but it does not offer insights on transfer mechanisms to new stages (e.g. types of investments, measures aimed at organizational restructuring) that should be covered in the future research.

**Analogue group:** Small and medium enterprises, some state-owned enterprises (SOE) and large companies from low-tech industries form this group. Typical examples may include firms active in agriculture and real estate. Digital technologies serve as extensions for current products and operations (mainly customer engagement and streamlining of workflows) and do not contribute to creating digital products, services and new business models based on advanced technological solutions. Firms in this group are not very perceptive to technological changes due to path-dependent dynamics of their industries, infancy of their business or a low market
competition. Unlike other world largest oil and gas companies, the state-owned enterprise Rosneft does not show much progress in adopting AI and big data analytics for productivity and efficiency improvement. Dominant market positions and an access to state money stifle innovations in many Russian SOEs, result into a low labor productivity and create a hostile environment for adoption of new technologies (Abramov et al, 2017; Sanghi & Yusuf, 2018).

**Coordinated transition:** Some small and medium enterprises and large companies from low-tech industries start digitalisation by setting strategic objectives and formulating initiatives aimed at a coordinated transition of a whole enterprise to digitally enabled solutions and practices. Companies in this group are being disrupted or are at a risk of being disrupted by more technology-intensive market players. A growing demand from clients and employees for new ways of communications and advanced digital experience calls for subsequent changes in a capacity of firms to exploit digital technologies on a deeper level. The global healthcare company Novartis wants to digitally transform by embracing advanced analytical solutions. The corporate strategy puts digitalisation in a centre of a long-term development. Yet, applications of recent advancements in digital technologies are still in infancy and are distinguished by an experimental nature.

**Digitally fragmented:** small and medium enterprises and large firms from technology-intensive sectors show high levels of use of digital technologies and data-driven approaches to improve productivity and operational efficiency. There are significant changes in levels of technology absorption across industrial sectors. Industries that used to show rather low levels of technology adoption are increasingly becoming technology intensive. The financial sector is leading in adoption of advanced forms of digital tools ranging from distributed ledger technology to deep learning networks. The Swiss multinational investment bank and financial services company UBS Group launched a number of digitalisation projects aimed at among others optimisation of workflows, development of an infrastructure for smart contracts and support of credit scoring. Although digitalisation is recognized as an important vector in a corporate strategy, digitalisation efforts at UBS are rather project-based and mostly occur in a fragmented manner.

**Full-fledged digital enterprise:** company size or industry type do not play a major role in shaping a full-fledged digital enterprise. For successful digitalisation firms need to build strong dynamic capabilities to identify opportunities and threats, rapidly and proactively react to technological trends and effectively transform business models and resource base (Teece, 2007; Teece & Linden 2017). Organisational reforms aimed at a more efficient and effective exploitation of digital technologies are instrumental for achieving full digital maturity. Netflix can be an example of a full-fledged digital enterprise. By investing in digital skills and new technologies and improving organisational settings, Netflix was able to transition from a DVD renting business to a world leading video streaming service and an entertainment company. Expertise in data analytics and AI enabled Netflix to design an industry-leading film recommendation algorithm and gain a deep understanding on user expectations and content engagement.

**Conclusion**
A combination of framework conditions including company sizes, industry types, technology push and market pull set trajectories for formulation and implementation of digital strategies. A transition to more advanced stages of digitalisation is mainly driven by organisational reforms that unleash a full potential of digital technologies and align them with business needs, in-house capabilities and external environment. Examples of such initiatives include, but are
not limited to the resolution of information asymmetries, flatter organisational hierarchies, small cross-functional teams and implementation of new types of incentive sets to accelerate innovations. Further research is needed to shed light on measures companies may require to implement to achieve full digital maturity and develop strong dynamic capabilities for successful digitalisation.

Whereas other three stages of digitalisation (analogue, in-transition; digitally fragmented) are shaped by the context in which companies operate, a stage of a full-fledged digital enterprise is not a given and can be reached only by overcoming external and internal path-dependent forces and investing into capabilities to transfer technological advances into a commercial value. In this context, corporate digitalisation strategies are seen as an essential enabler of a coordinated transition to a model of a full-fledged digital enterprise. Formulation and implementation of digitalisation strategy is most likely to happen, when market pull forces have a strong influence on a company’s development. When technology push is more dominant, digitalisation occurs in a project-based fashion often leading to duplications and fragmentations of efforts.

Abstract

Organisations are susceptible and vulnerable to crisis situations. These organisations have been able to exert resilience, and manage reputational damage, through crisis management protocols that include stakeholder engagement. However, given the rise of social media, a new cohort of stakeholders has emerged. Organisations are therefore faced with the task of managing new stakeholder relationships. This paper applies recent advancements in social media and crisis management discourse to investigate the prevalence of new, undiscovered stakeholders in crisis communications surrounding six prominent crisis situations. The results indicate that online stakeholders are becoming more powerful, urgent and legitimacy; thus shifting dynamics.

Keywords: Crisis Communication, Social Big Data, Stakeholder Salience

Introduction

Previous studies on crisis management have sought to identify effective methods and strategies for crisis communication. Crises can be unexpected and non-routine events or activities that interfere with an organisation’s normal business operations, jeopardise its public image and damage the bottom line (Faulkner, 2001). Managing crises is an important process to prevent or lessen such interference, repair images and disseminate the responding information. Therefore, ‘the communication following a crisis plays an integral role in this success’ (Ulmer, 2001, p592). According to Coombs (2015), crisis communication is ‘the collection, processing, and dissemination of information required to address a crisis situation’.

The recent prevalence of social media platforms has created a new and low-cost channel for
communication. These platforms have also changed the way that people search, publish and share information during crises (Oh et al., 2013). The use of new types of social interactions to report real-time crisis information somehow is more influential than the mainstream news. Given this, the main organisations are no longer the only influencer, rather, there are peripheral influencers that can gain legitimacy and become important stakeholders by creating and propagating crisis information. Hence, there is a new challenge for the main organisations to identify and engage with these emerging stakeholders to communicate crisis information.

In addition, the social media platform can encompass large amount of unverified information, including lies and false rumour (Oh et al., 2013), which can then easily spread anger, threats and aversion emotions to further worsen the crises (Jin et al., 2014). Assessing and scrutinising such information is therefore important for organisations to control crises, develop responses, and repair images. Previous studies in crisis management have identified an array of strategies for crisis communication and image repairing (e.g., Benoit, 2018). This study builds on the key lessons of from these studies, and builds on stakeholder theory and image repair theory to propose new solutions for crisis communication and stakeholder engagement via social media platforms.

Given the new role of social media platforms in crisis communication, scholars have put emphasis on the complex interconnectedness and centrality of emerging stakeholders in crises (e.g., Sedereviciute and Valentini, 2011). Using the stakeholder salience model (SSM) and social network analysis (SNA), this study aims to advance our understanding of the interface between image repair strategies and stakeholder salience. As such, this study aims to unbundle the critical W’s. These include: what is the conversation, who is framing the conversation, why do crisis-stricken organisations respond, and when they do.

To unbundle the W’s, this study is anchored in a research agenda to address:

RQ1: How do (emerging) stakeholders shape the conversation about crises using social media platforms?
RQ2: What topics of conversation, and which stakeholder groups, encourage crisis-stricken organisations to respond?
RQ3: Is stakeholder mapping an effective tool? And, can crisis-stricken organisations use stakeholder mapping to identify salient stakeholder groups?

**Literature review**

Grounded on traditional stakeholder theory, dominant logic in crisis communication discourse relates to the premise that: (i) a range of stakeholders will be involved in *ex-ante* and *ex-post* crisis communication (Wagner Mainardes et al., 2012), and (ii) organisations will attempt to communicate with certain stakeholder groups to manage the situation and reduce any reputational damage (Luoma-aho & Paloviita, 2010). To effectively manage crises, and reduce reputational risk (Benn et al., 2016), it is imperative for organisations to classify stakeholders and define dyadic stakeholder-organisation relationships. Parallel to the rise of social media platforms, however, interest and participation in crisis communication has become more accessible and fluid (Valentini & Kruckeberg, 2016), with organisations facing new challenges in stakeholder mapping procedures.

Traditionally, organisations could evaluate and categorise stakeholders with a scope to identify
the most salient stakeholder with prioritised stakeholder claims. Based on this evaluation process, an organisation could then respond directly to stakeholders with priori claims. Concomitant with the rise in social media, though, the evaluation of salience is becoming less static, with frequent changes in powerful, urgent, and legitimate stakeholders. What’s more, social media has also introduced a new environment in which ‘undiscovered’, ‘new’, and ‘unknown’ stakeholders can emerge (Himelboim et al., 2014).

The fundamental challenges for crisis-stricken organisations, therefore, are:

i. Requirements to grasp – and difficulties associated with grasping – the complex relationship between crisis situations and social media platforms;

ii. The emergence of new stakeholder groups, with Wan et al (2015) identifying new stakeholder labels, such as social media creators, social media followers, and social media inactives.

Addressing these challenges would make it possible for organisations to reconfigure their stakeholder maps, and thus recalculate salience calculations. Such possibilities could result in crisis-stricken organisations being better equipped to make optimal, rather than sub-optimal, crisis management decisions. An initial step toward providing a solution is provided by Sedereviciute and Valentini (2010). In their study, the author combined the Stakeholder Salience Model (SSM) and Social Network Analysis (SNA) to permit a mechanism to find and prioritise stakeholders on social media, with an emphasis on connectivity and content dimensions. The first dimension (i.e., connectivity), rooted in network theory, is based on connections between different online stakeholders on social media, as well as the dyadic connections between online stakeholders and the organisation. The core argument is that if an online stakeholder has a more prominent position in social media networks they will be viewed as more powerful. The second dimension (i.e., content), on the other hand, is preoccupied with the content and words propagated on social media platforms, such as Twitter, as well as the interest and relevance of this content for other online and offline stakeholders. Essentially, when an online stakeholder is seen as propagating interesting and relevant information on social media they will be deemed as urgent. When an online stakeholder is deemed both powerful (based on position) and urgent (based on content), they will be viewed as more legitimate by the crisis-stricken organisation, and thus will generally attract a response. As noted by Sedereviciute and Valentini (2010), these two dimensions will shift the traditional conceptualisation of powerful, urgent and legitimate stakeholders, and introduce new stakeholders into the mix, notably: unconcerned influencers (dormant stakeholders), concerned influencers (definitive stakeholders), unconcerned lurkers (non-stakeholder), and concerned lurkers (dependent stakeholders). This understanding will therefore be taken forward to assess who is important in crisis-related conversations on social media, and how they shape conversations on social platforms.

Methodology

Data Collection

This study develops a tweet analysing and stakeholder mapping tool to collect, extract and analyse the data from Twitter. The tool includes four analyses as illustrated in Figure 1: tweet word counts analysis (to classify trendy keywords); tweet cluster analysis (to identify dominant image repair strategies and prevalent crisis topics); tweet sentiment analysis (to identify the tweet sentiments and the pattern of information diffusion) and social network analysis (identify emerging stakeholders).
The tweet datasets in this study are captured by a Twitter Application Programming Interface (i.e. QDA Miner and NodeXL), they contain seven recent crises and extreme events (Table 1). The software is selected based on their extensive features on exploring and analysing textual data.

Prior to the analyses, the Twitter datasets are normalised and tokenised (Liau and Tan, 2014) in the QDA Miner software package to stem and remove stop words. Other high frequency but pointless words (e.g., HTTP, HTTPS, RT, etc.) are also removed and common misspellings are corrected.

**Word Count Analysis**

For word count analysis, the QDA Miner is used to generate word count frequency (Table 2) and predict the popular topics from the textual data. The major characteristics are also extracted in the proximity plot (Figure 2) (Mostafa, 2013).

Sentiment Analysis
The sentiment analysis is applied to understand the motive behind the tweets. This study uses the lexicon-based method to the tweets to measure the semantic orientation, adopts the SentiStrength classifier (Thelwall et al., 2010) to analyse the sentiment expressed in the tweets.

Social Network Analysis
The social network analysis (SNA) (Coombs, 2002) is performed to identify the key stakeholders who are accounted for the information distribution. NodeXL is employed to calculate the in-degree (the total mentions of a twitter account), eigenvector centrality (the total connections to other influential accounts) and betweenness centrality (the numbers of shortest connections with other non-neighbouring accounts) of each account in the network.
Table 5. The top 10 stakeholders based on in-degree, eigenvector centrality and betweenness centrality for the O2 UK Day-long Outage dataset

Results and implications
The word count frequency presented in Table 2 provides the basic tweet information on each dataset, the results help to construct key topics, identify main stakeholders, compare relationships between incidents and lay down the foundations for later sentiment analysis. In Table 2, the top keywords from each dataset are those mainly used to describe the crisis
situations, the cause of the crisis and the public expectations. They form the main topics during the crises which link to the main stakeholders. For instance, the keywords used in the Fiat-Chrysler Dieselgate dataset are related to the RECALL due to the VEHICLES EMISSIONS CHEATING, and expecting SETTLEMENT PAY. In Figure 2, these keywords are compared against ‘DIESEL’ problem and the ‘DIESELGATE’ crisis. It can be noted that stakeholders have mentioned more about whether or not AGREES have been given to SETTLE the DIESEL problem, compare the stakeholder in the DIESELGATE who are more concerned with the cost in MN (millions) to SETTLE.

Table 3 highlights the important and related keywords and how they form popular topics. For instance, tweets to describe the crisis incidents, provide information about the impacts are affected areas, products are focal topic groups in every datasets. However, there are also tweets, although less, that form topics to offer suggestions and give feedback (to reduce the crisis impacts), asking questions (to fix the problem). In addition, there are also tweets represent groups to express jokes (schadenfreude) and sending disappointed messages (blame).

From the results of the SentiStrength classifier illustrated in Table 4, the overall average sentiment of all between the band distribution of circa -1/+1, which may indicate that some tweets are not very affective (Mostafa, 2013) and suggest a more detailed analysis to look into the sentiment score of each topic group/stakeholder group at different timeframe for more meaningful explanations (Cao et al., 2018).

The results of the SNA to the O2 UK Day-long Outage dataset is illustrated in Figure 3 and explained in Table 10. Each of the three metrics used in this study indicate the influence of the tweeter users, such as a high in-degree indicates a high fluence of the account, a high eigenvector centrality represents a large number of connections with other influential accounts, and a high betweenness centrality shows an account with the most numbers of shortest connections with other non-neighbouring accounts. In this study, the key influential stakeholders are listed in Table 10. In particular, @sturdyAlex is the most influential stakeholder, as this account has the highest in-degree and eigenvector centrality, and a high betweenness centrality within the top 10 range. @2b_as and @EssexBuccaneer are two other important influential stakeholders.

**Conclusion and recommendations**

By adhering to Sedereviciute and Valentini’s (2010) holistic approach to stakeholder mapping, within the context of several novel and important crises, this research has uncovered a few important research notes. These are:

i. Concerned and definitive stakeholders have the capacity to shape crisis-related conversations based on their position within social media networks. For example, @sturdyAlex was seen to influence the narrative through a central position.

ii. Once categorised as non-powerful, non-urgent, and illegitimate, these undiscovered online stakeholders require responses from crisis-stricken organisations in order to control and mitigate reputational damage, as was seen in the O2 outage case.

iii. The combination of SSM and SNA facilitates the identification of new, undiscovered online stakeholders, which are integral in the narrative, tone, and longevity of crisis situations and their manageability.

To advance this research effort, and to generate managerial implications, the authors call for
further research on online stakeholders, especially those on Twitter, to identify the timeframe in which they are powerful, urgent, and legitimate. This can then be mapped against company response. Scholarship could also compare online stakeholders with offline counterparts to review salience across channels.

Abstract

The purpose of the paper is to extend the social media analytics frameworks reported in the existing literature to create value from the data captured from heterogenous social media and IoT sources in a global supply-chain. The paper will aid the practitioners to understand the importance of focussed analysis and the key requirements for this analysis by offering a guide to organisational needs. The framework and requirements proposed in the paper will aid managers to capture value from the data (i.e. gain key insights) and augment human decision-making.

Keywords: Social Media, Analytics framework, Value creation

Introduction

Social media has become a major phenomenon for different organisations globally, and the field of supply chain management has slowly recognised its value for organisations (Chae, 2015). Companies are creating their own online platforms to interact with customers (Correia Loureiro, Serra, & Guerreiro, 2019) or collecting information to use it to enhance customer loyalty (Gamboa & Gonçalves, 2014) and to improve the products offered to consumers. The purpose is to “win with data” (Hopkins & Lavalle, 2010). This perspective is very appealing because technological advances and the increase use of social media by customers.
How to properly harness the benefits of social media in supply chain management, however, it is still a growing area. Information from a multitude of sources is collected and analysed to take advantage of it, but that can become a complex and time-consuming task because of the large volume, variety and velocity of the data, along with its unstructured state (Singh, Shukla, & Mishra, 2018). This is an important consideration because poor quality of data can render the data useless (Hazen, Boone, Ezell, & Jones-Farmer, 2014). This paper states that a different approach is required. Instead of only looking at the volume and the quality of the data, it is important to start looking at the question that the data is trying to answer.

Current analytics frameworks assume that value is created at the final stages, once analytics are applied to the information to find some trends/insights. This article presents a review of two case studies in supply chain management to identify the important elements that create value from the use of social media and redefine current analytics framework. From a more practical perspective, this paper is looking at the most beneficial approach to create value for decision-makers. The objective is to offer a conceptual framework that can be used by stakeholders to take advantage of social media for value creation.

The contribution of this paper is to change the current paradigm from a more “exploratory” analysis of social media data to a focused process introducing “value creation” as a stage defining and guiding the analysis. This shift can become beneficial to address several of the shortcomings identified in the literature about the use of social media in organisations. The paper is also providing a guide with the value creation requirements and organisational needs to exploit the benefits of social media.

**Cases**

Currently, the role adopted by the social media is increasing world-wide with the advances of cross-platform Web 2.0 applications and services (Palen, Starbird, Vieweg, & Hughes, 2010). To analyse the impact of social media in the supply chain and to identify the needs to exploit its potential impact, this research is looking at two different supply chains: retail and humanitarian. Both supply chains have similar components, but the objectives and strategy of each one of them exhibit significant differences, allowing the authors to identify the common elements to exploit social media in supply chain management.

**Case study: Zara**

Zara has been a very interesting case in operations for a long time because of the fast response and flexibility stemming from their practices (Kasra Ferdows, Machuca, & Lewis, 2015). The concept of fast fashion and the high level of vertical integration applied by this company has shown the value of staying at the forefront of operations and its impact on performance. Zara is part of the Inditex group, with more than 650 stores over 50 countries (K. Ferdows, Lewis, & Machuca, 2004) which has led them to achieve nearly 75% of sales of the whole group (Kasra Ferdows et al., 2015).

Speed is an essential quality in the fashion industry. Responsiveness is one of the goals of different companies, but Zara is able to claim achieving responsiveness because of the agility embedded in its supply chain (Kasra Ferdows et al., 2015; Martínez, Errasti, & Rudberg, 2015) as a result of the high level of control rom the supply of materials until the customer purchases the garments (K. Ferdows et al., 2004). For instance, Zara has
been able to introduce new items of clothing to its different stores in around two weeks, from design until delivery (Kasra Ferdows et al., 2015).

Zara has been able to thrive by leveraging new technologies to support its fast fashion approach. The high degree of control over the different links of the supply chain has allowed Zara to have better information sharing as part of their supply chain. Knowledge from the links directly in contact with the customer in the supply chain have allowed the company to be more responsive, using private systems to reduce delays, and enhance the quality and attractiveness of the garments.

With the development of Web 2.0, e-commerce has become a valuable channel to sell products and services. Zara has taken advantage of that opportunity to make their products available to consumers (Fondevila Gascón, Del Olmo Arriaga, & Bravo Nieto, 2012; Gamboa & Gonçalves, 2014) and leveraging from brand enhancement from electronic word of mouth (Correia Loureiro et al., 2019). Similarly, consumers are taking a more prominent role through new communication channels opened by Web 2.0. The introduction communication channels supporting many-to-many interactions have allowed consumers to participate and even collaborate with companies (Gamboa & Gonçalves, 2014). Therefore, several companies are using online platforms in which customers can take part to become closer to the company (Correia Loureiro et al., 2019).

Social media has become a new battlefield for fashion companies because it has become essential to shape the reputation of the brand and achieve customer loyalty (Fondevila Gascón et al., 2012). Zara is the example of an organisation that has embraced social media, as it is one of the fashion companies with the highest number of fans on Facebook (Gamboa & Gonçalves, 2014), which allows them to enhance the engagement with consumers (Fondevila Gascón et al., 2012) and advertise new products and relevant updates about the brand (Correia Loureiro et al., 2019).

Zara’s engagement in social media involve constant interaction with customers and posting photos and videos with relevant content (Correia Loureiro et al., 2019), which has paid-off with an increased level of customer loyalty (Gamboa & Gonçalves, 2014) and improved advertising strategies, but it has also carried some challenges. For multinational organisations it is important to consider decentralisation, language, culture and campaign coordination across markets (Fondevila Gascón et al., 2012). The evolution of the content provided and aligning social media to the strategy of Zara is essential to continue enjoying the benefits of social media.

**Occupy Sandy: Social media for disaster relief**
U.S. Congresswoman Susan Brooks stated in 2013 the importance of social media and technology in disaster management, as well as the value of digital volunteers to enhance the potential of social media and increase situational awareness (Kirac & Milburn, 2018).

A good example of the potential of social media in disaster management is the situation occurred after Hurricane Sandy hit the US. Hurricane Sandy has been one of the costliest disasters that have affected the United States of America. The disaster had devastating impact in several states of the country after growing into a category 3 Hurricane (Yoo, Rand, Eftekhar, & Rabinovich, 2016), striking the East coast in October 2012. It was challenging for FEMA to cope with the situation because of the scale of the disaster, which allowed a small group stemming from the Occupy movement to show the potential of social media to support disaster management with their activities in Brooklyn (Feuer, 2012). In fact, disaster response from the Occupy movement was quicker than larger and more established organisations such as FEMA and Red Cross (Kavner, 2012).
Social media has been heavily linked to disseminating information in disaster situations and to target search and rescue activities (Panagiotopoulos, Barnett, Bigdeli, & Sams, 2016), but the potential of these tools go beyond that. FEMA has recognised the value of social media have a two-way conversation with people and to look at them as resources (Tobias, 2011). This was experienced after Hurricane Sandy hit the US, because the occupy movement was able to set-up communication hubs to re-establish communication and use it to create an emergent supply chain.

Procurement was performed appealing at donations from citizens in two ways. Financial donations using Webpay (Webpay, 2012) were collected to finance response activities and projects, with a total tally of $1,361,337.19 (Occupy, 2013). On the other hand, in-kind donations were also encouraged through the use of Amazon’s wedding registry (Occupy, 2012). In this alternative, an updated list of the most needed items in ravaged areas was posted online for donors to but the items directly and use Amazon retail services to deliver the items to one of the outposts from the movement (Feuer, 2012). The collection of in-kind relief was successful as well, as shown by the delivery of over 35,000 items in few weeks after the storm hit (Islam, Vate, Heggestuen, Nordenson, & Dolan, 2013). They used Sahara Eden to request assistance, to print waybills with items and delivery areas, and to track requests (Homeland_Security, 2013).

Exploiting both supply channels represented operational challenges to manage the relief. The relief was delivered to Occupy Sandy distribution sites split between two churches in Brooklyn, which were the facilities used to deploy relief end volunteers to affected areas (Kavner, 2012). Coordination of these volunteers and relief can become problematic task, especially with numbers between 5,000 and 10,000 volunteers (Homeland_Security, 2013). The Occupy movement used communication systems to enable collaboration by matching human resources with the required activities (Kavner, 2012; Occupy, 2012). That way, a set of borrowed cars and trucks were used to move items and people from the distribution hubs to the affected areas (Feuer, 2012) with the purpose of providing further support to the victims and distribute the relief available.

The size of the occupy movement, however, was not enough to supply all the affected areas. The integration of different organisations and initiatives quickly became a priority to manage operations. That is the reason a link between formal and informal response efforts was essential. Geeks without Bounds became that link for Occupy Sandy, allowing them to coordinate with FEMA and other formal organisations to make operations more efficient (Homeland_Security, 2013). Additionally, they provided situational awareness through crowd mapping. They worked with Hurricane Hackers NYC to provide a map of the affected areas (Homeland_Security, 2013). Therefore, the Occupy movement was able to use public social media as an enabler to create an emergent organisation to provide support online and on the ground (Kavner, 2012). Overall, Occupy Sandy was able to leverage social media across different parts of the supply chain to support disaster affected areas. The collaboration among different links of the supply chain, the constant monitoring of physical and financial aid, the ability to match supply and demand to coordinate different stakeholders, and the use of crowdsourcing to enhance information during the event are some of the examples of the potential of social media in these situations.

**Framework**
In this section, we extend the existing social media analytics framework (Figure 1) to include a value creation stage, which will aid the decision-makers and relevant supply-
chain entities to understand the purpose of using the analytics for processing the big data captured from social media sources. The key challenge with the voluminous and heterogenous data collected from different sources are lack of focussed analysis (i.e. what do we want from the data) and trying to find a pattern (generate insights without knowing what exactly we are exploring). Thus, the proposed framework extends the existing social media analytics frameworks reported in the extant literature (Lee, 2018; Stieglitz et al., 2018; Holsapple et al., 2018; Chae, 2015)

![Figure 1: Analytics process to create and capture value from social media data](image)

- **Inception:** The primary activities in this stage are collecting the data, followed by cleaning it (i.e. formatting with suitable annotations), then storing it in a structured-way for future use. The primary deliverable is not only a data repository but a report that can guide the next stage, where managers will identify the value of the stored data for purposeful use.

- **Value Creation:** This stage is essential to the outcome of the analytics and a component that has seldom been considered in the existing analytics frameworks. The main idea is for managers to use the inception report to understand what data is available from various social media sources and define the questions that they would like to pose to make the analysis focussed. The focussed analysis will aid in capturing value from the process and aid human-decision making.
• **Aggregation:** The relevant data from the inception stage will need to be integrated into a consistent format suitable for analysis (basic analytics and advanced analytics). The data selection will depend upon the problem (questions posed by the decision-makers), thus making the both the analysis and outcome focussed and purposeful (Govindan et al, 2018).

• **Sense-making:** The sense-making stage will employ algorithmic procedures depending upon the questions posed by the managers (in the value creation stage). This stage will include two deliverables: (1) a summarised snap-shot of the data which will help to gather suitable information from the data (which is likely to be voluminous and gathered from heterogeneous sources); (2) output of the analytics employed (such as predictive, prescriptive) using machine learning techniques (Fan and Gordon, 2014). The summary and output will help the managers to capture value from the data, i.e. gain suitable insights for the problem/question identified in the value creation stage, which in-turn will aid in formulating recommendations thus reducing the information and cognitive overload.

• **Sense-giving:** This final stage will present the information (summary and output of the analytics) in a visual form, which is intuitive and easy to understand using suitable pictorial representation (such as linked-graphs, trees, filters). The visual representation will help the managers to have a high-level understanding of the output and offer further drill—down to understand the rationale behind the recommendations (for a recommender system), which ought to depend upon historical information (data bias), heuristics used in the analysed (factor weighing) and source as well as type of data (textual, numerical values, audio and videos).

Overall, the proposed framework demonstrates the importance of value creation stage, which drives all the other stages in the analytics framework towards a focussed analysis. The outcome of the analysis will aid managers to understand the value of the data and have the potential to optimise business processes.

**Organisation Needs**
This section will discuss the key needs for an organisation to use the proposed framework for creating value and eventually capturing it through the analytics process. The key elements comprise of resources and activities that will aid organisations to build capabilities (such as technology, tools, skills) for successful deployment of the initiatives. The key elements (Figure 2) for consideration are as follows.

• **Organisation culture:** This represents the willingness and attitude of the business organisation (managers and team) to invest in contemporary initiatives (data-driven value creation), appreciate the associated long-term and short-term risks, and evolve the process over time (i.e. remain agile to the advent of technology and novel data contribution platforms). The mindset of the organisation will determine the keenness to take risks, make changes and evolve to create and capture value using data-driven initiatives.

• **Skills requirements:** This element pertains to the ability of the organisation, decision-makers, and key employees to understand, manage and align the value creation process to deliver the business needs of the organisation. Additionally, ability to create strategies that will co-ordinate and streamline business and
technical capabilities is pivotal for value creation and capture. It also requires managers to interpret and recognise the information presented in the sense-giving stage to make decisions.

- **Identifying relevant data sources:** This relates to identifying, capturing and storing real-time data obtained from social and physical sensors that will aid the organisation in creating value, which requires understanding of the data and business needs of the organisation. This element will require domain expertise (i.e. understanding the business needs to identify relevant sources) and knowledge about the analytics framework (not necessarily technical but conceptual).

- **Relevant Tools:** This represents the technological needs of the organisation to harvest relevant insights from the data, i.e. transform data into knowledge using suitable analytic tools, and infrastructure to support such techniques. It requires making decisions for purpose of the analytics to capture value, a strategy to identify and invest in the resources.

![Diagram](image_url)

*Figure 2: Needs of the organisation to employ the proposed analytics framework*

**Value creation process**

Business organisations in a supply-chain need to understand the key elements involved in the value creation stage, to formulate suitable questions that will be posed to the analytics process. The quality of the output derived from the automated analytics process will depend upon the quality of the question (or the problem formulated by the managers). This section provides an overview of the key elements (*Figure 3*) that managers will need to consider in the value creation stage of the proposed framework taking into account an array of factors preceding this stage.
• **Purpose:** It is necessary for the organisations (key decision-makers) to use their domain knowledge, understanding of the business needs, and knowledge of the data sources to outline the purpose of the analytics, i.e. what is the question the automated process will aid in answering. This will streamline and eventually coordinate the business needs, data availability, analytics process and value creation (Sanders, 2016). The purpose will also determine which social media streams should be used depending on the nature of the query, quality and type of data available from the stream, and organisational trust in the data stream.

• **Question:** The question (i.e. definition of the problem) is a critical element to guide the aggregation and sense-making stages of the analytics framework (Shah et al., 2012). The relevance of the question should be critically assessed considering four key factors: (1) whether the question can be answered, or key insights can be gained by employing analytics; (2) whether the organisation has relevant access to the data streams that will aid in answering the question; (3) how answering the question/gaining insights will add value to the business needs of the organisation; (4) whether the question is relevant to the contemporary needs of the organisation, i.e. relevance and alignment to business needs, objectives and existing strategy.

![Diagram](Image)

*Figure 3: Key elements to consider in the value creation process*

• **Relevance:** It is key for the organisation to assess the relevance of data stream, i.e. how much the data source can be trusted after the pre-processing, given the veracity involved in the data collected from social sensors. It is critical to assess the key features of the data which will include capturing platform, times-stamp, location, author, motivation to create the data and event associated with the data. Additionally, relevance of technology, expertise to use the technology, and suitable tools need to be considered as well, which should again streamline with the purpose of the analytics and potential intended benefits.
• **Evolve:** This is a critical consideration for the organisation to the evolving needs pertaining to technology turbulence and the supply-chain (at all levels – both upstream and downstream). The whole analytics process is evolutionary both in terms of value creation requirements and needs of the organisations. Organisations need to be agile to manage and respond to market movements and make changes dynamically, which will involve taking risks and strategically tackle the uncertainty. Therefore, organisations will be required to revisit their strategy and reflect on it, instead of sticking to a one-stop solution, which is unlikely to reap benefit over a period of time.

**Conclusion**
This paper demonstrates the need to include a value creation stage in the existing social media analytics framework, so that organisations can streamline the technological and business needs in a suitable manner, which will aid in reaping the benefits from social media data. In this context, organisation will need to adopt an agile strategy that will respond to changes in market as well as the technological turbulence in this digital era. The conceptual framework reported in this paper is yet to be validated in a practical business setting through a longitudinal study. In the future, we aim to conduct multiple case-studies with organisations (both small and large businesses) to validate the framework and identify the barriers stemming from the adoption of this framework. Nonetheless, the value-creation stage in social media framework is non-trivial because in a real-life business setting, organisations often delve into analytics (both social media and IoT data), without having substantial knowledge of the process and randomly searching for patterns in the hope of capturing some insights (which eventually becomes a barrier due to uncertainties stemming from an non-focussed analysis).

IS capabilities, service quality and environmental dynamism

Teng Teng (teng.teng@anglia.ac.uk)
Faculty of Business and Law, Anglia Ruskin University, Chelmsford, UK

Christos Tsinopoulos (chris.tsinopoulos@durham.ac.uk)
Durham University Business School, Durham University, Durham, UK

Abstract
Research on customer integration and Information Systems (IS) capabilities has mainly focused on manufacturing settings. Although some of the theoretical implications are likely to be similar in service contexts, the fragmented process induced by customer involvement during service delivery, requires a more process-specific focus. We, therefore, aim to explore the relationships between IS capabilities, customer connection, and service quality. The analysis indicates that for service firms, the integration of customer connection should be taken into account for its mediation effect in linking IS capabilities and service quality. We also investigate the impact of firm’s stable and dynamic environments.

Keywords: IS Capabilities, Customer Connection, Service Quality, Environmental Dynamism

Introduction
The application of Information Systems (IS) has become a significant effect on contemporary service operations. Firms invest in IS with the presumption that they will facilitate operations processes so that their performance will improve. Yet, IS resources by themselves are not sufficiently “unique” and thus it would be more useful and theoretically relevant to focus on the processes they affect (e.g., Bharadwaj, 2000; Santhanam and Hartono, 2003). One such organisational process, which has attracted a lot of research attention by supply chain management scholars, is the integration of customer connection, where IS-enabled customer connection enhances communication and contact processes, and with such customer resources integration comes greater success for the firm in its abilities to develop a good understanding of customer needs and set accurate customer profiles (Mithas, Tafti, Bardhan, & Mein Goh, 2012). Nevertheless, prior studies on IS capabilities have focused on either one specific type of technology or operationalised it as a highly aggregated concept. Moreover, although conceptual
frameworks have been identified to show customer integration is valuable in service provision (e.g., Moeller, 2008; Jaakkola and Alexander, 2014), there is much to learn about the practices of integrating customer resources (Kleinaltenkamp et al., 2012).

In this research, we break down IS capabilities into three dimensions based on the framework of Wade and Hulland (2004): IT for supply chain activities (outside-in), flexible IT infrastructure (inside-out), and IT operations shared knowledge (spanning); and focus on their impact on operational performance of firms in services. With this background, this paper addresses the following questions:

- How do IS capabilities affect the integration of customer connection, and service quality?
- What is the relationship between environmental dynamism and the relationship of customer connection and service quality?

**Theory and Hypotheses**

In this study, customer connection refers to the communicating and contacting activities in which the firm is involved with its customers. Specifically, these include the process of acquiring and assimilating customer requirements information, and related knowledge. These types of connection are important in the process of integrating with customers, as they help the firm to better understand customers’ preferences, and to build relationships with customers (Swink, Narasimhan, & Wang, 2007).

*IS capabilities and their impact on customer connection*

IT for supply chain activities (ITSCA) refers to the extent to which a firm has adopted IT for processing transactions, co-ordinating activities, and facilitating collaboration with suppliers and customers through information sharing. Previous research has highlighted the use of IT in improving customer connection processes by providing easier access to information, and developing more flexibility to respond to customer information requests (e.g., Lederer, Mirchandani, & Sims, 2001; Rai, Patnayakuni, & Seth, 2006). A firm’s use of ITSCA promotes its customer connection by digitally enabling the process of acquiring and assimilating customer requirements information and related knowledge. Specifically, ITSCA enables the firm to electronically communicate with customers, and to manage relationships with them (Bharadwaj, 2000; Feeny & Willcocks, 1998). For example, web-enabled customer interaction technologies provide the firm with an integrated set of functionalities at the customer interface to gather and store customer information and knowledge (Mithas, Krishnan, & Fornell, 2005). Therefore,

*Hypothesis 1a: The use of ITSCA has a positive influence on the degree of customer connection.*

Flexible IT infrastructure (ITINF) refers to a firm’s ability to deploy a shareable platform that supports a foundation for data management, communications network, and application portfolio. A flexible IT infrastructure provides an integrated platform that enforces standardisation of data and processes, making possible timely and accurate information gathering and sharing across business functional areas (Lu & Ramamurthy, 2011). ITINF provides a sharable platform for data warehousing, data mining, and reporting, thereby supporting the processes involved in connecting with customers...
Supported by the shareable and firm-wide databases, flexible IT infrastructure also facilitates an integrated communication presence, which enables online customer communication for after-sales services such as support for products bought or services delivered in physical stores as well as real-time live chat that provides online customers with access to customer service assistants (Jana, 2007; Oh, Teo, & Sambamurthy, 2012). Therefore, the discussion leads to the following hypothesis:

**Hypothesis 1b:** ITINF has a positive influence on the degree of customer connection.

IT operations shared knowledge (ITOSK) refers to the knowledge that the operations manager possesses regarding how IT can be used to improve operations processes. Previous research has emphasised the significance of business managers’ familiarity with information technologies and their potential business impacts (e.g., Bassellier, Benbasat, & Reich, 2003; Sambamurthy & Zmud, 1999). To promote IT in their business processes, business managers have to work closely with the department responsible for developing IT. Therefore, a business manager’s intention to further develop partnerships with the IT departments is considered to play a critical role in successfully implementing IT in business processes (Bassellier et al., 2003). Indeed, it is believed that the stronger the relationship between business and IT, the more effectively IT can be deployed in support of business goals (e.g., Chan & Reich, 2007). Placed within an operations context, IT knowledge shared by operations managers should promote and support IT utilisation in the firm’s communications with customers, hence facilitating customer connection processes. IT-knowledgeable operations managers are more likely to be involved in IT planning for customer connection processes. Furthermore, ITOSK should also ensure that the firm is able to respond swiftly, effectively, and efficiently to changes in customer connection processes, and this entails supporting technological innovation to facilitate those processes. To this end, ITOSK is expected to facilitate the firm’s customer connection. Therefore,

**Hypothesis 1c:** ITOSK has a positive influence on the degree of customer connection.

The mediating effect of customer connection on service quality

ITSCA can enhance and accomplish connection processes between a service firm and its customers in terms of acquiring customer requirements information, and related knowledge. Customer connection processes that are ITSCA-enabled allow a service firm to develop a good understanding of its customer needs and to focus efforts on meeting those needs, thereby precipitating improved service quality (Ellram, Tate, & Billington, 2004; Valarie A Zeithaml, Bitner, & Gremler, 2006). Customer knowledge that has been captured across service encounters can then be made available for all future transactions, enabling the firm to improve the accuracy of its customer profiles and to respond to any customer need in a contextual manner (Tsikriktsis, Lanzolla, & Frohlich, 2004). With accurate customer profiles, the service provider is able to enhance service quality by being responsive to customer requirements, and this in turn, increases the perception among customers that the services they are receiving are performed accurately and dependably, and can thus, be relied upon. Consequently,
Hypothesis 2a: Customer connection is positively related to quality performance and mediates the ITSCA–quality relationship.

Flexible IT infrastructure (ITINF) enhances customer connection processes by facilitating the accessibility of customer information and data across the firm. With such accessibility, a firm can leverage its stock of accumulated knowledge and experience for the purposes of effective customer relationship management (Lu & Ramamurthy, 2011). ITINF-enabled customer connection empowers the firm such that it becomes more familiar with the customer data management issues involved in initiating, maintaining, and terminating a customer relationship. This familiarity enables the firm to leverage its collection of customer data to customise offerings and respond to customer needs (Mithas et al., 2005). A firm’s ability to satisfy the needs of current customers will lead to improved service quality (Connor, 2007).

Hypothesis 2b: Customer connection is positively related to quality performance and mediates the ITINF–quality relationship.

ITOSK has the potential to promote and support IT utilisation in customer communication processes, and to facilitate customer connection. ITOSK-enabled technologies utilisation in customer connection contributes to improved quality performance of the service provider. For example, the use of online customer service processes enables the firm to respond to customer requirements in a quick, accurate and dependable way, increasing service reliability (Valarie A. Zeithaml, Parasuraman, & Malhotra, 2002). Using web-enabled customer interaction, the firm can help its customers to better understand their own needs, and can simultaneously facilitate the firm’s ability to customise service content and procedures according to individual requirements (Tan, Benbasat, & Cenfetelli, 2013). Customised offerings enhance the perceived quality of services from a customer’s point of view (Mithas et al., 2005). Therefore,

Hypothesis 2c: Customer connection is positively related to quality performance and mediates the ITOSK–quality relationship.

Figure 1 shows the hypothesised research framework of the proposed indirect effects of each dimension of IS capabilities (ITSCA, ITINF and ITOSK) on service quality through their positive effects on customer transactions.

Environmental dynamism refers to the ‘amount and unpredictability of change in customer tastes, production or service technologies, and the modes of competition in the firm’s principal industries’ (Miller and Friesen, 1983: 233). With increasing competition and advances in technology, firms are facing environments that are extremely dynamic (Yu et al., 2018). From dynamic capabilities view, firms with the capabilities that can extend, modify, change, and create business capabilities in response to environmental dynamism plays a fundamental role in changing operational routines and in ensuring that the firm can change its overall operations and have new sets of decision options (e.g., Winter, 2003). The fit between the firm’s customer connection capability and the competitive environment demands will positively affect the firm’s competitive position (Drnevich and Kriauciunas, 2010).
Hypothesis 3: The greater the degree of environmental dynamism, the stronger the positive impact of customer connection on service quality.

**Figure 1 – Hypothesised Framework**

**Data and methods**
We collected data via online survey from service establishments in the UK, with operations directors as the key informants. A total of 156 usable surveys were received. No statistically significant differences among variables were found, suggesting that the non-response bias is minimal.

**Measures**
The survey scales were either established scales or developed from the extant literature. *IT for supply chain activates* are represented in our survey by measuring the extent of implementation of 19 different types of process-level IT applications that used in service industry. Consistent with prior IS and OM research (e.g., Saldanha, Melville, Ramirez, & Richardson, 2013), we measure the extent of implementation (adoption) of each type of IT applications. *Flexible IT infrastructure* was measured using a two-item scale on a 1-7 Likert scale (from “Strongly Disagree” to “Strongly Agree”), assessing the degree to which the firm has established corporate rules and standards for hardware and operating systems to ensure platform compatibility; and has identified and standardized data to be shared across systems and operations department (Chen, Daugherty, & Landry, 2009; Lu & Ramamurthy, 2011; Ray, Muhanna, & Barney, 2005). *IT operations shared knowledge* was measured using a three-item scale on a 1-7 Likert scale (from “Strongly Disagree” to “Strongly Agree”), indicating the degree to which they agree with there is a common understanding between IT and operations managers regarding how to use IT to improve operational performance (Bassellier et al., 2003; Ray et al., 2005). *Customer connection* was assessed using a three-item scale on a 1-7 Likert scale (from ‘Not at all’ to ‘Extensive’), indicating the extent of integration or information sharing between their firms and customers on connection processes (Baltacioglu, Ada, Kaplan, Yurt, & Kaplan, 2007; Kulp, Lee, & Ofek, 2004). *Service Quality* was measured using a seven-item scale
on a 1-7 Likert scale (from “Much Worse than Competition” to “Much Better than Competition”), rating the external service quality (Parasuraman, Zeithaml, & Malhotra, 2005; Safizadeh, Field, & Ritzman, 2003).

Data analysis
Confirmatory factor analysis (CFA) was used to check convergent validity, following the two-step procedure suggested by Andersone and Gerbing (1988). CFA was conducted by corelating the constructs (ITINF, ITOSK, customer connection, and service quality). The measurement model shows a good model fit: CMIN/df is less than 4 (1.173), CFI = 0.937, RMSEA is less than 0.08 (0.033). GFI = 0.937, AGFI = 0.901, and IFI = 0.994 further confirm that the measurement model is acceptable. Moreover, the standardised coefficients, which range from 0.844 to 0.981; AVE values range from 0.76 to 0.84. The Cronbach’s alphas ranged from .801 to .956, consistent with the suggestion that alpha levels above .80 are very good (Hair, Black, Babin, & Anderson, 2009).

Findings
Figure 2 shows the overall results for the structural model (Numbers show above the arrow represent the standardised regression weight.). There is a good model fit, with acceptable values - CMIN/df = 1.657; CFI = 0.978; RMSEA = 0.065; GFI = 0.988; IFI = 0.979; NNFI = 0.925. Moderating effect of environmental dynamism on the relationship of customer connection and service quality is showed in Figure 3.

![Figure 2 – Structure Model Results](image-url)
Our results show that ITSCA, ITINF and ITOSK have a positive influence on the degree of the integration of customer connection. In addition, customer connection positively related to service quality; this relationship is further emphasised when firms work in a dynamic environment. Our results provide robust evidence for customer connection as a mechanism through which IS capabilities influence the quality performance of service firms. Put differently, customer connection, involving information sharing and operational co-ordination in respect of customer communication and contact processes, is the means by which the intrinsic value of ITSCA, ITINF, and ITOSK is translated into improved quality performance. The results suggest that manager in service firms should also consider the indirect role of IS capabilities in their firm performance, and the strength of the mediating role of integrated customer connection. Indeed, service firms that decide to develop and leverage their IS capabilities should also implement processes that encourage customer connection processes integration. More specifically, a higher degree of customer connection enables a service firm to collect the appropriate customer information, develop accurate customer profiles, and provide better customer support, all of which can enhance a firm’s ability to retain, improve, and extend its relationships with customers. When it engages in a long-term relationship with customers, the firm can at the same time improve the response to customer needs, and reducing demand uncertainty.

**Contribution**

We make the following contributions. Firstly, we contribute to a scarce but increasing body of research on customer and supply chain integration in service contexts. Specifically, we provide and validate a process-specific approach to empirically investigate customer integration (e.g., Moeller, 2008; Vargo & Lusch, 2008). We therefore respond to recent calls to better understand the practices of integrating customer resources (Kleinaltenkamp et al., 2012). Secondly, we explore the relationship between customer integration and operational performance in service contexts. We find that in service contexts IS capabilities lead to improved performance when they help develop processes for the integration of customer connection first. The practical implication of our finding is that service firms that embark on the development of IS capabilities should at the same time implement processes that encourage customer connection. This
development approach is even more significant for operations working in dynamic environments. Finally, we respond to calls from supply chain management literature to explore a comprehensive range of IT in SCM by developing and validating the measurement scale of IS capabilities in managing service supply chains (e.g., Ostrom et al., 2015; Zhang, van Donk, & van der Vaart, 2011).

Abstract

The literature on Blockchain suggests that the technology will enhance efficiency and trust in the supply chain due to its incorruptible and verifiable properties. This could also help in increasing sustainability due to the reduction of waste. This paper focuses on Blockchain technology and considers the feasibility of this technology within the domain of digital supply chains. The study utilises a systematic literature review process to review the literature in this domain. The topic of Blockchain is a new area of research and hence the academic literature is scarce. The study strives to identify current research gaps in this area.

Keywords: Blockchain, digital supply chains, literature review

Introduction

Satoshi Nakamoto proposed Bitcoin as a decentralised and non-refutable cryptocurrency (Nakamoto, 2008). As illustrated by Satoshi Nakamoto, blockchain is an accessible, distributed ledger that can record transactions between two parties without the authorisation of any intermediary (Nakamoto, 2008). Industry currently is investing huge sums of money in Blockchain-based solutions that bear the potential of revolutionising supply chains. This growing industry focus has inspired academic researchers to investigate the Blockchain technology from varying theoretical standpoints.

The distributed ledger characteristic of the Blockchain helps in working as a decentralised financial transaction. This also enables to provide a clear overview of supply chains. In order to scrutinise Blockchain technology and its potential implication on supply chain management, this paper provides a systematic literature review. The review strives to close a current research gap through exploring existing barriers, challenges and potential benefits, along with accessing the feasibility of Blockchain application for digital supply chains.

The shift from traditional supply chains to the digital supply chain requires to embrace a new way of linking physical and digital assets (Mussomeli et al., 2016). There are a great number of technologies available to significantly change the current SCM, such as
Cloud computing, IOT, 3D-printing, Blockchain and mobile technology. However, this paper concentrates on the feasibility assessment of using Blockchain for supply chain management. Due to the scarcity of knowledge and limited understanding of the new technology, there remains a considerable research gap between theory and practice. Based on a systematic literature review, this paper identifies current barriers and challenges of Blockchain applications that are pertaining to SCM. It also analysed benefits the Blockchain technology will bring to digital supply chains.

The research aims to answer the following research question: **How will blockchain technology influence digital supply chains?**

**Blockchain characteristics and application**

The five key characteristics of Blockchain technology are tamper-resistant, anti-counterfeit, immutable, time-stamped and accessible (Iansiti & Lakhani, 2017; Nakamoto, 2008). Blockchain provides irrefutability through a chain of blocks, each cryptographically linked to the previous, using a hash digest. The Blockchain is a sequence of records, each hashed and linked to the previous block with a unique timestamp. Hence, once a transaction is entered in the database and verification completed, the records cannot be tampered since they are permanent and chronologically ordered (Iansiti & Lakhani, 2018). The design and operation rules of Blockchain are based on computational logic. Various computational algorithms and approaches are deployed in the protocol. With complicated algorithms and encryption, the database could achieve cybersecurity theoretically, to resist malicious hack. Every transaction is visible to participants within the chain. However, access is not public to every user in a private Blockchain or consortium Blockchain, which requires permission for privacy protection. Without a central authority, any transaction or communication occurs directly between peers. Each involved party has access to track transmission in any time node. A single party will not control the database in terms of personal interests.

The current applications of blockchain technology are concentrated on cryptocurrencies and to an extent smart contract. Apart from Bitcoin (BTC), a considerable amount of cryptocurrency successively appears in the financial market after 2008. Litecoin (LTC), Ethereum (ETH), EOS, Peercoin and so on are multiple types of cryptocurrencies underlying the same distributed ledger technology but with a different encryption algorithm. The main advantage of such encrypted transactions is economic efficiency and cost-saving by trust-based peer-to-peer interaction (Swan, 2015). Smart contracts enable transfer of assets that are wider than simple cash transactions such as stocks, bonds, futures, loans, mortgages, titles, property etc. it is similar to standard contracts but without the need of trust between parties (Swan, 2015). A firm could signal via blockchain that a particular good has been received or obtain the update of location, in turn, triggered a payment (Iansiti & Lakhani, 2018).

Some leading global organisations, with a high level of supply chain digitalisation maturity, are already moving ahead in terms of Blockchain pilot test or empirical conceptual model for a potential reward. Alibaba, AusPost, Blackmores, and PwC has teamed together to explore the use of Blockchain technology to combat food fraud. Developing a "Food Trust Framework" is the major assignment of this cooperation. This framework is invented to fight against counterfeit ingredients and improve the integrity and traceability of worldwide supply chains (Bindi, 2017).

**Methodology**

For the consideration of clearly identifying what is known and not known about a given topic (Briner & Denyer, 2012), an explicit systematic literature review suggested by
Denyer, Tranfield, and Smart (2003) are adopted in this paper as a research methodology to select and synthesise data collected from databases. Distinct from traditional narrative reviews, an SLR follows a strict set of process which requires reviewers to analyse all existing information about the topic in a thorough and unbiased manner (Denyer & Tranfield, 2009). The structured Literature review approach provides a systematic, replicable, transparent, process that is based on an evidence-informed knowledge investigation. As a consequence, for creating new knowledge through rigour in the standards for selection and evaluation, this study conducting five distinctive processes as shown in Figure 2: (a) formulating research questions and establish focus, (b) locating studies, (c) selecting relevant information by rigour criteria, (d) analysing and synthesising findings, (d) summarize and report results.

The primary step of the systematic literature review is to framing research questions, as well as establish a research focus. The application of blockchain technology in an increasingly digitalised supply chain status quo is sought by analysing the existing literature to provide a comprehensive framework from barriers and potential advantage perspectives. For the consideration of building discussion based on exhaustive literature resources and high-quality evidence, this research acquired academic papers through Emeraldinsight, Science Direct, EBSCO (Academic Search Complete and Business Source Complete), ABI (ProQuest) and Scopus. The research string used for the search was “Blockchain” AND “supply chain. The time horizon of locating the review is from 2008 to 2019, since the blockchain technology has been prominent from 2008 with the emergence of bitcoin. The search on ABI and Science Direct provided a return between 165-185 papers. This number is low as the visibility of Blockchain technology within the supply chain domain is relatively new with the majority of papers being published in the first four months of 2019. The filtering process was focused on Operations Management and Supply chain journals and hence it was decided to use the journals rated as 2, 3 or 4 under the Operations management category in the Chartered Association of Business Schools journal guide. The filtering process provided 18 unique papers for further analysis.

**Thematic Analysis**
The 18 papers were analysed for two criteria: barriers and challenges, future opportunities. The focus for this has been the implementation of the Blockchain technology within the supply chain domain.

**Barriers and challenges**

1. **Throughput and scalability**
Throughput and scalability are considered as vital elements for implementing Blockchain. Swan (2017) and Vermeulen (2017) made a meaningful comparison between Blockchain technology transaction speed and traditional payment technology. The paper suggested that current bitcoin Blockchain network only processes about 7 transactions per second, which is lower than Ethereum that has an estimated speed limit of around 20 transactions per second. Nevertheless, VISANet can process nearly 2000 transactions per second. In comparison, the throughput of Twitter is as high as 5000 transactions per second. Vermeulen (2017) also pointed out that bitcoin uses a push method of paying while VISA uses both push and pull methods. Based on the data presented by Swan (2015), Reyna et al. (2018) and Li et al. (2018) proposed an argument that limited transaction throughput is a substantial challenge of Blockchain technology for wide implementation.
2. Security (Double-spend attack):
Swan (2015) stated that by combing peer to peer file-sharing network with public-key cryptocurrency, Blockchain technology created a new digital currency and solved a double-spending problem without a central intermediary. Double-spend is the particular situation that spends the same money more than once. However, during the transaction process, the risk of double-spend still exist. In order to prevent this issue, each transaction has to be verified before added to the chain. Since there is no central intermediary, Blockchain applications users should have tolerance with few minutes of verification time to ensure the security of transactions.

3. 51-per cent attack
The Blockchain technology was designed on the assumption that honest nodes will control the network (Nakamoto, 2008). However, a 51-per cent attack might occur when malicious users get together and manage to do more "virtual work" than the "good people" (Prashar, 2013). The entire network will be controlled by malicious users in such a situation. The probability of this attack happening will increase with the fast evolution of mining pools which compromise the integrity of Blockchain. Beikverdi et al. (2015) also argued that market-based centralisation of mining power is against the nature of a decentralised network. Further research is required to limit these challenges if supply chains need to consider adopting Blockchain applications.

4. Transparency vs privacy dilemma
There is an increasing amount of attention towards the anticounterfeiting ability, immutability, and reliability nature of Blockchain. However, without a central authority every involved user has access to make transactions. Since each transaction will be recorded chronologically and cannot be tampered; each member in the private supply chain network can trace and track goods, information, cash flow in time and geographic manner. The advantage of transparency discloses every single fraud and fault. Hence, it is important to maintain the integrity of private Blockchain networks. The concern that decision-makers have about business secrets, such as pricing strategy, product innovation and customer information will influence the adoption of Blockchain (Wang & Kogan, 2018). The private Blockchain protocol should normally face a comparatively lower risk of information leakage since users cannot have access without permission. However, Wang & Kogan (2018) have suggested a more serious situation, if the key-enabler department was controlled by a malicious party, the risk of privacy disclosure is still uncontrollable. Even worse, the entire private chain will be manipulated according to personal will.

5. Regulation absence
When applying the Blockchain technology in a domestic supply chain network, there is lack of exclusive governing laws and clauses to clarify rights and obligations of each involved company which courts can take charge if a dispute occurs (Mckinlay et al., 2016). A dedicated regulatory framework is necessary for building network architecture and further judging ownership issue like jurisdiction. In EU, the European Parliament voted to adopt a smart regulatory hands-off approach; it allows the regulator to develop sufficient capacity in such dynamic innovative environments, as well as regulating the application of Blockchain network (European Parliament, 2014). In the US, the Federal Reserve, the Securities Exchange Commission, the Treasury Department and relevant state regulators are taking charge to form and shape regulatory thinking towards Blockchain.
6. Wasted resource
Mining bitcoin requires a large quantity of energy for computing and verifying transactions (Swan, 2015). In the bitcoin system, the first internal factor causes the waste is the computation race game between miners. Clarified by Wang and Liu (2015), with the quantity of miners increasing, the difficulty level to maintain safety has increased. The growing time of verification reduces the bitcoin mining rate. Apart from the competitive mining situation and time-consuming encrypted mechanism; some scholars still see the potential in saving costs in a Blockchain-based supply chain network.

Strengths and Opportunities
1. Cybersecurity
Skwarek (2017), Kshetri (2017) have suggested that Blockchain in terms of decentralisation, autonomy and trustworthy, is likely to address key security challenges associated with cloud and IOT-system. The three main requirements for information security are: confidentiality, integrity and availability. Described by Li et al. (2018), confidentiality refers a set of rules to ensure all users were authorised which could be guaranteed by symmetric encryption. Integrity rules ensure that the sent data should be the same as received data. The hash mechanism of a block is designed for anti-tampering and to prevent any change through information transmission. Availability requires all authorised users to possess reliable access to information. Skwarek (2017) believed that the distributed ledger mechanism is able to withstand manipulation and errors. Kshetri (2017) proposed that the Blockchain could play a possible role in strengthening security and protecting the privacy of customers' information in the healthcare industry.

2. Traceability
From a conceptual perspective, Blockchain technology which provides real-time information about operations matches the pre-requisite of asynchronous supply chain. Blockchain can be used to track raw material into the supply chain both internally and externally. In the healthcare industry, Glover & Hermans (2017) outlined the benefits of using Blockchain technology to improve the traceability of medications from active pharmaceutical ingredient (API) to a patient, while facilitating the gathering of patient-level data in a HIPAA-compliant manner. Some researchers have also advocated the traceability capabilities of Blockchain technology to maintain safety in the food industry.

3. Trustworthy and Anti-counterfeit
Notheisen et al. (2017) & Scott et al. (2017) both analysed Blockchain technology and suggested that the trust-free transaction system allows companies to move value and manage ownership transformation even with divergent interest, and without a central institution. Nodes establish reliable communication between one another by generating transparent, cyber secure and immutable record of transactions.

4. Accessibility and Network facilitating
With today's digital supply chain, every strategic decision made is supported by sufficient data analysis. The Blockchain technology addresses the risky problem by ensuring users with permission add and access a permanent and time-verified record. Inter-organisational relationships will be influenced by the transparency and non-immutability of the data through the peer to peer transactions. The Blockchain technology therefore, has a significant potential to reduce communication costs among disconnected parties and promote information transaction efficiency in the supply chain.
5. Monitoring and value creation
Nowiński & Kozma (2017) summarised the Blockchain potential implication on business from three dimensions: strategic components, customer & market components and value creation components. Tapscott and Tapscott (2017) pointed out that Blockchain allows companies to eliminate transaction costs and create value both from internal and external. Vertical integration and central controlling may still make sense and maintain high efficiency in interior governing. Lanko et al. (2018) revealed an advantage of combining existing tracking technology with Blockchain. According to their research, the combination of RFID, GPS and Blockchain will significantly reduce losses caused by human error and intentionally fraudulent information, eliminate turnover problem caused by insufficient credit between participants.

6. Optimise SCM performance
Kshetri (2018) concluded that supply chain performance measurement is often conducted in terms of objectives such as cost-efficiency, dependability, speed, flexibility and risk control. Based on multiple-cases studies, Kshetri (2018) researched the Blockchain's potential in optimising supply chain performance. Cost however plays a major role in adoption of the technology. With constant tracing and tracking, defective products can be easily identified and removed early on thus reducing high cost of loss and reputation risk. Secondly, in the consortium protocol, every transmission could be validated by digitally signed documents. Paper records will gradually be discarded while developing digitalising SCs. Thirdly, regulatory compliance costs decrease since inter-organisational conflicts will be solved by technical code or commercial rules rather than intermediaries. Smart contracts will help in increasing procurement effectiveness and efficiency.

Future of Digital SCs with Blockchain application
Following a thorough review of Blockchain’ implication on digital supply chains, several trends that are developing can be identified.

Industry 4.0.
Blockchain was highlighted as the critical technology for facilitating Industry 4.0. The proof-of-work mechanism enables cyber secure guarantee for current Internet-facing organisations. The Blockchain is an important technology to establish a reliable protocol that ensuring cyber security and reliability by technical codes rather than central authority. Moreover, Blockchain can operate as a distributed ledger to develop a trusted and flexible relationship between upstream suppliers, downstream retailers or even end customers. For instance, applying smart contract that allows credible transactions without third parties, in managing supplier relationship, Blockchain technology could make it possible that digital signature replaces of signed documentary records; Which meet automation requirement of Industry 4.0.

Disintermediation
Disintermediation is the reduction in the use of intermediaries between various parties. Blockchain technology provides significant opportunities for disintermediation. The Blockchain-based protocol is recognised as trustworthy, reliable and decentralised. According to Joshi (2017), Blockchain is facilitating disintermediation from following three perspectives. Firstly, Blockchain supports trading products and services across a web of partner network, which allows trading whether tangible or intangible that is of value. This means here comes a trend of assets digitalisation. Secondly, a validity and
reputation system will be established by fairness and accessibility. Thirdly, Blockchain eliminates conflicts by supporting ownership clarification.

Incentivisation

The Blockchain concept provided Bitcoin as the incentive for processing the transactions and deriving the hash. The aspect of providing the incentive is an important element of the irrefutable and traceable network. However, this incentive until now has been provided on public networks due to the processing power required for deriving the hash. Private networks or supply chain platforms currently do not emulate the Bitcoin approach as-is but provides a very good possibility of providing incentivisation in other forms (not Bitcoin). Smart contracts and Blockchain-based supply chains could create some novel forms of incentives for members to participate.

Conclusion

Since the introduction of Bitcoin, Blockchain technology has been identified in various applications among different industry sectors. However, academic research on Blockchain relevant to supply chain management is mostly focussed after 2016 ad has increased in 2019. This study conducted a systematic literature review, extracted and analysed 18 academic papers from a operations management perspective. The paper has identified barriers from selected papers and outlined the potential opportunities brought by Blockchain technology in supply chain management. Blockchain can serve in different forms such as cryptocurrency, private platform, consortium protocol or public Blockchain. Blockchain could facilitate achievement of SCM objectives—Visibility and transparency, which are regarded as key challenges for shifting from traditional supply chain to a digital network. Based on the above study, four recommendations on future research directions of Blockchain technology application in SCM are identified:

1) Conduct more studies on balancing the transparency and privacy need. Provide solutions supported by practical experience to resolve the dilemma.
2) Continue to identify practical barriers for applying the technology. Propose solutions to narrow gaps between theory and varying operations.
3) Investigate technologies that have the potential to facilitate Blockchain application.
4) Propose new business models and incentivisation mechanisms.

Abstract

Supply chain visibility (SCV) has been in trend after the millennium and raised interest of both academics and practitioners. However, there is still an ambiguity on the topic, which hinders a proper SCV application. This study aims to clarify the fuzziness of the area by conducting a systematic literature review. By reviewing 67 articles, we have identified a conceptual model that covers three main roles of information sharing for SCV and their impacts on the positive and negative constructs of SCV. This framework illuminates the inter-construct interactions and, also provides diagnostic insights for the implementation of SCV in the firms.

Keywords: Supply chain visibility, information sharing, systematic literature review

Introduction

SC concept relies on the movement of materials from suppliers to customers and finance and information in the opposite direction (Baihaqi & Beaumont 2006). However, these flows generally go further beyond the horizon that the focal firms see. This situation sometimes creates problems because there is no capability of the focal companies to interfere with the issues beyond their visible boundaries (Carter et al. 2015). Moreover, this has become to be a bigger issue as once unimportant factors that are of no need to trace gain importance with the new requirements of dynamic market conditions (McKinney et al. 2015). For example, some problems related to social governance strategies that mega companies experienced are a result of not being aware of after boundaries. Similarly, being unaware of the processes within the boundary has been turning out as extra costs and problematic relationships. Therefore, as a result of the need to see, supply chain visibility (SCV) has become essential for supply chains, to mitigate the risks and maintain the confidence of supply chains (Fan et al. 2013). Various authors highlighted the importance of SCV (see (Barratt & Oke 2007; Dubey et al. 2017; Sarker et al. 2016; Nooraie & Parast 2015; Musa et al. 2014). Therewithal, practitioners have
also realised that importance (Bartlett et al. 2007). Enslow (2006)’s survey shows that 79% of the respondent companies mention that lack of SCV is one of their top concerns. Another study conducted by Sarker et al. (2016) affirms that results and demonstrate the importance of SCV among practitioners. However, the very same studies and some others also refer to SCV as one of the points that firms are incapable of achieving. Although there are various, contingent reasons for the issue, a dominant school of thought in the field believes that the gap between the targeted and achieved visibility levels can be a result of the ambiguity around the term of SCV (see Williams et al. 2013; Gunasekaran et al. 2017; Barratt & Oke 2007; Basole & Bellamy 2014; Zhang et al. 2011; Wang & Wei 2007) The vagueness starts with the definition of SCV. Since there is no consensus even in the definition, a misunderstanding dominates the topic (Francis 2008). Moving from Dubey et al. (2017)’s study, we suggest that the roots of the problem may be searched in delineating visibility from ‘information sharing’ term, which is a significant component of visibility and supply chain management (Baihaqi & Beaumont 2006).

Information sharing and SCV has been often used to state the same concept in supply chains: the state of the information prevalence among SC partners. In fact, moving from the previous studies, we can make a basic differentiation between these two terms with a resource-based view. As the visibility is basically accepted as the ‘capability of accessing and sharing information’, we can see the information as the main resource behind this capability and ‘information sharing’ as a single activity unit of that resource (Holcomb et al. 2011). However, the interaction between these two terms is not limited to only this. As there are authors that see information as a means of implementing visibility, some others regard it as a consequence of having information. Although all propositions are correct in theory, that situation blurs the field and hinders to constitute an SCV implementation roadmap for practitioners. Lack of a holistic study that will aggregate different schools and organise them into an applicable form motivates this study to construct a conceptual model of for the interactions between information sharing activity and the SCV dynamics.

Thus, this paper targets to investigate different interaction models between information and SCV dynamics and consequently produce a conceptual model. By that framework, the gap between theory and the practice will be narrowed down and the organisations with better SCV understanding will increase their SCV and overall SC performance. In order to achieve these aims, this paper utilises systematic literature review (SLR) methodology. Remainder of the paper will inform about the SLR methodology and the specific process of this paper and then demonstrate the descriptive and thematic findings of the study.

**Methodology**

A systematic review (or systematic literature review (SLR)) is defined as a review of a clearly formulated question conducted via a set of systematic and clear methods which identify, scope, and evaluate the relevant research in a critical way and then collect and analyse data of included studies (Siddaway 2014). It is adopted by researchers to identify, justify or refine the processes (Mulrow 1994). SLR, being a fundamental scientific activity in its nature, has various reasons to be preferable against traditional literature reviews. Characteristics of SLR compose some of the differences, such as replicability, positivity and transparency (Tranfield et al. 2003). Information overload is another reason to select SLR over traditional review. (Petticrew & Roberts 2006). In order to achieve the aims of this study, it was critical to conduct a holistic research and not to miss any perspective, so systematic literature review (SLR) has been adopted as the research methodology. Figure 1 demonstrates the phases of this SLR:
Denyer & Tranfield (2009) propose that less experienced researchers should tap into a scoping study in the field just ahead of the SLR. It is suggested in order to provide an introductory understanding of the constructs, so that they can conduct a better review with an increased awareness. In the planning step, this process has been achieved by the complete review of 28 papers, which deliver a good amount of background details about the variables. Together with scoping the research area, a review panel and an SLR protocol have been structured. Review panel helps the study increase objectivity by bringing distinct and expert perspectives, while protocol document formally captures the steps of the review and fulfil the transparency and replicability requirements (Tranfield et al. 2003).

Scoping the field and discussions in the review panel help the study to create specific review question or questions. They clearly put forth the variables of the study, which compose the keywords and search terms, and ultimately search strings (Tranfield et al. 2003). In light of this, the following main review question and sub-questions were identified to form the main framework of this research:

- How do supply chain visibility and information sharing interact to improve supply chain performance?
- What are the enabling and inhibiting factors for SC visibility?
- What are the benefits (improvements in SC performance) of improved SC visibility?
- What are the challenges (vulnerabilities) ensued by improved SC visibility?
- What are the core constructs of information sharing in its interaction with SC visibility?
- What are the relationship models between information sharing and SC visibility?

In order to be able to find successful and complete answers for these questions, following keywords and search terms were used (Table 1) to the final search string.

For searching, three major databases for management and organisations studies have been selected, namely Scopus, EBSCOHost, and Web of Science. Search ended up with 45,296 papers in the aggregate, which then are filtered and evaluated with three sets of results: eligibility filters, focus and relevancy criteria and quality evaluation. Eligibility filters included publication type and quality (only 3-4* journal articles in order to focus only on quality data and to avoid drowning in the excessive and repetitive data), research field (operations research and management, business, management and supply chain management), publication year (all included), and language (English). Filtered papers, then, were checked for their relevancy and focus by a title and abstract review. Next, remainder papers were evaluated according to four criteria: theory, contribution, methodology and results. In total, 54 journal articles were selected for the SLR. Lastly, they were supported with two main cross-referencing techniques (namely, snowballing and citation-tracking) in order to avoid missing essential information that is initially dismissed by the eligibility screening (Greenhalgh et al. 2005). It has brought 13 additional papers and, the study has been constructed on the review of 67 papers in total.

Along the review process, data have been extracted from papers in a systematic way. First, review sub-questions were considered as the main categories. Then, in order to create the granular codes within each category, a repetitive review process has been conducted. The findings of the review were analysed descriptively and thematically. Descriptive analysis demonstrates the trends in the field, in terms of publication year, resource, adopted methodology and theoretical approach. Thematic analysis, on the other hand, presents the context-based findings like state-of-the-art in the field, taxonomy of the constructs and related interrelationship.

**Descriptive Analysis**

In order to understand the main characteristics of the field, papers have been first analysed descriptively, in terms of their publication year, research methodology, and theory utilisations.

In the eligibility criteria, there was not any limitation for the publication year. However, descriptive analysis shows 2000 as the earliest publication year of 67 paper reviewed. Considering the non-existence of any restriction, we may infer that SCV is a rather new area. Moreover, we have identified that the last decade has an average of 5.7 publication on SCV. It indicates the importance of the area in academia and its need and fruitfulness to be illuminated.

In terms of paper type, we have observed that 15% of the papers (11) provide either conceptual or theoretical contribution to the field. These type of studies help researchers keep up-to-date with the state-of-the-field, and suggest promising directions for further research. On the other hand, the remained 85% (58) utilise empirical research methods, either in order to explain previously asserted conceptual phenomenon or to explore the area further. We suggest that the ratio of 15% to 85% is a good balance for the steady and continuous improvement of the SCV area. Among these 58 papers, 49 use three major research methods: case study (21), survey (17), and modelling (11). These figures tell that academics of SCV 1) are in a search of furthering the area with majorly doing exploratory case studies; 2) are interested in the correlations (of internal SCV constructs or with other SC constructs) related to SCV; 3) and look for creating a universal quantitative measurement for SCV. While these research methods dominate the field, there is a rarity in methodologies like field and laboratory experiments and action studies. These methodologies, comparing the others, give more control to researchers and help them investigate causal relationships. Hence, adopting them more will bring a holistic sharpness to SCV, and lead it to be a well-understood and applicable field.
Another descriptive area we assessed in this study is the theoretical approach of the reviewed papers. Utilising a theory in the research is essential because it defines the boundaries of the study and provides study to stay in that limits, not less or more. Therefore, the research field grows within robust blocks. Lack of theoretical base, on the other hand, ends up with suspending ideas and a fuzzy research field. SCV field also experiences this problem, where only 26 out of 58 papers adopt a theoretical approach. Considering that ambiguity is SCV field’s biggest problem, we can assert that this may be one of the reasons. Resource-based view is the most adopted theory, which accepts visibility as a capability for SCs. However, authors look at the phenomena from 18 other perspectives as well (Table 2).

**Thematic Analysis**

*Roles of information sharing in SCV*

Information sharing is accepted as a vital tool for many supply chain constructs like coordination, integration and flexibility (Baihaqi & Beaumont 2006; Williams et al. 2013). When it comes to visibility, the degree of that importance scales up, as information sharing constructs the core of SCV. This relationship, however, brings some problems as well: interchangeable usage of SCV and information sharing (Swaminathan & Tayur 2003). We believe that this interchangeability underlies the ambiguity of SCV context. Here, we define two main interactions between information sharing and SCV.

The first school of thought accepts information sharing as a source, which results in having visibility capability along the supply chain (Brandon-Jones et al. 2014; Holcomb et al. 2011; Barratt & Oke 2007). This relationship is obvious as the majority of SCV definitions rely on information sharing/accessing capability and information quality attributes. In this concept, we can tap into the resource-based perspective. We can infer that information sharing is only the activity that provides discrete benefits when the resource is used. On the other hand, a continuous information sharing powered by a completely visible supply chain will lead to a holistic set of benefits along the supply chain. The second group of authors, on the other hand, assert that when there is a viable visibility in supply chains, it can ease sharing information and getting benefit from that activity (Yu & Goh 2014; Caridi et al. 2010; Pfahl & Moxham 2014; Brandon-Jones et al. 2015). This relationship may be explained by the facilitating role of visibility, in terms of providing requisite technical and technological infrastructure. When the conditions are
more suitable to share and access information, it will be more possible to have more flow of information among supply chain partners. Other than technical assist, SCV can help construct the right environment for information sharing. The visibility-led higher level of trust between partners will make them more volunteer to share information (Baihaqi & Beaumont 2006).

Therefore, we can see that there is a cycling relationship between information sharing and SCV. While this brings the ambiguity and interchangeability for the field, it also complicates the practical implication of SCV. Since both concepts trigger each other, organisations may be confused about the starting point of visibility process. Somapa et al. (2018) bring an original set of ideas for information sharing and visibility interactions, which can be a solution to the issue. Authors look SCV from a process theory perspective and create three main categories for SCV characteristics. Then, they match the categories with suitable attributes of information: accessibility of information, quality of information and usefulness of information. These categories fit our findings and develop them by highlighting the difference between accessing information and the quality attributes of accessed information like completeness, accuracy, timeliness, usability, and format. Since quality-related information attributes are independent than the state of reaching information, we can accept it as another information sharing-SCV interaction model. Conclusively, we can classify these interaction modes as follows: information as-enabler-of-SCV, information as-means-of-SCV, and information as-result-of-SCV. Investigating SCV contributes amongst these interaction modes will increase the robustness of the field and ease the applicability of both concepts.

Positive SCV constructs
Review of 67 papers has provided us to have a comprehensive analysis of SCV constructs with 49 concepts that affect SCV in a positive way. However, without analysing and synthesising them, they were not suitable to use. They were dispersed, in some cases repeating or covering others, in other words, far from creating a systematic tool. After repetitive analysis of the reviews, we have identified two main taxonomies for positive constructs of SCV, namely antecedents, and enablers.

Antecedents represent the prerequisites, of which existence is required for a better or easier setting of an activity. In this context, their impact can be considered as a moderating variable. Literature has provided one tangible and five intangible groups of antecedents. The first antecedent is the connectivity, which is the only tangible one (Scholten & Schilder 2015; Hardgrave et al. 2013; Kyu Kim et al. 2011; Chew et al. 2013; Caridi et al. 2014; Pfahl & Moxham 2014; Brusset 2016) It refers to the technological infrastructure readiness for an end-to-end SCV. Many authors consider connectivity as a starting point for SCV implementation in the cycling interactions of information sharing and SCV. Other antecedents are related to intangible concepts. The first one is culture. It involves the interorganisational culture elements like shared language and narrative (Johnson et al. 2013) or country culture (Dubey et al. 2017) and intraorganisational culture elements like organisational culture (Dubey et al. 2017), knowledge management culture (Busse et al. 2017), joint learning culture (Scholten & Schilder 2015) and risk management culture (Rajagopal 2017). Second intangible concept, trust is accepted of a great essence, as it supports SCV and at the same time is supported by SCV (Johnson et al. 2013; Klueber & O’Keefe 2013). Relationship management is another antecedent for SCV. It can be assessed as two groups: strategic relationship management, including internal and external SC integration and collaboration (Williams et al. 2013; Rajagopal 2017).
2017; Scholten & Schilder 2015; Steinfield et al. 2011), and operational relationship management covering length of relationship, power distribution, enthusiasm, network ties and configurations (Akkermans et al. 2004; Klueber & O’Keefe 2013; Johnson et al. 2013; Scholten & Schilder 2015). Last antecedent group is related to external environment, which is demand uncertainty (Yang et al. 2018). It is suggested that visibility is best utilised in a problematic demand profile. It should be remembered that these factors have moderating impacts. In other words, they do not result with a better SCV implementation on their own, instead, their existence plays a supportive role for the initiation of SCV.

Second group of positive constructs of SCV is composed of enablers. Enablers play a role of initiating and driving visibility. Literature provides three main enablers. First and the most important one is information sharing and quality of information shared. Since previous section has elaborated this concept, we do not repeat the details here. Second enabler is about regulatory and contract requirements (Johnson et al. 2013; Yang et al. 2018). This enabler does not have an incentive role but instead has a directive function. Organisations may need to be more visible according to their industry-specific requirements (e.g. pharmaceuticals, cold-chain food industry). In the other aspect, an SME may be demanded to become more visible in a collaboration with a multinational corporate. The last enabler is about behavioural norms (Johnson et al. 2013). Behavioural preferences of managers or operators trigger the implementation of visibility. However, it should be kept in mind that this behavioural propensity can work as an inhibitor as well.

**Negative SCV constructs**

Similar to the positive constructs, there are negative factors that inhibit a prosper SCV implementation. The review of the literature has demonstrated that these negative factors can be classified into two main groups in order to comprehend them in the best manner: extant challenges, and inhibitors before SCV initiation.

Two main existing challenges hinder companies to consider adopting SCV in strategic perspective. The first one is related to the management of SCs. Lack of alignment among SC partners aggregates the integration. Hence, it turns into an obstacle before companies, and even inhibits them to consider being visible to their partners, which are mentally far to collaborate (Maghsoudi & Pazirandeh 2016; Busse et al. 2017). Second problem arouses from technological reasons. Since the technology plays an important role of reaching data and then disseminating it, adopting the right and integrated technology along SC is regarded as essential for SCV (Maghsoudi & Pazirandeh 2016). However, the short life-time of communication technologies and their increasing infrastructure costs make an end-to-end SCV implementation difficult, especially for SEMs (Steinfield et al. 2011). These two problems are the obstacles that should be solved before creating strategies for implementing a holistic SCV.

Second set of negative constructs appears when firms decide to become visible. The main problem is the ambiguity around the visibility field (Basole & Bellamy 2014; Dubey et al. 2017; Francis 2008). Its interchangeability with information sharing, its deficiency of not having a single definition prevent organisations to have a standard road map for the implementation process. Another setback is about the management of information. The difficulty of data standardisation, having low quality information and the discrepancies in the information sharing process lead firms to unsuccessful SCV initiatives from the beginning (Maghsoudi & Pazirandeh 2016; Steinfield et al. 2011; Williams et al. 2013).

Lastly, behavioural reasons play an important role before SCV applications in negative direction. Biases of managers against the dependability of information, their
underweighting manners against its importance cause reluctance in information sharing (Caridi et al. 2014; Williams et al. 2013). Besides, partners having trust issues have the fear of opportunistic behaviour from opposite side of relationship, when they give access to them for their information (Dubey et al. 2017). These hesitations hinder the relationship and prevent having the full benefit of SCV.

**Conceptual Model**

Concluding, this study has investigated the different impacts of information sharing roles on SCV. In order to elaborate their interactions, following conceptual model can be a base for future studies in the SCV area (Figure 2).

---

**Conclusion**

This paper aims to clarify the fuzziness in the supply chain visibility by investigating its interactions with information sharing activity. In order to achieve the aims of the study, SLR methodology has been adopted in this research. Analysing 67 papers, three main roles of information have been found and their impacts have been observed in their interactions with SCV constructs. Two main contributions have been gathered from the study: interaction between information sharing and supply chain visibility has been illuminated in order to abolish the fuzzy nature of the research field. Secondly, positive and negative constructs of SCV have been classified in relations to each other. This helps researchers and practitioners to detect the interactions between constructs and draw their own roadmaps for and end-to-end SCV. We recommend future studies to test the conceptual findings of this study in empirical settings.

Abstract

A manufacturing process with two stages of quality control is considered. Initial screening is performed following some critical operations that generate a high proportion of defections. This allows us to discard the defective items at an early production stage and increases the productivity downstream in the production line. The initial screening cost, as well as the defect detection rate, depend on the screening speed. A mathematical model is developed and the optimal production parameters are analytically determined. We provide numerical examples and sensitivity analysis to illustrate the results and to derive managerial insights and implications.

Keywords: Optimal lot sizing, Screening time, Imperfect quality

Introduction

For many companies – e.g. those in electronics and semiconductor industries – it is reasonable to have an initial screening after some initial processing, especially, critical operations such as chemical or mechanical handling like chemical etching, drilling, etc. The reason for this is that the proportion of defections at that particular stage of the process is relatively high, and the remaining production steps are time-consuming and costly. Discarding the defective items at an early production stage increases the productivity downstream in production line and improves the overall performance measures of the system. Therefore, companies sometimes have even more stages of quality checking than one. Cao et al. (2012) provide methods for optimal allocation of inspection stations. Bouslah (2018) provide a model with two stages and joint control of production, inspection and maintenance. The reason for the two stages is the existence of two machine lines. Even though, adding initial inspection to the system might be reasonable for a company because they want to check the parts or input materials from their suppliers. Of course, the extra effort of initial screening has its own costs, and we aim to optimize the time spent with this activity in order to minimize overall costs. The optimization is carried out in the framework of the classical models of inventory analysis.
Cárdenas-Barrón et al. (2014) stated that Harris (1913) published the first inventory model. A special issue of the International Journal of Production Economics celebrated the hundred years’ anniversary of this seminal paper. Among the papers published in this issue, Cárdenas-Barrón et al. (2014) contains a broad overview of the extensions of the original model as well as an extensive bibliography. Andriolo et al. (2014) provide a comprehensive summary on papers in the field, followed by Glock et al. (2014) with a survey on literature reviews in the area of lot sizing. We restrict our attention here on the papers closely related to our topic.

Our model belongs to the extensions of the Economic Production Quantity (EPQ) model, originally developed by Taft (1918) which assumes that the production rate is finite. The other research field we would like to join is focusing on imperfect quality items. A related Economic Order Quantity (EOQ) model is proposed in Salameh and Jaber (2000). It assumes that every single finished item is screened, and the imperfect ones leave the system at the end of the screening period in a batch. The authors draw up the explicit formula to calculate the economic lot size quantity and found that it is increasing with the growth of the average proportion of imperfect quality items. Khan et al. (2011) reviewed the extensions of this model where none of them considers the speed of the screening as a decision variable. Additionally, our paper is adding another stage of quality control to the EPQ version of the model.

Al-Salamah (2016) states that inventory models with imperfect quality can be classified in two categories: predictable and unpredictable identification, the former one being more often found in literature. The author considers imperfect inspection, destructive and non-destructive acceptance sampling. Reviewing most cited papers in the stream of imperfect quality, we found that perfectly reliable quality control is more often assumed which is more or less equivalent to the assumption that every single item is checked at the end of the production process. Alamri et al. (2016) argue that exhaustive inspection may eliminate the return service cost caused by defections, and the impact of letting through defective items could be severe. Instead of sampling techniques, exhaustive screening is more commonly applied in the industries we would like to analyse in this paper. Based on Sahling and Hahn (2019), the biopharmaceutical manufacturing does also belong to the stream of the possible examples with their flexible flow and very strict quality check requirements.

Moussawi-Haidar et al. (2016) were the first who integrated screening time into their production model with rework. Previous literature assumed either that all items are perfect or that screening is carried out continuously, making it possible to rework imperfect items immediately after detection. The authors provide closed form expressions for the optimal production lot size in a framework where inspection is finished later than production, and all defections are repaired. Chiu et al. (2007) consider a proportion of defections to be repairable and the remaining ones to be scrapped, and investigate the joint effects of stochastic machine breakdowns, scrap, and rework on the optimal production run time.

The speed of screening was first considered as a decision variable in Hauck and Vörös (2015). The authors built EOQ models to find the optimal lot size, screening speed, and level of investments to increase the speed of quality control. In this paper, we rather focus on the initial screening time. We assume that the defect detection rate depends on this time, i.e. the more time is spent on the screening, the higher proportion of initial defections are found. The detected defective items are discarded at this stage, saving energy and cost in the subsequent production steps.

Jaber et al. (2008) extended the model of Salameh and Jaber (2000) with the assumption that the proportion of defective items is lowering from cycle to cycle due to learning. Konstantaras et al. (2012) have further developed this model with the possible
occurrence of shortages, and managerial insights helping companies to choose suppliers. The ideas of both papers are applicable as possible extensions to our model.

**Model description**
A production process with two stages of screening is considered as illustrated by Figure 1. We face a deterministic, known and constant demand of rate $d$. At the beginning of each cycle, we launch the production of a lot of size $Q$ (decision variable). The production rate is $P$ and on average, a proportion $a$ ($0 < a < 1$) of the production is defective after an initial processing step. Since this proportion is typically relatively high, a screening stage is added right after, to the process. We decide on the amount of time ($0 \leq \sigma \leq \bar{\sigma}$) is spent on the screening of each unit. Both the screening cost and the defect detection rate depend on $\sigma$. To avoid creating a bottleneck at this stage, the screening rate must be higher than the production rate and consequently the maximum time that could be devoted to the screening is $\bar{\sigma} = 1/P$ (unit of time per item). We assume that a proportion $p_1(\sigma)$ of the defections ($0 \leq p_1(\sigma) \leq 1$) can be detected at this stage, and we get rid of the defect items at the end of the processing period. Initial screening cost is $c_1(\sigma)/$ per unit. It is natural to assume that if no time is spent on the screening ($\sigma = 0$) than $p_1(0) = 0$ (no defects are detected) and $c_1(0) = 0$ (no costs are incurred). We assume that $p_1(\sigma)$ and $c_1(\sigma)$ are continuous functions of $\sigma$ and at least twice differentiable.

![Figure 1: The production process with two stages of screening](image)

After having separated the defects detected during the initial screening, the production continues with more expensive but reliable operations, followed by the final screening stage. At this stage, all kinds of defects are detected so only the good output is shipped. The defective items found at this step are removed from the inventory at the end of the cycle, without rework. The time spent on final screening is fixed and its cost is $c_2$ per unit. We assume that no backlog arises, and there is no excess inventory at the end of the cycle. In order to satisfy the demand, the defection rate has to be accounted for. The defect compensated demand rate is $d/(1 - a)$ which must remain lower than the production rate (if not, the demand cannot be fully satisfied). We denote by $S = \frac{1 - a}{d} - \frac{1}{P}$ (it can be interpreted as the idle production time per unit).

Notations used in this paper are listed in Table 1, and the inventory build-up diagram of the deterministic EPQ model is shown in Figure 2. During the production period, the inventory raises at rate $(P - d)$, i.e., the production rate minus the demand rate. At the end of the production cycle $R_1 = Q/P$, the company gets rid of the initially detected defections, i.e. $Qap_1(\sigma)$ items. The defective items detected later at the final screening...
stage \((Qa(1 - p_1(\sigma))\) items) leave the system at the end of the cycle. The total cycle length is \(R = Q(1 - a)/d\). The average inventory level is \(I_1 = \frac{1}{2}(P - d)R_1\), during the screening period and \(I_2 = \frac{1}{2}[(P - d)R_1 - 2Qap_1(\sigma) + Qa]\) during the remaining time of the cycle.

\[\text{Figure 2. Inventory diagram of an EPQ model with two stages of screening}\]

Processing, screening and holding costs are considered at both stages as listed in Table 2. The initial processing cost contains the cost of initial production for every item, whereas final stage processing cost does only consist of production costs of the items that passed the first screening (good and undetected defective items). Speeding up initial screening (spending less time with this process) saves some cost. However, it does also result in a lower proportion of defective items detected. The undetected defective items go through the second stage of production as well as the final screening, which results in higher processing and screening costs in the second-stage.
Table 2. Variable costs in a cycle

<table>
<thead>
<tr>
<th>Costs</th>
<th>processing</th>
<th>screening</th>
<th>holding</th>
</tr>
</thead>
<tbody>
<tr>
<td>initial stage</td>
<td>$k_1Q$</td>
<td>$c_1(\sigma)Q$</td>

<td>$c_2Q(1 - ap_1(\sigma))$</td>
<td>$h(R - R_1)I_2 = \frac{Q^2}{2S}\left(\frac{P - d}{P} + a - 2ap_1(\sigma)\right)$</td>
</tr>
</tbody>
</table>

Additionally, a fixed setup cost $K$ is incurred once in every cycle. Thus, the total cycle cost writes:

$$TC(Q, \sigma) = K + k_1Q + c_1(\sigma)Q + k_2Q(1 - ap_1(\sigma)) + c_2Q(1 - ap_1(\sigma)) + hR_1I_1 + h(R - R_1)I_2$$

Dividing the total cost in (1) by the cycle length, we obtain the average cost $C(Q, \sigma) = \frac{TC(Q, \sigma)}{R}$. After some reduction we obtain the following formula:

$$C(Q, \sigma) = \frac{d}{(1 - a)}\left[\frac{K}{Q} + k_1 + c_1(\sigma) + k_2(1 - ap_1(\sigma)) + c_2(1 - ap_1(\sigma)) + \frac{1}{2}hQ\frac{P - d}{P^2} + \frac{1}{2}hQS\left(\frac{P - d}{P} + a - 2ap_1(\sigma)\right)\right]$$

and hence, the optimization problem can be formulated as:

$$\min_{Q, \sigma} C(Q, \sigma) \quad \text{s. t.} \quad 0 \leq \sigma \leq \frac{1}{P}.$$  

The average cost has to be minimized under the constraint that the initial screening should not be the bottleneck in the process, i.e., the screening rate must be higher than the production rate.

**Convexity of the cost function**

Let us suppose now that one of the two functions $p_1$ and $c_1$ is nonlinear but satisfy the assumptions A0-A1 and B0-B1:

**Assumption A0:** $c_1(0) = 0$ and $c_1'(\sigma) \geq 0$, $\forall \sigma \in [0, \frac{1}{P}]$.

**Assumption A1:** $c_1''(\sigma) \geq 0$, $\forall \sigma \in [0, \frac{1}{P}]$.

**Assumption B0:** $p_1(0) = 0$ and $p_1'(\sigma) > 0$, $\forall \sigma \in [0, \frac{1}{P}]$.

**Assumption B1:** $p_1''(\sigma) \leq 0$, $\forall \sigma \in [0, \frac{1}{P}]$.

The convexity of the cost function ensures that a stationary point is a global minimum which is also unique if the objective function is strictly convex.

Calculating the Hessian matrix:

$$H = \begin{bmatrix}
\frac{\partial^2 C(Q, \sigma)}{\partial Q^2} & \frac{\partial^2 C(Q, \sigma)}{\partial Q \partial \sigma} \\
\frac{\partial^2 C(Q, \sigma)}{\partial Q \partial \sigma} & \frac{\partial^2 C(Q, \sigma)}{\partial \sigma^2}
\end{bmatrix}$$
\[ H = \frac{d}{1-a} \begin{bmatrix} \frac{2K}{Q^3} & -hSap'_1(\sigma) \\ -hSap'_1(\sigma) & c''_1(\sigma) + (-k_2 - c_2 - hQS)ap''_1(\sigma) \end{bmatrix} \tag{4} \]

The Hessian is positive definite if and only if the Hessian determinant is positive (see, e.g. Chiang, 1984), and \( \frac{2K}{Q^3} \) is positive as well. The latter condition is true. Thus, the condition (H1) must be satisfied.

\[ \frac{2K}{Q^3} [c''_1(\sigma) - (k_2 + c_2 + hQSp_1(\sigma)] - [hSap'_1(\sigma)]^2 > 0. \tag{H1} \]

A more explicit form of Condition (H1) could be obtained for particular \( c_1 \) and \( p_1 \) functions under few assumptions.

**Optimal parameters**

We solve the above optimization problem under condition (H1) that guarantees the convexity of the objective function.

The Lagrangian writes

\[ L(Q, \sigma, \mu_1, \mu_2) = C(Q, \sigma) + \mu_1 \left( \sigma - \frac{1}{P} \right) - \mu_2 \sigma, \quad \mu_1, \mu_2 \geq 0. \]

The Karush-Kuhn-Tucker points (KKT) are obtained from the following conditions:

\[ \frac{\partial L(Q, \sigma, \mu_1, \mu_2)}{\partial Q} = \frac{\partial C(Q, \sigma)}{\partial Q} = 0 \tag{L1} \]

\[ \frac{\partial L(Q, \sigma, \mu_1, \mu_2)}{\partial \sigma} + \mu_1 - \mu_2 = 0 \tag{L2} \]

\[ \mu_1 \left( \sigma - \frac{1}{P} \right) = 0 \tag{C1} \]

\[ \mu_2 \sigma = 0 \tag{C2} \]

\[ \mu_1, \mu_2 \geq 0. \tag{P1} \]

Condition (L1) implies

\[ - \frac{K}{Q^2} + \frac{1}{2} h \frac{(P - d)}{p^2} + \frac{1}{2} hS \left( \frac{(P - d)}{P} - 2ap_1(\sigma) + a \right) = 0 \]

\[ Q^* = \sqrt{\frac{2K}{h} \left[ \frac{(P-d)}{p^2} + S \left( \frac{(P-d)}{P} - 2ap_1(\sigma^*) + a \right) \right]} \tag{5} \]

From the formula (5) we can see that higher detection rate \( (p_1(\sigma^*)) \) makes the optimal lot size increase.

Now, according to complementarity conditions (C1) and (C2), we have \( \sigma - \frac{1}{P} = 0 \) or \( \mu_1 = 0 \) and \( \sigma = 0 \) or \( \mu_2 = 0 \). These define four cases, from which \( \sigma - \frac{1}{P} = 0 \) and \( \sigma = 0 \) cannot be true at the same time. Hence, three possible solutions remain:

(a) \( \sigma - \frac{1}{P} = 0 \) which gives \( \sigma^* = \frac{1}{P} \) and \( \mu_2 = 0 \). In this case, condition (L2) implies...
\[
\frac{d}{(1-a)} \left[ c'_1 \left( \frac{1}{p} \right) - k_2 a p'_1 \left( \frac{1}{p} \right) - c_2 a p'_1 \left( \frac{1}{p} \right) - a p'_1 \left( \frac{1}{p} \right) hQ^*S \right] + \mu_1 = 0
\]

from which

\[
\mu_1 = -\frac{d}{(1-a)} \left[ c'_1 \left( \frac{1}{p} \right) - k_2 a p'_1 \left( \frac{1}{p} \right) - c_2 a p'_1 \left( \frac{1}{p} \right) - a p'_1 \left( \frac{1}{p} \right) hQ^*S \right]
\]

(6)

which must be positive in order for this solution to be feasible.

(b) \( \sigma^* = 0 \) therefore \( \mu_1 = 0 \). In this case, condition (L2) implies

\[
\frac{d}{(1-a)} \left[ c'_1(0) - k_2 a p'_1(0) - c_2 a p'_1(0) - a p'_1(0) hQ^*S \right] - \mu_2.
\]

Hence

\[
\mu_2 = \frac{d}{(1-a)} \left[ c'_1(0) - k_2 a p'_1(0) - c_2 a p'_1(0) - a p'_1(0) hQ^*S \right]
\]

(7)

which must be positive in order for this solution to be feasible.

(c) \( \mu_1 = 0 \) and \( \mu_2 = 0 \). In this case, condition (L2) implies

\[
\frac{d}{(1-a)} \left[ c'_1(\sigma) - k_2 a p'_1(\sigma) - c_2 a p'_1(\sigma) - a p'_1(\sigma) hQ^*S \right] = 0.
\]

Hence, \( \sigma^* \) is obtained from the solution of the following equation

\[
c'_1(\sigma) - k_2 a p'_1(\sigma) - c_2 a p'_1(\sigma) - a p'_1(\sigma) hQ^*S = 0
\]

(8)

which must satisfy feasibility conditions.

Note that if the initial screening cost is small and increases moderately with respect to the screening time, then we have case (a), which means that the maximum possible time should be spent on the initial screening. On the other hand, sharp increase in the initial screening cost makes zero initial screening time (case b) optimal. If initial screening cost is neither very high nor very small compared to second-stage screening, processing and holding costs, then the optimal screening time comes from equation (8) in case (c) which balances all the costs.

The condition (H1) is sufficient to guarantee the optimality of any feasible KKT point among the above.

**Numerical examples and sensitivity analysis**

In this section, we provide numerical examples to illustrate the computation procedure and to derive managerial insights from various scenarios regarding the shape of the underlying functions and the values of the different parameters of the model.

Assuming 40 working hours per week, the number of working minutes per year is \( T = 125000 \). Based on the production constraint, the maximum time that can be devoted to initial screening is 1 minute per unit. All the time related parameters are converted to minutes.
Table 3. General parameters to be used in the numerical examples

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Additionally, to the parameters above (Table 3), we define multiple scenarios in which we consider various levels of the screening cost and/or detection rate. Furthermore, we vary the proportion of the defective items in the production \((a)\) and observe the effect on the optimal parameters and total cost of the system.

We consider the parameters of the nonlinear detection function to be unchanged while calculating the optimal level of initial screening for cheap, moderate, and expensive parameters of the linear screening cost function. If the proportion of defective items is 4\%, then parameter values that are lower than \(\beta = 0.3\), the optimal initial screening time is 1, and for values higher than \(\beta = 2.5\), screening is not reasonable, i.e. \(\sigma^* = 0\).

</tr>
</tbody>
</table>

As to be seen in Table 4, the cheaper the screening, the more time should be spent with it. For rather low proportion of defective items in the production \((a = 0.04)\), we have shown the two extremes when initial screening is so cheap that the optimal value is the possible maximum \((\sigma^* = 1\), see #1), and when it is so expensive that no time should be spent with it at all (see #3). The optimal lot size increases with the higher optimal values of \(\sigma\). The minimum of the total cost decreases as the optimal initial screening time gets higher. The minimum of the total cost is higher if the proportion of defective items increases, and the differences are also bigger.

Let us also note that an increased proportion of defections, i.e. higher value of \( a \) makes initial screening more crucial. In the example above, it is optimal to do spend time with initial screening even if the costs are high and the maximal value is the optimum for a
moderate cost level already. As illustrated by Figure 3, the minimum of the total cost is increasing with both the initial screening cost and the defection rate.

![Figure 3. The total cost function with respect to σ, with low, medium and high initial screening costs, and higher defection rate in the second case](image)

**Conclusion**
This paper presents an inventory model with two stages of quality screening. Jointly with the production lot size, the time allocated to the initial screening is a decision variable as well. This problem is relevant for many companies that have complex operations and many defections in the first stage of the production process.

The time of initial screening determines the related costs but also the proportion of detected defections in linear or nonlinear form. With the objective of minimizing the total production cost, we proposed a procedure to calculate the optimal lot size jointly with the optimal time of initial screening.

There are several results with high relevance for managerial implications. Firstly, the decision regarding the screening time affects the total cost of the system and modifies the optimal lot size. We found out that if the cost of screening in the first stage is too high then it is more reasonable to avoid it and bear the second-stage holding, processing and screening costs. Vice versa, if first stage screening costs are small enough compared to the other types of costs, then the maximal time should be spent on initial screening to allow the detection of a maximum number of defective items. In many other cases, the optimal screening time allows us to balance the various cost components. Other parameters that can influence the decision regarding the screening time include the proportion of the defections in the production (reliability of the production process in the first stage). The findings show that doing quality control in the optimal manner and in the right time reduces the overall system cost while ensuring the desired quality level.

The model in this paper can be extended in several directions. Possible extensions include additional defections in the second production stage, backlogging or rework, random defections, errors in screening and learning effect.

Abstract

In this project, a collaboration mechanism in a centralized model will be designed and applied for empty container sharing between two firms. The developed model is based on two firms on two terminals. Both the firms accept the cargoes from consignee so both of them have the demands for the empty container. The two operators charge their customers separately once they accept the cargoes from consignee, which can affect the demand of empty container. Additionally, empty containers can be exchanged between two firms when the containers the operator has is insufficient whereas the other has surplus containers.

Keywords: Collaboration mechanism, Empty container, Centralized model

1. Introduction

With rapidly global trade and economic development of the world in the last few decades, port is playing more and more important and indispensable role for international trading. How to manage and re-allocate empty container takes a huge challenge to port managers. Typically, a reasonable solution is to divide whole huge port area into several terminals as individual operation entity and rent them to private port company to operate separately. Indeed, it is a right way to solve the problem, but it also takes a new question to port management, i.e. how to establish a mechanism system to collaborate and coordinate each individual terminal to maximize profit for whole port. Xie et al. (2017) solved the problem of empty container inventory sharing and coordination by using centralized model. According to these researches, therefore, in this research, firstly, several elements are included in the model, which are (1) office of firm 1 and 2 are responsible for operation
of product collection, dispatch, receive and transport in terminal A and B respectively, (2) a railway connect two terminals for exchanging empty container and (3) a central planner for operating two firms in the centralized model. Moreover, firm 1 and 2 own empty container at Container Yard (CY) in terminal A and B respectively (Xie et al. 2017). Secondly, in this research, we have two goals. We build a centralized model between two terminal firms to develop an optimal delivery policy for repositioning empty container, which means there is a central planner operate the whole system. In addition, two variables of initial inventory of empty container and charging price ‘p’ to empty container are considered simultaneously when deciding optimal delivery quantities in centralized model. Therefore, this research is based on this model.

2. Literature review

In this part, we are going to review the literature in terms of empty container repositioning problem and inventory sharing game to support this research.

There are many valuable previous researches about empty container repositioning problem in empty container supply chain management (Florez, 1986; Crainic, Gendreau and Dejax, 1993; Shintani et al., 2007; Song and Zhang, 2010, Zhang, Ng and Cheng, 2014). Some of the results have an important value this research. For example, in the research of Xie., et al (2017), they claimed that linear programming is a most commonly way to formulate empty container repositioning problem and they investigated the sharing and coordination problem for empty container inventory in an intermodal transport. In this system, there are one liner firm in a seaport and one rail firm in a dry port operating the whole port simultaneously. By using integer program, Choong, Cole and Kutanoglu (2002) solved the planning horizon problem of minimizing container repositioning cost in container-on-barge intermodal transportation network. They pointed out that planning horizon need to be carefully considered for slow speed of barge transportation and they think that the transportation way of container-on-barge could be a viable alternative to rail and truck if a long planning horizon is used. (Choong, Cole and Kutanoglu, 2002). In 2014, Pérez-Rodríguez and Holguín-Veras (2009) explored a stochastic model to formulate empty container accumulation process in urban areas over a time expanded network to investigate the influence of profit margins, acquisition costs and storage costs for accumulation of containers at areas which can be used for urban planning and policy making. They final confirm and quantify that demand uncertainty is a key factor which can affect port terminal's costs significantly. By literature review discussion and industrial practice observation, Song and Carter (2009) developed a research that they identified the critical factors which could affect empty container movement significantly. They adopted three main routes which are Trans-Pacific, Trans-Atlantic, Europe–Asia as an example to quantify the scale of empty container repositioning. They also use this example to contrast and evaluate different strategies of shipping lines and container operators which may reduce the cost of their empty container repositioning behaviour. Moreover, to minimize the expected total costs which includes inventory-holding costs, transportation costs and repositioning costs etc., Dong and Song (2009) investigated empty container repositioning problem in multi-vessel, multi-port and multi-voyage shipping systems considering joint container fleet sizing with circumstance of uncertain and imbalanced customer demand. They also developed a simulation-based evolutionary algorithm to solve the optimization problem which has been approved for its effectiveness by using a case study. They finally conducted a numerical example by using several repositioning policies which involves a heuristics repositioning policy (HRP), an evolutionary algorithm-based policy (EAP) and a non-repositioning policy (NRP) for comparison facilitation.
On the other hand, there is a very long history of the research of inventory sharing game. The most classical model of inventory sharing game is ‘Newsvendor model’ which is a basic model well known in operations research and applied economics, then the newsvendor model has been developed in many disciplines. The word of ‘newsboy’ is firstly used by Morse and Kimball (1951) in their research (Chen et al., 2016). Morse and Kimball (1951) originally explained it as “Let us consider the case of a newsboy who is required to buy his papers at 2 cents and sell them at 3 cents and is not allowed to return his unsold papers. He has found by experience that he has on the average 10 customers a day, and that customers appear at random. How many papers should he buy?” Normally, there are two players including supplier and retailer in newsvendor model, but these two names may vary in different meanings in different research. In inventory sharing game, which is included in the discipline of supply chain management, for instances, Rudi, Kapur and Pyke, (2001) studied inventory transshipment problem between two firms as two players in a newsvendor model. They realized that each local decision makers usually prefer to make their own performance rather than a central planner to collaborate overall performance.

It is now necessary to discuss the knowledge gap between this research and the others to show why this paper is valuable for operational research. To the best of author’s knowledge of relative literature, in centralized model, there is no evidence clearly shown that there existed researches about empty container repositioning problem in the circumstance of uncertain demand for empty container caused by empty container leasing price. (i.e. the demand of empty container is stochastic, and demand is also affected by price charging to empty container). This is the knowledge gap between this paper and previous research. Therefore, we will add the variable of “p” with the meaning of “Basic price charged for leasing empty container” to the centralized model to show demand of empty container is dependent with “p” and it is stochastic. Furthermore, based on this assumption, we will develop the centralized model with a central planner to develop an optimal policy for empty repositioning problem.

3. Model information
In this section, we fully introduce the model we design in this research with more details. For clarity and convenience reading, we will divide this section into 2 parts which are “basic model design” and “centralized model design”.

Basic model design
The model includes two firms (firm 1 and firm 2) operate two terminals named A and B respectively in one port area. They can both transport and ship cargoes on land or between overseas ports individually and both firms own inventory of empty container in their terminals Container Yard (CY) (Xie et al. 2017). Generally, the empty container of one of the firms can be borrowed by the other firm in some circumstances (e.g. empty container is not enough to satisfy the demand) if it is necessary and we assume that there will be a railway to connect both terminals to deliver empty container. The demand functions ($X_1$ and $X_2$) for terminal A and terminal B are denoted as below:

$$X_1 = D_1(p) + \xi_1 = a_1 - b_1 p + \xi_1, b_1 > 0$$

$$X_2 = D_2(p) + \xi_2 = a_2 - b_2 p + \xi_2, b_2 > 0$$

Where $D_1(p)$ and $D_2(p)$ are the demand function for firm 1 and 2, $a_1, a_2, b_1$ and $b_2$ are parameters. $p$ is the basic payment to firm for leasing empty container. $\xi_1$ and $\xi_2$ are
error term and they are denoted with probability density function (pdf) is \( f_i(x) \) and cumulative distribution function (cdf) is \( F_i(x) \), \( i=1,2 \). Furthermore, we assume that there is no demand for the firm 1 at terminal 2 which means that there is no empty container accumulations and inventory at terminal 2 for firm 1 and vice versa.

On the one hand, from the perspective of firms, one firm can deliver their empty container to the other firm as long as they have extra empty container after its self-optimization. Now, it is clear to show that a transhipment game between two firms is what we are going to investigate in this paper. Now, we can show an example to clearly explain the whole process. For firm 1, the empty container inventory in terminal 1 should be firstly used for satisfying its own demand and they should unload all containers from overseas. The unloaded container of firm 1 should be added to terminal 1’s inventory. The unloaded containers of firm 2 should satisfy firm 1’s extra demand in terminal 1 if it is necessary, finally, if there are still some firm 2’s extra empty containers in terminal 1 after demand satisfaction, these empty containers should be delivered to terminal 2 immediately. Vice versa.

![Figure 1 Model description](image_url)

On the other hand, for consignors who want to transport their cargoes to overseas, they can choose the firm what they want to export their product to overseas. Firstly, the cargoes should be delivered by corresponding consignor to container freight station (CFS) in firm 1 or firm 2. Secondly, consignor should pay firm 1 or firm 2 a basic fee for leasing empty container and ocean freight cost. Lastly, the cargoes should be transported to the corresponding terminal from firm’s CFS. If the inventory of empty container in any of the two firms cannot be satisfied with their own demand, then the basic price for empty container leasing will be changed to fulfill the demand in both terminals and rebalance the demand in whole system. However, there could still exist unsatisfied demands in one of the firms even if port office changing the basic price to affect demand. Therefore, at the same time, under this circumstance, the other firm should transport their extra empty containers to the firm which its own demands are not fully satisfied. In addition, for considering of simplify calculation, it is assumed that the basic price (p) for leasing empty container charged by firm 1 and firm 2 is same. Moreover, for the cargoes imported from overseas, we assume that any arriving container ship can be accepted in both terminals and unloaded regardless the ownership of the container belongs to which firm. Then, the unloaded container should be added to its corresponding terminal’s inventory. However, for example, if firm 1’s container arrive at terminal B and firm 2 has an extra demand for empty container, so this container can be borrowed by firm 2. Otherwise this container should be returned to terminal 1 immediately and vice versa. The whole process can be found in figure 1.
Now, it is better to show the notations for this model below. It has already denoted that $X_1$ and $X_2$ represent the random demands of empty container for firm 1 and firm 2 in the CFS, respectively. Denote $Y_1$ and $Y_2$ are the empty container's random arrivals in the container freight station of terminal 1 and 2, respectively. We let $n_1$ and $n_2$ are inventory of empty containers at CY of terminal 1 and 2, respectively. Let $r_1$ and $r_2$ are revenue from shipping out per loaded container at terminal 1 and 2. At the same time, we denote $\eta_1$ is revenue from leasing per empty container for both firms. We also consider a holding cost per empty container at terminal 1 and 2 are $h_1$ and $h_2$, respectively. Denote goodwill penalty per empty container at terminal 1 and 2 are $g_1$ and $g_2$. $c_t$ is transportation cost per empty container between two terminals.

Centralized model design
The number of empty containers delivered between two terminals ($q$) and basic price for leasing empty container ($p$) are the decision variable. Basically, there is a central planner operating the whole port including firm 1 and firm 2 in centralized model. The central planner decides the basic price for leasing empty container and quantity of delivered empty container between two firms. For example, given the inventory of empty container in both terminals, the decision variable of $q$ and $p$ can be calculated by the central planner. In opposite, given the delivery quantity and basic price, the inventory in both terminals ($n_1$ and $n_2$) also can be fixed. It is necessary to define that the value is positive (+q) when empty container delivered from terminal 2 to terminal 1 and is negative (-q) for the opposite. Figure 2 show the whole process for centralized system.

4. Centralized Model
In section 4, a centralized model will be developed which means there is a central planner operate two firms. According to this assumption, we are going to develop the optimal empty container delivery policy.

4.1 Profit function
For terminal 1 and terminal 2:

Let $Q_1(q, n_1, p_1)$ denote the satisfied demand for empty containers at terminal 1.

$Q_1(q, n_1, p_1) = E\min\{X_1, n_1 - q + Y_1\}$

$= E\min D_1(p) + \xi_1, n_1 - q + Y_1 = E\min a_1 - b_1p + \xi_1, n_1 - q + Y_1$

Let $I_1(q, n_1, p_1)$ denote the leftover inventory at terminal 1.

$I_1(q, n_1, p_1) = (n_1 - q + Y_1 - X_1)^+$

$= [n_1 - q + Y_1 - \xi_1]^+ = (n_1 - q + Y_1 - a_1 + b_1p - \xi_1)^+$
Let $L_1(q, n_1, p_1)$ denote the unsatisfied demand at the terminal 1.

$$L_1(q, n_1, p) = (X_1 + n_1 - q + Y_1)^+$$

$$= [D_1(p) + \xi_1 + n_1 - q + Y_1]^+ = (a_1 - b_1p + \xi_1 - n_1 + q - Y_1)^+$$

Let $Q_2(q, n_2, p)$ denote the satisfied demand for empty containers at terminal 2.

$$Q_2(q, n_2, p) = \text{Emin}\{X_2, n_2 + q + Y_2\}$$

$$= \text{Emin}\{D_2(p) + \xi_2, n_2 + q + Y_2\} = \text{Emin}\{a_2 - b_2p + \xi_2, n_2 + q + Y_2\}$$

Let $l_2(q, n_2, p_2)$ denote the leftover inventory at terminal 2.

$$l_2(q, n_2, p) = (n_2 + q + Y_2 - X_2)^+$$

$$= (n_2 + q + Y_2 - D_2(p) - \xi_2)^+ = (n_2 + q + Y_2 - a_2 + b_2p - \xi_2)^+$$

Let $L_2(q, n_2, p_2)$ denote the unsatisfied demand at the terminal 2.

$$L_2(q, n_2, p) = (X_2 + n_2 + q + Y_2)^+$$

$$= [D_2(p) + \xi_2 + n_2 + q + Y_2]^+ = (a_2 - b_2p + \xi_2 - n_2 - q - Y_2)^+$$

Furthermore, the transportation cost for the empty containers is $c_t|q|$ between terminal 1 and terminal 2. Then, the expected profit function $\Pi(q, n_1, n_2, p)$ can be written as follows:

$$\Pi(q, n_1, n_2, p) = (r_1 + r_l)E Q_1(q, n_1, p) + (r_1 + r_1 + r_2)E Q_2(q, n_2, p) - h_1E \lambda_1(q, n_1, p)$$

$$- h_2E l_2(q, n_2, p) - g_1E \lambda_1(q, n_1, p) - g_2E l_2(q, n_2, p) - c_t|q|$$

(3)

Finally, similar to that on page 9 in Cachon (2003), we can rewrite the profit function. Then, the final profit function can be stated below:

$$\Pi(q, n_1, n_2, p) = K[M - n(M)] + L[N - n(N)] - h_1M - h_2N - g_1E(\xi_1 - Y_1)$$

$$- g_2E(\xi_2 - Y_2) + (r_1 + r_l)E(Y_1 + a_1 - b_1p) + (r_1 + r_1 + r_2)E(Y_2 + a_2$$

$$- b_2p) - c_t|q|$$

(4)

Where $\bar{\Pi}()$ is the complementary loss function and $K = r_1 + r_l + h_1 + g_1, L = r_1 + r_1 + r_2 + h_2 + g_2, M = n_1 - q - a_1 + b_1p$ and $N = n_2 + q - a_2 + b_2p$. Moreover, from equation above, it is clear that $\Pi(q, n_1, n_2, p)$ is not differentiable at $q = 0$.

4.2 Optimal delivery policy

In this part, a basic analysis for centralized model will be provided. In order to explain clearly for the steps of calculation and its outcome, we adopt step-wise analysis. Firstly, we will give the proof for special case where $n_1$ and $n_2$ are given and $p$ and $q$ are given respectively. Then, a simultaneous decision-making process where, $n_1, n_2, p$ and $q$ are jointly affected will be stated.

We denote $Z_1()$ is the probability density function (pdf) for $\xi_1 - Y_1$ and $Z_2()$ is the cumulative distribution function (cdf) for $\xi_1 - Y_1$. Denote $z_2()$ is the probability density function (pdf) for $\xi_2 - Y_2$ and $Z_2()$ is the cumulative distribution function (cdf) for $\xi_2 - Y_2$. Now, we are going to prove $\Pi(q, n_1, n_2, p)$ is jointly concave in $q$ and $p$ where $n_1$ and $n_2$ are given. Then, based on this calculation of first order condition for the model, the optimal number of deliveries between two ports and price charging level from two firms will also be developed further.
Lemma 1  Given $n_1$ and $n_2$, $\prod(q, n_1, n_2)$ is jointly concave in $p$ and $q$, the unique optimal $q^*$ and $p^*$ can be determined.

To prove $\prod(q, n_1, n_2)$ is jointly concave in $q$ and $p$ is equivalent to prove that the determinants of Hessian matrix which is constituted with second-order partial derivatives of $\prod(q, n_1, n_2)$ in terms of $p$ and $q$ is negative semidefinite. In this case:

$$
\begin{vmatrix}
\frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial p^2} & \frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial p \partial q} \\
\frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial q \partial p} & \frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial q^2}
\end{vmatrix}
$$

Therefore, the result of determinant for the Hessian matrix is:

$$
\frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial p^2} \frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial q^2} - \frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial p \partial q} \frac{\partial^2 \prod(q, n_1, n_2, p)}{\partial q \partial p} = 2(r_1 + r_1 + h_1 + g_1)(r_1 + r_1 + h_2 + g_2)b_1b_2z_1(n_1 - q - a_1 + b_1p)z_2(n_2 + q - a_2 + b_2p) \geq 0
$$

(5)

Hence, $\prod(q, n_1, n_2, p)$ is jointly concave in $q$ and $p$, which means that there exists the unique optimal solution. Therefore, an unique optimal result for $p$ and $q$ in the model can be developed. We denote that they are $p^*$ and $q^*$ respectively, given $n_1$ and $n_2$. According to the first-order condition of the model, i.e. $\frac{\partial \prod(q, n_1, n_2, p)}{\partial p}$ and $\frac{\partial \prod(q, n_1, n_2, p)}{\partial p}$, we can further obtain the unique value of optimal charging price and unique optimal number of empty containers delivered between two terminals by unifying two first-order conditions.

For $q > 0$:

$$
\begin{cases}
    p^* = \frac{Z_2^{-1}(A) + Z_2^{-1}(B) + a_1 + a_2 - n_1 - n_2}{b_1 + b_2} \\
    q^* = \frac{Z_2^{-1}(B) - Z_1^{-1}(A) + b_2(n_1 - a_1) - b_1(n_2 - a_2)}{b_1 + b_2}
\end{cases}
$$

(6)

For $q < 0$:

$$
\begin{cases}
    p^* = \frac{Z_1^{-1}(A') + Z_2^{-1}(B') + a_1 + a_2 - n_1 - n_2}{b_1 + b_2} \\
    q^* = \frac{Z_2^{-1}(B') - Z_1^{-1}(A') + b_2(n_1 - a_1) - b_1(n_2 - a_2)}{b_1 + b_2}
\end{cases}
$$

(7)

where,

$K = r_1 + r_1 + h_1 + g_1 \neq 0$, $L = r_1 + r_1 + r_2 + h_2 + g_2 \neq 0$, $M = n_1 - q - a_1 + b_1p$, $N = n_2 + q - a_2 + b_2p$, $A = \frac{(b_1 + b_2)(K-h_1)-(r_1+r_2+r)l}{b_1+b_2}+\frac{b_1c_1}{b_1+b_2}$, $A' = \frac{(b_1+b_2)(K-h_1)-(r_1+r_2+r)l}{b_1+b_2}+\frac{b_2c_1}{b_1+b_2}$

$$
B = \frac{(b_1 + b_2)(L-h_2)-(r_1+r_2+r_1)l}{b_1+b_2}, A' = \frac{(b_1+b_2)(K-h_1)-(r_1+r_2+r)l}{b_1+b_2}+\frac{b_2c_1}{b_1+b_2}
$$

$$
B' = \frac{(b_1 + b_2)(L-h_2)-(r_1+r_2+r_1)l}{b_1+b_2}+\frac{b_2c_1}{b_1+b_2}
$$
Lemma 1 describes the connection between basic price $p^*$ for empty container and number of deliveries $q^*$ when both inventory level in two terminals are given. It also reveals that there exists an unique optimal solution for the joint number of deliveries between two firms and charging price setting given both firms' inventory level. From Lemma 1 and satisfied demand function $Q_1(q, n_1, p)$ and $Q_2(q, n_2, p)$, it is very easy to obtain the optimal satisfied demands number for empty containers in whole system as follows:

$$Q^*(q, p, n_1, n_2) = n_1 + n_2 + E(Y_1 + Y_2) - \bar{n}(n_1 - q^* - a_1 + b_1 p^*) - \bar{n}(n_2 + q^* - a_2 + b_2 p^*)$$

(8)

Lemma 2  Given $p$ and $q$, $\Pi(q, n_1, n_2, p)$ is jointly concave in $n_1$ and $n_2$, the unique optimal $n_1^*$ and $n_2^*$ can be determined

We drive the similar steps with Lemma 1, firstly, to prove $\Pi(q, n_1, n_2, p)$ is jointly concave in $n_1$ and $n_2$ is equivalent to prove that the determinants of Hessian matrix which is constituted with second-order partial derivatives of $\Pi(q, n_1, n_2, p)$ in terms of $n_1$ and $n_2$ is negative semidefinite. In this case:

$$
\begin{vmatrix}
\frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_1^2} & \frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_1 \partial n_2} \\
\frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_2 \partial n_1} & \frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_2^2}
\end{vmatrix}
$$

Therefore, the result of determinant for the Hessian matrix is:

$$
\frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_1^2} \frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_2^2} - \frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_1 \partial n_2} \frac{\partial^2 \Pi(q, n_1, n_2, p)}{\partial n_2 \partial n_1}
= (r_1 + r_i + h_1 + g_1)(r_1 + r_i + h_2 + g_2 + r_2)z_1(n_1 - q - a_1 + b_1 p)z_2(n_2 + q - a_2 + b_2 p) - 0 > 0
$$

(9)

Hence, $\Pi(q, n_1, n_2, p)$ is jointly concave in $n_1$ and $n_2$, which means that there exists the unique optimal solution. Then, we can easily obtain the optimal value of $n_1$ and $n_2$ by solving two first-order derivation. Therefore, an unique optimal result for $n_1$ and $n_2$ in the model can be developed. We denote that they are $n_1^*$ and $n_2^*$ respectively, given $p$ and $q$. According to the first-order condition of the model, i.e. $\frac{\partial \Pi(q, n_1, n_2, p)}{\partial n_1}$ and $\frac{\partial \Pi(q, n_1, n_2, p)}{\partial n_2}$, we can further obtain the unique value of initial inventory of empty container in terminal 1 and terminal 2.

$$
n_1^* = Z_1^{-1}\left(\frac{K - h_1}{K}\right) + q + a_1 - b_1 p
$$

$$
n_2^* = Z_2^{-1}\left(\frac{L - h_2}{L}\right) - q + a_2 - b_2 p
$$

(10)

where, $K = r_1 + r_i + h_1 + g_1 \neq 0$, $L = r_1 + r_i + r_2 + h_2 + g_2 \neq 0$, $M = n_1 - q - a_1 + b_1 p$, $N = n_2 + q - a_2 + b_2 p$
Now, we can easily recognize that Lemma 2 is a newsvendor problem solution. According to Lemma 2, it can be determined the optimal inventory level for each firm when the price charging for empty container and exchanging quantity are given. But there are still some differences between the problem that Lemma 2 solved and classical newsvendor problem solution. For instance, Bell and Zhang (2006) provided a classical newsvendor problem solution for maximizing systems profit by choosing a price when firms’ inventory level are fixed. Moreover, Zhang et al., (2010) found that it is relative independent for inventory level in each market segments when prices are given. However, Lemma 2 gives a result for a new newsvendor model that inventory level can be determined for each firm to maximize system’s profit when both charging price and the exchanging quantity of empty container between two firms are given simultaneously. Compared with Proposition 1 in Zhang, et al (2010), it is very clearly to notice that it is the value of q in Lemma 2 which is a key factor that cause this difference. Furthermore, the inventory level in each firm are also not relatively independent because of q existence (but the core reason is that the model of Zhang, et al (2010) was based on pricing competition), which is also different with Zhang, et al (2010). In general, although there exist some differences between these solutions for newsvendor problem, it is still an unanimous results that Lemma 2 reveals with the others, e.g. Zhang, et al (2010) and Bell and Zhang (2006).

Corollary 2 Assume \( Z_i(\xi_i - Y_i) \), \( i = 1,2 \) increase in \( \xi_i - Y_i \), customer order quantity in terminal 1 increases in \( r_1 \), \( p_1 \) and \( g_1 \), but decreases in \( h_1 \) and customer order quantity in terminal 2 increases in \( r_1 \), \( r_2 \) and \( g_2 \), but decreases in \( h_2 \). The result is opposite when assuming \( Z_i(\xi_i - Y_i) \), \( i = 1,2 \) decrease in \( \xi_i - Y_i \).

In this case, it is necessary to discuss in different situation because we cannot determine the monotonicity of the function \( Z_i(\xi_i - Y_i) \), \( i = 1,2 \). Firstly, We assume \( Z_i(\xi_i - Y_i) \), \( i = 1,2 \) increase in \( \xi_i - Y_i \). Corollary 2 reveals that inventory level increases in \( r_1 \), \( r_1 \) and \( g_1 \), but decreases in \( h_1 \) for firm 1. Inventory level in firm 2 increases \( r_1 \), \( r_1 \), \( r_2 \) and \( g_2 \), but decreases in \( h_2 \). Similarly, in the opposite situation, inventory level decreases in \( r_1 \), \( r_1 \) and \( g_1 \), but increases in \( h_1 \) for firm 1. Inventory level in firm 2 decreases in \( r_1 \), \( r_1 \), \( r_2 \) and \( g_2 \), but increases in \( h_2 \). It should be clearly stated that the inventory level in one of the firms is not independent from the price because of q existence, which means the inventory level is related to the value of q when price is given.

Lemma 1 and Lemma 2 provide a method to transform a four-decision variable problem into a two-dimensional research because of computational complexity (Zhang, et al, 2010). Next, we are going to show a unique solution in a general condition.

Lemma 3 \( \Pi(q, n_1, n_2, p) \) is jointly concave with respect to q, p, \( n_1 \) and \( n_2 \).

Lemma 3 provides a solution to find an optimal solution among inventory level, delivery quantity and price charging. It shows that \( \Pi(q, n_1, n_2, p) \) is concave in q, p, \( n_1 \) and \( n_2 \) and it also reveals that there exists a optimal group of q, p, \( n_1 \) and \( n_2 \) to satisfy a maximum \( \Pi \). Therefore, the optimal transhipments and optimal price charge can be determined. However, due to the computational complexity, we will show the optimal value of each variable in the future research.

Conclusion
In this research, we consider a system including two firms operating two terminals in a port area simultaneously. At the same time, we build a centralized model which means
there is a central planner to control the whole system. In this model, two variables considered are 1) the quantity of empty containers that need to be transferred between two terminals and 2) the price charged by each operator. In this centralized model, the two operators will be treated as a single company, which will lead to perfect collaboration to find an optimal policy for delivery of empty container. Finally, we provide three results which are: (1). Given \( n_1 \) and \( n_2 \), \( \Pi(q_1,n_1,n_2,p) \) is jointly concave in \( p \) and \( q \) and the unique optimal \( q^* \) and \( p^* \) are determined; (2). Given \( p \) and \( q \), \( \Pi(q_1,n_1,n_2,p) \) is jointly concave in \( n_1 \) and \( n_2 \) and the unique optimal \( n_1^* \) and \( n_2^* \) are determined. (3). It has been proofed that \( \Pi(q,n_1,n_2,p) \) is jointly concave with respect to \( q, p, n_1 \) and \( n_2 \) and there exists optimal group of \( q, p, n_1 \) and \( n_2 \) to satisfy a maximum \( \Pi \). Overall, in a centralized model, we find a policy to determine the quantity of transhipment of empty container between two terminals and constrained with leasing price ‘\( p \)’ for empty container. However, in this paper, we just focus on solving empty container repositioning problem by using centralized model. It is necessary to keep on research to solve this problem by using decentralized, which means there is no central planner to operate two terminals but using a contract to determine the empty container transhipment.

‘Lean 4.0’:
How can digital technologies support lean practices?

Abstract

The digitalisation of business offers great possibilities to create new products and processes, as well as improve existing ones. In this paper we seek to understand how digital technologies can support process improvement in a manufacturing context. Several studies have proposed synergies among digitalization and lean at a conceptual level, yet so far we lack any empirical proof. To this effect, we present exploratory quantitative research aimed at explaining how digital technologies can support lean practices, improving our understanding how to harness the potential of digitalisation in operational improvement. We conclude with areas for further research.

Keywords: Lean, process improvement, digitalization, manufacturing.

Introduction

Digital technologies are powerful innovations that have rightfully captured the imagination of manufacturing managers. It has been frequently stated that digital technologies can support or enhance lean practices. Here, technologies often associated with ‘Industry 4.0’ are cited, and we will refer to such digital enhancements of lean practices as ‘Lean 4.0’. For example, according to Wagner et al. (2017), digitalization will not only support lean practices, but it will also enlarge their scope. Even on the
performance point of view, researchers reached the consensus on the operational improvements lean practices yield thanks to digitalization (i.e. Davies et al., 2017; Kolberg and Zühlke, 2015; Tortorella et al., 2018). However, beyond these early studies, to the best of authors’ knowledge, conclusive proof of this claim is still outstanding.

It is easy to conceive areas where they directly support lean practices, yet so far much of this discourse is based on conjecture. With the underlying study we seek to provide a rigorous identification of the mechanisms explaining how digital technologies can support lean practices, and thus contribute to our theoretical understanding of the true impact of ‘Industry 4.0’ technologies, and to support managerial decision in making the business case for their adoption.

In this paper, we present a structured literature review of lean practices as well as digital technologies of relevance to operations management. We show findings of an initial survey that demonstrated the lack of maturity of digital technology adoption in practice and highlighted the needs for further qualitative research. We conclude with comments on preliminary results and presenting our next steps.

**Theoretical background**

*Lean: wastes and practices*

The concept of ‘lean production’ has been widely researched and discussed in the operations management literature (c.f. Holweg, 2007, Fujimoto, 1999, and many others). At the very heart of lean stands the concept of waste reduction, namely to improve a process by reducing non-value activities herein. Taiichi Ohno coined the original seven wastes (or ‘muda’) in manufacturing (often abbreviated as TIMWOOD – Transportation, (excess) Inventory, Motion, Waiting, Overproduction, Overprocessing and Defects), which later have been expanded to also include ‘Skills’, or wasted human talent and ideas. Muda, together with ‘mura’ (unevenness) and ‘muri’ (overburden), provides the original, and still the most succinct, way how to conceptualise lean (Bicheno and Holweg, 2016).

It is for that reason that we adopt the seven (eight) wastes for our study, coupled with the lean practices that have been built upon them to form an integrated management system (Shah and Ward, 2003; Womack, Jones and Roos, 1990). These practices work synergistically to achieve the main goals of lean production, which are related to the creation of a streamlined, high quality system that produces finished products at the pace of customer demand with little or no waste (Shah and Ward, 2003). For their nature, lean practices are applicable to the entire company (Ruiz-Benítez, López and Real, 2018). However, in the scientific community, there is no a unique classification of practices or consensus on which is the complete set of lean practices. Different authors, in fact, refers to them providing their own classification or list of practices. For this reason, and for the scope of this study, a systematic literature review has carried out, with the aim to define a comprehensive list of lean practices.

We adopted an ad-hoc keywords strategy to article title/abstract and keywords on Scopus database. Keywords selected are based on the term “lean” combined with the Boolean operator AND to terms referring to “practice” or “bundle”. Moreover, we
adopted five inclusion criteria. Firstly, we reviewed only contributions in English. Secondly, we considered only journal paper belonging to high-ranked journal (Q1 according to Scimago ranking), discarding conference contributions, books chapter or journal paper published in a medium-to-low ranked journal (according to Scimago ranking). Thirdly, we included only contributions with a proper and specified review/classification of practices. Fourthly, we restricted our focus to manufacturing industry, discarding then all contributions clearly referred to service industries. Eventually, we considered contributions from 2000 on.

The review process identified 528 eligible studies from all the keywords. We filtered the studies by scanning their titles and abstracts, removing duplicates and selecting those consistent with the aforementioned inclusion criteria, resulting in 179 articles. Full-texts were assessed with the same criteria, to discard out-of-scope documents, resulting in 81 articles. 140 practices have been identified, with more than 75% of them cited less than 10 times, highlighting the lack of structured and comprehensive list of practices. Following the final selected sample of practices considered, having each a number of citations at least equal to 10.

</table>

The resulted panel is made by 31 lean practices, with various degree of frequency. JIT and Pull systems are referred to most frequently, while Smaller number of suppliers and Takt time definition are of less interest in the reviewed literature.

As mentioned before, according to its definition, lean strives to minimize general understanding of waste (Womack, Jones and Roos, 1990). It is essential hence to
understand the role played by lean practices on the 8 wastes. Here following a table summarizing which lean practice acts on specific waste. As result of reviewing literature, some practices result to have a more horizontal impact on wastes compared to others. As example, Kaizen events affect positively all 8 wastes, while the takt time definition results to impact only on waiting and inventories.

**Digital technologies**

The availability of low-cost sensors, increases of computing power and high-speed internet connectivity are some of the enablers of massive advances in technologies for operations and supply chain management. Companies have always used new technologies to advance their process. The shipping container is probably the most successful example of a technical revolution that not only significantly improved supply chain processes but also shaped global trade flows in the long term (Cooper and Levinson, 2010).

On the other hand, there are also technologies like Radio Frequency Identification (RFID) that have triggered high expectations for process improvement in retailing operations, but have so far only been able to partially fulfil (Gaukler and Seifert, 2007). Ultimately, new technologies can provide benefits in two fundamentally different ways, i.e. either by increasing efficiency or by increasing revenues – many technologies aim to achieve both. As we are interested in the technology benefits that aim at waste reduction, we carefully screened for relevant technologies in this context. Since new technology developments are currently observed every day, we focused our literature analysis on practitioner articles as well as white papers and reports issued by large technology firms.
and big consultancies. While the mentioned technologies differ slightly and the terminology is also varying a comprehensive picture emerged that put six technology clusters in the focus of our interests. Table 3 provides a summary of the technologies that we identified as potentially most relevant for process improvement.

‘Lean 4.0’
The integration between lean and Industry 4.0 (Lean 4.0) is currently highly discussed in literature (Buer, Strandhagen and Chan, 2018). Even if academia seems to agree on the potentials of the aforementioned integration, there are different points of view depending on the author explaining the subject. Two main perspectives can be drafted in the academia. Some authors describe lean as a basis for the implementation of Industry 4.0 (Hambach, Kümmel and Metternich, 2017). Indeed, since lean practices are aimed at wastes reduction along the process (Womack and Jones, 2003), having a streamlined and under control process represents the prerequisite for any process digitalization (Buer, Strandhagen and Chan, 2018). Other studies have significantly confirmed that companies
with a higher associated level of lean implementation benefit the most in embracing Industry 4.0 and in grasping its potentials (Hoellthaler, Braunreuther and Reinhart, 2018).

Other researchers refer instead to Industry 4.0 as a completion of lean (Kolberg and Zühlke, 2015), that was declared as limited by some studies. Market requirements are nowadays more complex and customers demand for highly personalized products may hinder lean to be still effective. Lean could not only be able to keep up with the pace of personalization using the same tools used since the second half of the 20th century with no technological advancements supporting those tools (Sanders, Elangeswaran and Wulfsberg, 2016). In this sense, Industry 4.0 represents the mean lean can exploit to face new trends in the manufacturing world, preserving its process’ robustness.

The strong interest for the topic from the academia is evident, however due to the infancy of the Industry 4.0 topic, it is still difficult to assess the effect of Lean 4.0. To the best of authors’ knowledge, available scientific studies are mostly focused on theoretical research, and hence conclusive proof for Lean 4.0 potentials is still outstanding.

This research is an attempt to study the mechanisms explaining how digital technologies can enhance lean, and to assess the impact of ‘Lean 4.0’ on operational performance. The scope is limited to industrial operations management, including manufacturing, logistics and supply chain operations, since it is the traditional application space for lean.

**Exploratory survey**

In this section we will present our exploratory survey carried out in the European manufacturing sector aimed at deepen the relationship between Lean and digital technologies adoption, as well as the effects on operational performance. Firstly, we will describe the design of the survey and its instrument, as well as its implementation. Secondly, we will present first preliminary results of our quantitative study.

**Design**

A survey methodology has been selected as the most suitable one among quantitative methodologies.

The questionnaire is made by 19 questions, grouped into six main clusters: (i) companies’ profile; (ii) contextual factors; (iii) lean practice implementation; (iv) digital technology implementation; (v) the effect of ‘Lean 4.0’; (vi) operational performance. The constructs related to lean practices and digital technologies used in the questionnaire are based on the reviewed literature both on lean practices and on technologies. For what regards operational performance, both questions and response interval come from the study of Shah and Ward (2003). Moreover, set-up time and inventories have been included as additional items due to their relevance for the lean approach. The response interval for these items is built following the same structure suggested by Shah and Ward (2003).

The sample selected for this exploratory survey is limited to the European manufacturing sector, with plants as unit of analysis. Respondents are required to be
experienced in lean, therefore green belt and black belt experts have been targeted. These criteria led to a non-random choice of companies for the survey, a strategy used also in the study of Shah and Ward (2003). In order to define the size of the sample, it was considered that 15% is the average rate in management surveys and 100 is the minimum threshold of responses to perform a significant statistical analysis (Hair et al., 2007). On the base of these numbers, sample considered valid consisted in about 1200 experts.

Implementation
The questionnaire instrument has been tested with a sample of 56 lean experts to verify and to validate the constructs and the questions. Testing phase started in May 2018 and lasted 5 months. The final and improved online survey, through Google Module, has been submitted from November 2018 to February 2019 to more than 1200 lean experts. Questionnaire submission exploited three different waves: first wave addressed 700 people, second wave 300 people, and third wave about 200 people. Non-response bias has been managed through two actions: first, while sending the survey it was specified that the questionnaire lasts at least 10 minutes; secondly, the questionnaire was sent three times with a time window of about one week.

The final number of completed surveys was 162 corresponding to a response rate of approximately 13.32%. The validity of answers was verified excluding answers coming from experts involved in service sector (56 answers) and cleaning the dataset from clearly random responses (1 answer). The final dataset is composed by 105 responses, referring to 88 different companies. In addition to all the answers provided, final dataset comprehends two additional values for each expert/plant: lean level (LL) and digital level (DL). According to the model developed by Soriano-Meier and Forrester (2002), LL can be defined starting from a self-evaluation on the implementation of several lean practices. The final LL comes from the computation of the average value of self-evaluation values. The same reasoning of LL has been used for computing DL, exploiting the six digital tools considered in the survey.

Results
In terms of production technology, responses are equally distributed among process and discrete manufacturing. Moreover, several industrial sectors are represented in the sample. Most of the respondents report their plant age as higher than 20 years while only about 7% of the plants have been built in the last decade (Figure 1 - A). About the plant size, according to the European classification, the sample is representative of medium-large plants (Figure 1 - B). Only about the 6.7% of the respondents is indeed in small plants (i.e. less than 50 employees).

Eventually, it is interesting to understand how respondents are spread out on different departments. It is indeed necessary to stress that all the respondents are lean experts, endowed with green or black belt certification, and are working in different departments within companies. 31.4% of the respondents are involved in the Production and Maintenance departments. A remarkable percentage of experts, 27.6%, belongs instead
to the so-called Kaizen Promotion Office, that is usually a support-function in charge of continuous improvement activities of the company. Quality and Supply chain functions are also represented in the sample.

Data gathered from the online survey have been using SPSS, a software of data mining and data statistical analysis.

In order to study the dependence of DL on LL, a box plot analysis was carried out to better understand how the data are distributed. As displayed in Figure 2 - A, not only data are not normally distributed but also DL shows a lower variability than LL. It is interesting to note that there are three outliers at the top of the graph: these three plants are classified as “old” and “large” and are associated with a very high LL. Same data of DL and LL are plotted in a scatter plot to have a graphical representation of the relation between the two variables (Figure 2 - B).

The second quadrant of the matrix presents a high concentration of observation, meaning that most of the plants having a low DL report a high LL. Moreover, not only the fourth quadrant is empty - there are no plants with high DL and low LL, but also DL is never higher than LL. This may confirm what is stated in the literature: highly digitalized plants are also strongly implementing lean, making lean the prerequisite for digital transformation (e.g. Buer, Strandhagen and Chan, 2018).

---

Figure 1 - Age plants (A) and Size plants (B)

Figure 2 - DL and LL: Box plot (A) and scatter plot (B)
Despite this, too few plants registered an above average DL. Only about 10% of plants are belonging to the first quadrant, registering high DL and high LL. This prevented us to make meaningful statements on the possible digital mechanisms that affect lean.

Moreover, looking at operational performance results, the majority of plants is not at the moment affected by any significant operational performance increase. A cluster analysis of plants on operational performance highlights an interesting fact. Applying K-means methods, we ended with 3 different clusters (k=3 defined by Ward distance criterion) with plants not equally distributed among them. About 60% of plants indeed belongs to cluster 3. If cluster 1 and cluster 2 registered remarkable improvement in one or more operational performance, cluster 3 includes companies where Lean 4.0 did not affect operational performance. As shown in Figure 3, it is interesting to note that plants associated with high LL and high DL register a positive impact on operational performance. This represents an initial preliminary result on the performance improvement yielded by Lean 4.0. Unfortunately, further considerations cannot be draft due to the low numbers of observations available with high LL and high DL.

Figure 3 - Clustering analysis on operational performance

Conclusion and next steps
Preliminary results coming from our exploratory survey showed a positive relationship between the combined lean and digital adoption on operational performance. Low digital maturity levels however prevent us from fully disentangling the effects as the majority of plants still feature a low digital level. Thus, we will expand our research design to include qualitative research to identify the potential mechanisms how digital can support lean that practitioners foresee. Using a focus group-based study design (currently underway) we seek to identify both potential variation of impact, as well as level of importance, of the main digital technologies, as well as clustered mechanisms that vary across supply chain activities. In other words, we want to understand which digital technologies have the greatest impact on lean process improvement, and secondly, what the general mechanisms are how digital technologies support lean. Based on our combined survey and focus group findings we will provide a discourse on the how mechanisms identified link to the wide theoretical landscape of lean improvements, and how this can inform managerial practice to harness the potential that digital technologies offer to operations management more generally.

Lean Value Streams: how to integrate their design into Industry 4.0

Guilherme Luz Tortorella
Universidade Federal de Santa Catarina, Florianópolis, Brazil

Felipe Martinez (felipe.martinez@vse.cz)
University of Economics, Prague, Czech Republic

Abstract

This paper proposes guidelines for designing lean value streams considering their integration with Industry 4.0 (I4.0) technologies. We gathered experts' opinions regarding the relationship between eight traditional guidelines for designing a lean value stream and ten I4.0 technologies utilised in previous studies. The identification of the most important relationships then provided arguments for the proposition of enhanced guidelines for designing lean value streams within the Fourth Industrial Revolution context. The integration of I4.0 into the guidelines for designing a lean value stream raises a distinct approach that benefits from the simplicity of Lean Production with the agility of these technologies.

Keywords: Value stream mapping, Industry 4.0, Lean production.

Introduction

Lean Production (LP) is widely acknowledged as a systematic approach to reduce waste and improve flow through extensive employee involvement and continuous improvement (Womack et al., 1990; Womack, 2011). Despite its pervasiveness, generalizable implementation steps have not yet emerged (Marodin and Saurin, 2013). Nevertheless, an LP practice that seems to have a more extensive and accepted adoption is Value Stream Mapping (VSM). A value stream is the sum of all activities (value-added or not) needed to take value from its beginning through to the customer.

VSM is an LP practice for analysing the current state of a value stream and designing a future (desired) state for the series of activities, hence indicating systemic improvement opportunities (Rother and Shook, 2003). Furthermore, VSM consolidates the flows of information and material, showing how they interact with each other throughout the value stream. VSM's versatility is also represented by its extensive integration with different methodological approaches, such as discrete events simulation (Helleno et al., 2015), six-sigma (Salah et al., 2010), Monte Carlo simulation (Souza et al., 2018) and analytic hierarchy process (Tortorella et al., 2018).

With the acknowledgement of the Fourth Industrial Revolution, characterized by the integration of novel information and communication technologies (ICT) (e.g. Internet of Things, big data and cloud computing) into manufacturing processes, products and services, interconnectivity and real-data collection/analysis are potentially enhanced...
favouring more assertive managerial decisions (Zezulka et al., 2016; Yang et al., 2017). Such integration has also obtained the title of Industry 4.0 (I4.0), and it has been claimed that the ICT may lead manufacturers to a superior performance level (Züehlke, 2010; Liao et al., 2017). However, much still needs to be investigated to deeply comprehend the procedure to include I4.0 technologies into existing management systems. Thus, despite the envisioned interrelations (e.g. Meudt et al., 2017), the way I4.0 technologies can influence the design and implementation of lean value streams is still unknown, and there is still a lack of empirical evidence within the literature (Martinez et al., 2016).

Therefore, this article aims at proposing guidelines integrated with I4.0 technologies for designing lean value streams. For that, based upon experts’ opinion, we verify the relationship of the main I4.0 technologies with each guideline for a lean value stream design, discussing how they may impact the currently existing approach. Our proposal entails a shift on traditional guidelines for lean value stream design, providing an approach aligned with the ICT/i4.0 that is expected to revolutionise operations management.

**Literature review**

**Value stream mapping**

VSM development usually encompasses four main steps: (i) identify products/services families, (ii) draw current state map, (iii) design future (lean) state value stream, and (iv) consolidate a plan and implement improvement opportunities. Step (i), identify products/services families, aims at determining families of products/services whose items present similar processing needs, simplifying subsequent mapping activities. Generally, a product-process matrix, in which processes are in the columns and products are listed in the rows, is established allowing a simple visualisation of similarities (Duggan, 2012) or incorporating more complex mathematical models to identify them (De Lit et al., 2000; Eppinger and Browning, 2012).

The second step comprises drawing the current state map for the selected product/service family. Literature (e.g. Zahraee et al., 2014; Morlock and Meier, 2015; Tortorella et al., 2017) suggests that different methods can be simultaneously applied for this addressing this activity, such as oriented visits (Gemba walks), participatory observation, semi-structured interviews, system-data collection and focused groups with the improvement team. Based on these methods, information such as cycle times, inventory levels, machine downtimes, etc., is collected and inputted into the map. Moreover, the usual recommendation to draw a current state value streams is from downstream to upstream processes, which is supposed to facilitate the comprehension of value from customers' (internal or external) perspective.

Step (iii) concerns the design of the future state of the selected value stream. This future state is supposed to be an improved version (lean) of the current state map since it aims at addressing the opportunities previously identified using the variable of time (Womack and Jones, 2011). The recommendation for this step is to draw the current state map with the same team-based approach. According to Hines and Rich (1997) and Rother and Shook (2003), a lean value stream is focused on increasing system's flexibility to allow rapid adaptation to changes in demand, waste elimination, minimising inventory levels and enhancing the efficiency of materials and information flows.

Finally, step (iv) seeks to consolidate all necessary improvement initiatives and organise them into a strategic interdepartmental plan that is supposed to be followed-up in a regular basis (Edtmayr et al., 2016). Therefore, the recommendation is the establishment of specific working groups that, according to members' backgrounds and roles within the organisation, can address improvements with similar characteristics or
inter-related to each other. However, the existence of a value stream leader or coordinator is highly suggested to ensure the convergence of all initiatives and facilitate overcoming eventual barriers for change implementation (Bicheno and Holweg, 2000; Azizi, 2015).

**Industry 4.0**

Coined in the Hannover Fair in 2011, I4.0 has been referred to as the new paradigm in operations management (Hermann et al., 2016). In this ICT driven industrial context, prominent technological frameworks for manufacturing processes, products and services have been developed, entailing an array of solutions to the growing customised needs of informatisation (Kagermann et al., 2013). The novelty of this paradigm and its potential benefits envisioned have motivated a growing demand for research mainly related to its challenges, design solutions, implementation and management systems (Xu et al., 2018).

However, managers and practitioners still struggle to grasp I4.0 concepts. One of the reasons for such difficulty may be derived from the low readiness level of ICT infrastructures, undermining the adoption and understanding of I4.0 (Liao et al. 2017). Moreover, extensive incorporation of I4.0 technologies is also likely to influence other critical aspects of an organisational structure, such as customer/supplier relationship management (Schumacher et al., 2016) and human resources development (Dworschak and Zaiser, 2014). In this sense, while the adoption of cutting-edge technologies can facilitate the achievement of significant operational performance enhancement, at the same time it can also entail unknown structural shifts in organisations. Therefore, I4.0 essential features and impacts still deserve further investigation to provide a clearer comprehension for both managers and academicians (Yin et al., 2018).

**Method**

The proposed method comprises three main steps: (i) experts’ selection, (ii) interviews, (iii) consolidation and analysis of relationships. For experts’ selection, step (i), a few criteria were determined in terms of knowledge and experience level so that the gathered information was legitim and minimally reliable. First, the minimum professional experience of ten years was required. Second, experts should have deep theoretical and practical knowledge of LP practices, with particular emphasis on VSM. A third criterion consisted of a minimum familiarity level with I4.0 technologies, either employing practice or theory. Finally, to allow a diversified composition of perspectives, we looked for experts whose backgrounds were from academia, industry or both.

Initially, we identified twenty-two experts that met the criteria as mentioned earlier with easy access or with partnership relation from previous research. The first electronic message explains the research purposes and verifies their willingness to participate. Fifteen of them positively responded to the email, although only ten indicated their agenda availability. In the end, due to agenda availability mismatches, six experts had their interviews scheduled and registered, indicating a final response rate of 27.3%.

For step (ii), each expert holds an interview in meetings for about 45 to 80 minutes. To mitigate researcher bias, we verified issues of internal and external validity together with reliability and objectivity of information (Yin, 1994). Thus, two researchers (one associate professor and one PhD candidate) simultaneously participated in the interviews to enhance the ability of handling data and confidence in research findings (Dubé and Paré, 2003). Although the involved experts supposedly had a significant level of knowledge on the topics, we provided a brief explanation of I4.0 technologies and lean value stream guidelines to ensure a uniform understanding.

Regarding questions formulation, we adopted the eight lean value stream guidelines proposed by Rother and Shook (2003) and denoted here by $g_i$ ($i = 1,\ldots, 8$). Evidence of
their utilisation is vast (e.g., Abdulmalek and Rajgopal, 2007; Sa’udah et al., 2015) and they reasonably provide advice on how to design future state maps (Tortorella et al., 2018). In terms of I4.0, the research contains eleven technologies \( t_j (j = 1, \ldots, 11) \) due to their remarkable utilisation and citation. Therefore, during interviews experts were asked the following: "what is the intensity of the relationship \( r_{ij} \) between the development of lean value stream guideline \( g_i \) and the I4.0 technology \( t_j \)?". Responses follow an ordinal scale of nine points, where 0 indicated 'no relationship' and 9 indicated 'maximum intensity' of the relationship between \( g_i \) and \( t_j \).

Finally, step (iii) consisted of consolidating and analysing results obtained from the interviews with experts. Despite their large experience, due to differences in experts' backgrounds, there might be some variability among their responses for \( r_{ij} \). Hence, to consider such variability, the consolidated values for the relationship between the eight guidelines for lean value stream design and the eleven I4.0 technologies were weighted by the relative experts’ experience \( w_k \) \((k = 1, \ldots, 6)\).

Then, the study inserts values of \( r_{ij} \) in the intersections of matrix \( \mathbf{M} \), whose rows contain the eight guidelines \( g_i \) for designing a lean value stream and columns present the eleven I4.0 technologies \( t_j \). This matrix represents the overall scores for the relationship intensities. The sum of the scores of each row and column of \( \mathbf{M} \) denoted the overall potential for integration of each guideline and technology, respectively. In other words, higher total values for a determined \( g_i \) represented a guideline that can be more sensitive to the introduction of I4.0 technologies. In turn, higher total values for \( t_j \) represent the overall pervasiveness that such technology may have when designing lean value streams.

The differentiation index \( z_{ij} \) determines the most important relationships between the guidelines for a lean value stream design and the I4.0 technologies. This index represents the number of standard deviations of each individual value of \( r_{ij} \) in relation to the average values of the corresponding \( g_i \). Positive values of \( z_{ij} \) larger than 1.0 were used to indicate the most important relationships and, hence, prioritised for the proposed guidelines lean value stream design integrated with I4.0 technologies.

**Results**

Table 1 displays the consolidated results for \( \mathbf{M} \) obtained from the six interviews. Regarding the I4.0 technologies, the one with the highest pervasiveness level across all lean value stream guidelines (total score = 55.0) appeared to be \( t_{10} \) (Big Data). As a value stream is composed of several steps and activities in both material and information flows, the simultaneous generation of large quantities of data is potentially considerable. Traditional lean value stream guidelines may present difficulty or even neglect handling such data, impairing more certain managerial decisions. Therefore, according to experts' opinion, the integration of Big Data into Rother and Shook (2003)'s guidelines can be highly beneficial for a lean value stream design. More specifically, this technology presented a unique relationship (differentiation index > 1.0) with five guidelines; they are: \( g_1 \) (define takt time), \( g_2 \) (select finish goods strategy), \( g_5 \) (determine supermarket), \( g_6 \) (create one-point scheduling) and \( g_7 \) (define interval).

These results converge in some way to indications from Meudt et al. (2017), which suggest that the main contribution of integrating I4.0 technologies into VSM would be related to recording, handling, processing, analysing and optimising information processes and data gathering. This contribution appears to be especially relevant when considering the management of customers' demand (guidelines \( g_1 \) and \( g_2 \)) and production planning and scheduling (guidelines \( g_6 \) and \( g_7 \)). Furthermore, it is worth to mention that a few technologies, such as \( t_4 \) (augmented reality), \( t_5 \) (cloud computing system) and \( t_8 \) (integrated engineering systems), did not present a relatively high relationship (> 1.0)
with any of the eight guidelines. Nevertheless, these technologies may also influence the design of lean value streams, although not at the same extent as the remaining ones.

Note: Numbers in white cells represent the average weighted values \( r_{ij} \) of relationships for each guideline. Numbers in grey cells represent the standardised values \( z_{ij} \) of relationships for each guideline (differentiation index). Bold numbers refer to the most important relationships (>1.0) between I4.0 technologies and guidelines for lean value stream design.

In terms of lean value stream design, the guideline with the highest potential for integration with I4.0 technologies was \( g_3 \) (implement continuous flow), with a total score
of 68.2 and important relationships with \( t_1 \) (collaborative robots) and \( t_9 \) (additive manufacturing, rapid prototyping or 3D printing). ‘Continuous flow’ is also known as one-piece flow, single-piece flow, or make-one, move-one (Womack and Jones, 2011). It refers to producing and moving one item at a time (or a small and consistent batch of items) through a series of processing steps as continuously as possible, with each step making just what is requested by the next step (Rother and Shook, 2003). It can be achieved in many ways, ranging from moving assembly lines to manual cells. As it entails a minimum inventory level between workstations, material and information flow become much more sensitive to any variation or disruption in their processes (Braglia et al., 2009). Since the adoption of ‘collaborative robots’ and ‘additive manufacturing’ might provide a more flexible and agile productive flow (Brettel et al., 2014; Karre et al., 2017), it is reasonable to expect that these I4.0 technologies can positively favour the implementation of continuous flow.

It is noteworthy that although guidelines \( g_4 \) (establish first-in, first-out), \( g_5 \) (determine supermarket) and \( g_7 \) (define interval) had lower total scores than \( g_3 \), each one presented three important relationships with I4.0 technologies, instead of the only two ones for \( g_3 \). These findings indicate the overall potential of incorporating specific I4.0 technologies into a lean value stream design, which has been somewhat envisioned by Tamás et al. (2016) and Mrugalska and Wyrwicka (2017). Our results show that all lean value stream guidelines proposed by Rother and Shook (2003) can be influenced by at least one I4.0 technology. However, the practical changes implied by such relationships are not yet evident and deserve further attention from researchers and practitioners.

**Conclusion**

This study proposes integrated guidelines for designing lean value streams with I4.0 technologies. For that, we used experts’ opinion cross reference with relevant literature on the topic. The contribution of this research is relevant from both practical and theoretical perspectives.

First, in theoretical terms, our study raises arguments on the future of lean value stream design since it envisions the incorporation of novel I4.0 technologies into each of the traditional guidelines. Literature evidence on this subject is still scarce, and the existing studies lack further conceptual details. Thus, this research not only specifies how I4.0 technologies could benefit a lean value stream design, but it also suggests how these existing and widely accepted guidelines may change, so they became more robust and aligned with the Fourth Industrial Revolution era.

From a practical perspective, the proposed guidelines advise organisations under LP implementation about the potential changes that lean value stream design might face with the introduction of I4.0 technologies. Hence, our proposal entails a shift on traditional guidelines for lean value stream design, emphasising how novel ICT could support a distinguished and technology-integrated lean value stream management that benefits from the simplicity and efficiency of LP with the ease and agility of the technologies typical of the Fourth Industrial Revolution. Such technology-integrated guidelines may allow overcoming existing barriers while leading companies to superior performance results.

Certain limitations of this study are worth to be mentioned. Although the proposed guidelines have emerged from experts’ opinion, more extensive empirical validation is still required. The development of case studies and field applications based upon the proposed guidelines for a technology-integrated lean value stream design would add evidence that could potentially entail further changes and propositions. However, as the
adoption of I4.0 technologies is still incipient in most industries, such practical verifications would deserve particular attention to mitigate biased outcomes.

Abstract

Nowadays, lean researchers are focused on the role of organizational culture and contingencies factors in the success and sustainability of lean management. This research aims at contributing to the academia debate by analysing through a deep case study whether organizational culture based on lean management can enable companies in overcoming differences related to the national culture. Moreover, the study wants to provide evidences that companies can leverage on lean practice in order to spread organizational culture among different country-based plants.

Keywords: Lean practices, organizational culture, case study.

Introduction and research context

People, practices and culture are strongly interrelated in lean mindset: extant literature shows that the large majority of companies that fail in implementing lean lacks in understanding the required relationship among these concepts (Netland, 2016). Toyota, with its Toyota Production System, represents indeed an outstanding example of how acting on the people, their mindset and company’s culture will lead to success (Womack, Jones and Roos, 1990).

Companies have tried to reproduce this model but very few have been able to achieve the same performance levels (Spear, 2004): about two out of three organizational change projects fails (Netland, 2016). The reason may lay on the fact that Toyota model has been specifically deployed to fit perfectly to the Japanese culture. National culture plays indeed an essential role while companies start lean journey. There are many contingencies that can prevent companies to a successful implementation of lean practices, and national culture is with no doubts one of the strongest (Pagell, Katz and Sheu, 2005). For a multinational company, that has to deal with different national cultures, understanding
how integrating plants located all over the world and which role is played by the underlying context and by different national cultures represents a key issue (e.g. Van Oudenhoven, 2001; Testa, 2009). Considering cultural differences for companies that are keen to grow at an international level is not an option. Cross-cultural communication is imperative: it involves a comprehensive understanding of how people from different cultures speak, communicate, and perceive the world around them (Wang, 2008).

A good leverage to act on in order to reduce existing differences in national cultures is represented by organizational culture. It conceives membership in the organization and not in a country (Bortolotti, Boscari and Danese, 2015). In 1996, Schein defines organizational culture as: "the basic tacit assumptions, on how the world is and should be, that a group of people share and that determine their perceptions, thoughts, sensations and, their evident behavior" (Schein and Graduate, 1996). According to this definition, organizational culture can be seen as a set of shared assumptions that guide what happens in organizations by defining appropriate behavior for various situations (Ravasi and Schultz, 2006). Organizational culture affects not only the way people and groups interact with each other, but also how much employees identify themselves with the organization (Schrodt, 2002). It is possible to point out a parallel between Schein model and lean philosophy: lean practices can be seen as the visible part of the organizational culture. The interaction of appropriate attitudes and group norms with lean principles contribute to nurturing commitment and engagement inside employees (Angelis et al., 2011). Lean embraces the ability to constantly change as a keystone of organizational culture.

However, change does not just happen, it must be managed, and the establishment of a lean culture need to be pushed by the top management, whose strong commitment is a must. According to Shook (2010), companies should consider that a change in organizational culture must be managed properly: “trying to directly change the culture” will lead companies to fail in their scope. A deep organizational shift will happen indeed only if the company acts on its behaviours, the way they do things. In this sense, lean practices and their implementation will easier the adoption of a new culture within a company. Even Schein (1996) theorized that the only way to change organizational culture is to change the artefacts, as the observable data of an organization, the way people do thinks and how they behave. Even if it seems that the academia reached the consensus on the positive role of lean practices on organizational culture, it still remains unclear how national culture can affect them. In recent years Netland (2016) declares that belonging to specific national culture does not negatively impact on the lean success or on the implementation of its practices. Unfortunately, there are still few contributions in this sense.

This research aims at contributing to the academia debate by analysing through a real case study whether organizational culture based on lean can enable companies in overcoming differences related to the national culture. Moreover, the study wants to provide evidence that companies can leverage on lean in order to spread organizational culture among different country-based plants.

**Case study**

A deep case study has been carried out in an Italian automotive company characterized by a strong organizational culture based on lean management. Data have been gathered through secondary data, survey and direct observations.

*Company’s profile*

The firm selected to conduct the study is the Italian “Prometeon Srl” (Prometeon), the former Pirelli Industrial, that operates in the automotive industry. It mainly produces and
commercializes Pirelli branded Industrial tyres for trucks, bus, agro and OTR under license. Prometeon’s plants are spread all over the world, being two in South America, one in North Africa, one in Middle East and the headquarter in Europe. Prometeon started its journey towards lean management in 2008 and adapted lean practices to its own production management system, formalizing it in the so-called Prometeon manufacturing system (PMS). Prometeon needed at that time to create a strategic model to assure standardized performance, culture and results of their operations located all over the world.

PMS is built upon a panel of selected lean practices and tools aimed at improving production performance in all the plants owned by Prometeon around the world. All business units, and every single department (quality, R&D, processes, HR, logistics and production) are subjected to PMS. All functions are called to work together to optimize the whole process of value creation. PMS is shaped on people: every single employee highlights the difficulties, suggests improvements, feeling fully involved in the entire production process. Every plant is indeed embracing PMS and the related practices. When a plant outperforms in specific project, it becomes a model for the others. PMS brings together the experts of outperforming plants to other facilities to standardize processes, to share common practices and to spread culture.

Exactly in this direction, PMS comprehends a multi-plant improvement program, based on a full-immersion session on Gemba called Full Speed Day (FSD). FSD is aimed at improving a specific operational performance of a plant, supported by an internal and international benchmarking process. For its nature, FSD involves different functional teams belonging to different countries, that share knowledge among each other to reach the common goal of efficiency. Even though it is implemented in plants with very different national culture, being part of the same organization assures that all of them are oriented towards the common goal of improving the production process. Due to the stable structure and good results of the FSD, Prometeon considers it a strategic method for pursuing continuous improvement in the long term. As PMS in general, FSD is based on lean approach and some practices are shared between the two. Among others, Kaizen event is of a strong importance for FSD, aimed at creating value for the company while addressing efficiency and productivity performances in a defined period, involving inter-functional teams. In this view, the precise definition of both agenda and working team emphasizes the engagement of people, feeling them part of the project, keeping in mind the path that should be followed for reaching the best performance. These short and intense projects not only bring together small teams from different departments in order to find ways to work more efficiently, but also foster the learning cycle. Sometimes teams from different countries work together on a similar problem to share best practices. This enables more cross-enrichment among employees and benchmarking among plants, bringing outstanding results.

**Survey**

In order to understand whether the success of FSD and its perception by experts is somehow dependent by the national culture of plants where it is implemented, a survey design was been selected as the most suitable method. The survey is addressed to all the 19 managers involved in FSD having a strong lean expertise, from October 2017 to February 2018. Experts are from Brazil, China, Egypt, Italy and Turkey. All experts are managers of several departments as quality, R&D, maintenance, engineering and industrial engineering. Surely, the sample is not representative of the whole company, but it reflects the overall opinion of experts involved in FSD. The response rate has been 100%. Following a brief descriptive analysis of the sample.
The questionnaire designed is composed by 19 questions, grouped into two main clusters: (i) expert’s profile; (ii) human-related and lean-related perception. Both human-related aspects and the set of lean practices were defined according to the literature and to the intrinsic characteristics of FSD. A list is provided in the table below.

For the second cluster of questions (ii), respondents were asked to provide us with their perception on how human-related aspects impact on the effectiveness of lean practices on a 7-points Likert scale.

Results are studied according to Hofstede's model of national culture, recognized as a good framework to verify whether differences in perception of each country-based plant can be imputable to national culture. In the analysis, the dimensions related to the five countries in which the company has plants (Brazil, China, Egypt, Italy and Turkey) have been used.

![Figure 1 - Hofstede's variables](image-url)
Direct observation

In 2017, Prometeon started to support the management team of four Chinese plants (owned by Aeolus) spreading PMS. Aeolus is not sharing the same organizational culture as the one of Prometeon due to the recent integration between the two firms occurred in 2016. However, Aeolus was subjected to PMS.

With the aim to understand whether a company can act on internal lean practices to spread the organizational culture, data have been gathered through direct observation and interviews carried out during a specific PMS practice in one Chinese Aeolus’s plant. The PMS event under discussion is the already discussed FSD, as one of the most important lean initiatives developed within the company. Prometeon decided to export its FSD to Chinese Aeolus’s plant as first initiative to spread its organizational culture based upon PMS. However, due to the low level of lean implementation, some changes in FSD have been put in practice for the Aeolus plant.

One issue was represented by the selection of which experts’ team should practically export FSD. Egyptian team was selected as considered the Best in Class among Prometeon’s plants all over the world. It was composed by experts coming from several departments: R&D, quality, production, IE and maintenance. Moreover, Industrial Engineering team of the headquarter attended the Egyptian one during the entire project in order to guarantee the alignment among different people and scopes. Thanks to their previous experience gained of both Egyptian and Headquarter teams, potential problems of Aeolus plant were hypothesized in advance in order to overcome difficulties related to different languages and different organizational culture. Language problem was totally addressed thanks to the presence of three translators, one for each identified functional working area.

FSD in Aeolus plant followed a learning-by-doing approach in order firstly to make Chinese team able to gain the maximum advantage in a limited time span and secondly to foster the Prometeon’s culture transmission. The reason behind this choice relies on two models available in literature provided by Schein (1996) and Shook (2010). Both authors stress that in order to change organizational culture, it is fundamental to change “what we do”. Starting from changing behaviors, culture will change as result. Therefore, Aeolus plant experience was based on leveraging on lean practices, more specifically on FSD, in order to shape Chinese organizational culture and the way Chinese plant was working.

We spent two consequent weeks in the Aeolus plant together with the Egyptian and Headquarter Prometeon’s teams. In the first week, data collection and KPIs analysis has been performed for 2 days, followed by three days of workshop benchmarking with a series of Gemba walk sessions. Due to specific characteristic of Aeolus Chinese plant, this preparation phase lasted only 5 days compared to the 3 months of the typical FSD method. As already explained, this was due to foster the learning cycle. In the second week, an action plan was defined and then implemented during the first two days with the application of quick-wins improvement actions. It was followed by a session of 12 consecutively hours in the shop floor aimed at evaluating the improvement actions and developing a new action plan for the successive months. Even though FSD has been changed in terms of timing, the results were impressive. Quick-wins improvement actions allows the plant to succeed and gain around 8% of the capacity lost for the introduction of a new product in the production line.
Results
The case stresses the difference among experts already sharing Prometeon culture and Aeolus Chinese ones. More in detail, even though all Prometeon experts involved in the study are not sharing the same national culture, no significant differences in perceptions of both human-related aspects and lean practice exists. This is likely to be the result of a strong and already embraced organizational culture based on lean practices, which have enabled plants to overcome any existing difference due to national culture.

It is even interesting to notice the alignment on most of human-related aspects among the four plants of Prometeon: the first three positions of the ranking are covered by Management Commitment, Involvement of People and Training, Coaching and Mentoring. This is related to the organizational culture deeply rooted in these plants based on lean practices. Moreover, these results completely reflect the lean attitude founded on the proactive participation of people. Companies need to prioritize the sharing of knowledge and a training path which enable the personal growth (Fullerton and McWatters, 2001). The lean culture is indeed based on well trained employees to foster improvement and knowledge sharing (Alkhoraif, 2016). Teamwork enables the lean and continuous improvement attitude with the constant and recurring sharing of knowledge and information.

For what regards lean practices, all Prometeon experts agree on the high relevance of Problem solving tools and Gemba walks. For what regards Problem solving tools, the high ranking can be connected to the importance that each employee gives to the quick resolution of problems, that fosters the learning cycle. On the other hand, about Gemba Walk, all countries gave it strong relevance due to its effectiveness when implemented with inter-functional teams that, in a benchmarking context, can proceed in the best way thanks to their knowledge and capabilities. It is noteworthy to underline how in China it covers instead the fourth place. The alignment in experts’ perceptions may be related the well-established organizational culture based on lean.

In the Aeolus Chinese plant, instead, experts are still in their changing process and characteristics related to national culture result to be predominant. Here, for example, the most important human-related aspects are Leadership and Management Commitment. On the other hand, for what regards lean practices, they are Problem solving tools and standardized procedures. It is interesting to stress the different ranking obtained by standard procedures: this tool has got the most significant variance between countries. In Prometeon plants, it holds a position of less importance, while in Aeolus Chinese plant it is perceived as a critical one. The reason why may rely on the need of applying standard procedures under which each operator is subjected. According to Hofstede, Chinese
national culture is indeed characterized by willingness to receive practical and direct feedbacks oriented towards the standardization of operations and methods.

Consistently with the findings of Netland (2016), the case study performed in Prometeon suggest that the success of lean practice is not depending on national culture. A strong presence of organizational culture based on lean allows indeed companies to limit the existing cultural differences among countries. Moreover, lean can be exploited to manage change and to spread organizational culture among different firms.

What it is possible to conclude looking at different Prometeon plants is that the strong presence of an organization culture based on lean practices since 2008 makes the company succeeding in limiting the existing cultural differences between the countries. The Aeolus plant instead presents different results, in terms of both human-related activities and lean practices, and they are mainly imputable to national culture. In fact, it is worthy to stress that Aeolus did not share at that time the same organizational culture with Prometeon. The goal of Prometeon of spreading its organizational culture to Aeolus plant was the reason why FSD has been implemented in the first place: according to the literature, the most effective way to change a company culture is to change its way to behave. With this in mind, strong lean activities have been deployed by Prometeon in order to set the new culture in Aeolus, based on lean practices, considering together tools and techniques while involving people in their growth. Prometeon main challenge relies in sustaining its organizational culture while its organizational structure is characterized by strong differences, both in terms of anthropological and work culture point of view. According to the data collected, no significant differences among countries have been discovered, either in terms of human-related aspects or in terms of lean practices. This results in the strong power of organizational culture based on lean practices, that hence is able to overcome any difference existing in plants due to national culture. In the Chinese plant, although different organizational culture, experts team succeeded in significantly involving the local one, which showed willingness and openness to learning new techniques. Adjusting initiatives to better integrate the knowledge and capabilities of each country, keeping in mind the critical function played by the national culture and leveraging on well-known and universal lean practices are keystone for companies that want to spread organizational culture among different countries.

**Conclusion**

Prometeon, with its PMS implementation, is an interesting case to highlight that national culture does not play a significant role in the success of lean practices. Within Prometeon’s plants, according to data collected, no significant differences among countries have been discovered, either in terms of human-related or lean practice perception. This results in the strong power of lean practices: companies with organizational culture based upon lean are able to overcome differences related to national culture. Aeolus’s plant, instead, which at that time did not share the same organizational culture of Prometeon, presents different perception compared to Prometeon’s results, in terms of both human-related or lean practice. These differences are mainly imputable to national culture.

Therefore, case under discussion provides initial evidence on how a company should leverage on lean practice in order to limit the existing cultural differences among countries. Exploiting well-known and universal lean practices is the keystone for companies that are willing to spread their organizational culture among different countries. It is likely that more case studies will be collected in order to populate the database and to validate this initial evidence in the upcoming future.

Abstract

Many firms often struggle to link continuous improvement (CI) to operational performance because they fail to develop a people-centric organizational context that enhances employees’ engagement. Past literature has scarcely investigated the extent to which people-centric context and CI should be interrelated to improve performance. Based on a database of 330 firms across nine countries, a structural equation model is used to demonstrate that a closer fit in the relative magnitude of CI and people-centric context is associated with superior performance. Our results contribute to CI literature and contingency theory by providing evidence on the organizational circumstances that sustain effective CI.

Keywords: Continuous improvement, Organizational context, Operational performance.

Introduction

Lean firms aim at continuously improve their processes and products in order to gain a competitive advantage over their competitors and enhance operational performance. Continuous improvement (CI) triggers the evolution of a firm’s lean management system through stepwise adjustments and modifications in the process of solving problems and creating value-added activities (Anand et al., 2009; Furlan et al., 2019). Many firms often struggle to link CI to operational performance because they fail to develop an organizational context that provides the backbone to relentless initiatives of incremental improvements (Anand et al., 2009; Galeazzo et al., 2017). An organizational context deploys practices that facilitate an active, involved participation of employees.

Employees play a central role in CI, implying an organizational context is deemed to support them. Without an employee’s problem-solving behaviour that systematically searches for the root causes of problems, a firm would be hindered in detecting issues that prevent improvements (Tucker et al., 2002, 2007). Without an employee’s
interaction with her peers and supervisors, organizational learning is difficult to develop to expand the knowledge base of a firm and adopt improvement activities (Furlan et al., 2019). Without an employee’s involvement in CI objectives, it would be difficult for a firm to reduce waste and, thus, improve over time (Linderman et al., 2006). This results in the need of people-centric organizational contexts that deploy human-related practices to train employees in identifying and solving problems, support knowledge sharing and motivate them to pursue improvement goals.

Past literature has never questioned the central role of employees in explaining a firm’s ability to implement CI that enhances operational performance. A people-centric context seems a necessary condition to gain an understanding of how CI effectively works. However, these findings do not explicitly examine the interrelationship between people-centric context and CI with respect to firm performance. Some studies argue that the implementation of human-related practices are preconditions for effective CI (Anand et al., 2009; Zeng et al., 2017; Ma et al., 2019) whereas others argue that they strengthen the relationship between CI and performance (Sila, 2007; Uhrin et al., 2017), thus implicitly assuming they may not be adopted by a firm. Therefore, it is unclear the extent to which people-centric context and CI should be interrelated and the resulting effects on performance.

In this paper, we seek to explain whether the match between people-centric context and CI is relevant to improve operational performance by using contingency theory and the concept of organizational fit. As literature suggests that the implementation of people-centric organizational contexts is an antecedent of CI or is a moderator in the relationship between CI and operational performance, an organizational misfit should not affect performance. Based on a database of 330 firms across nine countries, we used a structural equation model to test whether the organizational fit between people-centric context and CI positively affects operational performance. We find that a closer fit in the relative magnitude of CI and people-centric context is associated with superior performance. Our results provide both theoretical and managerial insights. We explain the contingency relationship between the organizational context and CI, thus providing empirical evidence on the organizational circumstances that sustain successful implementation of CI (Anand et al., 2009; Galeazzo et al., 2017). By showing that the organizational fit leads to superior performance, our research also identifies for managers the timing for developing CI practices and organizational context oriented to employees’ involvement.

Theoretical background and hypothesis development

Organizational fit
Contingency theory argues that firms develop initiatives that more or less effectively improve performance under different organizational factors. Organizational fit is defined as the degree of coherence among activities within a firm (Siggelkow, 2001) that directly affects firm performance. In this study, organizational fit refers to the alignment between the magnitude of implementation of people-centric organizational context and CI. Instead, misfit implies that firms may either have consistently adopted CI practices with low employees’ involvement or have extensively adopted human-related practices while lagging behind in CI initiatives.

Only few studies in operations management empirically explore the role of organizational fit in improving performance. For example, Zhang et al. (2012) proposed that quality improvement initiatives, i.e., quality exploration and quality exploitation, differently benefit from mechanistic and organic structure. They found that quality
exploration is associated with higher performance when firms adopt organic structures with few hierarchical levels and decentralized decision-making systems whereas quality exploitation fits better with mechanistic structures characterized by narrow span of control and centralized decision-making. Most literature, however, investigates the effect of the internal fit between organizational factors and improvement initiatives to performance using different methods (Sila, 2007; Camuffo and Wilhelm, 2016; Zeng et al., 2017). Zeng et al. (2017) showed that centralization of authority negatively impacts human-related quality improvement initiatives and positively impacts process-related quality improvement initiatives that, in turn, improve performance. Moreover, inter-functional integration positively impacts human-related initiatives but negatively impacts process-related initiatives that, in turn, improve performance. Their conclusion indicates that improvement initiatives have different organizational antecedents but it does not investigate how these organizational characteristics should be combined with improvement initiatives in order to positively influence performance. Sila (2007) found that quality improvement initiatives are not depend on contextual factors, implying no need of adjustments across firms. He employed a subgroup analysis to test difference among groups of firms having different organizational characteristics. In this case a moderating effect of the organizational factors is assumed to affect the relationship between improvement and performance. Our study differs from Sila (2007) because it emphasizes the importance to find a balance between organizational context and improvement.

The effect of organizational fit between CI and people-centric organization on performance
Past literature suggests CI is a dynamic capability. “A dynamic capability is a learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness” (Zollo and Winter, 2002, p. 340). As suggested by Winter (2003), dynamic capabilities are high-order routines (or collection of routines) whose main objective is to change existing products and processes. Peng et al. (2008) operationalized CI as the combination of the three organizational routines of process management (PM), leadership involvement (LI) and improvement orientation (IO). PM includes activities that pursue process control and standardization by using techniques and charts that help reducing process variation, increasing efficiency, detecting incongruences, thus preventing problems occur and fostering improvement (Rondeau et al., 2000). LI refers to a set of practices that encourage top management and major department heads to support CI by triggering the participation of CI activities. Finally, IO refers to the development of an organizational culture oriented toward the continuous research of improvement in processes and products (Roth, 1996; Linderman et al., 2010).

A supportive organizational context enables CI to positively affect operational performance (Anand et al., 2009). Workforce plays a pivotal role in support of CI and, thus, a people-centric context is likely to be conducive to effective improvement activities. As firms aim at searching for the root causes of problems and implementing the most adequate solutions, employees’ knowledge and skills are paramount (Letmathe et al., 2012). Thus, a people-centric context should implement training programs that enable employees to acquire new skills and knowledge to detect problems and, in turn, increase performance. Moreover, a people-centric context emphasizes the need to form teams that foster knowledge articulation and knowledge codification (Furlan et al., 2019) with the objective of developing organizational learning (Choo et al., 2007) and performance. Finally, a people-centric context should support employees’ motivation
and encourage engagement in CI activities through goals management systems. For this reason, we operationalize a people-centric organizational context as the combination of the three human-related practices of training for quality, teamwork for problem solving and goal-based incentives.

We argue that a closer organizational fit between people-centric context and CI contributes to operational performance through a more balanced distribution of resources and a more synchronized modification of human-related and improvement activities. Conversely, a misfit between context and CI poses threats to performance through an increased risk of resource waste and poor adjustments of different activities. More specifically, when an organizational context is unable to involve employees, a firm striving for complex CI initiatives is susceptible to the risk of failure, thus wasting time. A synchronized adjustment of human-related practices and CI allows, instead, to develop reciprocal interdependencies (Thompson, 1967) that may, in turn, give rise to complementarities. In summary, the magnitude of people centrality in an organizational context should evolve at the same pace of CI maturity.

Hypothesis: The organizational fit between people-centric context and CI positively affects operational performance

Methods

Data collection and analysis
We use the fourth round of the High Performance Manufacturing (HPM) database to test our theoretical model. The HPM database is the result of an international project that involves researchers from nine countries: Brazil, mainland China, Finland, Germany, Israel, Italy, Japan, South Korea, Spain, Sweden, Taiwan, the United Kingdom, and Vietnam. Following a stratified sample procedure, all the participating researchers contacted plant managers of standalone manufacturing firms or subsidiaries with more than 250 employees from three industries: electronic, machinery, and transportation. A total of 330 firms accepted to participate to the project. These firms are both traditional firms as well as world-class manufacturers (randomly selected from a list of winners of one or more awards such as the Shingo Prize or industry leaders recognized by the literature, trade magazines, or newspapers). Data was based on questions from twelve different survey questionnaires that focus on various areas such as human resources, quality management, lean management and technology. More than one informant answered most questions. They were given the hard copy of the questionnaires, translated in their native language following recommendations of Brislin (1980). The use of multiple questionnaires responded by multiple informants helps mitigating common method bias. As the unit of analysis is the firm, data from multiple respondents answering the same questions were aggregated to the firm level and questions from different questionnaires were merged together to compile a comprehensive database.

Measures
All items are measured on a 5-point Likert scale if not differently specified. They are all based on prior literature, thus content validity is assumed. Following other studies using the HPM dataset (Peng et al., 2008; Galeazzo et al., 2017), items were standardized per country and industry.
Operational performance is the dependent variable of our model. Based on Zhang et al. (2012), it was measured as a weighted index of four performance dimensions: cost, quality, delivery and flexibility. As shown in Appendix A, all the performance dimensions have Cronbach’s alpha coefficients and composite reliability (CR) above their recommended cutoff values (0.7 and 0.6, respectively), thus showing construct reliability. They also load on their respective factors with values that exceed the recommended 0.5 cutoff value, thus showing construct validity. We weighted each dimension based on the extent to which a firm emphasizes it as a strategic goal. For example, a firm with a leadership cost strategy will have a high weight on the cost dimension. The formula is given in Appendix A.

CI was measured as a second-order latent variable based on Peng et al. (2008). A confirmatory factor analysis (CFA) was used to test whether manifest items loaded on the three first-order factors of process management (PM), improvement orientation (IO) and leadership involvement (LI), and, in turn, whether they loaded onto a super-ordinate factor of continuous improvement. Since the model provides a good fit ($\chi^2$/df=1.82, CFI=0.958, TLI=0.950, RMSEA=0.051) with all manifest variables and first-order variables loading significantly above the 0.5 standard on the respective constructs, these estimates demonstrate convergent validity (Bagozzi, 1994) (see Table 1). We assessed discriminant validity comparing the unconstrained three-factor CFA model with the constrained two- and single-factor CFA models. In each case, the three-factor model provided a significantly better fit than the constrained models. We also used the average variance extracted (AVE) to further validate our second-order latent variable. Table 1 shows that all the AVE are higher than the recommended threshold value of 0.5 (Fornell and Larcker, 1981). LI has an AVE equal to 0.48 that is only slightly below the 0.5 cutoff value. Overall, CI is found to be a reliable and valid construct, and it is computed by combining the factor score weights from CFA with the standardized items.

People-centric context was measured as a second-order latent variable based on Anand et al. (2009). It consisted of teamwork for problem solving, training for quality and goal-based incentives as first-order latent factors. Teamwork for problem solving deals with activities enabling employees to interact and exchange knowledge for solving problems and strive for improvement. Training for quality focuses on employees’ involvement in learning new tasks such as problem-solving and basic statistical techniques and improve their skills to detect quality issues. Goal-based incentives factor assesses the extent to which a firm defines rewards and salary levels to support the professional development of employees. Reliability is checked using Cronbach’s alpha and CR (see Table 2). A second-order CFA model was conducted to test convergent and discriminant validity. The measurement model shows a good fit ($\chi^2$/df=2.897, CFI=0.935, TLI=0.916, RMSEA=0.077). Convergent validity is supported because all factor loadings exceed the threshold of 0.5. Discriminant validity was assessed using a χ² different test for all the possible models combining the three first-order variables. Compared to the other models, the three-factor model presented better fit, thus supporting discriminant validity. Overall, people-centric context is a reliable and valid construct, and it is computed by combining the factor score weights from CFA with the standardized items.

- Training for quality  
- Goal-based incentives

Organizational fit between CI and people-centric context variable is operationalized as the absolute difference between CI and people-centric context in line with previous studies (e.g., Cao et al., 2009). High values imply a misalignment between CI and people-centric context with firms being mature on CI but having an organizational context that does not support employees’ involvement and vice versa. Low values imply a strong correlation between CI maturity and the level of a firm’s implementation of people-centric context.

We included size and age as control variables following previous literature (Zhang et al., 2012; Ma et al., 2019). Size was measured as the natural logarithm of the number of employees at plants. Age was measured as the number of years since the plant was established.

To test our hypothesis, we conducted a structural equation model (SEM). The measurement model fits well the data ($\chi^2$/df=1.695, CFI=0.918, TLI=0.903, RMSEA=0.071). Figure 1 shows the results of our model. It emerges that a greater distance between CI and people-centric context is negatively associated with operational performance, thus suggesting that organizational misfit between people-centric context and CI might explain poor operational results.

**Figure 1—SEM results**

**Conclusion**

Our research contributes to the CI literature by highlighting the importance of matching the development of people-centric organizations and CI capability. Most previous studies that examine the relationship between the organizational context and CI do not give consideration to the extent to which they should simultaneously evolve in order to pursue improved operational performance. In particular, past research has focused on the organizational context as a CI antecedent or as a moderator in the relationship between CI and performance (Sila, 2007; Galeazzo et al., 2017; Ma et al., 2019). Our findings demonstrate that it is important to understand the relative magnitude, rather than the relative position, of the organizational context with respect to CI and vice versa. Moreover, it emerges that different levels of CI maturity, i.e., the degree of CI implementation, require different conditions of employees’ involvement. By linking employees’ involvement to contingency theory, we therefore highlight that the development of human deployment should not be pursued in isolation, but it should be balanced with the degree of CI maturity. Finally, our paper suggests managers to place resources and efforts to create a balance between the emphasis given to employees’ involvement and the development of CI.

The present paper has a number of limitations that future research should investigate. First, CI’s scope is not limited to the three bundles of routines that we included based on
Peng et al (2008) and future research might investigate which additional bundles of routines underlie CI capability. Second, people-oriented organizational context is measured using three bundles of human-related practices. Future research could investigate additional practices to provide a more in-depth understanding of the dynamics between the organizational context and CI. Finally, future research may use alternative methods to assess the organizational fit between CI and the people-oriented organizational context.

*Operational performance*

Operational performance=$W_1 \times \text{cost}+W_2 \times \text{quality}+W_3 \times \text{delivery}+W_4 \times \text{flexibility}$.

Where $W_1$, $W_2$, $W_3$, $W_4$ are weights assessed in the following way:

Please indicate the importance of each goal for your company in its primary market:
1: Least important, 3: Neutral, 5: Absolutely crucial

- Low price (C)
- High performance quality (Q)
- Fast delivery (D)
- Ability to rapidly change over products on short notice (F)

Weights are computed in the following way:
$W_1 = C/(C + Q + D + F)$ (weight for cost performance)
$W_2 = Q/(C + Q + D + F)$ (weight for quality performance)
$W_3 = D/(C + Q + D + F)$ (weight for delivery performance)
$W_4 = F/(C + Q + D + F)$ (weight for flexibility performance)

And cost, quality, delivery and flexibility are the performance dimensions assessed in the following way:

Please circle the number that indicates your opinion about how your plant compares to its competitors in its industry, on a global basis.
1: Poor, much worse than global competitors, 3: Average, 5: Superior, much better than global competitors

Exploring the relationship between soft lean practices and innovative work behavior: A case study approach

Abstract
Taking soft lean practices into account, this exploratory study assesses their relationship with innovative work behavior (IWB) and demonstrates how soft lean practices affect the different dimensions of IWB (i.e. idea generation, idea promotion and idea implementation). Within an empirical case study, the results indicate that soft lean practices are conducive to different dimensions of IWB and that single soft lean practices can influence more than one dimension of IWB. The results provide managers with a better understanding of how they can create a breeding ground through soft lean practices for achieving higher levels of IWB.

Keywords: continuous improvement; lean sustainability; innovative work behavior

Setting the context
In general, continuous improvement (CI) involves ongoing endeavors to steadily improve the overall performance of the organization through incremental change. Through lean, organizations attempt to alter the way they operate in order to meet an ever-changing customer demand with as less resources as possible. Improvements, however, degrade over time and move back to their original state if they are not carefully managed (Bicheno and Holweg, 2016). For instance, many fail to implement lean successfully due to an overemphasis on the tools and techniques that it is associated with, disregarding the necessity for a cultural and a behavioral change (Liker and Rother, 2011). Although residual benefits due to implemented improvements may be retained indeed, the CI momentum degrades, which negatively affects the future CI capability of the business (Bicheno and Holweg, 2016). On that note, organizations often denote successes in the early stage in the form of guaranteed outcomes with minor efforts due to the application of lean tools and techniques. Yet, many still struggle with sustaining the CI momentum in the longer term (e.g. Bateman, 2005; Jørgensen et al., 2007; Bicheno and Holweg, 2016; Hirzel et al., 2017). Various studies that have been conducted in the UK report that no more than 10% managed to introduce lean effectively into their organization (Bhasin, 2012).
Lean soft practices
Recent literature emphasizes the importance of managing people (Hadid and Mansouri, 2014; Bortolotti, et al., 2015; Hadid et al., 2016), as lean itself is conceived as a socio-technical system, functioning as an interplay between hard and soft lean practices (Bortolotti et al., 2015; Hadid and Mansouri, 2014; Hadid et al., 2016). While hard lean practices involve tools and techniques that mainly help to identify and to eliminate waste (e.g. 5S or VSM), soft lean practices involve HRM practices that are conducive to behavioral change for the purpose of lean sustainability (e.g. training and development or recognition and reward systems) (Martínez-Jurado et al., 2013). A focus on soft lean practices promotes organizational change towards a lean-thinking culture (ibid) and is often suggested to be central to the success of lean (Jørgensen et al., 2007). In this regard, Hadid et al. (2016) discovered the positive synergistic effect on operational and financial performance when accompanying hard with soft lean practices. In addition, Bortolotti et al. (2015) identified that successful lean-adopting organizations make more use of soft lean practices than unsuccessful ones and could not ascertain a significant difference regarding the utilization of hard lean practices. Indeed, hard lean practices are seen to assist in removing non-value adding activities from the value chain but the use of soft lean practices is, however, indispensable when aiming for CI sustainability.

Innovative work behavior
When pursuing a lean philosophy, standard operating procedures provide the basis for incremental innovation as employees steadily seek improvement opportunities in their current-state operations. Initiatives that are conducive to generating and developing ideas are supportive to establish a culture of continuous change, which in turn is key to sustaining CI (Anand et al., 2009). Not surprisingly, there is consensus that people play a major part in sustaining lean (Hadid and Mansouri, 2014; Bortolotti et al., 2015; Hirzel et al., 2017; Bortolotti et al., 2018) because CI is highly reliant upon employee engagement through individual innovative initiatives, also termed as innovative work behavior (IWB). IWB involves intentional behavioral actions that an individual undertakes to engage in the CI process (de Jong and den Hartog, 2010). More precisely,

IWB is the combination of three behaviours: idea generation, i.e. the development of novel ideas to solve problems or exploit opportunities; idea promotion, i.e. the search for potential allies to support the innovative idea; and idea implementation, i.e. the application of the innovative idea in the real-life context of the organisation (Mura et al., 2016, p. 1224).

While innovation consists of various sequential stages, beginning with the generation of the idea and ending with its implementation, IWB does not necessarily cover each of them. Instead, IWB is rather an employee-level approach where individuals participate in one or more of the aforementioned stages at any given time (Scott and Bruce, 1994). In other words, employees do not necessarily display each behavior but often leave some other matters to colleagues with corresponding skills. With that said, it becomes obvious that employees require different skillsets during each of the stages in order to excel. High levels of IWB are thus very likely to promote CI from ‘bottom-up’ (Mura et al., 2016). Since organizations seek achieving high levels of IWB in order to sustain the CI momentum, they endeavor encouraging their employees to engage in the innovation process (Hirzel et al., 2017).

Development of the research question
Many scholars from the field of lean accentuate the power of soft lean practices to foster lean sustainability (e.g. Jørgensen et al., 2007; Hirzel et al., 2017) and although a few researchers from other disciplines have addressed the positive impact of HRM practices on IWB (e.g. Prieto and Pérez-Santana, 2014; Bos-Nehles et al., 2017), the relationship between soft lean
practices and IWB in particular remains unclear. In other words, the current knowledge of the positive impact of HRM practices on IWB could shed more light on the challenges of lean sustainability. In addition, previous research on the relationship between HRM practices and IWB considered IWB as a one-dimensional construct (e.g. for simplicity reasons; Bos-Nehles et al., 2017). A recent literature review by Seeck and Diehl (2017) on HRM and innovation reported a lack of studies explicitly considering the different dimensions of IWB (i.e. idea generation, idea promotion and idea implementation), and similarly, Bos-Nehles et al. (2017) emphasize the necessity to investigate this relationship by considering IWB as a multi-dimensional construct. Seeck and Diehl (2017) further deduce from their review that there are only a limited number of qualitative studies (e.g. de Jong and den Hartog, 2007; Messmann and Mulder, 2011; Tuominen and Toivonen, 2011). They argue that existing ones, however, demonstrated access to ‘the intangible and complex nature of […] innovation’ (p. 929) in the past, which quantitative studies might lack of. Together, these studies effectively call for an explorative approach, investigating the relationship between soft lean practices and the different dimensions of IWB in order to develop a more grounded understanding how lean can be sustained. This study proposes the following research question to address this gap.

**RQ.** How do soft lean practices influence innovative work behavior?

To address this question, this study develops an analysis through the ability-motivation-opportunity (AMO) framework, suggesting that employee performance emerges from interplay between ability, motivation and effort as well as opportunities to contribute (Lepak et al., 2006; Jiang et al., 2012). As soft lean practices aim at a behavioral change through the development of skills, the stimulation of motivation and the creation of opportunities, the AMO factors align with many aspects that have already been discussed in the literature on lean sustainability. That is, for instance, the development of skills to enhance the abilities (Hirzel et al., 2017), the necessity of involving and empowering employees to enhance the opportunities for the adoption of their acquired skills (Bateman, 2005; Jørgensen et al., 2007; Hadid et al., 2016), and rewarding and recognizing employees to enhance their motivation (Jørgensen et al., 2007; Anand et al., 2009). In this regard, the authors propose that the AMO framework may provide closer insights into this relationship.

**Methods**

*Case study design*

Since the research objective was exploratory in nature, a case study design was adopted (Yin, 2014). With regard to the company profile, an internationally operating manufacturing company for electronic appliances was chosen (from now on referred to as InterCo), in which soft lean practices are extensively used as part of a wider lean program, accompanying hard lean practices. The research was undertaken at one of their UK sites.

*Data collection*

The case study used a mixed-method approach for the data collection and took place over four site visits. During the following two-hour site tour, as agreed, the first two authors observed twelve operators (O12) at work and interacted with them. Interactions with operators occurred spontaneous, arose out of the situation and were thus not pre-determined. These data were recorded via field notes. Further supplementary data, including protocols of lean implementation and a company presentation were also recorded via field notes and photographs. Data from these sources were used for triangulation purposes (Eisenhardt, 1989). Then, the authors extended the dataset by conducting semi-structured in-depth interviews with three managers (Director of Manufacturing Support, M1; HR Manager, M2; Head of...
Manufacturing, M3) and three further operators (O1; O2; O3) (Yin, 2014). The interviews with managers generated a wider picture of the current situation and past experiences, as they have responsibility for managing the shop floor (Aoki, 2008). Each interview was tape-recorded and transcribed verbatim.

Data saturation
After the interviews, there was much data overlap and just little more new material of substance was being added. Most interviewees demonstrated a considerable knowledge about the area of inquiry and, noticeably, the views of managers and operators often merely differed in a perspectival manner, that is, “managing” and “being managed” (Guest et al., 2006). In any case, data become sufficient to elucidate the aim of the research (Patton, 2015), that is, the exploration of the relationship between soft lean practices and IWB. In view of this, the researchers agreed on finalizing the data collection after complementing the dataset with six semi-structured interviews.

Data analysis
Prior to the analysis, interview transcripts and field notes were reviewed. First-order coding was conducted. Guided by the AMO framework for the data aggregation, codes that represented a soft lean practice were grouped to first-order categories (van Maanen, 1979; Corley and Gioia, 2004) and then mapped to the according theme within each single factor of the AMO framework (Lepak et al., 2006). For instance, ‘cross-training’ was mapped to ‘training and development’, which constitutes an element of ‘ability’. In doing so, the third level of aggregation was indeed guided by each of the three factors within the AMO framework. Supplementary data were analyzed in the same manner or used for triangulation purposes (Eisenhardt, 1989). From this analysis, it became apparent that some codes match with more than one theme within the AMO factors and consequently were cross-coded.

Results
The following presents the results from the InterCo case. To begin with, operators on the shop floor are considered as a crucial source for novel ideas because they are the ones who are constantly doing the physical job.

The ideas come from the people who are involved in the everyday process. Especially here, we don’t work top-level down. It’s more from bottom-level up because the guys who are working constantly know what is a hindrance or an inefficiency to them (O1).

The weird and whacky ideas because someone may think it’s silly… an idea they are putting forward… 90% of that idea may be silly but then that 10% could be then involved into something phenomenal (M2).

Thus, management does not only seek encouraging their operators to engage in idea generation but also in idea promotion so that operators bring their ideas on the table.

Idea-generating soft lean practices
Training and development. As the general basis for lean implementation, InterCo launched an in-house learning academy, aiming at the training and development of operators and other staff through a range of different activities in order to sensitize the workforce in any realm of CI. For instance, master classes involve a top-down instrument to convey knowledge from internal experts and rather comprise the theoretical knowledge to be conveyed while operators further acquire practical skills through simulated workbenches in the academy. In this regard, the Head of Manufacturing particularly accentuates that the acquisition of on-the-job skills is ‘all about
self-learning’ (M3) and that these kinds of skills cannot be taught to operators as opposed to the theoretical knowledge. Besides that, higher levels of idea generation are particularly achieved as a result of job rotation and the participation in cross-trainings.

In addition, kaizen events facilitate on-the-job learning. Internally referred to as ‘red-jacket events’, they constitute cross-sectional meetings on the shop floor, in which employees with different expertise come together to collectively generate ideas for the sake of improvement and problem-solving. Lean champions, in particular, go around the factory and actively challenge existing procedures.

We have people from different sections of the factory and then we go and observe your process. We ask, ‘Why are you walking here? Why are you walking this way? What do you have to carry?’ (O2)

As soon as lean champions identify waste, they will never reveal what explicitly needs to be improved but rather give operators food for thought in order to encourage them to generate their own ideas.

**Performance management.** In view of kaizen events, the name ‘red-jacket event’ originates from the red jackets that are worn during the inspection. There are two particular reasons for this.

One [reason] is, so that anybody who wants to go over and ask questions… we say, ‘Be sensitive. They’re now working on CI activity. Please don’t interrupt them unless you’re going to help them.’ And the other reason for the red jackets is, it’s highly visible. So, the rest of the department and the rest of the factory can see, ‘Over there today, they are carrying out a continuous improvement event.’ So, it raises the profile of what is happening (M3).

Both the Head of Manufacturing and the Director of Manufacturing Support accentuated that the red jackets bring the CI activity into focus and encourage operators to think about ideas how improve their own workstation.

In retrospect, management learnt that production targets were not conducive to cultural change but rather pressurized their operators (O12).

We realized that [production targets] didn’t change the culture. That was just people reacting to an instruction. Then we said, ‘Now, forget about the targets – just do it’. And this changed it overnight. People don’t really have to push it anymore. People just do it because they enjoy it. It’s a break from the normal routine. It gets you off the line and then you actually do some things different to make your daily life easier – huge change (M1).

In contrast to production targets, management developed a bonus scheme, which rather encourages operators to display behaviors that relate to the satisfaction of quality standards, attendance and personal development.

To qualify for the bonus one third of that payment would be related to attendance and behavior – so, no disciplinary actions and no absence. Then, we introduced a quality measure where we said ‘Your department needs to achieve this quality standard.’ That was another third. Because we were growing and we wanted our people to engage in personal development. So, we added a learning requirement. It does sound a little bit like the carrot on the stick but without the stick because everything I just talked about is actually within their own control. So, they either want to or they don’t want to (M1).

**Reward and recognition.** Management perceives that reward and recognition are crucial success factors for keeping up the momentum of new ideas. InterCo, thus, draw upon various systems (e.g. peer-to-peer recognition, monetary rewards and a recognition wall). Monetary and non-monetary recognition are not only limited to individuals but also take place...
collectively as a result of exceptional team efforts. That is, for instance, because idea generators are not necessarily the ones who also implement them (O2).

Idea-promoting soft lean practices

Job security. Managers endeavor to help operators to think in terms of work simplification. Importantly alongside this, job safety is guaranteed, so that no one fears being replaced through new implementations, such as automation.

We’re very open with all the guys. Yes, we want a target to reduce from maybe ten down to eight people but we don’t make people redundant. We introduced robotics recently and it did replace people. Robotics are carrying out very demanding and very repetitive jobs. So, therefore those people now moved into a probably more interesting and enjoyable role as opposed to the traditional on-line placing where three thousand pieces a day can get quite repetitive. So, they also can understand that we are moving them to higher skill levels (M3).

In fact, InterCo experienced that being transparent in terms of job security makes operators more open to change and more willing to share their ideas as their fears of job loss are stilled.

Employee involvement. Upon inquiry, most of the operators reported that they mainly voice their ideas through the ‘request-for-action’ system. More precisely, the request-for-action system involves a standard form system that gives every operator the opportunity to make suggestions for an improvement in a formal way. Since operators are interested in receiving feedback as soon as possible (O12), two people have been assigned to deal with the request-for-action forms as part of their daily role in order to ensure a fluent and timely processing. Management strongly emphasizes that feeding back to the operators is essential for sustaining higher levels of idea generation because it gives them a feeling of being acknowledged whereas delayed feedback conveys a sense of unimportance and disinterest and (even if unintentional) has a demotivating effect.

We don’t get in the situation where a person thinks, ‘I’ve got all these ideas. I’ve submitted them all and nobody has come back to me with any information.’ That stops that person putting forward the next thing (O3).

The person who initially raised the idea will be asked to sign off the request-for-action form, either to double-check if he or she is satisfied with the change or to document that he or she has been informed why the idea will not be implemented.

The ‘breakfast club’ and a ‘shared employee blog’ constitute further communication channels, through which operators can share ideas or concerns with the Managing Director.

The breakfast club is where our Managing Director takes up time. He will invite members from all parts of the business – the ones who do the job. He will invite them to a breakfast event in the canteen […] and then it’s just a general chat around the table. Generally, he would say, ‘Okay, what’s going on? What things do you want me to know?’ He has gained many good suggestions and ideas through hearing it from the people who have to do the job of making a product (M3).

While the breakfast club is a face-to-face event, the shared employee blog provides the opportunity to share ideas and concerns anonymously. In retrospect, management noted that some employees seem to prefer different communication channels to raise their concerns.

There’s a blog on a shared PC in the canteen. They could write whatever they want. It’s totally anonymous and that gets to the Managing Director. Therefore, if it’s something they feel they don’t want to be named against, they can still say it […] There are many forms of communication and many roots to get communication heard. We think we can capture everybody’s opinion and certainly make sure that everybody will have at least one way that they prefer to speak out (M3).
Idea-implementing soft lean practices

Kaizen events do not only constitute an opportunity for a collective discussion centered around a problem but also involve a platform where operators can promote and elaborate their ideas. In addition, they are also conducive to getting an idea directly implemented.

Everyone from different departments gets together. People would pretty much gather in a meeting to try and find an improvement […] They will invite some people from engineering, some people from the line, maybe some people from training and different areas and then we all get together to come up with a solution and to come up with different ideas and then put those into practice (M2).

Many operators confirmed that less pressure freed time and enabled them to think about ideas how to facilitate their daily job and the workplace overall and to implement them rather than being busy with chasing their production targets (O12). In particular, one operator reported how this time-wise flexibility enabled him to form a coalition with colleagues and to implement and disseminate his idea.

Just from a get-together the idea was implemented. We moved it from our department to another department and to another department. Then, all of a sudden, we’ve got ten of these systems around the factory. That all stemmed from four or five guys sitting with a cup of coffee (O1).

Discussion and conclusion

Contribution to knowledge

The findings of this exploratory case study suggest that soft lean practices facilitate IWB amongst operators, and that together these can contribute to lean sustainability. The AMO framework helps to highlight both the role and the necessity of soft lean practices when striving to achieve lean sustainability. In addition, this study extends the scarce qualitative insights of research on IWB (e.g. de Jong and den Hartog, 2007; Messmann and Mulder, 2011; Tuominen and Toivonen, 2011), and identifies how soft lean practices have an influence on IWB through directly affecting single or sometimes multiple dimensions of IWB, catering to an employees’ abilities, their motivation and their opportunities to contribute to CI throughout the different developmental stages of the idea. Since the study suggests that soft lean practices most often affect single stages of IWB, the findings support the view that IWB constitutes a multi-dimensional construct (e.g. Veenendaal and Bondarouk, 2015; Mura et al., 2016). Framing IWB as a three-dimensional construct enabled a more fine-grained behavioral analysis of IWB than is often the case when conceived as one-dimensional. In addition, this facilitated an understanding of the relationship between soft lean practices and employees’ ability, motivation and opportunities in enhancing their engagement with the different stages of the idea development process on a daily basis.

Hutchinson and Purcell (2003) suggest that employee performance is achieved most effectively when organizations initially seek to develop the skillsets of individuals, then, to create incentives to utilize their abilities, and finally to introduce opportunities that facilitate the execution of individual actions. Likewise, the study demonstrates that the foundation to achieving lean sustainability involves training to develop a basic skillset and CI capabilities for idea generation (Hirzel et al., 2017). Bos-Nehles et al. (2017) concluded that training and development is the best and most-discussed ability-enhancing practice to nurture IWB. Besides that, however, being coached by a lean champion (individual level) and problem-solving groups, e.g. within kaizen events (collective level), are found to foster IWB in view of lean. In particular, the study confirms that learning itself does not only comprise the acquisition of theoretical knowledge but also a practical counterpart. On that note, both soft lean practices combine ‘knowing’ and ‘doing’ (Rother, 2010). While InterCo operationalized the necessity
for combining ‘knowing’ and ‘doing’ particularly via simulated training workbenches, challenging questions of lean champions were found to be conducive to transferring existing knowledge to new contexts, thus, encouraging idea generation. In particular, problem-solving groups are likely to engender collective learning cycles and constitute ‘an environment which respects questioning and inter-professional discussion’ (Bortolotti et al., 2018, p. 571). Aoki (2008) points out that successful organizations focus on collective approaches rather than on individual ones, as this facilitates that operators make suggestions. Kaizen events, in particular, provide evidence that soft lean practices can have an influence on all dimensions of IWB, that is, idea generation, idea promotion and idea implementation.

Similar to Gollan et al.’s (2014) case study, operators’ bonus payments were reliant upon criteria that are within their own control. While Gollan et al.’s (2014) measures included ‘teamworking, housekeeping, workplace organisation philosophy and standardisation of the workplace’ (p. 6441), this study’s findings extend this view and showcase that also the relevance of learning may enjoy a higher significance for operators once personal development activities become part of their annual targets. Likewise, Emiliani (1998) emphasizes the opportunities of linking personal development with organizational objectives when implementing lean in order to boost idea generation. Underpinned by key performance indicators, operators are not only encouraged to participate in ability-enhancing activities but also to submit a minimum number of idea suggestions in order to accelerate the input of novel ideas.

However, although stimuli generally aim at encouraging desired behaviors, they can also be misleading, thus, leading to adverse effects and unintended consequences (Bhasin, 2008). For instance, the findings exemplified that former production targets were imbalanced, too ambitious and limited the capacities of operators to dedicate themselves to seek optimization opportunities at their workstation. In contrast, a change to a lesser focus on performance measures freed capacities to seek improvement and generate ideas. In other words, it was found that organizations should reconsider the balance between freedom for creativity and structured work. This suggests that less focus on production targets could support the operators during their daily work and ensure business profitability on the long-run, offering a counterview to many studies, which refer to the relevance of performance measures for the success of lean (e.g. Bhasin, 2008).

Contemporary literature on IWB emphasizes the importance of feedback but rather perceives it as opportunity-enhancing, which effectively means that its understanding is limited to its informative nature (Bos-Nehles et al., 2017). However, feedback does not only enhance the opportunities through useful information but it also affects the motivation level of individuals. As found in this research, prompt feedback on idea submissions helps to sustain the momentum of novel inputs and to foster idea generation, as a particular interest in the employee’s inputs is shown. In contrast to this, this study has found that a lack of feedback is likely to demotivate employees, as a sense of unimportance or disinterest might be unintentionally conveyed. Likewise, the communication of job security was found to increase the willingness of operators to share and promote their ideas.

In terms of creating opportunities, the study indicates that an identification of the different individual needs along the developmental stages of the idea is necessary in order to develop a better understanding of the issues and challenges that an operator faces on a daily basis, and which they have to overcome to bring their ideas forward. For instance, the case illustrated the installation of various communication channels (i.e. suggestions boxes, the breakfast club and the shared blog) that offer different lateral ways to bring an idea forward, and proved useful and of value at InterCo. In addition, anonymous suggestion systems offer a way that serves an alternative for reserved employees to speak out and to get involved, as previous research
evidences that employees might come up with outstanding ideas, yet, they fear to share them (Zhou and George, 2001).

Managerial implications
Several different courses of action can be recommended from this research. Managers could strengthen the process of idea development by addressing each different stage of IWB through ensuring that adequate soft lean practices are in place. This would include qualifying operators to become CI-capable through the development of abilities, which may facilitate IWB-orientated attitudes. In addition, managers could stimulate individuals’ motivation through incentives to encourage them to adopt acquired skills, and outstanding performance should be recognized and rewarded in order to keep the flow of novel inputs running. With this, as seen at InterCo, the motivational role of prompt feedback in order to avoid discouragement for contributing with new idea inputs is also important. While these factors concern personal development and the stimulation to apply lessons learnt, managers should also have to consider the factors that are external to the individual and that might hinder IWB. Employees might be equipped with the required skillset and might be even motivated but if they are not also empowered to display desired behaviors due to environmental constraints, upskilling and motivation will remain ineffective. In this sense, organizations are responsible for creating opportunities for operators so that they can utilize their skills and their motivation, and in so doing, should also consider individual needs. The study suggests that striving for lean sustainability requires a consideration of all three AMO factors.

Research limitations and future research
Since this empirical research builds upon qualitative data of a holistic single case within the manufacturing sector, it is usually fair to contest the generalizability of the results. It would be thus worthwhile to investigate soft lean practices in other sectors in the future to see if similar or varying results could be found in the service or in the public sector.

Abstract

Shop floor management is an essential tool for manufacturing firms wanting to create a lean culture. Traditionally, shop floor management is operationalized through periodical meetings with the team on the shop floor in front of a visual management board (i.e., whiteboard). Some traditional lean researchers argue using such an analogue board improves employee engagement. However, others claim that digitalization offers new possibilities to lift shop floor management to the next level. To shed light on this discussion and provide empirical evidence, this paper explores the effects of digitalizing shop floor management in a multiple case study within a single firm.

Keywords: Digitalization, Lean, Shop floor management, Continuous Improvement

Introduction

Today’s manufacturing operations are complex processes with an increasing number of product variants. To ensure performance, operations managers need to motivate employees to strive for excellence. A popular tool to facilitate such a culture of continuous improvement is shop floor management (Hertle et al., 2015). This leadership approach stems from lean manufacturing and emphasizes continuous improvement (kaizen) among employees (Lanza et al., 2018). As there is no consensus about the definition of shop floor management (SFM), in this study we adopt the view of Hertle et al. (2015), who present SFM as an “integrated managerial system that facilitates the communication, control of performance, and implementation of lean methods on the shop floor”. Within the last decade, many manufacturing companies have been adopting some form of SFM to improve their processes (Lanza et al., 2018). Firms typically operationalize SFM by holding frequent meetings in front of visual management boards on the shop floor, where teams discuss current operational performance information and improvement suggestions. However, little research has been conducted on the success factors of SFM (Kurpjuweit et al., 2018). One reason for this is that the focus of SFM is the involvement of the employees (Hertle et al., 2015): therefore, cause and effects relationships are not easy to observe and successful practices not agreed upon.
On the one hand, the traditional lean literature often suggests the use of physical, analogue material (i.e., pen and paper) when it comes to information acquisition in problem-solving and improvement activities (Enke et al., 2018). They argue that digital technologies increase the complexity on the shop floor and thereby detach the operator from the problem-solving process (Parry and Turner, 2006).

On the other hand, advocates of digitalization and many consultancy firms favor the digitalization of as many operations as possible, including management activities. As digital possibilities increase, the shop floor must face the impending digitalization frontier, both embracing digital transformation and making use of the new opportunities it presents.

As the two streams differ in their perspective, the literature does not offer a clear guidance on whether or not to, or indeed when and how to, digitalize SFM. This research aims to enable improved understanding of how digitalization may affect SFM. Furthermore, it shall therefore shed light on the advantages and disadvantages of switching towards digital SFM.

**RQ: How does the transition from an analogue to a digital form of shop floor management affect its performance?**

**Theoretical background**

This chapter reveals an overview about the existing literature on digital shop floor management. To understand the rationale of shop floor management, this chapter first introduces its origins in the lean and the continuous improvement process literature. The paper continues with a brief review about the current trends in digitalization. Finally, it combines the two areas of shop floor management and digitalization by providing an insight on the current discussion about their synergies.

**Lean management and CI**

The history of lean management traces back to the research conducted by Krafcik (1988) on the International Motor Vehicle Program. This research has yielded in many following studies and contributions, in which *The Machine that Changed the World* and *Lean Thinking* were among the most popular ones (Womack et al., 1991; Womack and Jones, 1996). The aim of lean is to eliminate waste thus deliver more with less, encouraging firms to strive towards perfection. Womack and Jones (1996) define five principles to achieve this. *Specify customer value* aims to ensure that only products that address a customer need are designed and produced. *Identify the value stream* intends to identify and eliminate non-value adding activities in the entire value stream. *Flow production* enables short cycle times, low WIP inventory and high flexibility to produce a variety of products. According to the *pull* principle, products are pulled through the value chain based on actual customer demand. Overproduction is prevented as products are only released in the process if the downstream processes step requires replenishment. Finally, *strive for perfection* demands the critical scrutiny and continuous improvement (CI) of the status quo based on active involvement of qualified and empowered employees.

The latter principle is reflected in the continuous improvement process (CIP) and has received research not only from the stream of lean literature but also from total quality management (Lam et al., 2015). The CIP helps to constantly develop processes further towards an overarching goal or next target condition (Rother, 2010). The Japanese term *kaizen* is often seen as a synonym for the CIP. Kaizen was first introduced by Imai (1986). He differentiated the concept of kaizen into three different hierarchical areas of participation: management, group, and individual. On these different levels, kaizen aims
for small, incremental improvements. Bessant et al. (2001) define a maturity model for different levels of the CI. Starting from “no CI activity” through “strategic CI” up until “the learning organization” in which the CI is embodied in the organization. This latter stage not only includes the problem-solving at hand but also emphasizes the sharing of knowledge gained by that process throughout the organization. The literature further distinguishes between kaizen and kaikaku, the latter resembles step-change in contrast to the continuous, small improvements realized through kaizen (Bertagnolli, 2018). For instance, the implementation of a new manufacturing technology can resemble kaikaku, whereas the continuous incremental improvement of this technology can be related to kaizen.

To create a culture of CI, many organizations implemented shop floor management as a leadership method. The goal of SFM is to allow the participation of the employee and support him in his role as problem-solver. To operationalize SFM, companies lead regular (e.g.; every morning, every week) meetings on the shop floor. These SFM meetings shall help the leader to make important discoveries at the place where the value-adding processes happen (the gemba) and provide room for reflection and the exchange of ideas with employees on the shop floor (Peters, 2009). Such meetings on the shop floor often follow common patterns and discuss similar elements such as performance charts, resource allocation, or the continuous improvement process, for example (Lanza et al., 2018; Hertle et al., 2015). The meetings take place at a board on the shop floor where typically the production plan and status is displayed, together with key performance indicators (KPIs, eg. Right first time (RFT), delivery schedule achievement (DSA), overall equipment effectiveness (OEE), etc.) The current status of CI actions are also often visualized on these boards. Traditionally, however, simple analogue whiteboards have been used for the visualization of these measures.

**Digitalization of the shop floor management**

In recent years, the digitalization of manufacturing has received a high attention from both researchers (cf. Kusiak, 2018) and policy-makers (Prinz et al., 2018). It thereby constitutes one of the most significant trends in industry and society alike (Hagberg et al., 2016). Even though many of the digital technologies are not new, the rate at which they are recently finding their applications in manufacturing is increasing (Yoo et al., 2012; Brynjolfsson and McAfee, 2016). The potential of digitalization are able to increase revenue and productivity as well as innovation alike (Matt et al., 2015). This can be achieved by the successful implementation of existing and emerging digital technologies. Among other implications, these technologies allow for a horizontal and vertical connection of data within the production (Kagermann, 2014). This leads to an increased transparency over the processes within production.

With the technological possibilities of connectivity (e.g., manufacturing execution systems or cloud computing) and visualization (e.g. interactive screens and data analytics) organizations consider reducing the amount of paper within production by digitalizing such tasks instead. This often means that the traditional whiteboards used for SFM are considered as potential targets for digitalization. Several scholars have been discussing and studying the possibility and the effect of a digital SFM (Hertle et al., 2015; Lanza et al., 2018; Sven-Vegard Buer et al; Müller and Müller, 2018; Hambach et al., 2017).

Digitalization of SFM is related to the transfer of otherwise analogue tasks of data collection and / or visualization to automated digital solutions. Examples for data collection are obtaining daily production levels or the reoccurrences of certain failures. Even though this data might be collected digitally (e.g., through an ERP or MES), they can still be visualized analogue. For instance, when a shift leader prints retrieves the data,
prints it, and puts it on a white board. This analogue process is still widely happening within industry (Lanza et al., 2018).

Transitioning to digital SFM not only changes both, the collection and visualization of data, but also the analysis during the meeting (Hambach et al., 2017). Expected benefits from digitalizing the SFM tasks include increased transparency, quicker reactions on deviations, and improved decision making through data (Lanza et al., 2018). Hambach et al. (2017) also see potential in reducing time-consuming activities and further elaborate on visualizing the strategic alignment with company-wide goals as well as deviation management through real-time data.

Method
To investigate the effect of the digitalization of SFM we used a multiple case study within a single firm (Eisenhardt, 1989; Yin, 2013). The firm produces technological products for the maritime industry and is headquartered in Norway. At the site of the case study the firm has been implementing lean and shop floor management (SFM) since 2015 on teams at the shop floor and in 2017 scaled up to include the senior management team. It recently transitioned its SFM from analogue to digital throughout the organization, migrating its kaizen platform from whiteboards with paper cards to a digital, online solution. To increase the generalization, we conduct research at team level and investigate multiple teams. Thereby, we differentiate between different types of teams. In total, we investigate the CI activities of four teams, described in Table 1. The first two teams work on the shop floor at the headquarters in Norway. We choose two teams that differ in size (number of employees). The first team consists of a large number of employees whereas the second is a small team. The divisional management team forms the third team, representing possible differences from the hierarchical levels. We also choose a fourth team from a subsidiary in Germany.

We first quantitatively investigate the effect of digitalization on the CI performance. For constructing a relevant performance measure for the CI we use the number of completed (implemented) improvement suggestions from the employees per year. To compare the performance, we gathered data on the number of suggestions before and after the implementation.

In the qualitative part of the research, we conduct semi-structured interviews with the teams. We lead further interviews with other teams and employees of the company to obtain an external perspective and receive a holistic view. This enriches the quantitative analysis and helps to identify the antecedents for the changes. The interview guide can be found in Appendix A. We visit several shop floor management meetings and observe the meetings. This helps us in triangulating the data and ensures that what the interviewees answer can be found in the reality.

**Analysis**

Currently, the company has two types of shop floor management meetings. In the first one, called Kanban meetings, the teams meet every morning to define what they are working on today. The second meeting, called Kaizen meetings, takes place once every week and discusses the status of new and current improvement suggestions from the team. It is the kaizen process that has recently been digitalized – the firm currently maintains an analogue system for Kanban. The transition from before to after the digitalization is illustrated in Figure 1.

![Figure 1 – Shop floor management meeting before (left) and after digitalization (right)](image-url)

As such, the results of the quantitative analysis are illustrated in Figure 2. The digitalization of SFM (kaizen platform) seems to negatively affect the large team, resulting in a small reduction in improvement activity. We suggest that this may be due to a phenomenon we shall call *out of sight, out of mind*, which implies that the drop in performance of the larger team may be due to the fact that the larger the team, the easier it is for members to “disappear” into the digital world – with less perception of...
accountability for not presenting / realizing improvement suggestions. For the other three teams, however, we find a (significant) increase in improvements. The ongoing qualitative analysis shall help to investigate the causes for the different patterns.

![Figure 2 – Number of improvement suggestions per year and team (before and after digitalization)](image)

**Discussion**

The analysis shows that there are multiple fields of improvement with the digitalization of the shop floor management. In the following section we present propositions that have been derived from our analysis of the case study.

**P1: Digital CI systems can improve horizontal collaboration.**

First, the digitalization of SFM allows for greater horizontal collaboration. Improvements that are suggested by the employees do not always only affect the team from which it stems from. Sometimes other teams are affected or do not support in the problem-solving process. Before the digitalization this would mean that the team manually transfers the improvement suggestion to the other department in which it is taken care of. By transferring the card, the team also lost track of it. It was not clear whether or not the improvement was realized and which actions were initiated in order to do so. As one interviewee stated “[...] we did not know what happened to the suggestion when we were giving it to the other team”. After the implementation the team could digitally assign the improvement suggestion to another team without losing track on the progress of the card.

**P2: Digital CI systems can improve the vertical escalation.**

While some suggestions can be solved at the team level on the shop floor, some others might require the involvement of higher-level management. Such decisions might be related to higher investments or affect the strategic position and therefore need approval. An interviewee mentions this speed of escalation: “We get a quicker decision on whether the improvement can be implemented”. As for the horizontal connection a digital shop floor
management system also allows for vertical escalation towards higher-level management. Suggestions can be tagged and forwarded to the management board meetings. This increases the speed of decision-making and transparency for the employee that identified the improvement suggestion.

P3: Digital CI systems can optimize workflows by reducing administrative time.

In line with Lanza et al. (2018) the case reveals the benefit of reduced preparation time through digitalization. Data collection and visualization (i.e., printing, posting, etc.) can take time of the team leader. As one team leader states: “... before it took me around half an hour to prepare the meeting and assign tasks.” Having the data in real-time, digitally, allows the team leader to focus on other important activities that add value to the team’s performance. Follow up time

P4: Digitalization of shop floor management does not have to reduce employee engagement.

One of the central criticisms against the digitalization of shop floor management is the loss of engagement of the employee who cannot relate to the digital board in the same way as to the analogue. However, we did not find this in our interviews. The engagement was not affected by implementing the digital solution, neither negatively nor positively. As one interviewee puts it: “I don’t care whether I write it manually or on the screen. This doesn’t affect my suggestions.” The quantitative data supports this assumption. In contrast to the criticism, the amount of improvement suggestions went up after implementing the digital solution in most cases.

P5: Digitalization provides possibility for analyzing data on historical CI activities.

Even though some solutions promise benefits from analyzing historical CI data, none of the teams used that data. Potential benefits would include learning or suggestion prediction. Having the improvement suggestion written on paper restricts an automated inquiry. However, the digitalization allows for filtering and searching for specific historical suggestions. These previous suggestions could be used for revealing recommendations for current problems.

P6: Technological experience of the employees affect the transition.

Finally, the potential benefits are also influenced by the technological experience of the team. Being used to digital systems in private life helps to adopt to digital technologies at work as well. The case study revealed positive reactions of the employees on the digitalization of the shop floor management. However, this might have been different in other companies, especially in less technological developed countries. An interviewee confirms this by stating: “For people that are not used to digital technologies, the effect may be different and they might be less confident with the system”. But at the same time, it is important for the company to make use of the employees capabilities to use digital tools. If they are able to use them in their personal life to make it easier and more efficient, why should they refuse to do so at work?
Conclusion
This research contributes to the discussion between lean traditionalists and digital advocates about the digitalization of shop floor management. It helps in exploring the changes and their underlying antecedents that occur when an organization decides to implement digital SFM. Building up on the existing discussion in the literature the study derives several potential benefits and challenges when digitalizing shop floor management. To validate these, we empirically investigated the transition of a company from analogue to digital shop floor management. Thereby, the study suggests six propositions for the suitability of digital shop floor management. For practitioners this research supports deciding whether a digitalization of their SFM should be undertaken and what to expect from it.

Appendix A – Semi-structured interview guide

I Introduction

Characteristics of interviewee
1. Please briefly introduce yourself and your current position
   a. Position
   b. Career background
   c. Years of employment
2. What do you understand under the term SFM (meetings)? Which functions do you include under SFM.
3. How many of such SFM meetings do you attend in a working week?

II Application of digital shop floor management

General questions about SFM
4. How often do you perform SFM meetings? And who is involved? Does the SFM cascade?
5. Which topics do you address in SFM?
6. Why do you use SFM? What do you think would happen if you would stop doing it?
7. How do you measure the performance of your SFM itself?

Transition to digital SFM
8. Did you digitize parts of the SFM functions? If so, which ones?
9. What were the reasons for implementing digital functions into your SFM?
10. How did you digitize the SFM? Did you develop your own solution or bought an existing one?
11. How did the implementation work?
12. How is the data for the SFM collected? How do you visualize it?
13. Which KPIs do you track? How are they aligned with organizational goals (e.g., Hoshin Kanri)?
14. How do you feel has the SFM changed after the digitalization?
15. In your opinion, what are the benefits of the digital SFM in comparison to the analog?
16. What disadvantages do you see?
17. How did it affect the continuous improvement process?
18. How did the role of the employee change after the digitalization?

III Conclusion

19. Do you think the digitization of the SFM improved the SFM?
20. Do you want to add something?
Digital collaboration within the supply chain: New booster for hidden lean potential.

Jamila Alieva (Jamila.Alieva@hig.se)
University of Gävle

Robin von Haartman (Robin.vonHaartman@hig.se)
University of Gävle

Abstract
This paper explores the hidden lean potential exposed by manufacturers’ usage of enterprise resource planning (ERP) systems. The potential can be classified into three types: unlocked lean potential in a connected ERP system, unlocked lean potential in an un-connected ERP system, and the lean potential for further unlocking in companies that do not use ERP systems when collaborating with suppliers/customers. Empirical data is obtained from two cases of manufacturing companies in Sweden and one ERP system company. The findings indicate that hidden lean potential can be unlocked through digital collaboration within the supply chain.

Keywords: lean manufacturing, digital technologies, supply chain

Introduction
Nowadays a significant number of manufacturing companies around the world have become influenced by lean philosophy and actively use its techniques to increase competitiveness and profits (Fritzen et al., 2016; Hoe et al., 2017; Womack, 1990). Supply chain success is based on collaboration and trust, with a common goal to create more value working in a synchronized manner for mutual benefit. The lean approach spread over the supply chain share a common goal of value creation through the reduction of waste through the whole supply chain (Christopher et al., 2006; Goldsby et al., 2011). Technological progress offers manufacturers ERP systems that are aligned with lean values and increase the efficiency of manufacturing companies through the accurate data management and transparency of the processes (Palaniswamy and Frank, 2000). ERP systems have taken leading role in developing strategic decisions within manufacturing companies (Yen and Sheu, 2004). However, it is still unclear how to gain maximum benefit from the technological options available for modern manufacturers. Does a digital supply chain allow lean manufacturers to become even leaner, by discovering new lean potential? McDermott (2016) provide statistics showing that overall, digital supply chains lead to a 20% reduction of procurement costs, a 50% reduction in supply chain costs, and an increase in revenue of 10%. The figures suggested by consultancy companies promise a reduction of costs through investments into technologies. However, it is still to be discovered, whether the usage of technologies at a supply chain level can boost the internal lean potential of manufacturing companies. The purpose of the study is to discover hidden lean potential through ERP systems and the supply chain.
Lean & Supply Chain

Goldsby et al. (2006), provide a description of three of the most common and debated supply chain strategies: lean, agile and hybrid (leagile). Supply chain strategy should be designed in a logical sequence from market identification to the establishment of performance metrics. The approach aims to improve competitive standing by achieving the real market winning criteria (Towill and Christopher, 2002). Christopher and Towill (2001), support the development of a hybrid strategy to create a cost-effective supply chain. The key success factor for lean or agile strategy derives from the market selection, where one of the strategies is the most convenient approach to reach competitive advantage. Christopher and Towill (2001) proposed a framework combining lean and agile philosophies to achieve a greater effect within the supply chain. The hybrid strategy should reflect on market conditions and is very context specific. Martínez-Jurado and Moyano-Fuentes (2014) evaluated the links among lean management, supply chain management, and sustainability. According to the authors, companies would like to adopt lean management, but they are also concerned about the impact they have on society through their activities. The impact is not an isolated scene within the organization. Instead, it is spreading through the whole supply chain directly or indirectly.

Value management within the supply chain is a challenging task. When the goal is to make the supply process lean for the benefit of the supply chain, then responsibilities should be distributed following a different strategy (Lamming, 1996). Christopher et al. (2006) discuss the importance of the supply chain strategy selection based on analysis of the product, market, and company. Key dimensions in the selection process should be based on replacement lead-times and predictability of demand, which can be enriched further with the nature of the product and its life cycle. Naylor et al. (1999), arguing that consideration of market knowledge is primarily important when integrating the lean or agile manufacturing paradigm. They suggest avoiding the isolated consideration of operations management in the manufacturing sector. Operations need to be considered in combination with a supply chain carefully combining both lean and agile paradigms towards “leagility” (Naylor et al., 1999).

Manufacturing & ERP

ERP implementation is a complex act that manufacturing companies face to improve the interaction between customers and suppliers. According to Duplaga and Astani (2003), smaller companies are more successful in implementing ERP systems in the manufacturing sector. However, companies are more likely to view ERP implementation as the beginning of the development. Linking customers and suppliers to the ERP system in a perspective is more likely to be implemented by bigger manufacturers (Duplaga and Astani, 2003). According to Palaniswamy and Frank (2000), ERP systems enhance manufacturing performance. An ERP system is a powerful tool for coordinating production, reengineering business processes, and establishing a competitive innovative environment for future survival in the global marketplace (Palaniswamy and Frank, 2000). Yen and Sheu (2004) discuss challenges that companies have faced in implementing ERPs and the uncertainty about the benefits expected after the implementation. On the other hand, research state that failures are the results of business problems, not technical ones. Yen and Sheu (2004), suggest aligning ERP implementation with a competitive strategy. Software customization, information sharing, data accessibility, software maintenance, proactivity of managers, national culture, and government/corporate policies are among the key factors that need to be considered for successful ERP implementation in manufacturing firms.
Raymond and Uwizeyemungu (2007), developed a framework to analyze the propensity of small and medium enterprises (SMEs) in adopting an ERP system. The framework is a set of relations between environmental, organizational and technological contexts, leading towards an ERP adoption profile. The authors suggest starting from the assessment of the manufacturing company to evaluate how an SME is ready to adopt computer-integrated manufacturing technologies and an ERP system. Muscatello et al. (2003) propose a set of planning activities during the ERP implementation process for SMEs, such as strategic objectives and top management involvement, reengineering efforts, enterprise system analysis, and ERP profiles of the companies. Another important set of activities in the case of SMEs relates to installation activities including education and training requirements, project monitoring and reporting, and overall project performance.

Baki and Çakar (2005) investigated Turkish manufacturing companies using ERP systems, where the majority of the companies used their own program to regulate the process. The second most popular result of their study was an absence of unified software. A minority used manufacturing resource planning software or materials requirement planning software. Manufacturing companies in the minority that used the ERP, had a list of selection criteria while investing in such a complex decision as an ERP implementation. Top tree criteria were system functionality, technical aspect and the cost of the software (Baki and Çakar, 2005). Ranjan et al. (2018), believes that the operations and performance of the manufacturing company is very much dependent on the successful implementation of the ERP system. There are 25 critical success factors identified in the literature, however only 9 of them authors recognizing as the most important factors. These factors are change management, user need definition and expectation, IT infrastructure and architecture, performance measurement and evaluation, top management commitment and support, enterprise-wide communication, selection of the ERP software, user training and education, effective project management (Ranjan et al., 2018). New forms of organizations are based on close cooperation and networking. Manufacturing companies can increase the competitiveness by implementing ERP systems (Raymond and Uwizeyemungu, 2007). Powell (2013) was questioning if ERP systems and lean manufacturing are complementary or contradictory technologies. Authors developed a framework presenting ERR in lean manufacturing production with six major areas: Combining lean and ERP for competitive advantage; Methods for the concurrent application of lean and ERP; ERP support for lean production; Real-time information for intelligent planning and execution; ERP systems for the extended lean enterprise; e-Kanban as a platform for integrating ERP and pull systems.

**ERP & Supply Chain**

Many companies have successfully implemented ERP systems and gained competitive advantage through the strategic usage of the software. According to Chen (2001) the success of the ERP implementation is primarily associated with an adequate planning prior to installation, careful selection of an ERP product, prioritizing business process and organizational requirements when adopting the ERP, economic and strategic justification. Chen (2001) realize the potential of ERP systems to develop from being a link between suppliers and customers, to become a mediator managing supply chain management and customer relations management. Kelle and Akbulut (2005), discussing how the supply chain is impacted by ERP tools. First of all, ERP is positively impacting the information exchange process within the supply chain, with the most positive effect on negotiation procedures. Secondly, there are procedures to select and aggregate the data to share with partners within the supply chain. Thirdly, there is an opportunity to optimize existing
business models and enhance cooperation (Kelle and Akbulut, 2005). Búrca et al. (2005), investigated the challenges faced by SMEs when implementing ERP systems. Authors stating that strategic technology adoption is demanding ERP coverage over the whole supply chain. Change management should be applied through the whole supply chain when adopting the ERP (Búrca et al., 2005).

According to Forslund and Jonsson (2007), it is very common to share a customer’s demand forecast with suppliers. Consequently, the information flow is making an impact on the whole supply chain. The quality and the accuracy of the forecast could be very subjective, but the impact on the supply chain is inevitable. Li et al. (2009), analyzed the impact of IT implementation on supply chain integration and performance. According to the authors, IT offers accurate and reliable information that improving supply chain integration and supply chain performance. From the other hand, ERP system became very standard element of the business, which was initially designed to fulfil the internal needs of the organization, but not the entire supply chain (Akkermans et al., 2003).

Even if the ERP system successfully adopted in a strategic level covered the whole supply chain, it is still unclear what should be the best approach to measure the supply chain performance (Akyuz and Erkan, 2010). Akyuz and Erkan (2010), proposed metrics to measure the performance. One of the points is requiring an adoption of a proactive approach creating the platform for continuous improvement. Another interesting point is related to measuring partnership, collaboration, agility, flexibility, information productivity and ability to define business excellence. Bagchi et al. (2005), discussing the experiences of ERP integration by European manufacturer and establishment of electronic links with their supply chain. The study shows that only a few companies providing an ERP open access to their supply chain partners. Sharing sensitive data is still a barrier for many companies to lift relations with customers and suppliers on a strategic level through transparency and online access. Very few companies are overcoming the barrier and establishing joint decision-making with their key suppliers and customers (Bagchi et al., 2005). High level of complexity within the supply chain is another barrier to achieve high performance. Giannakis and Louis (2011), proposing a framework to manage the complex supply chain system with a support of IT. Multi-agent model allows real-time adaptability with analytical tools that offering integrated decision-making framework. The focus of the framework is on supply chain demand rather than the forecast (Giannakis and Louis, 2011). Framework application supporting a better decision process in disruption and risk management within the manufacturing supply chain.

Conceptual Framework

Manufacturing companies are working on waste reduction and continuous improvement to create more value from the available resources (Womack et al., 1990). At the same time, manufacturers are a part of a supply chain in which collaboration procedures take up a lot of resources. The lean approach influenced the whole supply chain as one of the strategies competing with agile supply chain strategy or being combined in hybrid strategy (Lamming, 1996; Towill and Christopher, 2002). The supply chain was influenced by lean, because lean was not expected to be observed as an isolated process (Martínez-Jurado and Moyano-Fuentes, 2014; Naylor et al., 1999). Collaboration could reveal bigger opportunities to be leaner through the whole supply chain.

For several decades it has been very common to use the ERP system to plan and control the processes in manufacturing organizations (Palaniswamy and Frank, 2000). The literature describes both failures and successful implementation of ERP systems in manufacturing companies of different sizes and production focus (Baki and Çakar, 2005;
The reasons for failure in adopting systems are not technical. They are related to challenging business processes, poor strategic decisions and low human resources motivation to reach high performance through the adoption of an ERP (Ranjan et al., 2018; Raymond and Uwizeyemungu, 2007).

The whole supply chain represents a set of linkages between suppliers and customers, where ERP systems can play a significant role in this complex process (Bürca et al., 2005; Kelle and Akbulut, 2005). Information technologies are the source of flexibility and leading to optimize and simplify the information flow within the supply chain. IT also leads to improved suppliers’ forecasts, accuracy, reliability of collaboration processes, and performance (Akkermans et al., 2003; Akyuz and Erkan, 2010; Forslund and Jonsson, 2007).

Previous studies also describe the importance of information technologies and digital tools, such as ERP systems to optimize the internal processes within the manufacturing organization as well as having limited or open access through the supply chain network to increase the performance. There are only a few studies investigating if manufacturing organizations can be leaner internally through supply chain collaboration and the active usage of technologies, such as ERP systems. The conceptual framework in Figure 1 was developed to understand the phenomena.

![Figure 1 – Conceptual framework](image)

**Method**

A multi-case study method was chosen as the approach to analyze the framework. The multi-case study allowed us to observe and analyze similarities and differences between the manufacturing companies that use ERP systems. The proposed framework includes different scenarios with a hidden lean potential. The multi-case study method allowed us to observe the contrast between the companies that are using ERP system to collaborate with their customers/suppliers and the companies that are using the ERP system only within their organizations with no flexibility to collaborate on a digital level. Case research is a tool in the development of new theory and one of the most powerful research methods in operations management (Voss et al., 2002). The decision to choose two cases, was based on intention to increase the validity of the proposed framework (Caniato et al., 2018).
According to Handfield and Melnyk (1998), there are three stages of research in operations management. At the discovery (first) stage, companies were observed as a part of the Lean Management & Digitalization project plan. Semi-structured interviews were conducted with managers of the companies (CEOs, plant managers, IT managers, sales managers and etc.). In total there were 16 interviews and three workshops. Interviews were one to two hours long. The second stage was aimed at mapping and relations-building stage to find out common challenges or experiences the companies faced. At the final (third) stage, the framework was tested. The paper covers three key topics: lean manufacturing with a focus on waste reduction and continuous improvement, supply chain management with a focus on customer/supplier relations, and digital technologies with a focus on ERP systems.

Results

Company A & Customer/Supplier

Company A is an SME with a turnover SEK 42 million and 60 full-time employees. They want to be the most “customer-close” partner in the industry. The company is aiming to be the easiest to work with and to be perceived flexible and solution-oriented. Company A is working continuously to develop "customer value" by developing an internal process as well as common process and product. Lean-principal is the "baseline" in the company’s job and working method such as continuous improvements, pulse meetings, and flow optimization are everyday concepts in the company.

Company A is a manufacturing company where the whole supply chain network is represented as a loop, where about 95% of all company orders are coming from the same customer who is providing all the raw materials for production. The raw materials are processed into aluminum frames and are delivered back to the customer to become a finished product. The company has no stock and is using JIT. The customer/supplier of Company A is a big company with complex infrastructure and long decision-making procedures based on organizational policies with a low flexibility to changes on a digital level.

Company A is actively using lean techniques to reduce waste and continuously improve their processes based on employees’ feedbacks and observations. Company A has a whole potential to be lean internally, but very much dependent on their customer/supplier participation. For example, the raw material can be delivered in wrong color or size. Employees are quick in finding out a mistake and report about it. However, the response will take time. Purchase and quality managers from the customer/supplier side are working only day time. To fix the mistake might take the time of the whole shift. Company A would need to reschedule their activities and it will affect their productivity, efficiency, employee’s satisfaction and the profit.

Company A is using in house developed ERP system that allows running the processes internally. Customer/supplier using the ERP which was closed for the access for any partners within the supply chain. Company A brainstormed how to improve their processes to leaner and reduce the waste in time when collaborating with a customer/supplier. Data transparency was recognized as the most powerful tool to reach the goal. Company A persuaded their key customer/supplier to share access to their stock and monitor the availability of the raw materials through the ERP systems communication. A total number of mistakes (e.g.: wrong material colors delivery) is reduced dramatically, according to managers’ experience. Mistakes are classified since it is possible now to analyze the nature of the mistakes and develop scenarios to prevent them with an opportunity for continuous improvement.
Company B & Monitor ERP Systems AB

Company B has more than 16 high-quality CNC lathes managed by competent operators. The production handles everything from prototype and single-piece production to medium-sized series up to 40,000 pieces per year. The company has a complete department for post-processing, laser marking, grinding, honing, washing and tumbling. The high quality, flexibility, and efficient processes, create good profitability for Company B customers, with the least possible environmental impact. There is a special family spirit in the company where you allow differences and let people grow.

Company B have a large number of customers, however, most of the revenue is arriving from a few big companies. Company B is using the ERP system developed by Monitor, whereas their suppliers and customers are using different ERPs or software tools to run their internal activities. There is no digital interaction within the supply chain and data sharing process. Most of the information is shared by e-mail and often requires extra communication such as phone calls to prevent misunderstanding, delays or mistakes. There are cases when orders or demands of the customer are available to be downloaded from their websites. However, the information is in excel files and is not constantly updated or synchronized with stock and real needs. Any adjustments and changes are very time-consuming procedures affecting operations of Company B dramatically and creating waste in terms of time and reorganization of activities, human allocation, machine programming, and purchases of raw materials. Another interesting aspect is that every supply chain member is saving the data in a different format. When the information is spread around the chain, Company B is always spending an extra time to convert (label) the products (data) in a format which is accepted to the ERP system for internal use. In other words, the whole supply chain is communicating different ‘digital languages’ and every time they are going thought the manual translation process, to keep the internal consistency and order.

Monitor ERP Systems AB was founded in 1974. Today's operations include Monitor business systems and consultancy services for manufacturing companies with a focus on SMEs. The company has more than 200 employees. The Monitor is currently installed at approximately 3,800 companies in over 30 countries and translated into 14 languages. In DataDIA's 2011 survey, Monitor had the highest customer satisfaction among the approximately 100 ERP systems in Sweden.

The Monitor is working in close collaboration with their existing and potential customers. The analysis lead Monitor team to extend the investigation of process beyond the borders of manufacturing plants. Since a lot of activities are based on collaboration, Monitor got interested in the supply chain of their customers. Putting Monitor customers on the map, managers realized that the vast majority of them are related to each other by being supplier of customers for their businesses. ERP developers established a feature called Monitor-to-Monitor (M2M). In a way, the ERP system created a buffer or ‘instant translator’ of the languages used by different companies using a Monitor ERP product. For example, when one send or receive an order or an order confirmation via e-mail in Monitor, an XML file is attached that the recipient can use in his/her Monitor system. One import/register the file by dragging and dropping it (using the mouse pointer) directly from the e-mail message to Monitor. There are also functions for maintaining basic data by sending and receiving part info, prices, lead times, annual volumes and suppliers' part numbers via e-mail. The only difference is that a TXT file is used for the import instead. Customers of Monitor found the feature as an extremely useful tool supporting their lean strategies. The main advantage is a reduction of waste in time, which was spent by different manufacturers to communicate. Another advantage is the opportunity for Monitor users to continuously improve their processes through the rapid data sharing and
the accuracy of the data synchronized with internal systems in local sides. Finally, the human factor as a valuable aspect of lean also was covered by M2M. Employees are more satisfied and feeling a better working environment by avoiding conflicts and trust issues when the data was lost or misinterpreted on the way causing financial losses.

**Discussion**

The frameworks developed (Figure 1) is proposing the idea of relations between customers and suppliers having a positive impact on lean manufacturing allowing the companies to be more efficient. The relations are stronger with the impact of digital technologies (Powell, 2013). This study is considering the ERP system as a digital technology. There is a lean potential in manufacturing company where the waste can be reduced, processes continuously improved, and the human factor can play one of the most significant roles in those activities. The processes of lean management is often quite isolated to let the improvements happen only within the manufacturing company. There is an approach to spread the lean management over the supply chain and let the customers and suppliers of manufacturing companies also to be leaner and more efficient during the collaboration process (Kelle & Akbulut, 2005). However, the hidden potential of the lean is also available to be explored and activated through the collaboration on a digital level (Akkermans et al., 2003), where each participant can benefit to become leaner (isolated) through the collaboration and use of technologies.

*Unlocking lean potential with a connected ERP systems*

The framework is supported by the Company A case where the hidden lean potential was identified and used. The company gained access to the customer/supplier ERP system (inventory) and improved the operations. Employees were able to independently predict and avoid many production mistakes by accessing customer/supplier inventory through the ERP systems communication. Based on managers’ experience, the company reduced the waste of time and materials using the same resources with increased efficiency and profit. They also managed to continuously improve by rapid processes reorganization if the mistake in process flow was identified.

*Unlocking lean potential with an unconnected ERP systems*

The framework is supported by the Company B case, where the company realized the hidden lean potential through the digital interaction within the supply chain and data sharing process, though it is not functioning perfectly well yet. Company B can unlock the lean potential if they can connect the ERP system with their customers and suppliers. Data duplication, data confirmation by phone and e-mail, as well as data transformation in different formats are causing waste of time and duplication of action. Connecting the ERP systems with their customers/suppliers would also reduce this waste. If transparency were to increase, operation managers would have an ability to improve the actual production from the planning stage, using the most updated customer demands. Operations would be continuously improved and the human factor would play a key role.

*Potential for further unlocking*

Monitor, the ERP system developer, also support the framework developed, by extending the network of clients using the same ERP and offering functionalities simplifying data exchange procedures within the supply chain. Based on Monitor customer feedback when using connected ERP systems within the supply chain, the number of mistakes in orders has decreased. The ERP system guarantees transparency and accuracy, avoiding the waste of time and resources that previously happened due to the mistakes caused by having no ERP systems connected. Customer/supplier relations with connected ERP systems
improved continuously by better planning of orders with the real-time data availability about the inventory, machine operations and workload of employees.

Conclusion
This study contributes to the research of Powell (2013) in discussing the role and implication of ERP system in lean production. This study of Powell (2013) developed a framework presenting ERP in lean manufacturing production with six major areas. This paper contributes to at least two of the areas proposed by Powell (2013): ERP support for lean production and real-time information for intelligent planning and execution. The study also contributes to the research of Akkermans et al. (2003) discussing the need for flexibility through the IT within the supply chain.

This research presents a perspective for practitioners to extend or boost the hidden lean potential of manufacturing companies through supply chain digitalization. The study shows how manufactures can develop relations with their suppliers and customers through the active integration of ERP systems, which will allow them to become leaner as an isolated part of the supply chain. Collaborating more and increasing digital transparency with suppliers and customers enables companies to develop new opportunities to become more efficient and more profitable.

The study is limited to two cases of companies based in Sweden. The framework proposed needs to be validated with a bigger number of companies located in different countries. Lean manufacturing was only considered in three key aspects, such as continuous improvement, waste reduction, and the human factor. The study is limited by its very specific interpretation of lean manufacturing. For future studies, we suggest investigating what factors support successful collaboration between manufacturers, suppliers, and customers with usage of digital technologies to boost the hidden lean potential. Another direction for a future study is identification and validation of alternative digital technologies (besides ERP systems) supporting the framework.

Configurations for Managing the Interplay between Process Improvement and Product Innovation

Warwick Business School

Abstract
This paper explores how organizations manage the interplay between process improvement (PI) approaches and product innovation. Using a qualitative multiple-case study method, four different configurations for managing the interplay emerged - “strategic and holistic”, “facilitating and empowering”, “operational”, “project-based” - and their associated mechanisms were identified. Under each configuration, the interplay is managed through integration or separation. PI has the potential to enable innovation if it is loosely integrated in the innovation processes. However, a tight integration of PI might constrain radical innovation. Findings provide empirical evidence on the varied and paradoxical use of PI in triggering different degrees of product innovation.

Keywords: process improvement, product innovation, ambidexterity

Introduction
For over a century, researchers in operations management have advocated the introduction of process improvement (PI) methods and standards to increase organizations’ efficiency and productivity (Taylor, 1911, Womack et al., 1990). At the same time, strategy and innovation scholars have stressed the negative effects of efficiency and productivity gains on organizations’ capacity to adapt and innovate. In this context, Abernathy (1978) introduced the notion of the productivity dilemma and “conjectured that short-term efficiency and long-term adaptability are inherently incompatible” (Adler et al., 2009, P.99). This argument has since been framed in different, but related ways, for example stating that “exploitation” crowds out “exploration”, that stability conflicts with change, and that standardization hinders creativity (Schad et al., 2016). In line with these perspectives, several researchers in strategy and innovation have considered PI and product innovation and their associated processes, practices and concepts as conflicting if not incompatible (e.g. Benner and Tushman, 2003, 2015, Mehri, 2006). For example, PI approaches such as lean, six sigma, and total quality management (TQM), have been associated with exploitation, stability, efficiency, standardization, alignment and control, whereas innovation has been associated with exploration, change, flexibility, creativity and adaptability (Benner and Tushman, 2002, 2003, 2015). As a consequence, many scholars have questioned the benefits of PI approaches (Benner and Tushman, 2003, 2015).

On the other hand, a considerable amount of research in the operations management literature highlights the benefits that PI approaches bring to organizations, not only in term of greater efficiency and flow, but also in creating customer value, increasing customer satisfaction and innovating products and services (Modig and Ahlstrom, 2012,
Sousa and Voss, 2002). In doing so, several scholars have suggested that PI approaches consist of two distinct dimensions; for example, Schroeder et al. (2008) argued that “Six Sigma can be viewed from two different structural dimensions: structural control and structural exploration” (p. 544). Also, Sitkin et al. (1994) identified two distinct approaches for TQM such as total quality control and total quality learning.

Moreover, while some researchers adopted a primarily control-oriented view of PI and argued that PI approaches hinder product innovation, other scholars adopted a learning-oriented view, arguing that PI approaches create a learning environment that fosters innovation (Pekovic and Galia, 2009, Prajogo and Sohal, 2001). Nonetheless, empirical research shows mixed results regarding the relationship between different PI approaches and product innovation (in particular radical innovation—see, e.g., Benner and Tushman, 2002, Kim et al., 2012). In addition to the varied theoretical and empirical arguments that exist in the literature, previous research focused on defining the elements of PI that affect different degrees of innovation. However, little is known about the mechanisms that shape the relationship between PI and product innovation (Raisch and Birkinshaw, 2008). Therefore, this research addresses the following question: **how do organizations manage the interplay between PI and product innovation?**

### Theoretical Framework

**The interplay between PI and innovation**

Extant literature was conducted on the relationship between PI approaches and product innovation. Overall, the literature shows divergent theoretical and empirical arguments, and two main groups of scholars can be identified. The first group adopts a control perspective and consider PI approaches mainly as sets of efficiency-oriented practices that are based on discipline, conformity and adherence to rules, formalization, reduction of variation, standardization, and exploitation of existing knowledge (Benner and Tushman, 2002, 2003). From this perspective, PI approaches are seen as promoting incremental product innovation and hindering a more radical one for three main reasons (Benner and Tushman, 2003, 2015). First, these approaches aim to reduce variation in processes (Benner and Tushman, 2002), whereas radical innovation requires variation-increasing activities and slack resources (Troilo et al., 2014). Second, PI approaches often rely on standardization and formalization to maintain improvements and stability; however, standardization may impede flexibility, creativity and innovativeness (Zeng et al., 2015). Third, the customer-centric element of PI approaches can trap organizations in improving their existing products instead of creating radically new ones (Sadikoglu and Zehir, 2010, Slater et al., 2014). Emphasis on existing products establishes “a focus on easily available efficiency and customer satisfaction measures” (Benner and Tushman, 2003: 239), which goes against radical innovation and penalizes adaptation and the achievement of long-term goals (Adler et al., 2009).

The second group of scholars’ views PI approaches as learning-oriented practices and suggests that PI can create a learning environment that is based on trust, collaboration, openness and knowledge creation. Consequently, PI approaches are regarded as mechanisms to support both incremental and radical product innovation (Gil-Marques and Moreno-Luzon, 2013, Gutierrez Gutierrez et al., 2012, Choo et al., 2007). Scholars that adopted this perspective have also regarded PI approaches as sets of principles and practices that create a fertile environment for innovation (Prajogo and Sohal, 2001). For example, these approaches use iterative cycles of continuous improvement (Slack et al., 2013) that involve employees in decision making (Prajogo and Sohal, 2001). This provides employees with a sense of responsibility, engagement and ownership (Slack et al., 2013), which enhance their creativity and their capacity to innovate (Gil-Marques and
Moreover, “control in process management is likely to assist firms to maintain stable goals, to reduce product development time, and to meet customer needs in both existing and emerging markets” (Kim et al., 2012: 304). Process management can also improve the product development process performance by reducing time-to-market (Kim et al., 2012).

While the first group focused on the tools and mechanistic side of PI, the second group used both the tools and the soft (behavioral) elements and suggests that using both elements of PI could facilitate innovation. However, apart from identifying the PI elements and tools that enable or hinder innovation, little is known about the contextual factors and the mechanisms that could help in facilitating both PI and innovation.

**Paradox and ambidexterity**

Over the past two decades a sizable literature has emerged around the concept of ambidexterity (Birkinshaw et al., 2016). The term “organizational ambidexterity” was coined by Duncan (1976). The use of the concept was renewed by March (1991), who stressed the importance and the difficulties in pursuing both “exploration” and “exploitation” in organizations. Exploration refers to activities related to “search, variation, risk-taking, experimentation, play, flexibility, discovery and innovation”, whereas exploitation is associated with “refinement, choice, production, efficiency, selection, implementation and execution” (March, 1991, p. 71).

Authors investigating the concept of organizational ambidexterity have tended to frame the argument and operationalize the main constructs in two different ways. For some, exploration and exploitation are the two opposite ends of a continuum (Lavie et al., 2010) and managers are confronted with two mutually exclusive sets of options (Farjoun, 2010, Smith and Lewis, 2011). On the contrary, other scholars have argued that exploration and exploitation are separate (orthogonal) concepts (Birkinshaw and Gupta, 2013, Gupta et al., 2006). According to this view, pursuing more exploration related activities does not necessarily means engaging less with exploitative ones and vice versa (Birkinshaw and Gupta, 2013). In a similar vein, paradox theorists have advocated a fundamental shift in organizations from an *either/or* to a *both/and* perspective (Raisch et al., 2018, Schad et al., 2016, Smith and Lewis, 2011). In this context, paradox denotes a “persistent contradiction between interdependent elements” (Schad et al., 2016, p.10). It concerns “how organizations can attend competing demands simultaneously” (Smith and Lewis, 2011, p. 381) instead of examining separately the conditions under which a certain set of activities (e.g., innovation, flexibility, exploration) or another set of activities (e.g., standardization, efficiency, exploitation) can be effective.

Even though paradoxes cannot be resolved, research suggests various approaches for managing competing demands in organizations. Poole and Van de Ven (1989) described four approaches for dealing with paradoxes: acceptance (keeping and living with tensions), spatial separation, temporal separation, and synthesis (integration). While most of these approaches were discussed in the subsequent research, “integration” and “separation” are the most commonly used ones (Raisch et al., 2009, Schad et al., 2016). In relation to *separation*, extant research in ambidexterity suggests spatial separation as a solution for managing conflicting goals (Raisch and Birkinshaw, 2008). In this case two units exist in the organization: one focuses on explorative activities and the other on exploitative ones (Tushman and Oreilly, 1996). Similarly, other scholars have proposed the introduction of parallel structures. This includes having a parallel team or project who undertake explorative activities alongside regular ones (Raisch and Birkinshaw, 2008). Another type of separation – temporal - involves cycles of exploration and exploitation that happen sequentially over time (Eisenhardt et al., 2010).
Integration entails concentrating on complementarities (Schad et al., 2016). For example, building on Ghoshal and Bartlett (1997), Gibson and Birkinshaw (2004) introduced the concept of “contextual ambidexterity” and suggested that the tension between alignment and adaptability can be managed in one unit by creating a context that builds on trust, empowerment, discipline and stretch, that allows individuals to pursue different contradictory goals. Similarly, Adler et al. (1999) provides a comprehensive description of a combination of various strategies for managing the tension between efficiency and flexibility in Toyota, including meta-routines, switching, partitioning and job enrichment.

The above review shows that there are two contradictory arguments and inconclusive empirical results concerning the impact of PI approaches on innovation. Drawing on the paradox and ambidexterity literature, this study aims to identify the mechanisms that organizations use to manage the interplay between PI and innovation.

Methodology
Case selection and Research context
This research adopted a qualitative multiple-case study method (Voss et al., 2002), where the selected firms were purposefully sampled with the aim of achieving maximum variation (Denzin and Lincoln, 2011). Specifically, four large international manufacturing companies were selected (Pseudonyms are used for confidentiality reasons). These firms are similar in terms of sector, size and location, but operate in different industries - automotive, aerospace and pharmaceutical. Two dimensions were used to purposefully sample the case organizations: the extent of PI usage and the degree of product innovativeness. While these criteria were identified at the beginning of the sampling phase, further validation of the initial assessment was sought during the data collection and analysis process. Table 1 summarizes the main characteristics of the case organizations and presents their position in the sampling matrix. PI characteristics were derived in two ways: first, the breadth and the depth of PI usage across the organization, as derived from the interviews and documentary evidence (Marodin et al., 2018, Netland and Ferdows, 2016). Second, key informants were explicitly asked regarding the use of PI in the organization. The degree of product innovativeness was evaluated in relation to both market and technology, consistently with extant research (e.g. Danneels and Kleinschmidt, 2001, Chandy and Tellis, 2000). A product that displays new technology, knowledge or capability and satisfies new customers was identified as a radical innovation. Conversely, instances where current technology, knowledge or capability were used, and the product satisfied existing customers were identified as incremental innovations. In order to derive this, informants were asked to provide examples of recent products and to classify them as incremental or radical.

1 A detailed description of the research context available from the authors
Data collection and analysis

Data were acquired through semi-structured interviews and internal documents; also, the first researcher kept a diary throughout the data collection and analysis phases (Voss et al., 2002). Over a 15-month period a total of 44 semi-structured interviews were conducted and 55 relevant documents were collected. The interviews were conducted with senior managers from different functional specialisms (strategy, R&D, manufacturing, engineering, design and marketing). A snowballing technique was used to ensure all key informants were included. Each interview lasted an average of one hour and field notes were taken throughout the research (Eisenhardt, 1989). The interviewing process continued until theoretical saturation was achieved. Data were analyzed within and across cases through a multi-stage iterative process which included several rounds of coding, categorization, and refinement using the NVivo software.

Findings

The cross-case comparison led to two main findings: first, two aspects appear to shape the interplay between PI and innovation: PI scope and its integration in the innovation processes, and PI formality. Second, configurations for managing the interplay between PI and innovation, each have different characteristics, associated mechanisms and potential outcomes.

Aspects that shape the interplay between PI and innovation

It is not a surprise that the case organizations deploy PI approaches differently. However, while one may expect greater use at Fast-CarCo and Excellent-AeroCo, and less use at PharmaCo and Cheap-CarCo to be associated to two separate patterns, this was not exactly the case. Indeed, the analysis shows that it is not only PI intensity that matters,

---

2 Details on the analysis and coding process can are available from the author
but also its formality, scope and integration in the innovation processes. PI formality refers to the degree to which PI usage is documented in the organization. In particular, in the selected companies PI formality varied between “expected” and “voluntary”. Expected means considering PI as part of the company’s strategic direction, as everyone in the organization / business unit is expected to use PI practices, and employees’ involvement in PI activities is monitored. Voluntary refers to individuals’ autonomy in deciding when to use PI or not. PI scope reflects the spread of PI usage in the organization and it varies between “pervasive” and “confined to a specific context”, as PI could be used everywhere in the organization, including the more innovative areas (e.g. R&D, product development, design and engineering) or be implemented mainly in one area, typically manufacturing. Integration captures the use of PI in the innovation processes and varies between “high integration” and separation (segregating PI from the innovation processes). (See Table 2).

**Four configurations for managing the interplay between PI and innovation**

Considering the four configurations that emerge from the analysis, under the strategic and holistic approach, PI is implemented as a company-wide strategy in which everyone should be involved in PI; under the facilitating and empowering approach, employees can decide which PI method to use; under the operational approach, PI approaches are used only in manufacturing and not imposed on people in the rest of the organization; under the project-based configuration, PI is occasionally used outside manufacturing. This section will compare the four identified configurations (see Table 2).

3 Data coding structure and illustrative quotes are available from the author.
Strategic and holistic configuration
Excellent-AeroCo uses a strategic and holistic configuration for managing the interplay between PI and innovation. The main characteristics of this configuration are pervasive PI scope and expected PI formality. More specifically, in Excellent-AeroCo, PI has been used for a long period of time and many people are trained in different PI programs. However, a few years ago, the company recognized that all employees should be involved in PI. Consequently, various PI programs were initiated, and PI was explicitly introduced in the company strategy. Thus, PI is considered as the current priority in Excellent-AeroCo as stated by the head of the production system: “We’re trying to move to a more standardized way of working...a standardized way of working is a more lean way of working”. Overall, the interplay between PI and innovation is managed by integrating PI in the innovation processes and across functions. However, the level of integration varies between functions and at different stages of the product development process. For instance, in R&D, where ideas for new products are generated and selected, lean is integrated with innovation and problem-solving tools. At this stage lean is used as a filtering mechanism to distinguish good from wasteful ideas. For example, the head of engineering strategy and enterprise architecture elaborated: “Where lean plays a part is spotting the good ideas and moving them efficiently to product. Where waste comes out is spotting the wrong one or spotting the right one and implementing it purely”.

PI is also adapted to the product development, design and engineering areas to maintain flexibility. This adaptation is achieved by mixing lean with agile and using standardization in a loose manner. This adaptation of PI helps to provide structure for product development, balancing flexibility and rigour, and allowing people space and time to innovate.

Additionally, other organizational mechanisms are used. Some of these are managerial mechanisms including the use of formal training and balanced performance indicators (both PI and innovation-related). For instance, some areas in the business have more PI-related objectives and others have more of innovation-related ones. Aligning the performance objectives with PI and innovation not only supports the expected PI formality in Excellent-AeroCo, but also helps in maintaining employees’ commitment toward PI and innovation initiatives. Additionally, various types of training are used for different PI approaches including Kaizen and six sigma certifications. At the same time, other training is provided through innovation workshops. Structure-related mechanisms are also used in Excellent-AeroCo for managing the interplay between PI and innovation using specialized teams for facilitating PI usage and innovation development.

However, despite the efforts for maintaining flexibility through the adaptive use of PI and innovation related training and performance measurement, the extensive use of standardization seems to hinder employees’ capacity to explore new ideas. Consequently, this appears to promote incremental innovation and to hinder radical innovation.

Facilitating and empowering configuration
Fast-CarCo has a high degree of PI usage and high level of product innovativeness and follows a “facilitating and empowering configuration” for managing the interplay between PI and innovation. PI is used everywhere in the organization, in different functions (HR, finance, manufacturing, research, product development and engineering) with voluntary formality. At Fast-CarCo, the current leadership decided to invest in PI, but made its use more voluntary than it used to be (under previous ownership, Fast-CarCo had adopted the same processes and standards of its then parent company). More recently, the firm created a central portal / toolbox that collects different PI approaches, examples
of improved processes from different functions and various “best practices.” The portal can be accessed by everyone in the company, but no specific approach is imposed.

Under the facilitating and empowering configuration, the interplay between PI and innovation is managed by integrating PI and innovation-related activities. This is achieved through different mechanisms: the adaptive use of PI, PI voluntary formality and entrepreneurial orientation, process-oriented structure, and balanced performance indicators. As an example of adaptation, in R&D a lean visual factory tool is used to facilitate collaboration and six sigma is used to maintain rigour in the technology development process. The same is true with the product development area, where not using people’s creativity is considered waste, a typical lean concept.

Some years ago, Fast-CarCo moved to a process-based structure: for example, there are codified processes for strategy and leadership, research, HR, etc. These processes are improved and reviewed regularly and added to the shared portal. This process-oriented structure helps in maintaining rigour in the company. At the same time, using this configuration, Fast-CarCo facilitates an entrepreneurial-oriented environment by allowing employees to autonomously use PI, start new innovative projects in the research area, and separate teams to develop innovations. As another example, in 2016 Fast-CarCo launched a high-tech start-up company to develop app-based transportation solutions. This company has provided the autonomy and flexibility for developing new technologies. Additionally, Fast-CarCo uses performance indicators to balance excellence- and innovation-related goals. For example, forward- and backward-looking objectives are used as performance indicators in marketing teams (internal document, Fast-CarCo).

Overall the voluntary PI formality, the adaptive use of PI in the area, together with the autonomy and flexibility that is provided to employees could possibly facilitate the development of various types of product innovation. Here, PI acts as an indirect facilitator for innovation through maintaining rigour and structure for the technology and product development processes while, at the same time, allowing employees the flexibility to innovate.

Operational configuration
PharmaCo displays high product innovativeness and limited use of PI. Here, the interplay between PI and innovation is managed through the use of an “operational” configuration whereby PI is used only in manufacturing. At the same time, PI is a priority and expected in that area; as a director in product design and development stated: “PI is a religion in [manufacturing].”

Under this configuration, the interplay between PI and innovation is managed through separation, as PI and innovation happen in different areas of the business and are disconnected from each other, as PI is considered inapplicable for the R&D and product development areas. For example, a director in product design and development argued: “I would say our approach is night and day in terms of similarities.” In R&D, employees are given the flexibility and resources to generate and develop new ideas. This entrepreneurial-oriented environment is created through flexibility that is given to employees in R&D and is seen as contributing to the development of different types of innovation (radical and incremental). However, this is not without disadvantages, as it creates inefficiencies and delays in the innovation process. Moreover, this flexibility has led to initiating projects that proved not feasible.

Another contributor to this disconnection between manufacturing and R&D is the stage in which the manufacturing area gets involved in the innovation process. Manufacturing involvement is at the very end of the drugs development process (the last
2-0.5 years) while it takes around 15 years to develop a new drug. This late manufacturing involvement contributes to the separation between R&D and manufacturing and, therefore, the area in which PI is used in (manufacturing) areas that innovation is developed in (R&D and product development). Therefore, in PharmaCo, when using “operational configuration” for managing the interplay between PI and innovation, PI is irrelevant for innovation as the two happen in two separate locations and are disconnected to each other.

Project-based configuration
Cheap-CarCo displays low use of PI and focuses on improving current products. For example, the head of propulsion and innovation at Cheap-CarCo elaborated: “[Cheap-CarCo] is typically a relatively low-end car manufacturer: We make cars that are very simple, not very feature-rich”. Cheap-CarCo uses a “project-based configuration” for managing the interplay between PI and innovation. This configuration is characterized by isolated PI scope and voluntary PI formality. Here, PI is mainly used in the manufacturing area and occasionally in other areas including engineering and product development. At Cheap-CarCo, PI usage is more present and expected in manufacturing, but its use is rather voluntary in engineering, design and product development. The use of PI outside manufacturing is enabled by employees’ awareness and competence in it. At the same time, PI is used informally at Cheap-CarCo as it is believed that it may hinder innovation.

Overall, the main mechanism that is used to manage the interplay between PI and innovation under this configuration is “separation”, which is achieved through the flexibility that is given to employees, first by making the use of PI voluntary, and, second, by running improvement and innovation initiatives to encourage employees’ engagement in innovation and PI activities. These initiatives aim to develop innovation and excellence in the company as Cheap-CarCo is developing its innovative and PI capabilities. In addition, Cheap-CarCo recently adopted a new technology development process from another automotive company. This process is used to develop new technologies that were not used before and another process is used to improve current technologies. By doing this, Cheap-CarCo started to separate radical from incremental innovation processes. Given the separation using a “project-based” configuration, informants in Cheap-CarCo view PI as more applicable at later stages (manufacturing) of the product development than at earlier stages (R&D, design and engineering).

Discussion and Conclusions
This paper makes two main contributions to theory. First, this study explored the ways in which different PI approaches - such as lean, six sigma and TQM - affect product innovation (Bourke and Roper, 2017, Kim et al., 2012). A considerable amount of research has been conducted on the impact of different PI approaches on product innovation. However, previous studies have proposed divergent arguments. For some, PI approaches are control-oriented practices that drive rigidity, efficiency and hinder innovation (Benner and Tushman, 2003, Abernathy, 1978). On the other hand, others considered PI approaches as learning-oriented practices that help in creating a context that facilitate an environment of trust, learning and creativity (Choo et al., 2007, Kim et al., 2012). The findings of this research depart from both streams and argue that the relationship between PI and product innovation depends on the used configuration. This research identified four different configurations for managing the interplay between PI and product innovation. These are: “strategic and holistic”, “facilitating and empowering”, “operational” and “project-based”. The identified typology suggests four manifestations of the interplay between PI and product innovation in organizations that
vary in their scope and level of integration (PI integration in the innovation processes and areas) on one side and PI formality on the other side. Therefore, considering a positive or negative impact of the use of PI on product innovation may not be accurate. For instance, if the “operational” configuration is being deployed where PI is confined to the manufacturing area and segregated from the innovation processes in R&D and product development then PI is irrelevant to innovation. In other cases, where the “strategic and holistic” or the “facilitating and empowering” configurations are used, PI is integrated in the innovation process. Therefore, this research shifts the perspective on the interplay by raising a different question; rather than asking ‘what is the impact of PI on innovation?’, the questions should first be, ‘how are PI and innovation getting deployed? And what is the configuration?’ Only then can the effect of PI on innovation be examined.

Second, this research revisited several enduring debates on the productivity dilemma, efficiency and innovation tension (Abernathy, 1978, Adler et al., 2009, Benner and Tushman, 2003, 2015, Papachroni et al., 2016). This literature has been often considering the interplay between two generic set of concepts such as productivity, standardization, efficiency, formalization, exploitation, and innovation, adaptability, flexibility and exploration, as dilemma and opposite to each other (Benner and Tushman, 2002, 2003, 2015, March, 1991, Schad et al., 2016, Smith and Lewis, 2011). In part, this due to the underlying conceptualization of the relationship between these two poles of concepts as mutually exclusive and opposite to each other (Farjoun, 2010, Smith and Lewis, 2011). This research redressed this and challenged the dichotomy perspective (Farjoun, 2010, Smith and Lewis, 2011), by offering four configurations for managing the interplay between PI and innovation. This, in turn, brought more variety into the productivity dilemma debate and suggests that this relationship is more complex than it was dominantly accepted. In other words, the relationship between productivity and efficiency-enhancing activities (such as PI) and innovation very much depends on the deployment of PI (scope, formality, usage) and locus of interaction (where innovation gets developed).

Abstract

Lean Supply Chain Management is an emerging research field in Operations Management that is attracting attention from researchers and practitioners. This paper presents a comprehensive analysis of the influence and productivity of the Lean Supply Chain Management literature and reports trends in journals, institutions, countries, and keywords. This study uses BibExcel and VOSviewer software to conduct a bibliometric analysis of 525 papers published in the Web of Science database from 1996 to January 2019. This analysis has enabled us to draw a number of conclusions and propose a roadmap for further research in the field.

Keywords: lean supply chain, bibliometrics, literature review

Introduction

Lean Management (LM) has evolved and expanded significantly in recent years, with numerous authors researching the subject. Womack & Jones (1996) showed that a systematic reduction of non-value-added activities in an organization and across its supply chain could improve business performance and the ability to achieve a competitive advantage. The application of LM along the supply chain to optimize all activities is called Lean Supply Chain Management (LSCM) and enables waste elimination, quality improvement, cost reductions and increased flexibility along the chain (Womack & Jones, 1996; Martinez-Jurado & Moyano-Fuentes, 2014; Swenseth & Olson 2016).

The Lean Supply Chain (LSC) concept has attracted growing attention since Lamming (1996) first coined the term in 1996. Proof of this interest is the number of papers recently published in the field. Previous research has reviewed the literature with different objectives in the past few years. Some of these literature reviews of LSC have been general and cover the entire field (Ugochukwu et al., 2012), while others have focused on specific aspects such as practices, barriers and contextual factors (Berger et al., 2018) and links between internal and external lean management and sustainability (Martinez-Jurado & Moyano-Fuentes, 2014).

Although all of these studies provide valuable information about the state-of-the-art of LSC, an additional analysis of the literature using bibliometric tools can provide further
insights not previously evaluated in other reviews. Network analysis via bibliometric tools can be effective for identifying established and emerging research topics. To date, only de Sousa et al. (2018) have used a bibliometric study to review the topic. However, these authors designed a rather restrictive search string that resulted in a reduced field of research and the selection of only 57 papers on LSC.

The present study presents a comprehensive overview of the scientific production on LSC with a bibliometric approach that uses BibExcel (Persson et al., 2009) and VOSviewer (van Eck & Waltman, 2010) software. The analysis covers a 22-year period from 1996 to January 2019 and reveals trends in journals, institutions, countries, and keywords. Our study goes beyond previous literature reviews by providing additional insights into current research interests and laying down a roadmap for further research into LSC.

The remainder of this work is structured as follows. The following section introduces the methodology used to identify the literature reviewed in this study, as well as the bibliometric techniques applied throughout the paper. Next, a brief descriptive analysis is presented to provide some initial insights into the topic. A detailed analysis using the BibExcel and VOSviewer bibliometric tools is presented in the following two sections. The closing section summarizes the results, presents some limitations of the study, and discusses opportunities for future research.

Research methodology
A bibliometric analysis is adopted in this research for its advantages over other literature review methods. Unlike other text analysis methods such as content analysis, bibliometric analysis can easily handle hundreds of papers. Furthermore, a bibliometric analysis is very useful for analyzing relationships among papers, citations, co-citations, and keywords and providing comprehensive information about the research area. Additionally, the powerful visualization afforded by bibliometric analysis helps readers to clearly identify research interests in the field.

The methodology used in this study has followed two different stages: 1) data search for data collection and refinement, and 2) data analysis for a comprehensive evaluation of the field.

Data search
This work analyzes scientific documents in the Web of Science (WoS) Core Collection database. WoS is a comprehensive search engine that can provide full results for an accurate analysis of this field as it contains a wide range of detailed information about each document. The search was conducted between December 2018 and January 2019 using the keywords “lean” and “supply chain” in the “Topic” field. Our search string [TS=(“lean”) AND TS=(“supply chain”)] generated 1,081 initial results. However, some exclusion criteria were considered to refine the search results: publication year (only the 1996-January 2019 period), document type (only journal articles and reviews), research area (considering only operations management-related areas) and language (exclusively publications in English). This process yielded a total of 579 papers in the WoS Core Collection.

Then, to improve quality control, the authors reviewed the title, abstract and keywords of each paper and, when required, read the full text. This discarded a further 54 papers not related to lean and/or supply chain management. The 525 records and their full descriptions (author, title, source, abstract, keyword, institution, etc.) were exported to a .txt file to assemble all the essential information in one place.
Data analysis
BibExcel was used to perform bibliometric and statistical analysis and to prepare the input data for additional network study in VOSviewer. The BibExcel bibliometric toolbox was chosen for its great flexibility for both data management and analysis and its ability to modify and adapt input data from several different databases (Persson et al., 2009). VOSviewer was then used to generate graphs of the bibliographic material. VOSviewer collects data and generates maps and different types of bibliographic data-based analyses: co-authorship, co-occurrence, citation, bibliographic counting, and co-citation. It was selected for the construction and display of bibliometric maps due to its viewing capabilities, which are especially useful for examining data in intricate detail (van Eck & Waltman, 2010).

Descriptive analysis
Initial data analysis can be useful for capturing basic information in the literature and presenting a preview of the topic. Figure 1 reports publication trends in LSC from the first articles in 1996 to January 2019. This figure describes the time period distribution of publications in the field and provides insights into the year-on-year evolution of the research topic. The growing number of publications shows that LSC has been the target of increasing attention from academia. An especially meaningful upward trend can be observed during the last 5 years, with over 55% of all papers in the field. The trend indicates that the number of publications will continue to grow in the future.

These 525 papers are scattered across some 170 different journals, 80 of which have contributed around 83% of all the publications reviewed. Table 1 shows the top 10 journals for numbers of publications on LSC. It should be noted that these top 10 journals have published 244 out of 525 papers and account for more than 45% of all the selected documents. The Journal of Cleaner Production is the leading journal among the sources that have most contributed to the LSC area, with 38 papers. An interest in sustainable strategies in lean contexts can be observed since the most productive journal focuses on environmental issues. However, most of the sources are operations research journals.

Bibliometric analysis
In this study, BibExcel has been used to process the data with some initial bibliometric and statistical analyses and to prepare the input data for additional network analysis in VOSviewer.

Author production
BibExcel was used to analyze the papers and identify the authors with most publications in the LSC field. Table 2 lists the top 10 most productive authors and the number of publications that they have authored or co-authored. As can be seen, Garza-Reyes has produced the highest number of publications on LSC with 12, closely followed by Kumar with 11. These results indicate that there are no dominant authors in this field as yet, even though all these authors have extensive backgrounds in operations research/management and supply chain management.

Affiliation statistics
Authors’ affiliation information was processed in BibExcel and the cities where the most productive organizations are located extracted for the analysis. Using the coordinates of these cities in gpsvisualizer.com, Figure 2 presents the geographic locations of the institutions that have most contributed to the LSC literature. Red circles indicate cities with at least two papers on LSC and the size of the circles indicates the degree to which the organizations have contributed. Those with greater contribution densities are in Western Europe and the Eastern United States. Nevertheless, the geographic dispersion of these institutions around the world indicates that LSC research and practice have received worldwide attention.

1 R: Ranking
2 TP: Total Papers
The most productive institutions are shown in Table 3. Cardiff University in Wales is the organization in the list that has made the highest number of most contributions, followed by Universidade Federal de Santa Catarina in Brazil. Considering Table 2 and Table 3, there is a connection between the most prolific authors and the most productive organizations. Thus, the University of Derby, the Universidade Federal de Santa Catarina, the National Institute of Technology and the Universidade Nova de Lisboa can be observed to be represented by the most prolific authors: Garza-Reyes, Tortorella, Kodali, and Cruz-Machado, respectively.

Table 4 presents the contributions of the most productive countries to the literature on LSC and its evolution over time with 6-year intervals (note that papers with authors from different institutions may have been assigned to multiple countries). The United States is the most productive country over time with 127 papers, closely followed by England with 102. In addition, India and Brazil show noteworthy rises in the numbers of papers.
published on LSC in the last 6 years, which indicates that emerging countries are taking an increasing interest in LSC.

**Keyword analysis**

A similar analysis has been conducted to identify the most frequently used words/phrases in the list of keywords in the selected papers. Table 5 presents the top 20 most popular keywords in the LSC field. The top keywords include a combination of lean, supply chain, operations strategies (agile, green and six sigma), performance, and research methodologies. Interestingly, “automotive industry” has frequently been used in the literature, which indicates the strong relationship between the sector and LSC. Sustainability also stands out in LSC, with three keywords in the list related to the subject.

**Network analysis**

A network analysis was subsequently performed based on citation and bibliographic coupling analyses. Various tools are available for this purpose, the most popular of which are Gephi, Pajek, and VOSviewer. VOSviewer was chosen for this study because of its viewing capabilities and flexible visualization, which provide graphical representations of the bibliometric networks in an easy-to-interpret way.

**Citation analysis**

Citation analysis has been carried out to examine the influence of the papers published on LSC. Table 6 shows the 10 most cited published papers on LSC in journals since 1996, based on the total number of citations. Total citation analysis provides the overall number of citations in our database, including citations from other disciplines and research areas.

Regarding total citations, the most cited paper in this field, with 869 citations to date, was published by Zhu and Sarkis (2004) in 2004. The same paper is also the most influential according to the “citations per year” measure, with almost 58 citations
annually. However, it should be noted that all of the top 10 frequently-cited papers were published over 8 years ago, so they have had ample time to accrue citations.

In addition, most of the papers in the table have been published in the top 10 journals contributing to LSC, which indicates that there is a strong correspondence between sources and production in the field. Interestingly, it must be pointed out that the most cited papers on LSC tend toward the study of some specific LSC practices, coinciding with the fields of interest identified in the analysis of the most popular keywords in Table 4.

### Bibliographic coupling analysis

Bibliographic coupling occurs when two documents have at least one reference in common (Kessler, 1963). In contrast, co-citation has been defined as the frequency with which two documents are cited together by others in the literature (Small, 1973). So, a co-citation is a similarity relationship between two cited publications, while bibliographic coupling is a measure of association between two citing publications. Bibliographic

³ TC: Total citations
⁴ C/Y: Citations per year
coupling is considered a suitable tool for detecting current trends and emerging research topics since it captures more recent contributions (Vogel and Güttel, 2013).

Bibliographic coupling has been used in this paper to identify current trends in the LSC field and provides further valuable information by conducting a content analysis. In the following, we outline the content of the publications that each cluster contains and the areas of research focus.

In Figure 3, the nodes are citations of papers, while the links are bibliographic couplings, i.e., the number of references that any two nodes share. The total link strength attribute indicates the total strength of a given paper’s coupling links with other papers. In VOSviewer, the size of the label of an item is determined by the weight of the item, while the color is determined by the cluster to which the item belongs. In addition, the distance between two items in the visualization indicates the items’ approximate relatedness (van Eck & Waltman, 2010).

Figure 3 shows blue and purple clusters to be located in very close approximation, which indicates that the connection between these papers is strong. The green cluster is spread out across the map, albeit closer to the purple and blue clusters. In contrast, the red and yellow clusters are particularly well-defined and reasonably separate from each other.

To facilitate content analysis of the network for clarity’s sake, the determination was taken to only examine thoroughly the papers in each cluster with the greatest total link strength. This decision was considered a suitable criterion for addressing the content of each cluster given the high total number of papers. Naturally, each of the clusters has a richer tradition and is far more complex than the brief description suggested.

Table 7 shows that Cluster 1 mainly introduces basic concepts linked to a literature review as the methodological approach. Cluster 2 is closely related to the first cluster since it also examines LSC’s state-of-the-art and the lean implementation process. Cluster 3 focuses on enablers, barriers, and the impact of the context in LSC implementation. Cluster 4 measures and evaluates LSC performance, while Cluster 5 combines LSC strategy with sustainability.
Table 7. The five major research clusters and their areas of research focus

</table>

The first group is formed of Clusters 1 and Cluster 2 and addresses the theoretical exploration process in the field. The lean management concept and its adoption through the supply chain are explored using the literature review as the approach par excellence that defines the basis of the research.

The second group is Cluster 3, which investigates the LSC implementation process. The authors have analyzed the complexity of the context, the existing barriers to LSC implementation, and some enablers that improve its impact on performance.

The third group is Cluster 4, which addresses LSC assessment. In this case, authors have focused on measuring operational performance. Some papers have studied the LSC strategy combined with an agile supply chain strategy with a focus on flexibility. The context has also been considered, e.g., emerging economies or uncertainty in the evaluation of LSC performance.

The last group, Cluster 5, focuses on green strategies. An increasing interest in sustainable issues can be identified, as a large number of papers have studied LSC from a sustainability approach.

Final considerations

In this paper, we have sought to use a bibliometric analysis to review the literature on LSC from 1996 to January 2019. All the papers published in impact journals from different countries and all the authors working in this field have been included, so the obtained results are as accurate and complete as possible. In addition, by analyzing 525 papers, this study has reviewed more papers on LSC than any previous work.

Our findings can help researchers to understand the evolution of research trends in the field. This bibliometric analysis provides comprehensive information on the LSC literature. The results show significant growth in the number of publications on LSC during the considered period, a trend that we can assume will continue in the future. This increasing interest in the LSC research field can be seen as a target to focus on in the future. This paper has also presented some well-regarded journals publishing articles on LSC and their influence in different research areas, as well as the most active institutions in the field. This information is helpful for researchers seeking to identify the best journal to address their papers to and the institution with which they should establish collaborative networks when publishing on LSC.

Our analysis enables some trends to be easily identified in the geographic distribution of LSCs influence and illustrates how different countries are conducting research in this field of knowledge. Furthermore, although English-speaking countries are the most productive, other countries are rapidly moving up the rankings, especially in Asia. This suggests that the study of LSC has not only begun but is spreading around the globe. Last but not least, content analysis has been conducted to identify current trends in the LSC field. This information is highly valuable since it enables future research directions to be

---

5 Some of the 525 papers in our network were not interconnected. Therefore, only 507 papers have been included in the bibliographic coupling analysis, since it is the largest set of connected items.
established: the implementation of the lean supply chain strategy, evaluation of lean performance in the supply chain, and the combination of lean and other supply chain strategies to achieve a competitive advantage.

This study aims to present the information from different perspectives in order to reveal the volume of the research carried out into LSC and enable individual readers to understand data according to their priorities and preferences. Nevertheless, some limitations exist: the use of a single database has determined which papers were selected for our study, as have the subjectively-defined exclusion criteria. Expanding the search to more databases, such as Scopus or ABI, and establishing different inclusion and exclusion criteria could result in a more exhaustive review of the field. Researchers might then explore and extend the research area.

Despite the aforementioned limitations, we believe our study provides a path for future research and an incentive for scholars to further explore the lean supply chain field.

Abstract

The purpose of this study is to investigate the impact of Lean Management on efficiency at the internal and supply chain levels. Three hypotheses have been formulated and tested in an empirical study of 285 companies in industrial sectors that occupy an intermediate position in the supply chain. The study revealed that there is an improvement in efficiency when Lean Management extends throughout the supply chain. In addition, Lean Management at the internal level was observed to impact positively on the firm’s efficiency only when it contributes to enhancing the implementation of Lean Supply Chain Management.

Keywords: Lean Management, Supply Chain Management, Lean Supply Chain Management, Efficiency

Introduction

A number of researchers have detected a trend towards the adoption of Lean Management (LM) that not only affects companies internally but also the way that they are organised externally (Shah and Ward, 2007).

Using a chronological perspective and giving prominence to LM’s impact on performance, this study first focuses on the internal level and then, with a broader-based focus, on the supply chain level. On the internal level, the contribution of LM implementation to improving operational performance is widely recognised (Shah and Ward, 2003; Marodin et al., 2019), although some authors find there to be no significant relationship between LM and performance (Browning and Heath, 2009; Zhu and Lin, 2018).
On the external level, one of the main challenges that companies face when they initiate their lean implementations is improving integration with their supply chain partners (Pérez et al., 2010); i.e., which LM practices can be applied right across the supply chain, from the placing of an order with suppliers to product distribution and delivery to the customer, so that all activities are optimised from the final customer’s point-of-view. This is known as Lean Supply Chain Management (LSCM) (Swenseth and Olson, 2016).

Despite the crucial importance of jointly analysing and managing internal and external lean approaches, the literature has focused on analysing these independently and there are few articles examining their interrelationships (Moyano-Fuentes et al., 2012; Bortolotti et al., 2016; Marodin et al., 2017). Moreover, most analyses isolate lean supply chain components, instead of using a holistic approach to study LSCM.

The aim of this study is to investigate Lean Management’s impact on efficiency at two levels of analysis: internal and supply chain. At the internal level, aspects of LM such as buffer minimisation, work systems and human resource practices lead to management practices that are more supportive of improvements in resource efficiency (Rothenberg et al., 2001). At the supply chain level, there are papers that analyse the impact of lean practices along the supply chain on operating results such as waiting time, inventory rotation and on-time delivery, and the influence on this relationship of factors such as the company’s position in the supply chain and the time that LM has been implemented (Marodin et al., 2016; Marodin et al., 2019). However, none uses a holistic approach to investigate LSCM’s impact on efficiency.

Hofer et al. (2012) and Qrunfleh and Tarafdar (2013) argue that Supply Chain Management (SCM) potentially mediates between LM and performance. Therefore, this paper examines LSCM’s mediating effects in predicting the impact of LM’s internal implementation on efficiency.

Following this introduction, the next section presents the theoretical framework. The methodology used is subsequently described. After a discussion of the findings the conclusions are set out.

**Theoretical Framework**

Empirical evidence supports a positive relationship between the implementation of internal lean practices and the implementation of external lean practices. For example, Furlan et al. (2011) suggest that lean internal human resource management practices may influence the successful implementation of LSCM practices, and Hofer et al. (2012) empirically support the tendency of firms with greater inventory leanness to implement external lean practices to a greater extent.

Prior research on the simultaneous study of the two complementary and synergistic lean approaches analyses internal LM influence on LSCM in the ways described below.

Internal lean implementation is considered to be a determinant driver or catalyst of LSCM (Bortolotti et al., 2016). Thus, individual supply chain members should first adopt and enhance the level of their internal LM implementation and then gradually deploy LSCM principles, practices and techniques (Lamming, 1996). Internal lean must therefore precede LSCM, since the lack of a high level of internal lean implementation is one of the reasons why LSCM initiatives derail (Furlan et al., 2011).

In addition, the reconfiguration of the supply chain structure in line with lean characteristics (e.g., supply base, supplier selection and evaluation, suppliers per item) and the establishment of a lean partnership model (e.g., long-term relationships based on mutual trust and commitment, frequent exchange of information, win-win relationship) with strategic supply chain partners (Lamming, 1996; Bortolotti et al., 2016) are essential
prerequisites for a lean company to effectively deploy LSCM principles, practices and techniques. In this regard, Bortolotti et al. (2016) found that the choice of LSCM practices and their aim and implementation mode are influenced not only by the state of the supply chain structure and its relationships but also by the level of supply chain members’ lean internal implementations.

LSCM principles, practices and techniques deployed by supply chain agents (owners) depend on their own levels of internal lean implementation and on the levels of supply chain members’ (recipients) (Bortolotti et al., 2016). If a supplier’s and its customer’s levels of internal lean implementation are high, advanced LSCM practices can be adopted to achieve streamlined and synchronised supply chain flows and, ultimately, to achieve greater integration of inter-organisational processes and lean systems (Cagliano et al., 2006).

However, the approach to LSCM implementation taken in the literature is observed to be lean practice and technique based alone, whereas an integrated or joint approach is needed for the implementation level of LSCM.

Combining all of this reasoning, the following hypothesis is formulated:

\textit{H1. A higher level of internal LM implementation leads to a higher level of LSCM.}

LSCM aims to reduce costs and increase flexibility in the delivery of products through a process of continuous improvement that eliminates inefficiencies and activities that do not add value along the supply chain (Mollenkopf et al., 2010). Heikkilä (2002) points out that a good customer-supplier relationship contributes to reliable information flows, and reliable demand information flows, in turn, contribute to high efficiency. Simpson and Power (2005) and So and Sun (2010) find that supplier integration strategy has a positive influence on the long-term level of LM implementation for both suppliers and customers and improves global lean supply chain results. Prajogo and Olhager (2012) state that integrated logistics also allows firms to adopt LM, which leads to reliable order cycles, inventory reduction, and cost reduction, amongst other benefits.

Indeed, many authors (Marodin et al., 2016; Marodin et al., 2019) have analysed the impact of lean practices via the supply chain on a range of company operating results such as waiting time, inventory rotation and on-time delivery.

It must be taken into account that LSCM is not a set of isolated lean practices along the supply chain but a global strategy for the chain and that the extent to which this strategy is developed can greatly impact efficiency.

The following hypothesis is therefore put forward based on the above arguments:

\textit{H2: A higher level of LSCM leads to a higher level of efficiency.}

Past research has found the potential existence of SCM-related mediating effects between internal lean implementation and performance (Hofer et al., 2012; Qrunfleh and Tarafdar, 2013) and LSCM may be the cause of these mediating effects. In this sense, as was stated above, the level of internal lean implementation drives the spread of LSCM principles and practices (Bortolotti et al., 2016). There is a temporal sequence in this process. Firstly, both the focal company and supply chain members should adopt and enhance their levels of internal lean implementation (Lamming, 1996; Towill, 1997; Bortolotti et al., 2016). Then, they should gradually but quickly deploy LSCM principles, practices and techniques along the supply chain (Swenseth and Olson, 2016). The success of managing a lean supply chain strategy depends on accumulated valuable knowledge, competencies and cultural change linked to internal LM implementation (Furlan et al., 2011). In this context, the indirect impact of internal lean implementation on performance would be expected to be greater via LSCM than its direct impact.
It would be advisable to investigate how efficiency would be affected when LM is simultaneously implemented at the internal and supply chain levels. Internal level implementation would be expected to be eclipsed by the greater impact of LSCM on efficiency indicators.

On the one hand, at the LSCM operational level (Moyano-Fuentes et al., 2018), the joint use of lean techniques and practices to eliminate waste and the reduction of sources of variability in the supply chain have a major added impact on these efficiency indicators (Danese et al., 2012). The unit cost of manufacturing decreases drastically when Value Stream Mapping (VSM) is used in lean supply chain environments (Wee and Wu, 2009; Oberhausen and Plapper, 2017). Likewise, the use of Kanban cards and pull flow systems in a JIT supply chain reduces manufacturing costs (Rossini and Portioli-Staudacher, 2016). Also, generally-speaking, integrated inventory management reduces inventory-related costs (Hooshang, 2010) and, in particular, the cost of preparing JIT purchase orders (Parveen and Rao, 2009; Hooshang, 2010), JIT distribution transport and delivery costs (Wang et al., 2004), and JIT delivery transport costs (Chen and Sarker, 2010), and achieves higher stock turnover while minimising inventory (Pagani et al., 2016; Rossini and Portioli-Staudacher, 2016). In addition, the joint use of lean techniques along the supply chain and the reduction of variability can increase efficiency by minimising cycle time (Apte and Goh, 2004).

In addition, efficiency improvements at the LSCM planning level (Moyano-Fuentes et al., 2018) would come from long-term customer demand forecasting and focusing exclusively on current market segments, resulting in a lower per-unit manufacturing cost, high stock turnover (Qrunfleh and Tarafdar, 2013) and the minimisation of cycle time (Apte and Goh, 2004). Also, using queues and buffers to protect sub-processes along the supply chain improves efficiency by reducing the variability associated with inventory.

Thus, integrating these two levels of LSCM (operationalisation and planning) (Moyano-Fuentes et al., 2018) would have a multiplier effect on efficiency greater than the impact that internal lean implementation has on efficiency on its own. LSCM implementation implies that chain members have internally implemented LM (Bortolotti et al., 2016; Swenseth and Olson, 2016). However, it is only when LM is implemented on both levels (internal and external) that LSCM gains prominence for efficiency. In this case, the cumulative effect of each supply chain member’s contribution to efficiency and the synergistic effects of the joint use of multiple lean techniques and practices would eclipse the direct effect on efficiency of using lean internally in a company (Hofer et al., 2012). Therefore, LSCM may play a mediating role in the relationship that links internal lean implementation and efficiency.

Taking all these arguments together, the following hypothesis can now be proposed:

H3: LSCM implementation has a mediating effect between internal LM implementation and efficiency.

Methodology
Population, questionnaire and data gathering
The hypotheses have been tested using data gathered via a questionnaire with items drawn from the literature.

Before it was sent out, a draft version of the questionnaire was tested with a panel of five internationally-recognised SCM researchers and a pilot study was conducted with five heads of SCM to guarantee content validity. The questionnaire was directed at the head of SCM, logistics or operations management.
A population of 2,763 Spanish manufacturing companies from sectors occupying an intermediate position in their supply chain was taken from the SABI (Iberian Balance Sheet Analysis System) website.

The data gathering method consisted of a telephone survey using a computer-assisted telephone interviewing (CATI) system.

Fieldwork commenced on 30 January 2018 and ended on 20 July 2018. During the fieldwork period, 113 firms were determined not to form part of the population. The final population was therefore formed of 2,650 companies, with 285 of these responding (10.8% response rate). As several recent studies on SCM have had a similar or even smaller sample size (Qrunfleh and Tarafdar, 2013; Rojo et al., 2016), that used in this study is thus appropriate and does not jeopardise the reliability of the results.

A similar sector distribution of companies can also be observed. More precisely, the food, chemical and pharmaceutical, metal products, machinery and equipment and motor vehicles sectors are shown to jointly represent 71.6% of the companies in the sample and 69.2% of the companies in the population.

No evidence of response bias was found in a comparison of respondents with non-respondents. Thus, no significant differences were found between the population and the sample for distribution by annual sales, number of employees and gross operating profit (for 2015 and 2016).

Finally, the first forty responses and the last forty responses were compared and no significant differences ($\alpha = 0.05$) were found for any of the variables included in the questionnaire.

**Variables**

*Internal Lean Implementation.* The questionnaire included a question concerning the firm’s overall level of lean implementation compared to its competitors, scored on a scale of 1-5 (1 = poor, low; 5 = much higher than average) (Bortolotti et al., 2015). This variable was scored as “0” when the firm had not implemented LM.

*Lean Supply Chain Management.* This is a reflective construct composed of 8 items that relies on multiple-item scales derived from a construct structure proposed and validated by Moyano-Fuentes et al. (2018). LSCM is measured according to three dimensions. The first two are related to lean supply chain operationalisation. Specifically, the first is related to techniques for eliminating waste in the supply chain and the second to the reduction of sources of variability in the supply chain. Finally, the third dimension is related to lean supply chain planning (Moyano-Fuentes et al., 2018). The informants were asked about the degree to which they agreed with a series of LSCM-related statements on a scale of 1-5 (1 = totally disagree; 3 = neither agree nor disagree; 5 = totally agree).

*Efficiency.* This is a measure related to operational performance and includes three items that measure the unit cost of manufacturing, inventory turnover and cycle time (from raw materials to delivery) (Danese et al., 2012). Following several authors, it was decided to focus on perceptual and relative measures of performance by asking respondents to compare their firms’ efficiency with their competitors’ on a five-point Likert scale (1 = poor, low; 5 = much better than average) (Liu et al., 2009; Danese et al., 2012).

**Analysis and results**

**Measurement Model**

Content validity was ensured by the pretesting of the questionnaire. Scale unidimensionality was assessed by exploratory factor analysis. This gave eigenvalues
higher than one, standardised factor loads greater than 0.5 and significant explained variance for each extracted factor, and high values for chi-squared/degrees of freedom in Barlett’s sphericity test (p < 0.05). One second-order factor was used to measure LSCM. Results for the exploratory factor analysis and a description of observable variables are given in Table 1. Items with an asterisk (*) were dropped after exploratory factor analysis and reliability analysis. Reliability was tested using Cronbach’s alpha with scores of 0.7 or higher considered acceptable and 0.6 adequate, since a high coefficient alpha does not always mean a high degree of internal consistency, as alpha is also affected by the length of the test or number of items per construct (Nunnally, 1978; Merschmann and Thonemann, 2011).

Divergent validity was confirmed by two tests. Firstly, the Cronbach’s alpha coefficients for the scales were greater than their correlations with other scales. Secondly, the average item-to-total correlations with items not in the scales were substantially lower than the average item-to-total correlations with items in the respective scales. Finally, confirmatory factor analysis (CFA) was performed using EQS 6.1 software. The final fit of the CFA was highly satisfactory.

**Structural equation model and mediating effects**

A Structural Equation Model (SEM) was developed to test the hypotheses (Figure 1). EQS 6.1 software and the Robust Maximum Likelihood Method were used in CBSEM analysis. The baseline model in Figure 1 was run first. This included the effects of lean’s internal implementation on LSCM and the relationship between LSCM and efficiency. This model yielded an overall good fit (Satorra-Bentler’s scaled $\chi^2 = 51.94$; df = 26; $\chi^2 / df = 1.997$; RMSEA: 0.060; CFI: 0.946; IFI: 0.948; MFI: 0.954). The relationships in H1 and H2 (p < 0.05) were shown to be significant.
The baseline model was modified to measure the mediating effect considered in H3 with the addition of a direct path from internal lean implementation to efficiency (Model 1, Figure 2). The results of CBSEM analysis showed that Model 1 did not provide an adequate fit with the data (Satorra-Bentler’s scaled $\chi^2 = 83.41$; $df = 29$; $\chi^2 / df = 2.876$; RMSEA: 0.083; CFI: 0.886; IFI: 0.890; MFI: 0.905). The significant path coefficients again remained the same as in the baseline model with no significant coefficient for the new path between internal lean implementation and efficiency (see Figure 2). The $\chi^2$ difference test was not significant for Model 1 versus the baseline model ($\Delta \chi^2 (3df) = 31.47, p > 0.05$), indicating that the baseline model would be a better explanation of the data than Model 1.

In Model 1, the fit did not improve when the direct (non-mediating) effect was included. H3 is supported due to a significant effect in the baseline model and a lack of improvement in fit in Model 1, which considers the direct relationship between internal lean implementation and efficiency.

Note: *$p < 0.05$

$$\begin{array}{|c|c|c|c|c|c|c|c|c|}

**Conclusions**

This study has analysed the mutual influence between internal lean implementation and LSCM and demonstrates that there are differences in the importance of both for and in the contributions that they make to efficiency improvement. Thus, company efficiency is observed to improve when LM extends throughout the supply chain. This result is in line
with Azadegan et al. (2013) and indicates that firms must work with supply chain partners to reduce or minimise waste and achieve better performance.

Our findings are aligned with previous empirical evidence that states that LM on the internal level does not significantly impact on performance (Browning and Heath, 2009; Zhu and Lin, 2018). In other words, internal lean implementation alone is not enough to achieve the breakthrough improvements that lean offers, for which lean principles must be extended across the supply chain. However, our results indicate that internal lean implementation is a driver of LSCM, as has previously been found in the literature (Bortolotti et al., 2016).

Our results confirm the idea found in previous works (Hofer et al., 2012; Qrunfleh and Tarafdar, 2013) that SCM potentially mediates between LM and performance. In this sense, LSCM is confirmed to have a mediating effect in the impact of internal lean implementation on efficiency. This finding shows that LM strategy must be implemented sequentially if a firm wants to achieve the expected results that derive from its implementation.

Therefore, the results of this study indicate that a wider level is needed to investigate the impact of LM on performance and to provide a sustainable competitive advantage. Lean implementation needs to be a goal shared by all supply chain members for supply chain effectiveness to be improved through better efficiency outcomes.

In other respects, unlike previous studies that use partial approaches focused on lean practices applied along the supply chain (Berger et al., 2018; Tortorella et al., 2017; Tortorella et al., 2018), this study uses a holistic focus on LSCM. Thus, a validated measurement instrument is applied to LSCM for the first time (Moyano-Fuentes et al., 2018). This instrument is composed of three different dimensions related to the operational aspects of lean supply strategy implementation and to lean supply chain planning. This should push the boundaries of LSCM research and its relationship with outcomes such as efficiency.

From a practical perspective, these findings can help make managers aware of the major role played by LSCM implementation and prioritise their efforts to minimise the use of resources and improve efficiency by adopting a holistic approach to their lean implementations. To achieve the best operational performance derived from LM, managers should pay attention to the transfer of knowledge, competencies and cultural change linked with the level of internal lean implementation to their supply chain members.

In more general terms, this study provides a tool for managers to assess the operational aspects of lean supply strategy implementation and the aspects related to lean supply chain planning and, eventually, to identify some weaknesses that enable them to enhance their LSCM implementations.

Regarding the limitations of this study and further research lines, this work evaluates LSCM implementation from the perspective of the focal company, which may distort the analysis. So, further research on LSCM should consider the vision of the level of LSCM implementation from the perspective of a range of upstream and downstream members of the same supply chain.

Past empirical evidence points to the absence of an appropriate organisational culture or lack of trust among supply chain agents being vital factors for sustaining LSCM (Jadhav et al., 2014). So, examining the association between these factors and lean implementation at the internal and supply chain levels and their impact on efficiency is an additional opportunity with both theoretical and practical implications.

Abstract

We conduct a comprehensive review of lean journey in healthcare institutions to synthesize its key aspects along the three major stages of lean journey. Following a systematic delimiting criteria, research articles published in journals until December 2018 were considered. This study documents how performance measures improved due to rollout of lean and how healthcare institutions have adopted assessment procedures to reflect the entire lean journey. The current study is believed to be the first one to document the motives, practices implemented and performance measures evaluated while implementing lean in the healthcare context in a single paper.

Keywords: Lean Journey, Healthcare, Literature Review

Introduction

Healthcare institutions, in today’s generation, need to strike a balance between two key objectives, namely efficiency and effectiveness (i.e. ensuring cost effective health care services to patients without compromising high quality care) (Dyrybe et al., 2017). These seemingly mutually opposite but essential objectives have pushed hospitals to reduce inefficiencies in its care delivery processes such that the cost of care comes down without compromising the quality of care (Trzeciak et al., 2018). Health care professionals have therefore attempted to address flow and waste issues by adopting process improvement strategies such as lean while focusing on variation and design to promote business and operational excellence (Wani et al., 2018). This explains the maturity of lean based process improvement literature in the context of healthcare institutions (Sunder et al., 2018).
Lean has been found instrumental in eliminating wastes throughout the healthcare institution especially in preventing medical errors (Jimmerson et al., 2005), decreasing mortality rates (Dimick et al., 2004), reducing patient’s length of stay (McDermott and Stock, 2007), reducing patient’s waiting time (Aherne, 2007), minimizing patient’s movement (Kelly et al., 2007), and improving patient care (LaGanga, 2011). Therefore, lean has proven to deliver positive results by reducing non-value added processes (waste) and assisted healthcare institutions in improving process efficiency, thereby leading to affordable quality care coupled with patient satisfaction (Narayananamurthy and Anand, 2018). NHS Institute for Improvement and Innovation has identified important inefficiencies or wastes in the hospital sector (NHSIII, 2007).

Although conceptually simple, ‘Lean’ as a concept is not easy to define. The fundamental philosophy is to continuously improve processes within a system by removing non value added steps, which are commonly known as ‘waste’ (Poksinska, 2010). Womack & Jones (1996) defined lean through the adoption of “five principles”. The basic assumption for adoption of these principles were that organizations are made of processes and adopting the principles in such processes would add value, reduce waste and thereby increase efficiency in the process (Radnor et al., 2012). Pettersen (2009), on the other hand, outlined key collective terms through which one may define lean and pointed individual characteristics of each collective terms (Burgess and Radnor, 2013).

The lean literature in health care is quite rich and diverse in terms of its objective behind the choice of lean journey. Deblois and Lepanto (2016) reviewed literature reviews concerning the application of lean in acute care setting. Holden (2011) illustrates the application of lean implementation in emergency departments in United States. Carter et al., (2012) described the application of lean in a teaching hospital in Ghana where health related resources are low. van Rossum et al., (2016) conducted a cross sectional survey in an operation theatre at a Dutch University medical centre to highlight the influence of leadership and workforce flexibility on change management perspective of lean. However, all studies in this literature can be plotted onto one or multiple of the three stages in lean journey spectrum – readiness (pre-implementation), rollout (implementation), and reflection (post-implementation) (Narayananamurthy and Gurumurthy, 2016). Studies discussing motives, barriers, and drivers for rolling out lean are contributing to readiness stage. Following it, a stream of lean rollout studies have discussed the lean practices implemented by healthcare institutions for the attainment of profit maximization (LaGanga, 2011) or process improvement (Aronsson et al., 2011) . Diverse studies have also discussed the different types of wastes targeted during lean rollout in healthcare institutions. For example, Papadopoulos et al. (2011) discussed about the issue of rework in hospital administration in the form of inefficiencies in collecting and diagnosing medical specimens in the hospital. Castle and Harvey (2009), on the other hand, identified all major wastes in a hospital, which includes over-processing due to inaccurate information flow, underutilization of human resources etc. Finally, post-implementation studies have focused on the reflection of lean rollout by conducting assessment through the comparison of performance measures before and after (Matthias and Brown, 2016) or through a mathematical technique (Dogan and Unutulmaz, 2016). Improvements attained through lean rollout are quantified in this stage by the healthcare institution travelling the lean journey. Therefore, clustering the discussion on lean journey in healthcare institutions literature into these three stages will help in synthesizing the various crucial aspects from motive to preparation,
implementation, and assessment of lean. Anchoring to this motivation, we conduct a comprehensive review of lean journey in healthcare institutions literature to understand and synthesize its key aspects along the three major stages of lean journey. We purposefully chose those articles which have used case study as a primary methodology in explaining lean implementation in health care. Analyzing case studies provides an option to understand how lean principles and techniques can be applied. In addition, it gives us additional information regarding different structural attributes such as role of top management, motive of lean and different types of waste eliminated etc.

In this study, we attempt to answer the following research questions:

**Stage 1: Readiness stage**
- RQ 1.1 - Why do healthcare institutions adopt lean (motivation)?
- RQ 1.2 - What are the barriers for adopting lean?
- RQ 1.3 – How should different stakeholders be prepared for lean journey?

**Stage 2: Rollout stage**
- RQ 2.1 – What are the different types of wastes targeted by healthcare institutions through lean rollout?
- RQ 2.2 - What are the different types of lean practices implemented by the healthcare institutions to eliminate the wastes identified?

**Stage 3: Reflection stage**
- RQ 3.1 – What are the performance measures used by healthcare institutions to assess the impact of lean rollout?
- RQ 3.2 – How have the performance measures improved due to the rollout of lean?
- RQ 3.3 – What are the different types of assessment procedures adopted by healthcare institutions?

The remainder of the paper is structured as follows. Section 2 reviews the literature review studies published so far on the topic “lean in healthcare”. Section 3 explains the methodology adopted for the literature review and the structural attributes selected for the review. Section 4 details the results and inferences gathered from the review analysis and answer the above-listed research questions. Section 5 concludes by proposing future research directions as well as a framework for health care practitioners as a guideline for lean journey in healthcare institutions.

**Review of Literature Reviews**

Kollberg et al. (2006) was one of the first few studies in lean healthcare context where the authors first introduced a performance measurement system in the domain of lean health care. Subsequently, the review focus primarily concentrated on four disparate areas, namely, patient care delivery (Butler, 2016), overall lean implementation in hospitals and/or health care domain (D’Andreamatteo et al., 2015), role of leadership and organization in lean healthcare context (Lawal et al., 2014) and tools currently applied in the overall lean journey (Curatolo et al., 2014).
We argue that our paper contributes to the existing research gap in many ways. First, we observe that no study, to the best of our knowledge, has focused on lean journey at a case study level in healthcare institutions from the perspective of past literature reviews. Second, we notice that almost all the published literature reviews have not followed a structured methodology. For instance, most of the studies have failed to mention either the time period of their study, criteria used for short listing papers, or number of papers finally shortlisted for review (Kollberg et al., 2006). Third, most of the studies have either revisited lean implementation in healthcare context with a perspective focus, giving less importance to the overall lean journey (Poksinka, 2010; Moraros et al., 2016; Aij and Rapsaniotis, 2017) or have focused the review from the clinical side of patient care (Butler, 2016). Fourth, many of the review papers are published in healthcare journals and not in the mainstream operations management journals, which conveys that a detailed focus to operational aspects of lean implementation in healthcare (e.g. practices, performance measures, etc.) have not been given (Trzeciak et al., 2018). Fifth, majority of the review articles have superficially explained how lean has helped in manufacturing and argued how the same logic can be relevant for healthcare (Zattar et al., 2017).

By anchoring to the above-listed gaps, we believe our paper would contribute meaningfully to the lean literature in health care by integrating and focusing on different stages of lean journey (i.e. starting from readiness stage to rollout stage, and finally to the reflection stage). Understanding how healthcare institutions progress in their lean journey by looking back at the literature is very helpful in identifying the common drivers, barriers, practices, performance measures, etc. Analyzing case study literature provides an additional advantage of documenting different structural attributes implemented in single or multiple healthcare institutions. It also helps in projecting a pattern based on the past experience documented in literature.

**Methodology**

Lean and health care are individually mature topics in OM literature and its knowledge base has developed and expanded for the last few decades. There is a corresponding growth in the size of the academic literature at the intersection of lean and healthcare. Because the knowledge base is large and diversified to clinical health, quality, operations, process improvement, and policy literature, an integrative literature review methodology will be prudent to capture the dynamics of the knowledge creation on the topic (Torraco, 2005). We achieve this by analysing and reviewing the literature followed by a systematic synthesis of the current state of knowledge through re-conceptualization of the literature (Torraco, 2016). In addition to the plethora of integrative literature reviews in human resource management literature, there has been a recent trend to do integrative literature review in both health care (Nibbelink and Brewer, 2018; Christmals and Gross, 2017; Jinks et al., 2011; Swider, 2002) and operations management (Gligor, 2014; Ringsberg, 2014; Bask et al., 2010; Mollenkopf et al., 2010; Young Kim et al., 2010). Following Gligor (2014), we present five distinct stages in an integrative literature review process. While research questions were formulated (Stage 1) in section 1, Stage 4 and Stage 5 will be explained in the subsequent sections. In this section, we explain the literature search and material selection (Stage 2) followed by the selection of structural attributes for evaluation of the literature (Stage 3).

**Literature Search**
To collect relevant literature for our review, we followed a systematic approach using different delimiting criteria anchored to the research questions. Research articles published in journals until December 2017 were gathered from search engines and databases, which include EBSCO, ScienceDirect, Springer, Taylor & Francis, Wiley and Google Scholar. We used different combination of keywords from lean (set 1 = {lean thinking, just in time, Toyota production system}) and healthcare (set 2 = {Healthcare, Hospital, Clinic, Medicine, pharmacy}) in our searches. The initial search yielded 3160 articles related to lean and healthcare. However, several of the articles did not pertain to the broad theme of lean journey of healthcare institutions (i.e. adopting case study methodology). For example, the search included articles discussing conceptually or by taking anecdotal evidences about why and how lean is applicable in healthcare (Keating and Heck, 2018; Barnabè et al., 2018; Waring and Bishop, 2010). Therefore, we restricted our search to articles that are capturing the actual experience of lean journey in healthcare institutions by adopting case study methodology. To achieve it, we added the keyword “case study” to all our searches. To ensure that all the relevant and impactful articles are included, we also adopted a systematic snowballing technique. We investigated the references and citations of all shortlisted articles to ensure that the relevant articles were included. After including all the relevant papers that satisfied the delimiting and inclusion criteria, we reviewed 227 abstracts to shortlist our final list of articles.

Structural Attributes Identification
We carefully identified the structural attributes for our paper. The first round of structural attributes was performed by the first author and third author. It was then cross-validated by the second and fourth author of the paper. Each structural attributes can be explained further by sub-attributes or choices of those attributes. For instance, research paradigm has two choices, qualitative or quantitative approach. On similar lines, lean motive has two choices, profit motive and process motive On the other hand, there are many attributes comprising of different sub-attributes. For example, assessed lean effectiveness can be further classified into nature of assessment (comparison of measures or mathematical technique) and the actual mathematical technique used for lean assessment. We present a detailed categorical analysis of such attributes in subsequent sections. However, we conducted a thorough classification of the attributes to answer our research questions. For instance, to answer RQ1, we need to understand the motivation of lean adoption in healthcare institutions, its barriers and the role of stakeholders for the lean journey. We therefore, chose lean motive and initiator and practice reports as broad attributes to answer the questions. Further, we segregated lean motive and initiator into two sub-attributes, lean motive and lean initiator which aid in answering the first and third part of RQ1. The practice report attribute was further segregated into two sub-attributes, performance improvement report and practice improvement report. The practice improvement report was used to answer the second part of RQ2 whereas the performance improvement report was used to answer second part of RQ3.

Analysis and Results
The section is divided into three parts. The first part presents the descriptive statistics of the papers gathered through the material collection step discussed in the previous section. After understanding the basic overview and trend of the papers through descriptive analysis, we performed categorical analysis with respect to the structural
attributes. Based on the results from the analysis, we answered the research questions of each stage (i.e. readiness stage, rollout stage and reflection stage).

Descriptive Analysis

The descriptive analysis presents an overview of the selected literature with the objective of providing relevant trends and discussions concerning journals, articles, citations, and authors. The papers were not concentrated in few journals but were spread across diverse set of journals. This also warrants the need for reviewing this topic to connect the bits and pieces for gaining a holistic understanding on the current status. This exercise will provide meaningful directions for future research focus by helping to avoid the redoing of same research. Our analysis brings us to our attention that International journal of health care quality assurance, Journal of health organization and management, Leadership in Health Services, Health Affairs and Joint Commission Journal on Quality and Patient Safety are the top journals where 5 or more articles have been published. It is interesting to note that all these journals primarily belong to the health care domain. However, there is no trend in terms of distribution of articles in such journals. For example, on one hand articles published in Leadership in Health Services are distributed somewhat evenly from 2007 to 2016, on the other hand, all six articles got published in Journal of health organization and management in 2014 (Drotz and Poksinska, 2014; Hayes et al., 2014; Mazzocato et al., 2014; Morrow et al., 2014; Timmons et al., 2014; Ulhassan et al., 2014). As a result, it is difficult to ascertain the trend of articles in the mentioned journals. Surprisingly, there has been a dearth of attention of lean health care papers in operations journals (Tay et al., 2017; Matthias & Brown, 2016; da Silva et al., 2015; Aronsson et al., 2011; Papadopoulos et al., 2011; LaGanga, 2011; Setijono et al., 2010; Castle and Harvey, 2009; Shah et al., 2008) (Refer Figure 4). Research as expected is being published in two different category of outlets – one related to operational excellence and process improvement and another related to healthcare management.

Categorical Analysis

In terms of clinical focus, 83% of the selected literature focuses on multi speciality clinics. Among all, 39% of the hospitals are public and 15% are private. The rest of the literature did not mention the ownership of the hospital. Most of the studies (80%) have adopted a qualitative research paradigm focusing on the importance of evidence driven lean implementation in hospitals (Shojania and Grimshaw, 2005). The exact methodology adopted includes Interviews, Participant Observation, Primary Survey, Secondary Databases and different combinations of such mentioned methods thereby,
highlighting the importance of mixed methods in management research (Johnson and Onwuegbuzie, 2004). We also analyzed how quantitative and qualitative studies were performed over the years in private and public hospitals. Approximately 42% of the qualitative studies were conducted in public hospitals and only 14.5% of the same was conducted in private hospitals. The balance work on qualitative domain did not specify the type of hospitals in which the study was conducted. In the case of quantitative studies, 50% of the papers did not mention the type of hospital ownership and the balance 50% was equally distributed between private and public hospitals. With regard to the clinical focus, approximately 39% of the studies in the multi-speciality hospitals are public hospitals whereas, as observed before, 46% of the studies in the multi-speciality hospitals did not specify the type of hospital ownership. Out of 115 studies in multi-speciality hospitals, 86 papers have adopted case study methodology and 13 papers have adopted ethnography as their research methodology highlighting the role of pure qualitative tradition in the lean health care sector. Most of such studies have occurred from 2007 to 2014. The focus has been the same in the case of single speciality too where other than case study methodology, the next dominant research tradition is mixed methods. Surprisingly, there are very few studies on pre-implementation and post-implementation phase of lean. Most of the studies have adopted case based methodology. However the trend shows the emergence of mixed method in lean implementation studies in the last decade. 92% of the studies did not perform benchmarking. 96% of the studies focused on lean implementation with negligible importance to pre and post implementation scenarios. The studies mainly focus on operational aspect of lean implementation (61%) whereas only a small fraction of study (25%) focused on the strategic aspect of lean implementation. 56% of the articles analyzed lean implementation in hospitals from within whereas 28% of the articles had a macroscopic viewpoint while implementing lean in hospitals. This included analyzing the entire supply chain operations of the hospital rather than focusing on the internal processes. In terms of leanness index, there was no article except one that created a quantifiable metrics to assess lean (Pearsoon et al., 2006).

**Lean Journey Analysis**

A close scrutiny of the barriers suggests that employees are still not convinced regarding the potential benefits of lean implementation. Further, apprehensions such as job cuts can seriously derail the adoption of lean. It is the responsibility of the top management leadership to see through that such apprehensions do not occur. Further, if the top leadership is committed towards lean adoption, it is their responsibility to ensure proper financial incentives are in place especially if the work load of employees exceed beyond a certain limit over certain duration of time. One cannot expect employees to be highly motivated without financial leverage. Second, the leadership needs to create an efficient system where staffs and employees do not feel the pressure of constant changes in day to day processes. Further, intra-departmental cooperation is utmost necessary which can be only brought about from a top down approach. Third, doctors need to be instructed that hierarchical inhibitions can seriously impede lean adoption. Similar results are obtained from wastes (48 identified and analyzed), practice reports (35 unique practices analyzed for waste reduction) and performance improvements (50 unique indicators analyzed from manual content analysis). Further, we proposed a conceptual framework highlighting the do’s and don’ts of lean journey starting from the readiness stage, followed by the rollout stage and finally to the reflection stage.

**Conclusion and Discussion**
This study successfully integrated the entire lean journey by addressing important facets of each stage of the journey. Specifically, this study offers interesting insights on the different types of wastes targeted by healthcare institutions and how lean practices have successfully eliminated those wastes. In addition to acknowledging how different stakeholders should be prepared for lean journey, this study documents how performance measures improved due to rollout of lean and how healthcare institutions have adopted assessment procedures to reflect the entire lean journey. Even though the practices implemented were based on the principles of LT, they were adapted to the healthcare setting based on the problem faced and process studied. Performance measures used were observed to be completely contextual and most of them were unique to the problem addressed.

Abstract

The purpose of this study is the identification of the most influential contributors in the field of lean management research and the analysis of the changes that have occurred in the intellectual structure of the discipline over the last three decades. We employ a citation and co-citation analysis on a dataset of 8,081 lean contributions comprising 192,512 citations that we exported from the Scopus database. Our findings show the emergence of many knowledge groups within the recent years. We further identify a few central contributors with influence on the overall field or only within their specific knowledge groups.

Keywords: Bibliometric analysis, literature review, lean management

Introduction

Three decades after the term ‘lean’ was introduced by Krafick (1988) and promoted by Womack et al. (1990), there seems to be no limit to the continued popularity of Lean Management. Today, we have a rich and ever expanding body of knowledge on “one of the most influential manufacturing paradigms of recent times” (Holweg, 2007). Research on lean management (LM) has evolved through different stages (Hines et al., 2004; Bhamu and Singh Sangwan, 2014; Netland and Powell, 2016), whereby different research streams have emerged, sustained, or died.

In its early phases, research on LM started to raise awareness by disseminating best practices and first benchmarking reports. Later, the approach started to spread out to other parts of the value chain (e.g., supply chain management, product development) (Hines et al., 2004). At the same time, other industries than only automotive manufacturing (e.g. service industry) started to adopt the approach as well (Stone, 2012).

Due to the widespread interest in LM from both, academia and practice, a new sub discipline within OM research has emerged. To trace its history, first literature reviews appeared already shortly after the term was coined. However, these articles mainly focused on single elements of LM, for example, on Just-in-Time (JIT) (Sohal et al., 1989; Golhar and Stamm, 1991), or Kanban systems (Berkley, 1992) with small sample sizes. Only by the turn of the millennium, the first reviews conceiving LM as a whole started to be carried out. Landsberghis et al. (1996), for example, reviewed the impact of lean production systems on various industries. Later on, researchers have started to also review
the body of knowledge about LM. Hines et al. (2004) reviewed the evolution of lean thinking and identified key criticisms related to it. Papadopoulou and Özbayrak (2005) as well as Holweg (2007) reviewed various LM definitions, summarized its main elements and also criticism on it. Especially in the last decade, the research community around LM experienced a wave of many more literature reviews (Moyano-Fuentes and Sacristán-Díaz, 2012; Marodin and Saurin, 2013; Bhamu and Singh Sangwan, 2014; Jasti and Kodali, 2014, 2015; Danese et al., 2017). A commonality of all these qualitative literature reviews is their limitation with regard to the covered time period or number of articles considered. Due to this, prior literature reviews were not able to objectively capture how different pieces of research on LM cohere and changed over time. A scientific analysis of the research on lean to reveal the evolution of its intellectual structure is lacking.

In this study, we evaluate the evolution of the field’s intellectual structure in an objective and comprehensive manner. To achieve this, we take a new approach of reviewing the literature on LM from 1988 on and follow the suggestion of White and McCain (1998) to study how a discipline has evolved by performing a citation and co-citation analysis. Specifically, we aim to answer the following research questions:

1. Who are the most influential authors in the field of LM?
2. What are the major knowledge groups in the field of LM and how do they relate to each other?
3. How can the evolution of the identified knowledge groups and their relationships be characterized and illustrated?

In the following, this paper introduces the bibliometric methods and data we used for the study. Next, we present the results of the analysis and describe the intellectual structure of the field and its evolution over the last three decades. Eventually, we offer conclusions, discuss the implications for both, theory and practice, raise awareness for the limitations of the study and show potentials for future research.

**Research method and data**

Bibliometric analyses are a powerful measure to investigate and characterize a field of research. They can be distinguished into two categories depending on whether they yield activity indicators, such as citation analyses, or relationship indicators, such as co-citation analyses (Ramos-Rodriguez and Ruiz-Navarro, 2004). We employ both methods, citation and co-citation analysis, on author level. The former is based on the premise that highly cited literature is likely to have had more influence on the subject than literature less frequently referenced (Sharplin and Mabry, 1985; Culnan, 1986), and is hence representative for the activity or importance to the field. Bearing in mind that it represents “the field’s view of itself” (White and Griffith, 1981), citation analysis can provide useful insights into which authors in the field of LM are considered influential. We use citation analysis to address our first research question.

Since citation analyses do not capture the structure of influence within a field (Leong, 1989), we also employ a co-citation analysis to address the second and third research question. Co-citation analysis is based on the distribution frequencies obtained from counting the number of articles or books that list the same pair of authors in their references. Due to this, it allows to identify the relationships among authors, evaluate their strength, and to illustrate structural groupings within the co-citation network (White, 1990) (see Figure 1).
To calculate and visualize the bibliometric networks, we use a software tool called VOSviewer (Van Eck and Waltman, 2014). Compared to similar software tools like Gephi or Pajek, it combines analytical and visual strengths and thus serves as an appropriate tool for mapping bibliometric networks (Leydesdorff and Rafols, 2012). VOSviewer takes a distance-based approach using stress-minimization as in multidimensional scaling (MDS). To show how authors within a network relate to each other, VOSviewer illustrates authors as circles, whereas the size of the circles represents the author’s number of citations. The proximity to another knot (author) indicates similarity of the authors perceived by their citers (see Figure 1). By default, each node in the network is assigned to (exactly) one (individually colored) cluster, a set of closely related nodes. The number of clusters can be determined by a resolution parameter. With the help of these maps, we trace the relationships between the authors and identify different knowledge groups. By comparing maps from different periods with each other, we follow the evolution of these relationships over time.

Data
Since LM has spread out to many different disciplines, we aim to appreciate its full reach and to capture the whole picture of the LM research community. Therefore, we deliberately do not limit our study to any type of research contributions, be it books, chapters, research articles, theses, etc., though the majority consisted of research articles (86.3 %). For the same reason, we also include conference proceedings and less influential journals with regard to their citation scores. Instead, we conduct an advanced literature research in the Scopus web database and limit our search to a small number of keywords either used in the work’s title, abstract, or keywords (“lean management”, “lean production”, “lean manufacturing”, and “lean thinking”). We thereupon export the dataset including relevant information like author, title, year, source, and references as a csv-file. Before analyzing the data, we take extreme care to identify different variants of an author’s name and use VOSviewer thesaurus files to ensure that these are merged and treated as one.

As it was our goal to track the changes in the research field of LM, we consider research contributions over the period of 1988-2018. However, we divide the studied time span into smaller sub-periods of decades and create a bibliometric network for each one to keep track of minor intellectual movements that might have faded out from the field.

The following figure illustrates a growing trend of research articles on LM over the last 30 years. Despite being introduced already three decades ago, the manufacturing paradigm has still kept on attracting interest from more and more researchers showing a particularly high momentum in the recent years. So far, most contributions were made in the year 2018 (919 articles). Overall, our research resulted in 8,081 contributions related to LM, comprising 192,512 citations in total.
Findings
According to our methodological procedure, we also separate the findings section into two stages. First, we present the results on the top 10 most cited authors in the field of LM (see Table 2) to address our first research question. Then, we present the insights from creating the bibliometric networks of the last three decades to target our further research questions.

Most cited authors
The 10 most cited authors in the field of LM over the last three decades are listed in Table 2, along with their number of citations and rank per each period. The absence of a citation count means that the author was not among the top 500 most cited authors of the respective decade, most likely due to later publications.

Not surprisingly, Womack, Jones, and Roos are among the four most cited authors. Due to their books “The Machine that Changed the World” (Womack et al., 1990) or “Lean Thinking” (Womack and Jones, 1996), they made the idea of LM known worldwide. Liker, who is on third position, had a high citation count in the recent years thanks to his bestselling book describing 14 management principles that the Japanese automotive manufacturer Toyota applied (Liker, 2004). Further significant contributions on the understanding of lean production were made by Shad and Ward by characterizing and measuring it with the help of different groups of manufacturing practices (Shah and Ward, 2003, 2007).

Bibliometric network of 1988-1998

For each decade we investigate, we create a bibliometric network and visualize it to better understand its intellectual structure and the evolution of the field. Our first network relates to the time span 1988-1998 and is characterized by three central contributors. Womack, Jones, and Roos do not only have a high citation count, but also strong co-citation links not only within their own cluster but within other clusters as well. Other main contributors of this cluster are Schonberger, Fujimoto, and Monden who also described the way how Japanese companies design and manufacture their products (Monden, 1983; Schonberger, 1986; Clark and Fujimoto, 1991).

Another cluster is located in the top right-hand area of the graph formed by a series of works related to flexible manufacturing. Central author is Hyötyläinen with co-cited authors such as Toikka, Schultz-Wild, or Kuivanen. In the lower part of the graph, we identify a cluster of authors who criticize LM, and examine how Japanese manufacturing techniques, such as JIT, contrast to Western/European manufacturing (Williams et al., 1990). Delbridge, Turnbull, Garrahan, and Stewart, among others, take on a human resource perspective, and discuss effects on management of labor and work organization (Garrahan and Stewart, 1991; Delbridge and Turnbull, 1992).

The remaining clusters of the graph show weaker co-citation links. Nevertheless, there remain some influential authors. Mathews, Badham, or Berggren, for example, also participated in the debate whether LM has the potential to overcome existing manufacturing paradigms (Badham and Mathews, 1989; Berggren, 1993).

Figure 3 – Bibliometric Network of Lean Management Literature 1988-1998

Bibliometric network of 1999-2008

The bibliometric network representing co-citation data from 1999 to 2008 shows four main clusters. Again, Womack and Jones dominate the network with most co-citation links, whereby Roos appears farther away from the two authors with now significantly less co-citation links. This indicates the significant influence of the second book by
Womack and Jones “Lean Thinking” (Womack and Jones, 1996). Also, part of this cluster are many authors as Liker, Hines, Rich, Shook, and Rother, who have some consulting work in common and documented their experience on the application of LM by writing books.

In the top right-hand side of the graph, a new cluster emerged, comprising the authors from the field of lean construction. Notably, this cluster is the most distant cluster from the center of the network, which means that the authors represent a mostly independent knowledge group except for a few co-citation links with key authors like Womack, Jones, Roos, Ohno and Shingo.

The lower right-hand area of the graph is taken up by a large group of authors who cover a broad range of topics like organization theory, sociology, and the environmental impact of LM. It includes, among others, the cluster from the previous decade that discussed the implications of LM for human resources and collected criticism on the approach. Further, it extends it with authors like Florida or Adler who touch upon the intersection between manufacturing and the environmental respectively organizational aspects, but were previously outside of this cluster.

The lower left-hand area of the graph shows two more knowledge groups. One of them comprises, among others, the authors Wheelwright, Hayes, Schroeder, Flynn, and Schonberger, i.e. authors who contributed fundamental knowledge about operations strategy and how manufacturing approaches can affect firm performance. A further group of authors within this cluster, including Towill, Christopher, and Mason-Jones, is related to the combination of lean and agile manufacturing and supply chains.

Our third bibliometric network is the most diverse network and notably very substantial for the overall body of LM knowledge. Due to the ever-growing interest in LM, most contributions and accordingly most citations were made in the respective period from
2009 to 2018. For this reason, we find many different knowledge groups in the network, which even exceed the maximum number of possible clusters (seven) VOSviewer can detect.

Similarly to the previous network, Womack and Jones, who still have most citations and co-citation links, are in the center of the graph. Further, we find a small group of authors located closely around the center, out of which some had a close research relationship with Japanese manufacturers but most of them had practical experience with Toyota such as Ohno, Shingo, Shook, or Hines. Farther right, there is a group addressing lean product/software development and even farther the lean construction community.

In the top of the graph, we identify a research group on lean services, with a focus on healthcare in the middle of it. In the top left-hand side of the graph, the knowledge group of lean six sigma is located. In between these two groups, we find some authors from one of the previous clusters we identified in the decade before. These authors, who discussed the different implications of LM for workers, like MacDuffie or Delbridge, show relatively little influence on the network now.

The bottom of the graph shows knowledge groups related to sustainable manufacturing, the application of value stream mapping (VSM), and a group of researchers who reported their case studies in SMEs. The lower left-hand side of the graph contains authors who worked on the combination of lean and agile manufacturing. In the left part of the network, we find a highly populated knowledge group that covers mostly empirical research on the implementation, assessment, and performance effects of LM.

Discussion

Most influential authors
The first research objective was to identify the most influential authors in the field of LM. Our results showed that Womack and Jones received most attention among LM
researchers in terms of both, total citation counts and co-citation links, and throughout all periods that we analyzed. Other than that, research on LM experienced quite some change regarding the influence of their authors. In the beginning, the LM approach was relatively unknown to the world and influential researchers like Adler, Oliver, Berggren or Williams, who perceived a change of manufacturing strategies, elaborated on the consequences LM might have for industry. Their studies did not only build on the work of Womack, Jones, and Roos, but also on others’ as Monden, Ohno, or Schonberger who shared their perception of Japanese manufacturing techniques in books. Therefore, it was a mix of books and research articles that had influence on LM research.

In the later decades, practitioners and consultants showed much influence on LM research. Authors such as Ohno, Shingo, Liker, Hines, Rother, or Shook had high citation counts with their books. Moreover, many knowledge groups emerged that appreciated the various interpretations of LM. As research interests have become more specific, not only books appeared to be influential. Research articles from Shah, Ward, Ballard, Koskela, or Antony equally find their recognition and influence in the form of many citations and also co-citation links within their respective clusters. The relatively fast and recent increase of citation counts of researchers as Antony (lean six sigma) or Radnor (lean services) indicates how much potential lean management can still unleash in unexplored fields.

**Evolution of knowledge groups**

The identification of knowledge groups and their relationships was defined as the second research objective, and the description of their evolution as our third one. The bibliometric network of the first decade shows that in the beginning LM has just started establishing itself as a knowledge group among others. Besides Womack, Jones, and Roos who were spreading their interpretation of the Toyota Production System (TPS), also other authors described new manufacturing strategies, often inspired by Japanese manufacturers.

One decade later, the LM research landscape looked a bit different. New, more specific research groups directly related to LM were emerging. Authors within these groups appeared closer to each other and more interrelated with each other. In addition, a large group of authors had a controversial discourse about LM and its effects on the workforce, the organization of firms, and the environment. In the last decade, the skepticism and criticism on LM seemed to lose its significance as can be seen in the low influence of the respective group of authors. On the contrary, the latest graph shows that a large number of individual knowledge groups emerged.

Similarly to prior research (Hines et al., 2004; Danese et al., 2017), this study also shows that the research interests on LM are constantly evolving. The rapid increase of contributions and the evolution of different knowledge groups show that LM is not only still gaining attention, but also has particularly in the recent years found its way into different disciplines and evolved as much as never before. We see that research has moved away from asking what LM is and why it should be applied, to where and how it can be applied. Particularly, we expect to see more studies to follow the trend of uncovering new fields of application.

**Conclusion**

The purpose of this study was to identify central contributors and sub-disciplines that have emerged in the field of LM, to show how they relate to each other and to analyze their roles over the three decades. We fulfilled this purpose by applying a bibliometric network analysis, which is a novelty in LM literature research and thereby managed to capture the wealth of a great number of previous LM studies.
Our results show that there is a core of contributors with high influence on the individual knowledge groups of LM. Within these knowledge groups, single authors with internal influence exist as well. Particularly in the recent years, we experienced quite strong dynamics in the evolution of the field. Many contributions have been made and the management paradigm has spread from its origin in automotive manufacturing into many different fields covering not only different parts of the value chain but also different industries. Research has been following these trends and creating new knowledge groups that in some cases prosper autonomously and in other cases draw on other groups.

This study has several theoretical implications for lean management research. It presents visually how LM as a research discipline has evolved since its creation and gives other researchers an idea where the field is headed. The most recent bibliometric network shows how dispersed the field has become and can help to identify unexplored fields of application.

One limitation of this study is the separation of periods into decades. To grasp the recent movement in the field better, a more fine-grained separation would provide more insights. Another limitation resulting from the research design is related to the choice of keywords. Some work has been done on the TPS and might not be considered in this study because of the focus on the term ‘lean’. The limitations of the method are the subjective interpretations of the bibliometric maps and the neglect of single studies due to the author level of our study.

Future literature research should aim to overcome these limitations. Potential for more further research seems to lay in the underrepresented areas of lean services, sustainable manufacturing, and the application of LM in specific processes or industries.

Abstract

Effective lean adoption requires running Kaizen events (KE) effectively. Yet, the behavioural tendencies of each of the team members involved in such events often hamper KE outcomes. This longitudinal study examines whether team members’ awareness of their own and team members’ problem-solving styles impacts KE effectiveness. After a survey about these styles, we video-filmed two events of nine kaizen teams: One prior to and the other after a team workshop intervention that boosted members’ awareness of these tendencies. Our finding is that being aware of one’s own and team members’ problem-solving styles has an impact on KE effectiveness and behaviours.

Keywords: Lean/Kaizen, Problem-solving style, Team effectiveness

Introduction

A key aspect of lean management is the mastery of kaizen. Kaizen stands for ‘improving for the better’ and is a fundamental mind-set of the lean philosophy (Liker, 2004). Moreover, a Kaizen event (KE) (Bicheno and Holweg, 2000) is defined as “a structured project performed by a multi-disciplinary team with the aim of improving a targeted work area or process in a given timeframe” (Bortolotti et al., 2018, p. 555). Being able to solve problems and implement improvements through KEs is critical for the effective adoption of lean (Bessant et al., 2001). Typically, KEs are one-hour, half-day, full-day or, occasionally, five-day group events (Glover et al., 2013). Effective KEs improve work-floor operations, stimulate employees’ problem-solving capabilities and create a positive attitude towards continuous improvement (Bortolotti et al., 2018).

However, if a KE does not lead to improvements, employees might get frustrated and resist participating in future KEs (Glover et al., 2013). But why are some kaizen teams effective in solving problems whilst others are struggling? Farris et al. (2009) distinguished various team (input-process-output type) determinants of effective KEs. An
important team-process factor is intra-team member interaction (Farris et al., 2009). The behaviours involved in such an interaction are known to affect (the emergence of) team processes (Kozlowski, 2015). One specific individual characteristic that may contribute to the effectiveness of behavioural interactions during KEs is team-member’s problem-solving style (Buffinton et al., 2002). The current study started by assuming that people’s awareness of their own and peers’ problem-solving styles can help (kaizen) teams increase their effectiveness (Gardner and Martinko, 1996). This paper offers an initial result of our examination of the question: How does team-members’ awareness of their own and peers’ individual problem-solving style affect individual behaviour, the process and outcome of Kaizen events?

**Theory: Kaizen Phases and Personal Styles**

Most kaizen studies consider kaizen to be a whole event (e.g., Bortolotti et al., 2018; Farris et al., 2009; Glover et al., 2013). In practice, however, kaizen is a structured, phased team approach to problem solving. Table 1 summarizes a selection of popular problem-solving instruments. Each instrument uses different labels, and the number of phases range from four to nine. After content analyses of each of these and other seminal sources, six basic phases of kaizen were distinguished (Table 1: left column).

<table>
<thead>
<tr>
<th>Table 1 – Overview of the Phases of Popular Kaizen Instruments</th>
</tr>
</thead>
</table>

All reviewed instruments emphasize that to be most effective, the KE phases should be performed in a particular order. Hence, KE effectiveness is widely assumed to depend on the ability of the team to perform each subsequent phase in an orderly manner (Kepner and Tregoe, 1965; Liker, 2004). Orderly here means that the team, after reaching consensus about the result of each phase, continues to the next phase, without the need to return to a previous one. Each kaizen phase has a particular goal (Table 2). Although open team-member discussion is key during a KE, a specific orientation and related core question ought to be addressed during each phase (Kepner and Tregoe, 1965; Liker, 2004; Shingō, 2007). Asking and answering phase-specific questions appropriately requires
each team member to have specific KE capabilities. Team members’ individual behavioural contributions, in terms of knowledge and skill, to each KE phase can thus be seen as crucial for KE’s effectiveness (Hackman and Morris, 1975; Wagaman et al., 2005). The general team-effectiveness literature acknowledges the influence of team member’s personal styles on the effective composition of teams (Mathieu et al., 2017). Different personality types or styles develop different capabilities, skills and preferences that can show up in team behaviour (Jung et al., 1964). The effectiveness of a KE is thus likely to be dependent on members’ problem-solving styles and the consequent behavioural display in each phase (Buffinton et al., 2002).

To link personal problem-solving behavioural tendencies to the kaizen phases, we used the Myers and Briggs model which operationalises Jung’s seminal theory of psychological types (Gardner and Martinko, 1996). The four dichotomies denoted in the Myers-Briggs Type Indicator (MBTI) are: source of energy (extraversion vs. introversion), mode of taking in information (sensing vs. intuition), decision making (thinking vs. feeling), and lifestyle (judging vs. perceiving) (Gardner and Martinko, 1996). While the model has been critiqued for its explanatory value (Stein and Swan, 2019) it is widely used for increasing people’s awareness of their own personal preferences at work (Gardner and Martinko, 1996). The different preferences within MBTI’s four dichotomies seem to be closely related to the key questions in the kaizen phases ( Hirsh and Hirsh, 2007). Although KE team members typically embody a (random) variety of MBTI preference styles, part of this research explores to what extent certain MBTI preferences ought to be more dominant in each kaizen phase. Given the predominance of task-orientation during KEs, only three of the four MBTI categories were mapped with the KE phases: taking in information, decision making, and lifestyle. Source of energy is not taken into account in Table 2 as it is assumed that both people with a more extraversion style and a more introversion style are just as good at showing the key capabilities described in Table 2. We expect that if people are aware of their problem-solving styles, the process and outcome of KE improves. Moreover, we expect that individuals will feel more capable in particular KE phases: those that match their own problem-solving style best.

Design/methodology/approach
We video-filmed KE team members’ contributions to two KEs about real-life problems within their team. Figure 1 displays the time points, over a period of two months, in which we collected the survey data and engaged in the awareness-raising intervention.

Sampling
After a pilot, ten kaizen teams within two Dutch knowledge-intensive organizations were approached, based on convenience sampling (Barratt et al., 2011). Nine teams (in total 42 members) participated in the study: on average five members per team, see Table 3.

Measures
At T1, each team member’s personal MBTI style was measured using the MBTI instrument (Hirsh et al., 1992). The instrument consists of 88 forced-choice items. Best-fit types were determined following official MBTI procedures.

We video-taped each team’s KE at both T2 and T4 in order to be able to code members’ behaviours per kaizen phase.

Perceived KE effectiveness was assessed immediately after each of the two filmed KEs. Based on the Team Diagnostic Survey (Wageman et al., 2005), a composite measure
that incorporated both technical and social KE outcomes was applied (Farris et al., 2009): 1) productive process, three sub scales with a total of nine items e.g., “Our team often comes up with innovative ways of proceeding with the work that turn out to be just what is needed”; 2) team interpersonal process, two sub scales with seven items in total e.g., “Working together energizes and uplifts the members of our team”; and 3) individual learning and well-being, three sub scales with a total of ten items e.g., “I learn a great deal from my work with this team”. All items were scored on a 5-point Likert scale, ranging from 1 “totally disagree” to 5 “totally agree”. Although the instrument was chosen because of its proven validity, the Cronbach’s alpha analysis of our study was poor so two sub scales and in total 13 items had to be removed. The reliabilities of the remaining sub scales at T2 were between .51 and .76.

The survey at T2 and T4 also measured team member’s perceived capability in each phase of kaizen: with a newly-developed questionnaire consisting of 48 items with a 7-point Likert scale ranging from 1 “totally disagree” to 7 “totally agree”; six sub scales consisting of eight items per kaizen phase. The items dealt with the required type of behaviour within each kaizen phase. They were constructed with the help of five lean master black belt consultants each of whom had over ten years of lean experience. After eliminating two items, the six sub scales had acceptable to good Cronbach’s alphas, ranging between 0.65 and 0.82 (T2) and between 0.65 and 0.84 (T4).

At T3, each team participated in a workshop during which the members first discussed the six kaizen phases. Then, they received feedback on their personal styles related to each phase of problem solving (as in Table 2). Moreover, a visualised KE-behavioural team assessment (of T2) was fed back to them. Immediately afterwards, they assessed the workshop quality with seven survey items e.g., “The provided knowledge is interesting”, on a 7-point Likert scale ranging from 1 “totally disagree” to 7 “totally agree”. The mean quality rating was 5.80 (s.d. = 0.43; 69% response rate).

Data-analysis
We calculated the means of each of the KE effectiveness variables and executed one-tailed t-tests to verify the expected improvement between T2 and T4.

The KE videotapes were transcribed and minutely coded in terms of members’ contributions. Each remark from every single participant was categorized into one of the six kaizen phases, based on the code rules created in Table 2. These categorized member contributions were then plotted over time. The resulting team graphs visualised what happened during the subsequent phases of the two KEs (Figure 5).

Finally, we analysed to what extent members rated themselves as more capable at T4 compared to T2 in terms of the kaizen phases that we expected to fit their MBTI functional and lifestyle styles (Table 2). Each participant was thus categorized twice. We then performed a one-tailed t-test, since we expected an improved link, after the workshop, between best-fit MBTI styles and perceived capability in the related kaizen phases.

Results
Table 4 shows the perceived KE effectiveness per team, both at T2 and T4. Only three teams improved (marginally) significantly on some of the KE effectiveness variables. Surprisingly, in this table one may also notice some drops in perceived KE effectiveness: due perhaps to people’s increased self-awareness of their own and team member’s behavioural shortcomings.

To provide a more detailed example of the video-based analysis, Figures 3 and 4 show the result of the minute coding of team 4’s video-taped KEs at T2 and at T4. Regarding KE process effectiveness it can be seen that after the intervention the team showed a more

phased approach. Specifically, at T4 (in Figure 4) the team engaged in a root-cause analysis phase after its problem-definition phase. A root cause analysis phase was not clearly visible at all at T2 (Figure 3). Figure 5 shows a visual comparison of the video sessions at T2 and T4 of all the studied teams. From this Figure we find that, at T4, teams typically spent more time on defining the problem, and most teams took a more structured or gradual approach: according to the ideal-typical KE phases.

Table 5 reports the results of the changes in the respondents perceived capabilities in their preferred phase (linked to their best-fit MBTI style). Significant changes were found for the functional styles, esp. for the team members who indicated a preference for the ‘Plan implementation’ phase. An even stronger intervention, or more (or less) time between T3 and T4, is likely to lead to more remarkable changes in terms of the exposed preference style (see Table 5). Although not always visible in their perceptions, the people certainly showed an increased individual awareness of personal problem-solving style during the KEs at T4. Various quotes from the participants during and after the workshops at T3 and T4 support this (Table 6).

| Table 5 – Perceived Kaizen Phase Capabilities in Terms of Function and Lifestyle MBTI Styles |

**Discussion**

We explore how KE member’s awareness of own and others’ problem-solving styles affect the effectiveness of KEs. We undertook a multi-case analysis of combining behavioural profiling with an innovative micro-behavioural video-method as well as customized feedback and an awareness-rising workshop. After the workshop, whose aim is to raise members’ behavioural styles awareness some teams demonstrate a positive effect in terms of a more phased KE process. In terms of KE outcome effectiveness: both positive and negative changes are found regarding different elements of team effectiveness. Moreover, individuals feel increasingly capable related to their preferred phase of problem solving. The preliminary findings are linked to Buffinton et al.’s (2002) suggestion that problem-solving styles and project teams’ interpersonal dynamics are critical factors for effective team functioning. Moreover, Kozlowski (2015) refers to the critical role of team processes in resolving team task demands. Hence, this exploratory
study shows the potential for further investigations of how people’s awareness of their own and team members’ styles may contribute to KE effectiveness. Possible pathways are expanded below.

The video data could be analysed more extensively. The video analyses of the KEs at T2 and T4 show interesting visual changes in terms of KE process. We may need to come up with a more objective comparison between T2 with T4 across the teams. Coming up with a measurable indicator (i.e., a slope coefficient) that justifies the phased approach should be part of future discussions and research with statisticians and academic peers.

In terms of limitations, all the measurements occurred immediately after the intervention hence, the long-term impact of personal problem-solving style awareness on KE effectiveness has not been taken into account yet. Another point is that we left the source of energy (extraversion/introversion) out of the scope. This should be included in future research. It can be argued that one’s source of energy will influence KE process performance in line with a team’s action orientation (Farris et al., 2009). Of course, larger-scale studies that include control groups are warranted. They may enable further fine-tuning and validation of the self-developed scale which we used to assess team member’s perceived capability in each kaizen phase, plus more robust statistical analyses with more reliable KE outcome measures.

Although this study uniquely focussed on the factor of problem-solving style awareness within teams, no other factors were taken into account, e.g., KE’s goal clarity (Farris et al., 2009); The teams were instructed to solve a problem of their own day-to-day work. Each team session had to start with the question: “How do we solve...?” In effect, the videos showed members’ mutual collaboration as well as the maturity with which teams were able to perform kaizen. The established fact that not all teams followed a neat KE process, as shown in Figure 5, might be related to the degree of team kaizen experience (Farris et al., 2009). In future behavioural KE research, specifications of the problem-solving phases to be followed by a team might need to be matched to the nature of the status of the particular problem at hand. Explicit articulation of the required phases on each KE agenda might indeed help the members to stick better to what the problem requires rather than to let their behavioural preference determine the KE process.

This study contributes to our understanding of the individual as a component of kaizen and to what extent awareness of team members’ diverse problem-solving styles should be present in a team to be successful in kaizen. While most prior kaizen research focused on team functional heterogeneity (Farris et al., 2009), perhaps focusing on member’s contributions per KE phase would illuminate problem-solving style heterogeneity. Although it may not always be possible to compose teams based on members’ problem-solving styles in practice, people’s awareness of their own and peers’ styles is found to contribute to KE effectiveness. The practical relevance of our work is further evidenced by the positive responses of our respondents and their requests for additional tools to make effective use of their behavioural preferences in team settings. Understanding kaizen as a phased approach, including its enablers at the individual and team level, provides a new line of research in which many interesting questions can be explored.

Value Stream Management:
From Dysfunctional Organization to Cross-Functional, Collaborative Learning and Improvement

Daryl Powell (daryl.j.powell@ntnu.no)

Abstract

A value stream is defined as the set of all the specific actions required to bring a product through the three critical management tasks of any business: the problem-solving task, the information management task, and the physical transformation task (Womack and Jones, 1996). However, the popular Value Stream Mapping tool (c.f Rother and Shook, 1999) simply reduces the value stream to the information management and physical transformation tasks. In this paper, we present an alternative method for value stream mapping that also incorporates the problem-solving task. What emerges is a cross-functional approach to learning and improvement.

Keywords: Lean Production, Value Stream Management, Continuous Improvement

Introduction

Lean Production was popularized as an alternative approach to production management in the 1990s. In The Machine that Changed the World (Womack et al., 1990), the Lean Production paradigm was presented as five parts of a system (i.e. the Lean Enterprise): Dealing with the customer, Designing the car, Running the factory, Coordinating the supply chain and Managing the enterprise. The cross-functional nature of the Lean Production model was therefore well-defined from the outset. However, in subsequent years, Lean Thinking has in many instances simply been reduced to ‘something for factory operations and shop floor management’.

As such, Value Stream Mapping (VSM) has become one of the default tools for organizations embarking on a lean journey. Spawning from what is referred to as Big Picture Mapping or Material and Information Flow Mapping at Toyota Motor Company, VSM was popularized in the book Learning to See (Rother & Shook, 1999), which unfortunately covers only the “door-to-door” production flow inside a plant. Though this is perhaps a good level at which to begin a “mapping and lean implementation effort”, many companies neglect to scale up their efforts in order to see value streams across the entire enterprise, focusing simply on value analysis and disregarding value engineering. For example, more recently, Sakai (2018) highlights the Toyota Product Development
System (TPDS) as the key to Toyota’s success, suggesting that an overemphasis on Toyota Production System (TPS) alone has resulted in many failed lean transformations in the West. Sakai presents TPS simply as an “efficient duplication system” and indicates that developments around the Shusa (Chief Engineer) System and use of Obeya in the product development process is the real secret behind the success of Toyota – through creating constancy of purpose and cross-functional clarity and alignment.

In this paper, based on the authors’ practical experiences from an action research initiative, we present an alternative approach to value stream mapping that encompasses the organization in its entirety with the aim of fostering cross-functional collaboration, learning and improvement.

**Value Stream Management**

A value stream can be defined as “the set of all of the specific actions required to bring a specific product (whether a good, service or, increasingly, a combination of the two) through the three critical management tasks of any business: **the problem-solving task** running from concept through detailed design and engineering to product launch, **the information management task** running from order-taking through detailed scheduling and inventory, and **the physical transformation task** proceeding from raw materials to a finished product in the hands of the customer” (Womack and Jones, 1996). Seeing, understanding, managing and improving value streams as they cut across the different functions (often starting from traditional, functionally organized enterprises) is fundamental to lean thinking and practice. As such, Value Stream Mapping (VSM) has become one of the default tools for organizations embarking on a lean journey and a core requirement for effective Value Stream Management.

However, VSM efforts often fail to cut across such functional borders, typically covering only the “door-to-door” material- and information flows inside a plant. In doing so, organizations omit a wealth of improvement opportunities that are to be found at the interfaces between functions – for example Research and Development, Engineering, Supply Chain, Sales, and Customer Support. As such, a major weakness that we observe in this traditional approach to VSM is that many companies neglect to scale up their efforts in learning to see value streams in their entirety, i.e. scaling efforts from what Womack and Jones (1996) define as the information management and physical transformation tasks to also include the problem-solving task, as well as capturing additional important information once the product has indeed found its way into the hands of the customer, what we shall refer to as the maintenance and end-of-life tasks. This effort requires input and collaboration spanning the entire organization in order to encourage value stream learning and improvement at the organizational level rather than purely at the business process / function level.

While value stream maps are powerful tools for improving manufacturing / production workflows (Martin and Osterling, 2014), we advocate that they are even more powerful when used to visualize entire value stream “work systems”, often uncovering organizational disconnects and unnecessarily complicating business processes and practices, that are otherwise unknown to other functions / stakeholders and make for a dysfunctional organization. This is particularly relevant for engineer-to-order (ETO) manufacturers, that do not typically exhibit highly linear material and information flows (Powell and van der Stoel, 2017). Therefore, in the following sections, we develop and present value stream mapping as a collaborative, enterprise-wide initiative to see, understand, manage and improve value streams in their entirety.
Research Design
As this investigation involves research in action rather than research about action (Coughlan and Coghlan, 2002), we adopt action research for our enquiry into the development and application of collaborative value stream mapping at the enterprise level. Action research can be considered as a reflective process of progressive problem solving led by individuals working with others in teams or as part of a community of practice to improve the way they address issues and solve problems (Stringer, 2014). As such, the authors have led a “reflective problem-solving process” with an ETO manufacturer. We take insight into the current lean transformation activities within a global division of a Norwegian technology and solution provider to the maritime industry in order to develop a value stream mapping tool based on swim lane diagrams. Powell and van der Stoel (2017) suggest that swim lane diagrams are a visual management tool that can be used to visualize value streams in ETO and take into account non-linear and returning material and information flows, as an alternative to traditional value stream maps. The technique was developed in order to visualize enterprise workflows and identify improvement opportunities within and between the organizational functions that constitute product-centric value streams.

Towards a Means for Cross-functional Value Stream Mapping
One of the authors has been actively involved in the lean transformation at KM Subsea since 2014. What began as a pilot implementation of lean thinking and practice in the production department quickly transpired into an organization-wide lean transformation, which subsequently earned the company the Norwegian Lean Enterprise of the Year Award in 2017. VSM has been used from the outset, first focusing on the door-to-door material and information flow using traditional VSM, and more recently encompassing all business functions throughout the enterprise using a swim-lane diagram type technique for mapping product-centric value streams.

A traditional, current-state value stream map can be seen in Figure 1:

Notice the linearity of the door-to-door material and information flows, as well as the ‘kaizen bursts’ (improvement suggestions arising from the mapping exercise). From such a current-state map, one would typically continue to develop a future-state map (Figure 2):
Notice here the grouping of two cells – what we may call the fabrication cell and the assembly and test cell. The idea of course is to create continuous flow, in this case decoupled by supermarket between the two cells. Notice also that the Assembly process has become the single pacemaker process, utilizing a pull system upstream and continuous flow downstream. This of course generates satisfactory results – increasing efficiency in the duplication process and maybe also favourably impacting the cost-of-goods-sold (COGS) on the balance sheet. However, when we begin to adopt an organization-wide view, we quickly begin to see that there are in fact many more improvement opportunities that can be realized, some of which automatically influence the decisions and requirements that are otherwise later needed in the shop floor operations.

Figure 3 represents a simplified enterprise-wide value stream map. Regardless of the efforts made in improving the duplication process (here labelled Production / Supply Chain) through value analysis, what we in fact discovered in the lean transformation efforts of KM Subsea was that there is much greater potential to be realized in re-focusing the improvement efforts to include other areas of the business as well, in particular the value engineering (value creation) processes consisting Product Management, R&D / Engineering, Sales and Marketing, and even Customer Support, functions which, together with Production / Supply Chain constitute the product-centric value stream (and in particular the interfaces between such functions).
Discussion
Rather than settling for the adoption of the popular “door-to-door” production flow perspective of value stream mapping, representatives from all business functions (product management, research and development/engineering, operations, supply chain, sales and customer support) at KM Subsea were assembled to map entire “product-centric” value streams as holistic work systems. The investigation showed that the physical transformation task and associated information management task that constitute the supply chain (or manufacturing) function were in fact the most streamlined and effective “tasks” within the enterprise. More importantly, during the process of “learning to see” the enterprise as a complete work system distributed across one or more value streams, the most significant improvement opportunities appeared to be found at the interfaces between different functions (e.g. product management and supply chain; sales and engineering; customer support and operations), or indeed within functions other than production/supply chain. This highlights the potential for adopting a more holistic approach to VSM, what we will refer to as enterprise-wide value stream mapping.

Conclusion
Value Stream Mapping (VSM) is a practical and highly effective way to learn to see and resolve disconnects, redundancies and gaps in how work gets done (Martin and Osterling, 2014). Unfortunately, however, there has been an all-to-common focus on applying value stream mapping as a tool for operational improvement in production (and in some instances supply chain) operations. In this paper we present swim lane mapping as an alternative technique for enterprise-wide value stream mapping. In line with Powell and van der Stoel (2017) we see the potential for such a mapping technique in ETO manufacturing in particular – engaging all stakeholders in cross-functional, collaborative learning and improvement.

This article presents the yet unexploited potential for enterprise-wide value stream mapping as a tool to foster cross-functional, collaborative value stream management – allowing all stakeholders in an enterprise to see, understand, manage and improve value streams in their entirety. We adopted a simple, effective tool (swim lane diagram) for visualizing value streams as complete systems of work, rather than simply focusing on the physical transformation of materials; and suggest that such a tool can be used by researchers and practitioners to promote organizational learning and improvement, particularly in technology-/R&D-intensive, engineer-to-order environments.

Abstract

Whereas lean production is widely adopted in industry, there is a gap in the current literature regarding studies that consider implementation of lean production from a regional context. Hence, this study addresses the impact and contingencies of regional context on the implementation of lean production. More specifically, the results of two case studies in Romania are presented and discussed. Data collection included in-depth semi-structured interviews as well as observations of processes. The results show that using four dimensions of regional context does influence the implementation of lean production and the operational performance of the company.

Keywords: Lean production, regional dimensions, case study

Introduction

Lean production has been widely implemented by companies in different regions with the aim to improve performance. However, the impact of regional context when implementing lean production remains a gap in the literature (e.g., Bortolotti et al. 2015, Bhasin 2013). Few studies (e.g., Hines et al. 2004) that have looked into this issue lack sufficient in-depth analysis. Therefore, this study sets out to investigate in detail the impact that regional context may have on the implementation of lean production.

Research Objectives

Thus, this study aims at asserting the influence of the regional context on the implementation of lean production. It has become apparent that a few number of firms that adopted lean production, which relates to organisation culture (Bhasin 2013). In this
respect, regional context covers what members of society share and what leads to behaviour of the people, i.e. employees, suppliers and managerial mind (Wiengarten et al. 2015). More generically, some (e.g. Yadav et al. 2010) assert that firms struggle with implementing the concept of lean production, thinking that Toyota’s success lies in their cultural roots and, hence, the concept is not transferable. However, Toyota has been successful in multiple countries, and not only Japan. Moreover, some (e.g. Kull et al., 2014; Wangwacharakul et al., 2014; Wang, 2008) have noted that the implementation of the concept of lean production varies for different regions, albeit without going into much detail. This study will address the gap about the adoption of lean production in regional contexts. Hence, the study addresses three research review questions:

1- To what extent the regional context contingencies affect the implementation of lean production as set of practices.
2- Are regional contexts a contingency for the design of lean production system?
3- How the regional context differs from a company to another?

To answer these questions, two case studies have been investigated in Romania, including an in-depth interviews and observation.

Outline of Paper

This paper is structured as follows. First, the literature review, which includes lean production and the regional context, is presented. Next, the methodology section, followed by an analysis of the papers. After that, there is a discussion of the findings. Then at last, conclusion of the study.

Literature Review

Before looking at the regional context, is necessary to look at what the concept of lean production constitutes. Although Womack et al. (1990) were the first researchers to propagate the conceptualisation of lean production, they never gave a specific definition for ‘lean thinking’. This lack of definition in literature about lean production has reverberated until today, as Petterson (2009) notes. The only ones that have given a more specific description (rather than definition) of lean are Shah and Ward (2007), who have mentioned that lean production is about socio-technical system. However, even lean production practices and principles vary; some researchers list as few as five principles (Womack & Jones 1996), whereas others list over twenty practices or principles with more details for every aspect (e.g. Kull et al. 2014; Shah & Ward 2003; Shah & Ward 2007; Yadav et al. 2010). This implies that the concept of lean production is relatively undefined.

Hence, this lack of definition for lean production offers a unique opportunity to evaluate literature; the distinction of two strands of research into lean production serves as base for the further analysis. Therefore, this section of the paper will look with more detail into two different lenses: (i) lean production as a set of practices, (ii) lean production as design of production systems and to the regional context.

Two Lenses for Lean Production

The first lens, lean production as a set of practices, considers the process that a firm follows for implementing lean production, its methods, and tools, and practices. The practices can be defined as ‘an activity or action which is performed to a standard which is better or equal to the standard achieved by other companies’ (Davies and Kochhar 2002, p. 290). The tools that can be applied on Just-In-Time, total quality management, kanban, total preventive maintenance (e.g. Flynn et al. 1995; Shah & Ward 2003; Shah & Ward
2007). Lean practices lens is what most studies are addressing, what are those practices, what should be considered fundamental practices for implementing the lean production.

More specifically, some studies categories practices for lean production (e.g. people, process, tools). Shah and Ward (2003) grouped the practices into four categories: Just-In-Time (JIT), total quality management (TQM), total preventive maintenance (TPM), and human resource management (HRM), while this has 22 lean practices. Rahman et al. (2010) enumerate 13 practices out of the practices identified by Shah and Ward (2003) and they have grouped them in four categories. Moreover, Shah and Ward (2007) divide 10 factors into supplier-related, customer-related and internally-related (the process inside a firm). Chavez et al. (2013) describing the internal lean practices that is mostly used on a shop floor of a firm, in another word hard practices and its effect on other dimensions such as quality and flexibility. Several studies have addressed lean practices in a different way by dividing them into two: soft practices and hard practices, such as (Kochan & Lansbury (1997); Rahman & Bullock (2005); Shah & Ward (2003); Yang et al. (2011)). Whereas, soft practices are focusing on people, for example, managerial practices and relationships (i.e. continuous improvement, top management leadership, and customer and supplier involvement), hard practices are concerned with technical and analytical tools, for instance, statistical process control and Kanban (Bortolotti et al. 2015). The latter also noted that the reason that most companies struggle with adopting lean production or getting the success they are looking for, resides mostly in ignoring soft practices and applying only the hard practices. Some practices may not be suitable for other region’s employees; in this respond, Oudhuis and Olsson (2015) noted that regional differences should be taking in to account before implementing a production system. This all indicates that contingencies related to regional context may have a noticeable impact on the implementation of lean practices.

The second lens concerns the application of lean production principles (Bhasin 2012) to the design of production systems. For example, Low et al. (2015) study how to apply the lean principles to the design of a factory. In this strand of research, some studies use the principles for designing the firm, whereas (Black 2007 and Sobek II et al. 1999) fall back on the ‘pure’ Toyota production system. In addition, there are studies mentioning the lean principles for production as key to the design of production system (Black 2007; Mund et al. 2015; Low et al. 2015; Sobek II et al. 1999; Yadav et al. 2010). According to Yadav et al. (2010), the Toyota production system can be captured by four basic rules: (i) activities (how people work); (ii) connections (how the people connect); (iii) how the production line is constructed (pathways); and (iv) continuous improvement. According to Low et al. (2015), there are 11 key principles for lean production and the core is reducing the non-value-adding activities.

Some studies addressed applying the different principles on different regions without generalisation of the regional contexts such as Low et al. (2015) and Yadav et al. (2010). On the other hand, Sobek II et al. (1999) believed that applying the design principles of the Toyota production system is not related to the regional contexts. This all points to the necessity for evaluation whether contingencies related to the regional context have an impact on the design of production system.

**Regional Context**

For both lenses - lean production as a set of practices and lean as design of production system – contingencies related to the regional context need to be further specified, four dimensions could serve as initial classification (Aldossary et al., 2016). More specifically, the distance between a supplier and a manufacturing company to expand the most benefits from JIT (Cook 2001); also Arkader (2001) mentioned the location as barrier to JIT.
Culture differences between two nations (Wangwacharakul et al. 2014) or different cultural perspectives in an organisation, which includes the employees’ relations and issues; which leads to cultural dimension. Another dimension concerns that get in the way of doing the business or smoothing the flowing of goods from a location to another or from a supplier to a company, as few studies described it as regulation and certificates (see Maleyeff et al. 2012; Rodgers & Wong 1996), which can be named as legislative dimension. Finally, considering the different ways that an organisation can look at its financial performance that may be a challenge in the implementation, as well as not having the right investment to help with the implementation change (Ketokivi & Schoeder, 2004), which can be linked to a financial affect. The geographical, cultural, legislative, and financial-economic dimensions can serve as classification of contingencies within regional context.

**Research Methodology**

Given the limited literature on this topic, and with the aim to achieve a deeper understanding of the effects related to regional context on the implementation of lean production, the study applied an exploratory multiple-case study methodology (Creswell 2003; Yin 2009). According to Eisenhardt (1989), case studies are useful when the phenomenon has not yet received appropriate ascertainment within the literature and when theoretical knowledge lacks clearness with respect to underlying issue. Moreover, multiple cases may help to understand the meaning and nature of real-life events, such as processes, relations and changes on organisational and individual levels (Yin, 2009).

In this respect, and for the explorative purpose aimed towards understanding, the empirical data for the case studies was collected through multiple methods and sources (Miles & Huberman, 1994; Yin, 2009). These included mainly semi-structured interviews and observations. Multiple interviews with top management and shop floor employees were conducted which lasted between 60 and 75 minutes. The interview data were supplemented with data collected through secondary sources, such as, project documentation, company guidelines, and web sites, and observations during the guided tours in the companies.

**Case Study R1**

The first empirical case (R1) concerns a manufacturing company in the aerospace industry. The company is in the medium size range with number of employees between 200 to 300 employees. R1 was founded in 2010 and the design of lean production was implemented from the beginning, adopted since they are a subsidiary of a conglomerate. Company R1 a full-service company includes extrusion, machining, and assembly into a single facility. Which serve customers all over the world from the far west as the United states to the far east Japan and China.

The value chain process followed by the company involves five main steps: (i) billet casting, (ii) extrusion, (iii) machining, (vi) surface treatment, and (v) assembly. In those steps for the analysis of the case study, they were assessed and investigated based on the dimensions mentioned before. Taking in perspective the plant size of the company, which almost includes three plants in one, which are the main three extrusion, machining and assembly. The delivery time of the company if the external suppliers are not involved the time is 8 days, however, when external suppliers get involved the time varies with no certainty.

**Case Study R2**

The second empirical case study (R2) is also a company in the aerospace industry, they focused on overhaul. Also, the company is a medium-sized company with the number of
The company started implementing lean production with aim to cut waste, identification of internal benchmarks and giving ideas and concepts for specific problems. Therefore, they are using five steps of the product line; starting with (i) the product comes in to the plant, (ii) the company assessed the product, (iii) orders placed for needed parts, (vi) components get reassembled, and finally (v) components are shipped back to the customer. The delivery time varies in between minor to major remanufacturing on the unit. The delivery time from the unit register to the plant to the time of leaving the facility ranges between 3 months to 18 months.

Results and Findings
The analysis followed the general thematic analysis approach indicated by Braun and Clarke (2006): i) familiarisation with data, ii) coding, iii) searching for themes, vi) reviewing themes, and vii) defining and naming themes. Interview and focus group transcriptions were coded, checked and rechecked throughout the coding process for consistency. Whereas some themes were already latently found in literature discussed at the previous section, the analysis of the data gave rise to additional themes. The themes were reviewed and re-categorised resulting in to four main themes (Table 1), also can see Aldossary et al. (2016). The following sections will discuss in detail the findings of each dimension. The themes also

Geographical Dimension
The geographical dimension, is concerned with the location of companies, location of suppliers being in a cluster (Porter 1998), the relationship between the company and their supplier, and any geographical barriers related to the implementation of lean production. Whereas company R1 can manufacture all the necessary parts in site, there are cases when it is required to order these from external suppliers. More specifically, there are certain customers who may require from R1 to use specific external suppliers. These suppliers can be based in different places either in the U.S. or in Europe, consequently, R1 faces constant challenge with time deliveries. For example, a delivery to the US may take up to six weeks, which exceeds standards of R1 of time deliveries to customers. Similarly, is the situation when a shipment goes to the far East (e.g. China).

Company R2 manufactures some parts, meaning that their inventory level has certain parts that are used commonly. However, when it comes to certain parts related to the core of engines, these are all supplied from two external suppliers based in central-west Europe. These two suppliers, based in different countries, will have to be involved for the remanufacturing of one component. As a result, depending on the condition of the unit received, the delivery time from the external suppliers can take 2-3 months for minor remanufacturing and up to 18 months for major remanufacturing. As a senior manager of R2 explained, that makes it very hard to meet the delivery time; mainly because most of the times the suppliers will take longer time in delivering the parts.

Hence, due to geographical proximities, both companies R1 and R2 are facing challenge with the delivery of parts. In company R1 the main issue appears to be the distance, and for company R2 distance as well as uncertain delivery coming from suppliers’ contingent on the state of parts. Finally, both companies are also affected by the poor infrastructure of the region they are based in; which can significantly increase the lead-time for logistics.

Cultural Dimension
The second theme concerns the cultural dimension which is focusing on the employees’ behaviour towards lean implementation. In the case of R1, from the beginning
of the company’s found the company was designed to implement lean production system; and therefore, the employees did not go through any transformation period. Irrespective, it is important to note that R1 operates in the north of Romania. Specifically, in this part of the country, people have a high level of education, and at the same time, they are very family-oriented meaning that employees prefer to work close to their hometown with most of them willing to do so, even if it means there will be less pay. This is clear in the case of R1 where more than 90% of the employees come from the same region. But the company is having very skilled and well-educated employees, due to the strong family oriented mind-set in this part of the country, businesses do not operate during the weekends. That means that R1 is not able to receive or send deliveries of parts during the weekends, which reduces the flexibility to respond to logistic perturbations.

Opposite to first case, R2 did not have a lean production system from the beginning, and therefore, when the management decided to implement lean production practises and lean design of production system, all the employees had to go through a transformation period. As a result, management faced challenges with employees accepting the change. As a senior manager explained, it has taken a lot of time and effort to smoothly transit to lean production and even now (at the time of the interview), they are still dealing with some negative attitudes from employees who find this system more demanding.

**Legislative Dimension**

The third theme, legal dimension, is mainly related to certification of some aerospace parts and the intellectual property agreements that the companies must obey. This means that without the necessary agreements, the company cannot produce certain parts they need. The legal dimension also concerns with the legal agreement that links each company with suppliers overseas. These legal issues contribute on the factors that affect the implementation of lean production. Whereas, companies R1 and R2, have this dimension as a contingency on the implementation of lean production, the legal factors are recognised as a way for controlling in this industry. For instance, in R1 there are fixed contracts with certain customers indicating that the customer’s suppliers must be used on producing a product to that customer. Furthermore, they are certifying the products and some parts the companies R1 and R2 produced by the top customers in the industry.

**Financial Dimension**

The fourth and final theme, financial dimension, concerns the investment of implementing lean production and the plants’ layout. In this regard, company R1 has invested heavily on the plant, and they are expanding the volume of production for the plant to reach its full capacity. Moreover, R1 is planning strategically to have another plant ready when the capacity of the first plant hits the maximum. At the same time, also tries to have duel source of producing all the parts needed to cut their costs and save time. However, the extrusion part of the company is in full capacity, and it causes delays to the other parts of the plant such as assembly line.

In Company R2, the case is slightly different. The budget for investing on the design of the production system is very limited, and the company tries to develop year by year. The flow of the units is not as smooth as it should be, but the company is making the most of the resources they have. Despite all the shortages in budget regarding the design, R2 is functioning is high-quality outputs.

The results of the two case studies confirm that the regional context does have an impact on the implementation of lean production. For instance, the cultural dimension within company and country shows a variety of aspects that have an impact on the implementation, such as; the employees’ acceptance of change. Moreover, from the
geographical perspective, it is shown that the location of suppliers plays a considerable role in the implementation of lean production since both companies had first-tier suppliers abroad. Also, looking at the financial dimension of the companies, the support for the transformation of the production system varied from one company to another. Finally, the analysis of the legislative dimension in this study revealed challenges regarding intellectual property rights; more specifically, exclusive suppliers that were holding these rights for certain parts impeded on the flow of the production line, as the parts are only allowed to be produced from certain company.

In comparing the two cases, cross-case analysis was used to identify similarities and differences. Table 1 shows the findings of each case as well as the cross-case analysis of the two cases conducted.

</table>
| Geographical dimension             | • Difficulty in connecting with customer and suppliers outside of EU, 6 weeks’ shipment  
• Ideally one week is delivery time out of the plant  
• Delivery time sometimes gets delayed if external suppliers involved  
• Unpredicted the external suppliers with deliveries  
• Some customers prefer to be in reach with them location wise (not possible) | • The company deals with customers all over the world  
• Delivery time is not that accurate as dealing with multiple local and external suppliers  
• Using mainly external suppliers in EU  
• Issues in delivery with customers in outside of EU  
• Overall, quality wise is top in EU few times | • Delivery time goes beyond expected if shipping outside of EU  
• Using external suppliers that slows JIT |
| Cultural dimension                | • In this region ‘up north’ workers prefer to work at the same place as where their family (parents) live  
• Workers are family oriented  
• All workers here ‘north’ are educated  
• Minimum with a bachelor's degree, no less  
• Weekends are out of business for the company as well as delivery  
• Sometimes teamwork between plants are difficult, ‘they would give each other hard time to help out’  
• 12% is the workers turnover (avg. in region) | • Employees not happy with the change  
• Took time and effort to get into the change  
• Supportive top management but lower level workers nor cooperative with the change  
• Employees wanted to free times they had with the previous system  
• Number of training to be added  
• Knowledge of lean in not quite high between the workers | • Employees prefer living where the family lives (hometown)  
• Highly educated in the North  
• For old workers accepting the change to lean was not very successful  
• Shipments are limited to mid-week |
| Legislative dimension             | • Fixed contracts to have customers’ parts to be used in product they ordered.  
• Having the company dealing with the customer’s suppliers  
• Some parts have to be delivered by externals suppliers in IP rights  
• Produced any parts they need if no IP restrictions  
• Big customers to visit plant and check quality themselves | • Certifying parts by big companies  
• All crucial mechanical parts from external certified suppliers outside of Romania  
• Company R2 authorise local suppliers | • Having main certified suppliers in EU – close in distance  
• Customers to certifies new products, as well as top companies in the industry  
• Contracts to link companies with certain suppliers of customers |
| Financial dimension               | • Fully supported financially  
• Manufactured what they need to cut off costs and relatability on suppliers  
• Intended to improve the production line by cutting off extra ‘check points’  
• Having dual source of getting parts  
• Intention of extended the plant To improve capacity | • Budget and investment of change is limited  
• Developing slowly  
• Using the plant layout as best for the budget  
• Layout is semi flow smoothly  
• Needs more development | • Design of plant is sufficient, it is developing to the best standard  
• Cut on costs as possible with local suppliers or manufacturing parts |

Table 1 cross-cases analysis of contengencies related to regional contex
Discussion of Findings

The first finding of this study is related to the financial investment of R1 and R2 on the design of the lean production operation system and the layout of the plant. In R1, the philosophy of was introduced when the company was founded; therefore, the company is accustomed to the system from the beginning, as well as having the footprint set for the production system. In the case of R2, the company started implementing lean production in 2012, and due to poor financial support they had a limited design developed to have the best design of the production system. The R1 has very slight disruption in the flow of the products, where the reason relates to the full capacity reached of the extrusion part of the plant and the unadjusted machines in the machinery side of the plant. However, in R2, the disruption in the flow of the units is caused due to the design structure not being on the highest standard, and not having considered and included all the necessary aspects as discussed by Black (2007) and Sobek II et al. (1999). Hence, the financial dimension plays a crucial role and more specifically, the limited investment affects in a high degree the design of the lean production system and therefore the operational performance of the companies.

The second finding concerns the effect of the geographical dimension has on the implementation of lean production. The location of the suppliers and ease of the supplier access play huge role in the success of applying the lean production. It was found that JIT is the practice mostly affected by the supplier access and location. For instance, company R2 is dealing mainly with two main external suppliers outside of Romania, which proves to be as one of their biggest challenges causing shortages in delivery time and delays. The situation is slightly different in company R1, it goes mostly the other way around which is the delivery to the customers. In both cases, once the supplier is located outside of the country and with the weekend work restrictions, that makes the impact on this dimension more tangible on the implementation. Therefore, the geographical dimension is found to be a barrier for successful implementation of lean production practices such as JIT, Kanban and Kaizen. This finding of the role of geographical dimension on the lean production practices supports the findings in literature of Cook (2001, p. 967) and Arkader (2001, pp. 91-2). Moreover, according to the analysis of the data gathered from both case R1 and case R2, it is evident that the role of the geographical dimension is the most challenging one for successful implementation of lean production.

The third finding is related to the organisational and regional culture. Our findings agree with the suggestions of Bortolotti et al. (2015) and Semeds (1994) that the organisational culture of a company may have significant effect on the successful implementation of lean production. More specifically, in case R2 the management faced the challenge of having the change to the lean production system. The acceptance is not easy from the employees’ side. The company had to face some issues they have dealt with in some ways as they explained. Moreover, regarding the cultural dimension, the people who live in the north part of the country tend to be more educated and family oriented, who does not prefer to be working away from their hometown. As a cultural background of Romania with some ties of the religious beliefs, the weekends in the country is blocked, the companies R1 and R2 are affected by this, as they are unable to make deliveries during the weekends.

The fourth and final finding in this study is about the legal dimension and how it may affect the implementation of lean production. The two companies mainly dealing with companies for the parts needed. Some of the companies are involved in certifying a product to be sold to top customers. Furthermore, some of the top customers relate their suppliers to be in link with Company R1. For example, if R1 want to have business with one of the leader in the industry, that customer requires R1 to deal with all materials
needed from the same supplier they deal with. Company R2 on the other hand, the suppliers they deal with are externals, and they are the ones who certify the R2 products based on legal ties. The reasons for having the connection only with these external suppliers is the intellectual property (IP) holders for certain parts; and therefore, the parts must come from them. Hence, whereas it is acknowledged that this dimension may affect in some degree the implementation of lean production, the companies have little to no control on most of the legal issues.

The four findings of this study show how regional dimensions can have different effects on the successful implementation of lean production. It is concluded that the most dominant regional dimension with the highest degree of effects is found to be the geographical dimension and the one with the least important effects is the legal dimension; it has effect but it could be mitigated.

**Conclusion**

The results of the case studies show that successful implementation of lean production is affected by dimensions related to the regional context they operate in. Therefore, this investigation study overcomes shortcomings of previous studies that have not considered this in sufficient detail. Hence, the conjectures and findings add new insight to the current literature. These findings are expected to give direction to managers about the successful implementation of lean production using the four dimensions.

Abstract

This study aims at investigating the effect of lean-related work aspects on employee well-being. Based on the job demands-resources theory, we propose that soft lean practices (SLP), acting as job resources, and negative lean-related job characteristics, acting as job demands (JD), interact each other in affecting employee work engagement and exhaustion. Data from 147 shop-floor workers from a multinational manufacturer supports SLP positive effect on engagement and JD negative effect on exhaustion. Moreover, there is evidence of a signficative interaction supporting that SLP may reduce JD negative effect on exhaustion, and that JD may enhance SLP effect on engagement.

Keywords: Lean Management, Soft Lean Practices, Employee Well-being

1. Introduction and Purpose

The impact of Lean Manufacturing (LM) on employee well-being has been discussed in many fields such as OM, applied psychology and industrial relations (Hasle et al., 2012). In spite of many contributions from different literature streams, the debate is far from being closed. Scholars have recently assumed a fine-grained perspective onto the question, going beyond the simplistic view that LM is either totally good or bad.

This research intends to contribute to this debate by analysing whether and how positive and negative lean-related job characteristics in a lean company can influence employee well-being, in terms of work engagement (ENG) and exhaustion (EXH).

In comparison to previous research, a first element of originality of this study is the adoption of a relatively novel psychological model to address this research question: the Job Demands-Resources model (JDRM - Bakker and Demerouti, 2017). This is particularly valuable since the purpose of the present research is to account for both positive and negative lean-related work characteristics – called job demands (JD) and
job resources (JR), respectively. The JDRM provides interesting arguments to develop precise hypotheses on how negative and positive lean-related aspects can influence work engagement and exhaustion. In human resource management literature, we found some few works (not published in OM journals) (i.e., Cullinane et al., 2014; Huo and Boxall, 2018) which try to investigate the lean-well-being relation through JDRM. However, results are not conclusive, and they showed important limitations in their research frameworks, since they consider very few lean-related job resources and, in Huo and Boxall (2018), lean-related job demands focus only on job requirements due to problem-solving pressure. A second element of originality of this research, instead, is the attempt to develop and test a more holistic model including several soft practices as lean-related job resources and two distinct types of lean-related job demands: JIT-related hindrance job demands (JIT-JD), and problem-solving-related challenge job demands (PS-JD).

Section 2 introduces the literature on the lean effect on employee well-being. Section 3 provides the theoretical framework and section 4 presents the hypotheses. In section 5 we present the methods and the results and in section 6 we discuss our findings.

2. Lean and Employee Well-being
Since initial studies on lean manufacturing, its effect on workers has been a crucial subject of discussion (Landsbergis et al., 1999). Even Womack and Jones (1990, pp. 99–103), in their seminal book on the Toyota Production System, discussed about the hypotheses that lean may have a negative effect on working conditions, reassuring that in a lean plant, teamwork and autonomy are fundamental aspects able to replace mass-production “mind-numbing stress”.

Generally, in scientific literature evidences supporting both positive and negative effects of lean can be found. On one side, lean opponents reported that the systematic waste elimination (e.g., buffer reduction) through process analysis and standardization may have an impact on employees, reducing their autonomy and increasing work pace and interdependence, leading to psychological strain and musculoskeletal disorders (Landsbergis et al., 1999). On the other side, in agreement with Womack and Jones, other researches showed that working conditions may be improved by LM in comparison to previous Tayloristic systems, since employee participation in continuous improvement teams and suggestion campaigns may increase experienced autonomy, positively affecting employee well-being (Hasle et al., 2012).

Recently, scholars proposed to move beyond the simplistic view that lean is entirely good or bad, suggesting to assess the impact of different lean dimensions on employee well-being and the role of specific contextual factors such as lean implementation strategy, in modifying this relationship (Hasle et al., 2012).

In particular, some researchers investigated the specific contributions of soft lean practices (SLP - i.e., practices focused on employee involvement - Bortolotti, Boscari, et al., 2015) and hard lean practices (e.g., kanban, JIT, etc.) suggesting that just-in-time (JIT) may increase negative work characteristics (e.g., work pace) and damage employee well-being, specifically when overlooking human-related elements that may act as balancing factors (Hasle et al., 2012). A first piece of evidence on this claim can be traced back to the early study of Parker et al. (1995) in the British automotive industry. They reported that lean led to negative effects where introduced without employee participation, whilst a positive impact was found when employees were actively involved. In this direction, Longoni et al. (2013) in a qualitative exploratory study, propose again that Lean HR
bundle is fundamental in reducing the harmful effect of JIT, suggesting further research efforts in confirmatory large sample studies.

3. Theoretical Framework: The Job Demands-Resources model

One relatively novel psychological model that can help to shed light on the contradictory results available in literature is the job demands-resource model (JDRM - Demerouti et al., 2001). This model hypothesizes two distinct but interrelated mechanisms, named health-impairment process and motivational process, that concurrently affect burnout and work engagement, respectively. The health impairment mechanism is activated by those physical, social, or organizational aspects, called job demands, that require sustained physical or mental effort and are associated with a psychological or physiological cost. In contrast, the motivational process suggests that job resources, defined as those physical, psychological, social or organizational job aspects, functional in achieving work goals, reducing job demands and their costs, stimulating personal growth and development, have a motivational effect and foster work engagement.

In addition, consistently with other stress theories (Hobfall, 2002; Karasek, 1979), the JDRM hypothesizes that resources and demands interact each other, reciprocally modifying their impact on burnout and work engagement. Specifically, it posits that job resources can buffer the impact of job demands on burnout and that job resources plays a higher salience on work engagement when job demands are high. The underlying idea is that positive work characteristics acquire relevance for well-being particularly under demanding conditions. Moreover, they can offset the negative impact of other stressors in fostering burnout.

Recently the JDRM has been updated introducing an important distinction between two types of job demands: hindrance and challenge job demands (van den Broeck et al., 2010; Crawford et al., 2010). Whilst both job demands are considered as positively affecting burnout (in agreement with JDRM health impairment mechanism), hindrance job demands are even negatively linked to engagement, while job demands that are interpreted as challenging, are positively related to engagement.

Moreover, even job resources main impact on exhaustion has been subject of investigation. Indeed, recent reviews provided pieces of evidence on a weak direct impact of job resources on exhaustion (Bakker and Demerouti, 2017; van den Broeck et al., 2010; Crawford et al., 2010).

4. Lean and the Job Demands-Resources model

The JDRM can be used to explain lean literature previous findings and particularly the crucial role of SLP in affecting employee well-being. In general, lean literature agrees to consider SLP as positive work aspects that may improve employee well-being, generally through specific work characteristics (Conti et al., 2006; Cullinane et al., 2014). For example, researches often link SLP with an increase of workers’ autonomy and skill variety thanks to workers’ participation in small group problem solving activities or employee suggestion campaigns, that in turn are associated with employee well-being (Conti et al., 2006; Cullinane et al., 2014; Huo and Boxall, 2018). Moreover, other lean aspects like management leadership for lean, management presence on the shop-floor and coaching can enhance other positive work aspects like feedback from the job, feedback from the others and work facilitation, positively affecting employee overall engagement (Drotz and Poksinska, 2014; de Treville and Antonakis, 2006).
Given these considerations, we posit that SLP act directly as organizational job resources and thus, in agreement with the JDRM, we hypothesize that:

H1: SLP are positively related to ENG.
H2: SLP are negatively related to EXH.

Regarding the health impairment mechanism, empirical research suggested that JIT tools are associated with an increase of specific negative work characteristics such as work pace and task interdependence (Hasle, 2014; Landsbergis et al., 1999). In particular, this is due to an excessive focus on muda reduction such as inventories that may intensify workforce pace and interconnections. Since these job characteristics have been associated with an increase of stress by organizational psychology literature (Karasek, 1979; Wong et al., 2007), we hypothesize that these JIT-related job demands (JIT-JD) act as hindrance demands. Therefore, we posit:

H3: JIT-JD, acting as hindrance job demands, are positively related to EXH.
H4: JIT-JD, acting as hindrance job demands, are negatively related to ENG.

Another work characteristic that has been recognized by previous studies as a potential negative lean element, is problem-solving-related job demand (PS-JD), defined as the degree to which the worker perceives that his/her job requires unique ideas or solutions (Cullinane et al., 2014). However, there is no agreement on PS-JD positive or negative impact on employee well-being. In line with Huo and Boxall’s recent study (2018), we posit that PS-JD may act as a challenge job demand fostering work engagement but even having a potential exhausting effect on workers:

H5: PS-JD, acting as challenge job demands, is positively related to EXH.
H6: PS-JD, acting as challenge job demands, is positively related to ENG.

In agreement with the interaction mechanism hypothesized by the JDRM we even suggest that job demands and SLP interact each other. We hypothesize that SLP have a higher impact for those workers experiencing more demanding conditions, either in terms of JIT or problem-solving. Furthermore, we posit that JIT-JD and PS-JD impact on exhaustion is mitigated by SLP, acting as job resources:

H7 (a and b): SLP reduces the positive impact of JIT-JD (a) and PS-JD (b) on EXH.
H8 (a and b): JIT-JD (a) and PS-JD (b) increase the positive impact of SLP on ENG.

Figure 1 represents the framework underlying this research and the developed hypotheses derived from the Job Demands-Resources model and LM literature.

![Figure 1: Theoretical model](image)

5. Methodology and Results

*Context and methods*

This study was performed in an Italian subsidiary plant of a multinational home appliance manufacturer which employs 530 production workers. Lean manufacturing was
introduced in 2006 as part of the group operations strategy. The plant was chosen for the research since it has a stable financial position and it has embraced all lean bundles and it has a good lean reputation, certified by the lean group audits.

We verified lean implementation visiting the plant, checking company audits and interviewing change agents and management, following a protocol based on Shah and Ward’s (2007) lean bundles. Regarding SLP, the company has extensively invested in employee involvement in lean. Implemented practices include multifunctional groups to solve production and quality problems, suggestion system, top and middle management involvement in lean implementation and lean coaching inspired by Toyota Kata approach (Rother, 2009). Despite the broad application of these SLP, managers recognize an internal variability in perception of these practices among employees, due to the heterogeneous workforce involvement.

Based on lean-employee well-being scientific literature and the JDRM, we developed a survey questionnaire with most relevant SLPs, lean-related job demands and employee well-being measures, validated with company managers and pilot tested with employees. All utilized items were adapted from previously validated scales in order to measure, at individual level, all relevant constructs. The survey was administrated to 147 randomly selected workers that filled in a paper-based version during their work shift. During analysis 9 respondents were dropped due to improper completion.

Table 1 reports utilized first-order constructs, their definition, mean, standard deviation and the final number of items kept.

Dependent variables are work engagement and exhaustion in agreement with previous studies adopting the job demands-resources model (e.g., Demerouti et al., 2001) and the two mechanisms hypothesized by the model. Both variables were measured using OLBI scale (Demerouti et al., 2010). SLP were measured as a second-order construct that included five specific first-order soft lean practices: small group problem solving, employee suggestions, shop floor contact, top management leadership for lean and coaching (Bortolotti, Danese, et al., 2015; Chi Anh and Matsui, 2011; Ellinger et al., 2003; Flynn et al., 1994; Ugboro and Obeng, 2000). JIT-JD were measured using a
second-order construct including two work characteristics: work pace adapted from Pejtersen et al. (2010) and task interdependence from Morgeson and Humphrey (2006). Problem-solving demand was measured using Morgeson and Humphrey (2006) scale.

For each item, respondents indicated their level of agreement on a seven-point Likert scale, from 1 (strongly disagree) to 7 (strongly agree). In addition, we included age, gender, shift vs. day work, organizational tenure, experience with the current position and current work unit, as control variables in our hierarchical regression analysis.

We verified items normality checking kurtosis and skewness and, in agreement with other previous studies (e.g., Bou-Llusar et al., 2009; Wu et al., 2015), to additionally protect our structural equation analyses from possible deviations from normality, we used Satorra and Bentler (1994) scaled goodness- of-fit test statistics, that, under non-normality conditions, generally outperform traditional fit indices (Byrne, 2016).

We control for common method bias a priori via items shuffling and a posteriori we statistically verified the poor fit of a single-factor model ($\chi^2$=1327; $\chi^2$/df = 1,99; CFI=0.65; RMSEA=0.0963; SRMR=0.096).

In order to validate our measures, we performed maximum likelihood confirmatory factor analysis (CFA), running a single-factor-model for every first-order construct (Jöreskog and Sörbom, 1989). All models showed adequate fit ($\chi^2$/df<3.0, CFI >0.90, RMSEA<0.08, SRMR<0.08) and convergent validity in terms of significance and magnitude of factor loadings (>0.50), except for one interdependence item (loading 0.45) that was kept for content validity reason.

Then, we tested our second-order soft lean practices and JIT-related job demands constructs together in a single model since JIT-related job demands is composed by only two first-order factors. The model showed good fit ($\chi^2$(292) = 358,6; $\chi^2$/df = 1.228; CFI=0.950; RMSEA=0.047; SRMR=0.067) and all first-order factors loaded on the specified second-order latent construct with factor loadings significant at p-value <0.001 and higher than 0.50. In agreement with some previous studies (Bortolotti, Danese, et al., 2015; Sila, 2007), after second-order construct validation, we parcelled first-order constructs belonging to second-order constructs, to get an simplified testable structural model (Little et al., 2002).

Finally, we tested a simplified model containing all constructs related to our hypotheses. The CFA model showed a good fit ($\chi^2$(143) = 213,8; $\chi^2$/df = 1.495; CFI=0.932; RMSEA=0.066; SRMR=0.066), providing further evidence of convergent validity (all loadings >0. 50 and significant for p-value<0.001).

Discriminant validity was assessed through Bagozzi and Phillips’s approach (1991), using Chi-square difference among two nested models for each pair of constructs, adjusted for Satorra and Bentler Chi-square values. All tests were significant for p-value<0.01. Reliability was assessed through composite reliability (CR). For all constructs CR exceeds the minimum level of 0.60 suggested by Bagozzi and Yi (1988) (see Table 1).

Results
We tested our hypotheses through hierarchical regression (HR) and structural equation modelling (SEM). HR results are reported in Table 3. For HR, we controlled residuals normality and homoscedasticity graphically checking P-P plot residuals against predicted values distribution. We controlled for multicollinearity, mean-centering interaction variables (Jaccard et al., 1990) and checking variance inflation factors.
HR results are reported in Table 2. In Models 1 to 4 results regarding work engagement are depicted and in models 5 to 8 results refer to exhaustion.

Results found show that hypotheses H1 and H2 are supported, being SLP positively linked to engagement and negatively to exhaustion. Moreover, there is empirical support to H3 and H4, being JIT-JD positively related to exhaustion and negatively related to work engagement. PS-JD is positively related to engagement (H6 held) but not to exhaustion (H5 not held). Finally, the findings support H7a and H8a. In particular, we found that soft lean practices may be more effective under more JIT-demanding conditions and JIT-related characteristics are less exhausting for those workers that experience higher SLP.

It is worth noting that the hypothesized interaction between SLP and problem-solving-related job demands is significant but negative for the effect on engagement, in contrast with H7b, and that there is no significant evidence for H8b as regards exhaustion.

To triangulate our HR findings, we performed moderated structural equation modelling (MSEM) to test our hypotheses. The interactions were computed through Ping’s (1995) two-step procedure. Given that in previous HR models, there wasn’t a consistent effect of any of the included control variables, for parsimonious reasons we didn’t include controls in SEM.

Figure 2 reports SEM results. Fit indices prove an acceptable fit ($\chi^2(172) = 243.94; \chi^2/df = 1.418; CFI=0.934; RMSEA=0.060; SRMR=0.0621$).

SEM results mostly confirm HR results. An exception is the negative impact of the interaction between SLP and PS-JD on engagement in HR, that is non-significant in SEM. For this reason, we do not consider as significant this interaction.

6. Discussion and conclusion
Our findings confirm that SLP significantly increase employee well-being, being positively related to engagement (H1 held) and negatively related to exhaustion (H2 held). Regarding job demands, JIT-JD has a negative impact on engagement and positive on exhaustion, as hypothesized (H3 and H4 held). In addition, its interaction with SLP has a significant impact on both exhaustion and engagement, as expected (H7a and H8a held). As concerns PS-JD, instead, while it is positively and significantly related to engagement, it hasn’t a significant effect on exhaustion, nor its interaction with SLP significantly impacts exhaustion and engagement (H5, H7b and H8b not held).

This research contributes to research and practice in different ways.

Firstly, by applying the Job Demands-Resources model, we developed and tested precise relationships, confirming that soft lean practices act as job resources by increasing employee engagement and reducing exhaustion. As regards engagement, our result extend Cullinane et al. (2014) findings, providing empirical evidence that SLP have a higher impact on engagement when job demands are high. This means that SLP acquires incremental relevance for those workers that cover more demanding conditions and are more exposed to JIT negative effects. Most importantly, SLP seems to play a crucial role in reducing the negative effect of JIT-related job demands, such as work pace or interdependence, on exhaustion. This is a novel finding, not quantitatively confirmed in previous research. It offers support to anecdotal evidences claiming that soft side of lean is crucial to avoid a negative effect on workers.

Secondly, the result that problem-solving demand is significantly related to engagement and not to exhaustion opens a debate on whether problem-solving demand in a lean company really represents a challenge job demand.

Thirdly, this research shows that the link between lean and well-being cannot be studied at a plant level. In our case, hard and soft lean practices were well-diffused and widely implemented in the whole plant, but workers’ perceptions about lean-related job demands and resources varied significantly at an individual level, and as a consequence also employees’ wellbeing.
From a practitioners’ perspective, our research provides a scientific basis regarding the fundamental role played by SLP in LM implementation for worker well-being. This research advises managers that workers experiencing higher JIT-JD may benefit more from SLP, since these extra-resources are more needed in more demanding working conditions. Instead, an improper lean implementation, without adequate SLP, may harm employee well-being due to JIT negative effect.

Abstract

The gemba walk is a common management practice that differs in service operations from production. We explore the concept of gemba walk with a multiple case study in the service sector. We study the application within a utility service provider, a telecommunication company and a hospital. We investigate different service settings and find relevant conditions for its suitability. We find that gemba walks are useful when processes are codified and visual. Gemba walks seem not suited for geographically distributed service teams. In addition, the organisations’ lean maturity level, management turnover and agile transformation streams affect the walks’ form, scope, purpose and efficiency.

Keywords: Gemba walk, management-by-walking-around, go and see

Introduction

Management-by-walking-around (MBWA) is a leadership practice that emphasize visible leaders (Peters and Waterman, 1984). In the lean production literature, this leadership practice is known as the ‘gemba walk’ (Imai, 2012, Womack, 2013). ‘Gemba’ is a Japanese word for ‘the real place’, meaning the place where value is created. A common English term for gemba walks is ‘go and see’. Managers go to the place where value is created to observe work processes and talk with the people conducting the work. The purpose is to enable managers to lead based on facts and provide them an opportunity to motivate and coach employees for the work. Gemba walks are a widespread and integrated part of many lean transformation programs (Womack and Jones, 2010) and believed to be essential for their success (Mann, 2014). However, how effective is this management practice if the work cannot be observed?

Many services are intangible, heterogeneous, perishable and inseparable from consumption. Does the gemba walk concept still apply? Many authors of lean books suggest that the answer to this question is ‘yes’ (Petruska, 2012, Womack, 2013). However, common sense suggest that the answer may be ‘no’ in many service contexts. First, if an important part of gemba walks is that managers observe work in order to learn about it, it requires that the work can actually be observed. In difference from the physical process in manufacturing, it can be difficult to observe service processes that are done on computers. Second, if service processes are taking place in the field where the customers are located, it can be impractical for managers to conduct regular gemba walks. Third,
when service processes include close customer interaction, managers must be careful not to disturb the service process (Hampson and Junor, 2005, Tucker and Singer, 2015). Fourth, because service processes vary, it can be difficult for managers to assess the quality of the work. Fifth, many services processes are high-level cognitive processes, often knowledge intensive and tacit, which makes is hard for leaders to coach the work (Leonard-Barton, 1995). All these arguments question the applicability of gemba walks in different service contexts.

We set out to explore the suitability, forms, challenges and opportunities of gemba walks in service operations. We start with a literature review before presenting our qualitative research method and setting. Subsequently we analyse the data for each case before discussing findings and developing propositions. In the last section, we conclude.

**Literature review**

MBWA was proposed in Peters and Waterman (1984) bestselling book *In search of excellence*. They studied 43 companies deemed as “excellent” and observed that successful managers were often purposefully wandering in the offices or factories to observe work processes and talk with and listen to their employees. CEOs and managers engaging in the *field* instead of their offices are considered a ‘technology of keeping in touch, keeping in constant informal contact’ (p.123.), a better way of solving problems on the job and therefore an essential management practice for successful business organisations. In the lean manufacturing world, MBWA is known as *gemba walks*. ‘Gemba’ (sometimes, ‘genba’) is a Japanese term that means ‘actual place’ or ‘real place’, meaning where work that adds value for the customer takes place (Imai, 2012).

Gemba walks aspire managers to verify facts over data (Rother, 2010, p. 135), to lead from the workplace and prevent virtual isolation (Ballé, 2014, Serrat, 2017) and to promote and track lean transformation (Mann, 2014, Liker and Ross, 2017). Go and sees achieve also understanding of the purpose and underlying processes of managers and their subordinates’ work, develop and empower people (Bremer, 2016, p. 15) and practice desired leadership behaviours with biggest impact on employee and customer satisfaction (Folkman, 2016, Bicheno and Holweg, 2016). The gemba walk’s most essential purpose however is to teach people, to learn from *on the job* and to achieve improvement while ‘doing’ (Rother, 2010). This teaching practice is typically in alignment with Toyota’s ‘master-apprentice’ model: the master or in Japan ‘sensei’ going to the floor, asking questions promoting the subordinate’s lean thinking ability and triggering consistent improvement (Mann, 2014). The idea is that the apprentice learns ‘through experience and consequences in live situations’ (Mann, 2014).

The forms and characteristics of gemba walks are diverse and build on intention, scope and extent of the walk. According to Bremer (2016, p. 53) there are four different types: the department walk, the leadership team walk, the value stream walk, the outside executives walk and the fake walk (Table 1). Fake walks should be prevented as they represent an untruthful view of the gemba.

Table 1: Gemba walk types (Bremer, 2016)

Gemba walks in service operations differ from production. In services, the gemba is nothing physical and observation therefore constricted or impossible (Drucker, 2012, p. 44). Managers must rely on ‘reduction, isolation and codification’ to turn service products into something tangible which can lead to misjudgement and false directions (McColl-Kennedy and Schneider, 2000).

Service gembas are often geographically dispersed and visits to retail outlets, the field or offshore teams time consuming and sometimes infeasible (Corso et al., 2006). Leaders must therefore rely on technical evaluation means to facilitate a gemba walk at distance or compromise on visit frequency.

With the inseparability of service production and consumption and the direct customer involvement (Hill, 1977) a gemba visit can affect service operations negatively. Walkers have to find ways of ‘observing without disturbing’ and at the same time avoid distrust and stress in customer and service supplier (Hampson and Junor, 2005, Baggs and Kleiner, 1996). Some organisations hire ‘mystery shoppers’ to assess customer satisfaction (Finn and Kayande, 1999). Could they perform gemba walks on the manager’s behalf?

Service quality is essential to go and sees. The determination and assessment of service quality is however highly complex as perceived differently by executives and employees plus dependent on employee’s individual performance. Furthermore, the service provision is highly variable and the definition of service quality standards therefore nearly impossible (Parasuraman et al., 1985).

With these service peculiarities in mind, we will explore the gemba walk in different service settings and verify its practice.
Research method
We investigate the applicability of gemba walks using a qualitative case-based design (Voss et al., 2002). We chose a multiple case allowing the exploration of different contexts, within case and cross-case comparison (Baxter and Jack, 2008). We looked for ‘extreme cases’ that applied gemba walks in service settings. We selected three companies from three sectors that have all won awards for the lean transformation programs. A utility service provider (hereafter referred as ‘UtilityCo’), a telecommunication company (‘TelCo’), and a hospital (‘SpitalCo’). All organisations have been championing lean services for the past five years. They have recently received external awards for their efforts. All organisations prescribe gemba walks as one of their lean practices, but none of them has defined a corporate standard for how to conduct them. The gemba walk of each case is our unit of analysis (Yin, 2013, Patton, 2014). Following ‘perceptual triangulation’ (Bonoma, 1985) we analysed multiple data comprising of interviews, observations, discussions and findings from reviewing documents and field notes. Applying a purposeful, intensity sampling strategy (Patton, 2014, p. 267), we chose departments who have conducted information-rich go and sees. In total, we examined seven gemba walk practices in three Swiss organisations.

During site visits, interviews, discussions and observations we gathered significant amount of information relevant to our research. In order to increase the reliability of the study the interviews were carried out with different stakeholders. Interviewees included managers, staff and lean coaches. We conducted 10 interviews. The interviews were partially conducted face-to-face during on-site visits and partially through telecom conferences. An interview guide was carefully designed and pre-tested. The interviews were semi-structured allowing the ‘reconstruction of the interviewee’s subjective view’ about gemba walks (Flick, 2014). Interviews ranged from 20 min to 50 min and were conducted in German and Swiss German. With approval of the interviewees, we tape-recorded all interviews and shared recordings or transcripts on request. Besides the interviews, we attended three gemba walks and a half-day workshop consolidating the findings from all the walks within one department of one organisation. Observing walks, discussions and feedback sessions provided rich information about perceptions, challenges and employee-supervisor relationships.

Further, we assessed secondary data that included team descriptions, gemba walk reports and the lean practices of the three cases.

As suggested by Eisenhardt (1989) we combined the data collection with data analysis enabling early data assessment and allowing flexible data collection. To facilitate data analysis we created a data inventory and edited interviews and notes electronically. We condensed data by organising, labelling and summarising. The use of tables, charts and networks allowed some early conclusions, which we continuously verified with existing field notes and further data collections.

Findings
We structured the findings by case. For each case, we briefly describe the service setting, the gemba walk application, followed by the walk’s success stories and challenges.

Case 1: UtilityCo.
UtilityCo is a leading international company in its industry, headquartered in Germany, employs 43,000 people, serves over 33 million customers and has an annual revenue of approximately 40 billion Euros. The company focuses on renewables, energy networks
and energy-related customer solutions. UtilityCo introduced their corporate lean programme in 2014 and has since made regular use of the gemba walk practice.

We visited a German call centre dealing with customer care, complaint management, error handling and customer intention initiatives. The centre occupies around 300 employees within 14 divisions. We interviewed the centre leader, a local lean coach and a division manager. Depending on the management level in scope we find different go and see forms and intentions.

The call centre leader handles fortnightly unannounced ‘side-by-side walks’, visiting the division managers on-site, attending a performance dialogue with their teams and followed by interviewing his subordinate with a set of Kata questions (Rother, 2010, p. 155). While the division manager is moderating his team’s performance dialogue, the centre leader observes his subordinate’s leadership behaviour. The centre leader observes the way he challenges the division’s objectives, ongoing or outstanding actions and issues recorded on the team’s performance board. He reviews the division manager’s drive for problem solution activities, his sense for employee coaching and development. Further, he verifies the team leader’s function as a role model for considering work standards. After completion of the performance dialogue, the call centre leader tracks the division’s continuous improvement stream by interviewing his subordinate with a set of Kata reflection questions (Rother, 2010, p. 155). Any actions resulting from those questions are either incorporated into the division’s action log or the overall call centre actions, which are apparent on the performance board on-site. The purpose of the side-by-side walk at the call centre is to foster knowhow exchange within the centre and to improve continuously. Formerly this walk used to be conducted every week. With the site’s increased lean maturity, a fortnightly assessment seems sufficient.

Executives and subordinates reported the closeness to the individual teams, the associated work appreciation as well as the removal of hierarchies of the side-by-side walk positively. Some teams perceive the visit as a disturbance and pure control mechanism. A team manager explains. ‘There are certain team internals that only concern the team. And if you suddenly have the centre leader in front of you, no one will dare to speak up.’ The centre leader therefore sees a need for ‘management by perception’ and sensitivity.

In addition to the ‘side-by-sides’, department or team leaders also conduct weekly gemba walks by visiting one or two employees at their workstation. They verify the call agent’s adherence of work standards by using checklists to assess the workplace’s tidiness, the individual routine or telephone scripts. Any discrepancies are directly addressed with the employee and associated measurements incorporated into the team’s actions list.

Employee coaching seems an essential element of the weekly department gemba walk. The division leader provides examples for improvement and ensures knowledge transfer. We heard that thereby call agents achieved significant improvements in their sales conversations with distribution clients. This type of go and see used to take place daily but since the division has achieved a higher lean maturity level a weekly walk is sufficient. The team leader explains, ‘in the beginning of our lean journey we checked whether everyone’s desk was tidy. Today it’s more about reviewing and coaching the employee’s knowhow.’ We learned that the department walk supports the supervisor’s personnel development initiatives as it provides clarity on the staff’s strengths and weaknesses. Besides the go and see also increases the transparency across other divisions. Using the same checklists and assessment means enables knowledge transfer with other teams. From the division manager we heard: ‘if a colleague talks about an issue in his
team, I can share my experiences when dealing with similar issues in the past.’ Negative
consider managers the high amount of documentation. Transferring the right intentions
of the walk to the employees seems also challenging. A team leader explains, ‘I don’t
want to control them. I want to help them. That’s why I always announce my visits.’

We also inspected a German power grid centre with 21 employees, responsible for grid
(electric and gas) operation, maintenance and development. We interviewed the grid
centre leader.

We learned from the centre leader that he ceased go and sees in the field. In the past,
only before an upcoming lean maturity assessment, he would accompany a technician
into the field, evaluate his adherence to safety guidelines, and work standards. Due to the
grid centre leader’s perceived interference with staff’s privacy, he never performed any
gemba walks in the office.

Despite the walk’s benefits, he never repeated the practice in the past year. ‘When you
are out there you get a great sense for the work of the colleagues in the field. However,
spending half a day away from the desk is simply too time-consuming. We have a
thousand other things to do’. An English field services team we spoke to shared similar
findings. The manager explains ‘we are spread out across the whole country. Doing a go
and see would take up 50% of our times.’

Case 2: TelCo.
TelCo, a Swiss leading telecoms company, occupying 20,000 employees, generating sales
of more than 11 billion, is considered as one of Switzerland’s most sustainable and
innovative companies. TelCo’s lean journey dates back to early 2013 and the company is
currently developing a standard for gemba walks to be integrated into the on-boarding
training of executives.

We visited a datacentre and connectivity division responsible for server infrastructure and
firewall setup. We interviewed a lean coach, gemba walk executor and recipient. The
team consists of 114 employees, occupies a mix between consultants, engineers and
coordinators. Overall, the division has conducted 12 gemba walks in the past three weeks.
In consultation with TelCo’s central lean experts and to obtain a baseline study of his
team, the division manager initiated the go and sees. The gemba walks were conducted
unannounced and carried out either by line managers or TelCo qualified lean experts. The
walk consisted of a presentation of the employee’s main tasks on his screen at his
workstation and lasted four hours. The walker asked many questions. Instead of the direc
tor supervisor, it was another line manager or lean expert doing the visit. Apparently to
prevent the employee’s ‘intimidation’ and to allow him to speak openly.

The main objective of the walk is to review current issues, actions, contributions to
objectives and to identify waste. With some of the company’s lean experts conducting the
visits, the gemba walk also has a lean coaching purpose. The walker does not adhere to a
strict checklist. He rather observes the employees work, asks clarifying questions and
takes notes to track calls for action. After the gemba walk, the visitor provides written
feedback to the employee and the division manager. With support of the company’s lean
experts, the division manager derives necessary measurements. The department sees no
need for frequent gemba walks currently. ‘The agile transformation needs to be completed
first…there are too many conflicting interfaces.’

We sensed mixed feelings towards go and sees. Walkers like the closeness to the
employees and establish appreciation for their work. They also find it beneficial not to
examine their direct subordinate as ‘you get to see a lot more’. We recorded a lot of
‘moaning’ during the gemba walk and question whether this is due to a lacking reporting line. Recipients do not see any benefits. An employee illustrates, ‘it is too abstract. I am not able to demonstrate all of my problems. I feel disturbed’. He wondered if a higher visit frequency would improve the circumstances. Both parties reported a clash of the promoted adherence of lean standards with the company’s agile efforts. Given TelCo’s agile environment, most measurements resulting from gemba walks seem therefore ‘unplannable’.

Case 3: SpitalCo.
SpitalCo is a leading Swiss hospital with over 33 disciplines. The clinic occupies 2200 employees, treats over 17000 stationary and 75000 ambulant patients a year. In response of the 2012 introduced national diagnosis related flat fees, SpitalCo embarked on their lean journey in 2014.

We visited one of the 16 wards the clinic maintains. The ward specialises in care of internal and general medicine with focus on stroke patients, consists of 28 beds and occupies 32 employees. According to the hospital’s lean programme master, SpitalCo has not established a go and see routine yet. Besides, the organisation has undergone a high management turnover. Without the clinic’s lean management initiative, gemba walks would not take place. Therefore a third go and see cycle was launched. As part of this ‘re-gemba’ initiative three walks per ward take place. The gemba walks are conducted announced and carried out by ward management personnel and partially by SpitalCo’s lean programme master. The go and sees last half a day where a care team is followed and all value adding tasks, value supporting tasks and non-value adding processes are recorded. For this, the walkers maintain a list capturing all jobs and deficiencies. In order to ensure cross-departmental improvement the gemba walks are not solely executed by direct supervisors but also by executives from other wards. The focus of the walk is to observe the value process and register deficiencies. With SpitalCo’s lean programme master accompanying many go and sees the gemba walk maintains also a lean coaching and training intention. The walkers do not follow a standard checklist. Instead, they observe the carers work processes and discuss in a feedback session any necessary measurements.

The gemba walks at Spital Co. are mostly positively perceived. Employees appreciate the one-to-one feedback as valuable leadership and career input. Go and sees prevent departmental ‘island solutions’ and enable quick-fixes and little improvements directly on-site. Some employees however consider the visit negative. ‘All seems a bit staged’. A ward manager wonders if this could be prevented by means of higher gemba walk frequency. Sometimes leadership lack process knowhow, which can question their assessment and problem-solving skills. According to a ward manager it requires a lot of sensitivity when ‘walking that thin line’ and providing feedback. We learned that gemba walks cannot be conducted everywhere in the same way. The accident and emergency department for example struggles to follow standards and uniform waste definitions. Ward managers visiting departments other than their own can also cause a negative impression on other teams. A ward manager explained: ‘my colleague suddenly does not greet me anymore.’

Discussion
This study aimed to explore the suitability of gemba walks in service operations. The analysis of the gemba walk practice at our three cases, Utility Co, TelCo and SpitalCo,
has led us to some potential answers. We will discuss these further and propose some research propositions.

**Proposition 1a: Gemba walks are useful if service value is apparent.**

This hypothesis sounds obvious but not always viable in service settings. UtilityCo call centres use recordings of customer care calls, which managers can assess and align with customer care standards or scripts. At SpitalCo we found that the patient’s direct response to the carer’s service, such as pain, relief, happiness, discomfort etc. corresponds to the service’s product.

On the contrary, our research at TelCo has shown that invisible services being performed within workers’ mind or computers cannot be observed and lead to extended and sometimes false presentation of problems instead of normal work processes. We therefore suggest:

**Proposition 1b: Gemba walks are not suited if service value is not apparent.**

**Proposition 2: Gemba walks are useful if service supply metrics are apparent.**

Gemba walks include the measurement of service supply. Intangible services can however only be measured by means of strict ‘reduction, isolation and codification’ of service operations and by making these codes or standards for everyone visible (McColl-Kennedy and Schneider, 2000). UtilityCo and SpitalCo use performance boards or checklists containing gemba walk relevant standards and metrics accessible and apparent for the entire team.

**Proposition 3: Gemba walks are not suited for distributed service teams.**

Visiting the service gemba of geographically dispersed teams is not sustainable (Corso et al 2006). UtilityCo’s grid field operation showed that managers could not maintain the go and see practice due to long travel time and individual dispersed field technicians with a high degree of autonomy.

In addition, we have found some additional factors that influence the application of gemba walks in services.

*Lean maturity level*

Different lean maturity levels affect the form, purpose and scope of gemba walks (Jones et al., 2017). A more mature service setting requires less standard measurement walks as standards are in place and staff aware of value adding and non-value adding processes. The focus shifts from policing to learning. UtilityCo’s lean maturity context showed a decrease in gemba walk frequency.

*Management turnover*

A high management turnover affects the gemba walk’s efficiency. Teams cannot improve and learn as the view of the gemba changes with every new sensei (Mann, 2014). Due to a high management turnover, SpitalCo has not managed to establish a stable go and see routine and had to launch a third re-gemba walk cycle.

*Agile transformation*

With the information technology industry’s increasing interest in combining agile with lean transformation (Rodríguez et al., 2012) gemba walks experience conflicts in complexity, visibility, people relationships, understanding of customer needs and metrics (Maguire, 2016). Some of these conflicts were also apparent at TelCo.
Conclusion
Despite the widespread practice of gemba walks across service operations, there is almost no scientific evidence of its effectiveness. The concept has been left completely to the popular literature. This paper has investigated how and if gemba walks apply in different service settings.

We argue that even though many organisations drive the practice, it is not well suited to every service setting. We propose to apply extra attention to the visibility of service value, metrics, team dispersion, lean maturity level, management turnover and agile transformation initiatives.

This study has limitations in theoretical framework, methodology and data collection. A significant methodological limitation of this study is the case study design. This contradicts with the general validity of our findings and propositions. Additionally, this research is still ongoing and therefore lacks sufficient data to support our findings further.

In order to test validity of our gemba walk propositions, we suggest quantitative studies of many service operations with established and operating gemba walk practices.

Pathways to develop a lean organization: configurations of lean practices for different business strategies

HAN University of Applied Sciences

Abstract

This paper identifies pathways to develop a lean organization. Previous research identified complementarity between supplier related, customer related, just-in-time, total productive maintenance, and human resource management bundles. This research identifies strategy related configurations of these bundles linked to substantive operational performance. Data on operational performance and lean bundles were gathered from 44 manufacturers using multiple respondent self-assessments and analysed using Qualitative Comparative Analysis. Three different pathways to substantive operational performance were identified. Our findings provide focus to both research and practice as they suggest that lean bundles are not consistently linked to each other nor equally important for different organizations.

Keywords: Lean bundles; Operational performance; Qualitative comparative analysis

Introduction

To develop a lean organization, it is important to focus on the most important lean bundles for that organization. This focus is ill addressed in the literature. Most research studies the link between lean bundles as well as their link with operational performance (like McKone, Schroeder and Cua, 2001; Rahman and Bullock, 2005; Fotopoulos and Psomas, 2009; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012; Danese and Bortolotti, 2014). Some incorporate generic contingencies like country or age (like McKone, Schroeder and Cua, 1999; Cua, McKone and Schroeder, 2001; Dal Pont, Furlan and Vinelli, 2008; Furlan, Dal Pont and Vinelli, 2011; Furlan, Vinelli and Dal Pont, 2011; Alsmadi, Almani and Jerisat, 2012; Bortolotti, Boscari and Danese, 2015). And a few take market conditions like demand variability into account (like Sakakibara et al., 1997; Ketokivi and Schroeder, 2004; Bortolotti, Danese and Romano, 2013). This paper sets out to explore strategy related configurations of lean bundles that are linked to substantive operational performance.

From its introduction onwards, the lean philosophy of increasing customer value and decreasing waste through just-in-time production and respect-for-employees (Sugimori et al., 1977) has been important for organizations trying to improve their organizational
processes (Naylor, Naim and Berry, 1999; Shah and Ward, 2003; Liker and Morgan, 2006; Radnor and Walley, 2008; de Souza, 2009). Lean however constitutes a diversity of bundles regarding total productive maintenance (TPM), just-in-time (JIT), human resource management (HRM), suppliers and customers (Shah and Ward, 2003, 2007). This diversity of bundles adds to the challenge of developing a lean organization (Hines, 2010; Mann, 2014).

It is shown that not all lean bundles are equally important for every organization (Sakakibara et al., 1997; Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Brown, Squire and Blackmon, 2007; Ward, McCreery and Anand, 2007). For example, a customer link might be more important for organizations striving for customer intimacy while TPM might be more important for organizations striving for operational excellence (Treacy and Wiersema, 1996; Ward, McCreery and Anand, 2007). Rather than equally important it might be that lean bundles are best performed in configurations (Ward, Bickford and Keong Leong, 1996; Cua, McKone and Schroeder, 2001). Configurations are “multidimensional constellation[s] of conceptually distinct characteristics that commonly occur together” (Meyer, Tsui and Hinings, 1993, p. 1175). Related concepts are typologies (Miles et al., 1978), gestals (Miller, 1981), types (Mintzberg, 1990) or forms (Short, Payne and Ketchen, 2008). A configurational approach identifies dominant types of observable characteristics of behaviour which appear to lead to a particular performance.

Given the configurational approach, it is proposed that configurations of lean bundles can be developed depending on how an organization strives to distinguish itself (Filippini, Forza and Vinelli, 1996; Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007; Galeazzo and Furlan, 2018). Only one study explored configurations of lean bundles in relation to performance (Galeazzo and Furlan, 2018). Using data from 78 informants from 19 manufacturing medium and large firms, they found configurations of lean bundles that were linked to successful financial performance; JIT combined with total quality management or with TPM and HRM. However, their study focusses on internal related lean bundles only, neglecting bundles regarding the supply chain (supplier and customer related) and their study linked lean bundles to financial rather than operational performance. This study tries to add to this literature as it aims to explore strategy related configurations of lean bundles that are linked to substantive operational performance.

An overview of business strategies and related configurations of lean bundles is followed by an explanation why and how we used Qualitative Comparative Analysis (Ragin, 2008) to analyse our data and come to different pathways to develop a lean organization.

**Configurations of lean bundles**

To explore strategy related configurations of lean bundles that are linked to substantive operational performance, we identify different business strategies which we link to different lean bundles to conceptualize configurations that are linked to operational performance.

**Business strategies**

Brown, Squire and Blackmon (2007) showed that world-class plants link lean operations to business strategy. Many approaches to business strategy have been taken (like Miles et al., 1978; Porter, 1985). Treacy and Wiersema (1996) distinguish three basic ones; product leadership, operational excellence and customer intimacy. In line with these, Ward, McCreery and Anand (2007) identified three types; broad-based competitors,
differentiators and price leaders. As Treacy and Wiersema (1996) focus specifically on customer value (Zacharias, Nijssen and Stock, 2016) and as they show considerable overlap with the types of Ward, McCreery and Anand (2007) we will continue with these.

First, according to Treacy and Wiersema (1996) product leadership aims to excel on product quality, innovation and brand marketing. The focus is on design and development of a variety of good products, produced in low volume, with high margins and a quick time-to-market (Ward, McCreery and Anand, 2007). Second, operational excellence is about an outstanding production process with superior operations and execution. The focus is on efficiency and streamlined operations and supply chain management as the organization tries to offer a reasonable quality for a very low price (Ward, McCreery and Anand, 2007). Third, customer intimacy aims to excel in customer focus and customer service. The focus is on delivering customer specific products and services on time and above customer expectations as the organization adapts products and services for the benefit of individual or almost individual customers (Ward, McCreery and Anand, 2007).

According to Treacy and Wiersema (1996), organizations should strive to meet the threshold of all three strategies but at the same time excel at one of them. Research (Sakakibara et al., 1997; Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007) has shown that proper alignment of business strategy strengthens the connection between lean bundles and operational performance. So lean bundles can help to meet strategic aims and market demands on an operational level.

**Lean practices and lean bundles**

Shah and Ward (2003, 2007) identified lean bundles from ten lean practices. Their practices are widely used in the literature because of their comprehensive view; they include people, process and technology aspects as well as supplier, internal and customer aspects. Following others, we grouped these lean practices into five internally consistent lean bundles. The supplier related bundle consists of supplier feedback, JIT delivery and developing suppliers (Shah and Ward, 2007). The customer related and HRM bundles each consist of one lean practice (Shah and Ward, 2007). Deviating from Shah and Ward, we split the internally related group into TPM consisting of controlled processes and productive maintenance, and JIT consisting of pull, flow and low setup (McKone, Schroeder and Cua, 1999, 2001; Cua, McKone and Schroeder, 2001). Like the ten lean practices, these five lean bundles are widely used in the literature (Mackelprang and Nair, 2010).

**Configurations of lean bundles**

The lean bundles can be conceptualized in the following configurations. First, to achieve product leadership short delivery times are paramount. To this end, the most important bundle seems JIT as this mainly helps to reduce product lead time (Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012). Prerequisites for JIT appear to be the bundles TPM for a steady production process (Swink, Narasimhan and Kim, 2005) and supplier related for steady deliveries (Panizzolo, 1998; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012). Bundles of lesser importance, though not irrelevant, seem customer related (Furlan, Dal Pont and Vinelli, 2011) and HRM (Furlan, Vinelli and Dal Pont, 2011). There appear to be no bundles counterproductive for this configuration.

Second, to achieve operational excellence low variety and high volume is produced for low margins. To this end, a steady marketing mix combined with a stable production
line seem most important. This is achieved by the bundle TPM (McKone, Schroeder and Cua, 1999, 2001). Bundles of lesser importance seem JIT (Danese, Romano and Bortolotti, 2012) and supplier related (Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012) as the high volume permits production to be done in small batches rather than single pieces. Some even find JIT (Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007) and supplier related (Ward, McCreery and Anand, 2007) to be counterproductive for this strategy. The customer related and HRM bundles (Ward, McCreery and Anand, 2007) might be too expensive for this configuration as the low variety permits steady designs and production. Though for these two bundles too, some researchers find otherwise (Ketokivi and Schroeder, 2004).

And third, to achieve customer intimacy direct contact with customers is most important making customer related the most important bundle (Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Ward, McCreery and Anand, 2007). Furthermore, because of the complexity in production, the bundles HRM (Swink, Narasimhan and Kim, 2005) and JIT (Swink, Narasimhan and Kim, 2005) seem to be required as well. TPM might be of lesser importance as unicity of the products does not require very high levels of productive maintenance or process control (Swink, Narasimhan and Kim, 2005). The supplier related bundle might be least important in this configuration as lead time oftentimes is not an order winner in this strategy (Furlan, Dal Pont and Vinelli, 2011). These configurations are also given in Figure 1.

**Methodology**

To analyse the identified configurations of lean bundles that are linked to substantive operational performance, we first explain why we used multiple respondent self-assessments to gather data on operational performance and lean bundles before we explain why and how we used Qualitative Comparative Analysis (Ragin, 2008) to analyse this data and come to different pathways to develop a lean organization.

**Data gathering**

Data was gathered from 44 Dutch manufacturing SMEs through the network of the research group World Class Performance/Lean of the HAN University of Applied Sciences in The Netherlands. Multiple respondents (6 on average, over 250 in total) from
different levels (executives till team leaders) and functions (Sales till Expedition) filled in a questionnaire on their operational performance (costs, quality, delivery speed, delivery dependability, product flexibility and volume flexibility) (White, 1996; Slack, Chambers and Johnston, 2010) and lean practices (See Shah and Ward (2007) for details). The lean practices were grouped in five bundles to enable data analysis with QCA; supplier related (supplier feedback, JIT delivery and developing suppliers), customer related, HRM, TPM (controlled processes and productive maintenance) and JIT (pull, flow and low setup).

Data quality
To estimate construct validity, an exploratory factor analysis (EFA with varimax) and a confirmatory factor analysis (CFA with direct oblimin) were performed for operational performance and lean practices respectively and given in Fout! Verwijzingsbron niet gevonden. and Table 2. KMO’s were >0.5 and Bartlett’s tests of sphericity were both <0.001 hence all were significant. All meet the excellent threshold of >.7 while costs, JIT delivery, developing suppliers, pull and productive maintenance meet the very good threshold of >.6. Also following judgemental criteria (Wieland et al., 2017) and considering the content of the deflecting items (content validity) we decided to keep all items to maintain coverage of the identified groups.

Data analysis
Data were analysed with QCA (Ragin, 2008; Schneider and Wagemann, 2012) in fsQCA 3.0 (Ragin, Drass and Davey, 2017). QCA is a technique which allows a systematic comparison of cases. Rather than statistics, it uses Boolean logic to find configurations of conditions for a certain outcome (Fiss, 2007). To do a QCA, several steps must be performed.
In preparation, both bundles of operational performance and lean practices were calibrated as shown in Table 3. Operational performance was measured on a nine-point scale with 1-3 being lower, 4-6 equal and 7-9 better than competition. Therefore, 6.5 was chosen as the threshold for cases outperforming competition. As there were no cases above 8 nor below 5 these acted as full and non-membership thresholds respectively. Lean practices were calibrated based on groups identified in our own dataset. As lean bundles for most cases were below 4 and above 2 these acted as full- and non-membership values respectively.

Next, the actual QCA was performed. Necessary or sufficient conditions were identified, a truth table was made with each row representing each possible configuration, and for each outcome consistency and coverage were calculated. To improve confidence in the identified configurations, two robustness tests were performed. These tested whether the findings were the same for different cross over points; one based on groups identified using the average per lean bundle and one based on the industry average from three studies (Alsma, Almani and Jerisat, 2012; Hofer, Eroglu and Rossiter Hofer, 2012; Bortolotti, Boscari and Danese, 2015).

| Customer related | 4     | 2.6  | 3.2  | 3.8  | 2

Results
To find which configurations of bundles of lean practices were linked to increased operational performance for different business strategies, we first performed the QCA-test for necessity but found no bundles that were necessary for each configuration. We then performed the truth table algorithm to identify which bundles of lean practices were sufficient for cases to outperform competitors. Results are given in Table 4 and show that there are three configurations of lean bundles with substantive operational performance. First, JIT combined with supplier related and TPM. Second, TPM combined with supplier related but with absence of HRM and customer related. And third customer related and HRM combined with supplier related and JIT. These configurations of lean bundles show considerable overlap with the configurations identified from the literature.

Discussion
The aim of this paper was to explore strategy related configurations of lean bundles that are linked to substantive operational performance. This section will elaborate on our results and their theoretical and practical contributions.

Pathways to develop a lean organization
Our results confirm earlier work on configurations of lean bundles linked to operational performance (Filippini, Forza and Vinelli, 1996; Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007; Galeazzo and Furlan, 2018) while we specify these configurations into three specific pathways to develop a lean organization. It appears that for product leadership, JIT is the most important bundle (Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012) while the TPM (Swink, Narasimhan and Kim, 2005) and supplier related bundles (Panizzolo, 1998; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012) are required as well. Like others, we too find that the customer related (Furlan, Dal Pont and Vinelli, 2011) and HRM bundles (Furlan, Vinelli and Dal Pont, 2011) are not required for this configuration.

Regarding operational excellence there is less agreement. We too find that the TPM (McKone, Schroeder and Cua, 1999, 2001) and supplier related bundles (Ketokivi and Schroeder, 2004; Swink, Narasimhan and Kim, 2005; Romano, Danese and Bortolotti, 2010; Danese, Romano and Bortolotti, 2012) are important for this configuration. However this contradicts findings of others (Ward, McCreery and Anand, 2007) regarding supplier related. Furthermore, we too find that JIT is not important for this configuration (Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007) contradicting those that find it is (Danese, Romano and Bortolotti, 2012). This might be due to lower variety and higher volumes hence less setups, pull and flow. Contradicting findings of others (Ketokivi and Schroeder, 2004), our results show that HRM and customer related are not required for this configuration (Ward, McCreery and Anand, 2007) as these might be too expensive.

Regarding customer intimacy, we mostly confirm earlier findings. The customer related bundle was most important (Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Ward, McCreery and Anand, 2007) while HRM (Swink, Narasimhan and Kim, 2005) and JIT (Swink, Narasimhan and Kim, 2005) were required as well. However, contradicting others (Swink, Narasimhan and Kim, 2005) our results show that TPM was not required
for this configuration. This might be because unicity of the products does not require very high levels of productive maintenance or process control. Finally, contradicting others (Furlan, Dal Pont and Vinelli, 2011) our results indicate that supplier related was important for this configuration. This might be due to the increasing importance of lead time. In sum our findings refine our understanding of configurations of lean bundles for substantive operational performance.

Contributions and future research
This paper confirms that not all lean bundles are equally important for every organization (Sakakibara et al., 1997; Ketokivi and Schroeder, 2004; Brown, Squire and Blackmon, 2007) while it specifies a previously identified direction for analysis (Filippini, Forza and Vinelli, 1996; Panizzolo, 1998; Cua, McKone and Schroeder, 2001; Swink, Narasimhan and Kim, 2005; Ward, McCreery and Anand, 2007). Managers trying to develop a lean organization can use these findings to focus their efforts depending on their external environment and related business strategy. Future research could take the same approach to elaborate and refine our findings using different samples from different industries or cultures as well as samples with different combinations of lean bundles.

Abstract

One of the main aspects in creating the competitive advantage of organizations and the survival condition in the competitive market is to reduce the product cost. Accurate calculation of the components of product cost, can lead to help the organizations to identify potential opportunities for their business improvement. Some of these components in product cost like: monetary value of time are hidden and are not usually found in the traditional accounting methods. By emerging the lean production and implementation of the principles of lean thinking in the area of manufacturing and services, significant improvements have been found in reducing waste, creating value-added activities and consequently reduction of product cost in various organizations. The main aim of this paper is using a lean approach in order to accurate calculation of product direct cost (PDC) as a main component of product cost. In this paper, lean tools such as value stream map (VSM) and cost-time profile (CTP) have been utilized and the effect of the monetary value of time have been considered in PDC calculation. By drawing the current state and future state maps of VSM and CTP as well as calculating the cost-time investment of a product for the both states, organizations will be able to have a reasonable analysis of monetary effect of reducing waste and time corresponding to non-value added activities. Hence, the PDC amounts for current and future state maps can be calculated and compared to each other. Furthermore, these PDC amounts can be compared to the PDC amount which is calculated through traditional accounting method which has not considered the monetary value of time. At first glance, this approach might not seem sensitive and substantial for a unit of product in a manufacturing organization, but for a large volume of products in a long-run period of time, it will be much too considerable. Finally, this approach has been implemented in SAIPA automotive manufacturing group as a second largest automotive manufacturer in Iran in order to explain the efficiency and applicability of the proposed method and the obtained results have been analysed.

Keywords: Lean Production, Cost-Time Profile, Product Direct Cost
Introduction
The accurate estimation of product costs has a direct impact on the performance and effectiveness of a business since unrealistic estimation can lead to the outflow of the organization financial resources. Hence, product cost estimation is considered as one of the key factors in designing operational strategies and management policies as well as business decision making due to this critical role in the organization. There are different techniques for estimating and accurately calculating product costs according to Figure 1 (Niazi & Dai, 2006).

![Figure 1 – Classification of product cost estimation techniques (Niazi and Daei, 2006)](image)

According to the categorization presented in Figure 1, product cost estimation techniques are divided into two main categories: 1. Quantitative product cost estimation techniques, 2. Qualitative product cost estimation techniques.

Quantitative product cost estimation techniques are mostly used in the new analysis and product that is currently being produce while, Qualitative product cost estimation techniques are based more on the detailed analysis of product costs from product design to production processes and are not based on past information or prior estimates.

Excluding the time factor, only the product cumulative cost was considered in traditional costing systems. Value stream mapping (VSM) tool provides a very good image of the time needed to produce a product, however it cannot take into account the cost factor. The cost-time profile is an applied tool to show the product cumulative cost over production time within the cost-time-investment and product costs indices (Rivera & Chen, 2007)

Literature review on product cost calculation
A number of studies carried out in this area have been mentioned in the following: (Zhang, et al., 1996) Pointed out the critical role of Product Cost Estimation (PCE) in the product development cycle and emphasized that the correct cost estimation can help balance product structures, raw materials, and production processes with designers' decisions. They also divided the methods of estimating product costs into 5 categories according to the research in this area: 1) Traditional Detailed Breakdown 2) Simplified Breakdown Cost Estimation 3) Group Technology-Based Cost Estimation 4) Regression-
Based Cost Estimation, 5) Activity-Based Cost Estimation. (Shehab & Abdalla, 2001) Interpreted a product cost estimates as the prediction of a product operations costs before implementation and provided three categories for cost estimation methods: Intuitive method, Parametric Techniques, Variant-Based Models and Generative Cost Estimating Models. (Ben-Arieh & Qian, 2003) Provided four categories of cost estimation methods including: Intuitive, Analogical, Parametric and Analytical. Intuitive methods are based on past calculations of cost estimates. Analogical methods are used to estimate costs using similar product information with specific costs. Parametric methods for estimating product costs are based on product parameters that are most commonly used by product designers. The parameter is effective on costs and is usually calculated based on simple formulas. Analytical methods, such as the activity-based costing decompose and break down the sub-activities to the level at which the resources and financial costs are measurable. (Niazi & Dai, 2006) Examined various techniques and methods to calculate the cost of the product, as well as to categorize and review the related literature in this field during a 10- year period. (Rivera & Chen, 2007) Investigated and measured the impact of lean manufacturing tools on cost-time investment of a product using a cost-time profile.

**Value Stream Mapping**

The VSM, also known as the "materials and information flow map", is a graphical device that displays the process map of a production system using standard icons and firstly introduced by (Rother & Shook, 2009) in a book entitled: "Learning to see". This map, covering the production movement from the factory entrance door to the exit door, the door to door value flow, is a good start for mapping and leaness. There are two types of mapping in the VSM: 1. Current State Map (CSM), which indicates the leaness of the current plant system. 2. Future State Map (FSM) or improved state map that indicates the system's leaness after improvements (Womak, et al., 1990) (Seyedhosseini, et al., 2013).

A brief overview of the literature on VSM is provided in the following: (Abdulmalek & Rajgopal, 2007) used the simulation process to provide improvement scenarios to reduce production waiting times and as a result, they could evaluate the use of lean manufacturing tools in the steel industry. (Ebrahimi-Talaghani, et al., 2013) Could reduce the time and the total waiting time of production using a non-deterministic VSM tool by the PERT technique to take into account the uncertainty of the activity of a part automobile manufacturer. (Sasikumar & Kumar, 2013) Succeeded to reduce the total waiting time of production and the number of production operators and process time by implementing the VSM tool to detect the loss in manufacturing processes of an electromechanical circuit breaker manufacturer in India. (Singh, et al., 2015) Reduced supply time by warehouse, reduced overall production waiting time and process time utilizing VSM tools in the automotive-related small industries through drawing on the current situation, analysing and presenting improved conditions. With the aim of improving customer service performance management, (Morlock & Meier, 2015) reduced the response time and customer service time by implementing value streaming mapping in the service area. (Kasava, et al., 2015) Improved repair time and calculated the sustainability through mathematical modelling using the VSM tool in the aircraft repair industry in the Boeing 737 aircraft repair department to reduce repair time and calculating the index of sustainability of the VSM in the form of a numerical index.
Cost-time profile
The term cost-time profile (CTP) developed by Westinghouse Corporation. CTP is a graph displaying the Cumulative and gradual Costs of a product over time. The total costs in the cost-time profile graph are equal to the height of the graph, when the product is completed. Actually, the total cost represents all the direct costs of the product, regardless of the impact of the cost-time of the investment (Rivera & Chen, 2007). In simple terms, the CTP calculates how much money and how much time is spent in the production process to produce a product (Rivera, 2006). The CTP graph includes elements such as activities, materials, expectations, total cost, Cost-time Investment and direct costs. These elements are represented in Figure 3 (Seyedhosseini & Ebrahimi-Taleghani, 2014).

![Cost-Time Profile](image)

Figure 3 – Cost-Time Profile, (Seyedhosseini and Ebrahimi Taleghani, 2014)

Activities: Activities are displayed as a positive-slope line, representing the cost of them, in the graph of the CTP. Activity Cost Rate is the amount of money spent on a activity during the event time.

Material: the materials are displayed as a vertical line in the CTP graph because the materials and components are received at the beginning of the process. Materials costs are part of the cumulative cost.

Waiting costs: Costs occurred when no activity is performed during the production process which is not accounted as cumulative costs. These costs are displayed as the horizontal line.

Total cost: the total cost is equal to the height of the graph when the product is complete in the CTP graph. The total cost includes all direct costs of the product, regardless of the impact of Cost-time Investment and the time value of money (Rivera & Chen, 2007).

Cost-time Investment: The area below the graph is cost-time investment and indicates how much cost, and how long is accumulated during the production process. This area is effective on both cost and time factor.

The product direct cost: CTI represents the amount of cost-time investment by the organization; however the organizations also expect the return on investment cost, so this critical issue can be considered by adding the Minimum Attractive Rate of Return (MARR) or the Internal rate of return (IRR) and the product direct cost can be obtained by adding the total cost (Rivera, 2006).
Therefore, it is possible to calculate the direct cost according to relation 1 by calculating the amount of time-cost investment, considering the internal rate of return and adding the total cost (Seyedhosseini & Ebrahimi-Taleghani, 2014).

\[
Direct\ cost = Total\ cost + (Cost - time\ Investment \times Internal\ return\ rate) \quad (1)
\]

The CTP is based on the idea that any business can be investigated in terms of organization cumulated cost over time (Gracanin, et al., 2013).

**Research method**

As mentioned earlier, the VSM tool can represent the production time of a product from raw material to the delivery time including the total time of the production process and the total waiting time of the production, and also the CTP tool makes it possible to simultaneously display the time and cost indicators in order to accurately estimate the product direct cost.

![Figure 4 – research framework and steps](image)

Actually, the simultaneous analysis of the two indicators of cost and time, as the main factors of the competitive advantage of organizations.

**Implementing the method in the SAIPA automotive group**

**About SAIPA Automotive Group**

As one of the largest industrial groups in Iran with more than 80 sub-companies and nearly 40,000 human resources, the SAIPA Automobile Group started operating as the Iranian Citroën Co. in 1964. The company is currently cooperating with more than 1,000 suppliers in the country and has an annual production capacity of 950,000 vehicles. The method provided in this paper is being implemented in the SAIPA Company press room and in the side door hemming production line. According to engineering layout, this unit has two main sectors, each with eight workstations. Four products of front right side door, left front, rear right and rear left doors are manufactured in this unit by the operators at all stations and at the last station, the hemming operation is performed by Robot. In this research, the front left side door is selected as the product family under study.

**Current State Map**

Comprehensive information such as information flow, number of machines and manpower, customer demand, turnover, etc. should be collected in order to draw up the
CSM. At the moment, there are 180 units of production demand per day. Time Study has been done for the side door manufacturing activities. The CSM is presented in Fig. 5 according to the available information.

![Figure 5 – Current State Map (CSM)](image)

**Cost-Time profile for current state map**

The amount of product cumulated costs can be calculated using the CTP, over the production time and according to the information provided in Table 1, the total costs and product CTI is calculated, and the CTP is presented in Fig. 6.

**Calculating the product direct cost in the Current Stream Map**

Product direct costs are calculated using the sum of the product total cost with the cost of the product-time investment, which should also include the return rate on internal investment in the investment-time cost. It should be noted that the return rate on internal investment is considered 20% in this paper. Hence, according to relation (1), the direct cost of a product is $ 85.65 in the Current Stream Map.

\[
\text{Direct cost} = 59 + (190.881 \times 20\%) = 59.07
\]

**Future (Improved) state map**

It is possible to improve significantly the existing wastes with the lean principles by a full review of the CSM processes, and a careful review of the production activities at the floor of the workshop. The operator's distance with the primary components that will be charged in the production line is one of the main wastes that exist in the company's side door production line. Production operators at different stations are forced to travel, then return to the manufacturing fixture location for the purpose of producing pre-assembly parts by taking the parts, that takes a part of their time that can be considered as a transportation waste. At station 1 (namely the door reinforce assembly), the operator travels a distance of about 4 meters to reach the primary parts pallet. Then, by the picking of the piece, he puts on assembly of reinforce door. It is possible to use one of the lean production strategies called the supermarket pull system. For instance, the operator can easily assemble his pre-assembled parts in order to assemble at its closest distance, which can significantly improve the cost with a very low cost of the production process by creating a smaller pallet near the manufacturing fixture, considering the ergonomic conditions. Another time waste is the lack of timely supply of the first input that occurs in the warehouse and between the workstations. Failure to comply with the FIFO system will cause the components to remain in the input parts warehouse and production stations for a long time.

One of the main goals of the lean principals can be achieved by improving the above mention items, which is to synchronize the takt time with the operations time. The rate of the assembly of the press room has improved. The FSM is also presented in Fig. 7.
Implementation of cost-time profile for future state map

According to the improved value stream of the production process, the total cost and product CTI are calculated in this section based on the information provided in Table 2 and the CTP of FSM is presented within the Fig. 8.

Calculating the product direct cost for the future state map

According to the information obtained from the CTP of the FSM, and by calculating the cost-time investment, considering the internal rate of return and adding the total cost, the product direct cost is calculated in this section according to the relation (1).

Direct cost = $ 49 + (46,974 $-\text{min} \times 20\%) = $ 49.017

Conclusion

Since the traditional system approach of calculating product costs is not responsive to the time effect of money and the cost-time investment in the accurate calculation production costs, this makes the calculated product direct cost different from its real rate that challenges the strategic decisions of the organization. In the present study, the product direct cost was $ 59 on a CSM, regardless of the time effect of money and time-cost investment; while its real value is calculated at $ 85.65 considering the time effect of money and cost-time investment. Also, the product direct cost in the future state map was $ 49 regardless of the time effect of the money and the cost-time investment; this is while its real value is $ 55.52 considering the time effect of money and cost-time investment. The improvement in the product direct cost was 35.17% in the future state map.

Disregarding the cost of carried out activities in a production process and the cost of consumable raw materials, are among the limitations of flow-charting tools that this paper tried to resolve them by combining cost-time profile and VSM tools and considering two important indicators of cost and time in order to provide a precise estimate of the producing cost a product, a different approach from traditional systems and a new method for calculating the product direct cost. Using this different approach, manufacturing organizations can reduce the Total Production Lead Time (TPLT) and increase the Total Value-Added Time (TVAT) in addition to identify wastes and non-value added activities, and consequently, more precisely calculate the products direct cost by considering the cost-time profiles, the time value of money and cost-time investments.

Abstract

This paper aims to determine the effect that key competitive drivers like human capital, quality, and cost have on supply chain performance, whether this effect is in turn related to the firm’s outsourcing strategy, and whether firm size is relevant in explaining such relationships. Structural equation modeling was used to test the hypothesized relationships for small-to-medium enterprises and large organizations. Initial findings show that human capital strategies are essential for an effective deployment of quality and cost management, which in turn impact supply chain performance by means of effective outsourcing strategies. These relationships, however, are dissimilar for different sizes organizations.

Keywords: Supply chain performance, Outsourcing, Human Talent.

Introduction

To be competitive, firms implement value-adding strategies that build on key competitive drivers (M. V. Ferrer, Santa, & Almadani, 2013; Sha & Chen, 2008). To better understand competitiveness at the firm level, it is necessary to identify the key drivers that impact the performance of the supply chain. Therefore, this research looks at the strategic role of a skilled workforce influence on key competitive drivers such as quality and costs, and seeks to test the
effect of these drivers on supply chain performance, and determine whether outsourcing activities mediate such an effect.

Based on a review of extant literature on supply chain cost, quality, outsourcing practices, and supply chain performance, this research found that human capital strategies are essential to ensure cost-effective and high-quality operations. Also, that outsourcing is important to facilitate the effectiveness of such drivers, and that effective deployment of these key drivers positively influences supply chain performance and a competitive supply chain.

Literature review

Human capital

Strategic human capital management is inherent to business strategy, and greatly determines a firm’s supply chain and, in the long run, competitive advantage (Narasimha, 2000). Not surprisingly, the interest in talent management has grown consistently over the last decade. Human capital is widely assumed to be a key driver of firm and supply chain performance (Jabbour & de Sousa Jabbour, 2016). Human capital is spawned when organizations deploy resources for the development of people who work in the business. Similar to other investment choices, human capital investment is targeted to higher returns as long as the organization is rational.

The effect of human capital on supply chain performance, however, is not always clear. Human capital management is afflicted with misunderstandings, uncertainties, and lack of clarity, implying that the field is not grounded in practice and thus reinforcing why it is viewed by many experts as a puzzle (Stahl et al., 2012). The effect that human capital management has on the outcome of an organization remains an issue particularly in situations where only highly ranked staff is considered to be an asset to a business (Kehinde, 2012). It is on this basis that this paper aims to clarify the effect of human capital management on the outcomes of the supply chain and, consequently, the business performance and competitiveness. Rather than directly impacting performance, it is through its role in facilitating the adoption of value-adding organizational practices that human capital management can indirectly impact firm and supply chain performance and competitiveness. In particular, this research contends that human capital is a significant driver of firm and supply chain performance through its combined relationship with other, more direct drivers, such as cost and quality strategies.

Costs

The cost is the financial expense incurred in engaging in business which is essential to evaluating a firm’s performance. Effective supply chain management will reduce the costs for a firm. Cost can be measured in terms of the total supply chain, each supply chain process, or the logistical costs only (SÖderber & Bengtsson, 2010). Supply chain cost is defined as all relevant costs in the supply chain of the company or organization in question. Analysis of supply chain cost can be performed in different ways. Different kinds of cost groupings can be found in the literature including transportation, production, inventory, packaging, materials holding, and order processing (Sachan, Sahay, & Sharma, 2005).

In this research, we are especially interested in two important, and often overlooked, cost elements: transaction costs and switching costs (Williamson, 1985). Information becomes available to supply chain participants at a cost. Firms incur in costs when searching for information and safeguarding against opportunistic behavior from other participants. When information is shared more frequently, searching costs and information-sharing transaction costs tend to decrease (Simpson, Power, & Samson, 2007), which in turn decrease the overall cost of
products and services (Brynjolfsson & Smith, 2000). On the other hand, asset specificity tends to increase as information is shared more freely and more frequently. Thus, interestingly, the reduction in transaction costs come as a trade-off to an increase in switching costs, given that it becomes increasingly costly for supply chain partners to seek new partners in the marketplace.

**Quality**

There is no unique definition of quality, and different meanings might be equally appropriate under different circumstances. The manufacturing literature, for instance, refers to quality as the conformance to standards (Elshennawy, 2004; Heizer & Render, 2006), a product-based approach that ensures that goods are manufactured well from the beginning. From a marketing perspective, quality relates to meeting or exceeding customer’s expectations (Dean & Bowen, 1994; Slack, Stuart, Johnston, & Betts, 2006), a challenging definition indeed given that identifying such expectations is a complex task, to say the least.

From the point of view of quality management, supply chain could be recognized as providing quality products and services across every organization in the supply chain, to clients’ expectations. Improving the quality of all supply chain processes leads to cost reductions, improved resource utilization, and improved process efficiency (M. Ferrer, Santa, Storer, & Hyland, 2011). There are a few studies that investigate how quality management can be used to improve the performance of the entire supply chain and also solve some problems within the supply network (Lin & Gibson, 2011) and other studies that identify various theoretical and methodological characteristics of the way in which knowledge management applications are proposed in the supply chain context.

Some authors suggest that further research is needed to provide more understanding about quality practices in the supply chain context and the association between quality practices and a system’s overall performance, so there are suggestions for future research that could be very helpful for the companies (Marra et al., 2012; Craighead et al., 2009). For example, Terziovski and Hermel, 2011, in their exploratory study on the role of quality management practice in the performance of integrated supply chain, proposed that future research should focus on why quality practices are strong predictors of an integrated supply chain. Notably, relatively little research has been conducted on the association between quality and supply chain performance with the mediation of strategic practices such as outsourcing.

**Outsourcing**

Outsourcing of activities has been historically linked to cost-saving, third-party logistics (3PL) procurement strategies in manufacturing firms (Elango, 2008). With increasing frequency, though, outsourcing is becoming an important strategic option for all types of firms, and its benefits transcend the usual cost reductions associated with economies of scope and productivity by specialization. Outsourcing can take various forms, including outsourcing for some components, computer programming, services, tax and accounting services, customer services, transportation and logistics, compensation and human resources activities. Logistics outsourcing is one of the most common outsourcing forms that has attracted the attention of firms, academics, and researchers in recent years. According to Erturgut (2012), logistics outsourcing serves five basic purposes: providing the cost leadership, capable to use the basic perfections, providing the competitive edge, harmonizing with technology alterations and downsizing. The following section summarizes the expected logistics outsourcing advantages and disadvantages.

Hsu et al. (2012) find that logistics outsourcing can reduce fixed costs and increase flexibility, allowing greater focus on the core activities, reduce heavy asset investments and
improve the quality of service provided. Because logistics service providers (LSPs) are more efficient than logistics service users (LSUs) in terms of warehousing and transportation, costs reduction is the major benefit that LSPs offer to LSUs (Deepen, 2007). LSP outsourcing directly affects the LSUs cost position through reducing capital investment requirements. Additionally, LSPs help LSUs to avoid any unnecessary investment in workforce and to manage their supply chain at an affordable cost. Another major benefit is the increase in flexibility. LSPs help firms to become more responsive to the customers' requirements. Furthermore, a survey has found that the primary reason for outsourcing is the capability to focus on the core competencies, not cost reduction.

Most Fortune 500 firms are involved in some form of outsourcing, a pattern that is growing throughout industries and regions around the world. Such popularity notwithstanding, there are still untapped areas where outsourcing still has to prove its full potential, such as small and medium firms, outsourcing in emerging economies, and exploiting leveraging capability development on outsourcing strategies. In a globalized marketplace, small-to-medium enterprises (SMEs) are increasingly pressed to proactively seek and develop strategic partnerships in the supply chain (Kumar, K. Singh, & Shankar, 2014). Outsourcing can be a catalyst for innovation, quality, and supply chain flexibility, and thus contribute to level the battlefield and attain competitive advantage, provided that cross-functional in-house activities within the firm are effectively linked to externally executed processes (M. Beheshti, Oghazi, Mostaghel, & Hultman, 2014).

**Supply Chain performance**
As global economic order unfolds, firms are increasingly aware of measuring their performance outcomes and the impact of strategic supply chain on competitiveness. Researchers have argued that more often firms implement quality management initiatives to improve the overall quality of operations by the reduction on operational cost and the increase of agility practices. Hubbard (2009) suggested that measuring performance is likely to become more complex as stakeholder expectations about companies’ economic, environmental, and social responsibilities are constantly shifting.

Supply chain management assists organizations to control the flow of information, materials, and cash from suppliers, manufacturers, distributors, and retailers to customers. Through an effective planning, controlling, and coordination of the supply chain activities, organizations are able to accomplish fast response, low inventory, high quality, and customer satisfaction, which in turns lead to a competitive advantage (M. V. Ferrer & Santa, 2017). Therefore, performance is the measure which aims to benchmark and evaluate the effectiveness and efficiency of any organization. Different stakeholders require different performance indicators to enable value-adding reporting, starting improvement activities to outperform competitors, and understanding customers’ reading of the services and products offered by the firm.

The SCOR model approach directly addresses the needs of supply chain management with balanced measurements. These measures are characteristics of a supply chain that permit it to be analyzed and evaluated against other supply chains with competing strategies. Supply chain goals express the balanced needs of a supply chain’s stakeholders including suppliers, manufacturers, distributors, and retailers at different levels (Najmi and Makui, 2011). Through SCOR, companies try to release financial resources, reduce costs, lighten the company management, and improve global performance. Hence, SCOR is close to the outsourcing concept, because the latter also supposes the restructuring of the organization by relocating a part of its
activities outside the company to reduce costs. Similarly, Ellram and Stanley (2008) discuss various performance measures applicable to strategic as well as in tactical outsourcing which include cost reduction, time to market on new products/services, meeting customer needs, product/service performance, new product/service launches, responsive supply chain, working capital and cost savings/increased profitability.

A number of disadvantages and challenges related to outsourcing as a strategic performance enhancer are also mentioned in the literature. Dabhilkar and Bengtsson (2008) argue that outsourcing has negative effects when used as a main strategy for performance improvement. Similarly, Broedner et al. (2009), states that the reliance on outside suppliers may lead to a loss of overall market performance and, according to Gilley and Rasheed (2000), the consequence of outsourcing is lower innovation capacity and the cost savings associated with outsourcing may be overestimated. Some other reasons why companies are against outsourcing include sacrificing their competitive base, opportunistic behavior, rising transaction and coordination costs, limited innovation, and higher procurement costs.

**Hypotheses**

Based on our literature review, this research contends that human capital strategies are essential to ensure cost-effective and high-quality operations; that outsourcing is important to facilitate the effectiveness of such drivers; and that effective deployment of these key drivers positively impacts the performance of the supply chain and, consequently, the competitiveness of the organization. Therefore,

*H1:* There is a positive relationship between human capital and a firm’s quality strategy

*H2:* There is a positive relationship between human capital and a firm’s cost strategy

*H3:* There is a positive relationship between human capital and a firm’s outsourcing strategy

*H4:* There is a positive relationship between a firm’s cost strategy and its outsourcing strategy

*H5:* There is a positive relationship between a firm’s quality strategy and its outsourcing strategy

*H6:* There is a positive relationship between a firm’s cost strategy and the supply chain performance

*H7:* There is a positive relationship between a firm’s quality strategy and the supply chain performance

*H8:* There is a positive relationship between a firm’s outsourcing strategy and the supply chain performance

Figure 1 illustrates the hypothesized relationships, and the corresponding structural equation model.
**Figure 1.** Research model with hypotheses.

**Research methods**

To test our hypotheses, we submitted an online survey to 600 multi-sectorial firms in the Valle del Cauca agro-industrial region, in Colombia. Similar studies that consider the impact of human capital on operational strategies focused on cost, quality, and outsourcing initiatives have been conducted in other countries (M. V. Ferrer & Santa, 2017). However, to the best of our knowledge, there are no precedents to this kind of study in our region.

A five-point Likert-type scale, ranging from 1—strongly agree to 5—strongly disagree, was used to rate statements related to the operationalization of the model’s variables. In total, 435 participants submitted their responses, for a 72.5% response rate. We discarded 31 surveys owing to inconsistencies or significant missing data, for a final count of 404 usable surveys (67.3% effective response rate). We used the average mean values of the statements’ ratings to construct the structural equation model’s variables. To gain a better understanding of how competitive priorities relate to firm size, we split the collected surveys into two distinct groups, small to middle enterprises SME (N=167) and largo organizations LO (N=237).

The analyses included confirmation of the conceptualized model shown in Figure 1 by estimating the model variables’ predictive relationship and the model’s fit indices to determine overall confidence level. We also conducted confirmatory factor analysis (CFA) to assess the relationships between the observed and continuous latent variables, and to determine the measurement model’s overall fit (Cooksey, 2007; Hair, Black, & Babin, 2010). We estimated factor loadings, confirming that items loaded on only one construct (i.e., no cross loading), and correlated our latent constructs (equivalent to conducting an oblique rotation in exploratory factor analysis). We assessed internal consistency using Cronbach’s alpha coefficient and the items-to-total correlation.

To support the model, we computed goodness-of-fit indices (GFI). The resulting indices (SME: CMIN/DF=2.945, probability=0.000; and LO: CMIN/DF=4.168, probability=0.000) fall within the accepted criterion of CMIN/DF≤5.0 (Wheaton, Muthen, Alwin, & Summers, 1977). Whereas Marsh and Hocevar (1985) recommended using ratios as low as two or as high as five, Carmines and McIver (1981) suggested ratios in the range of 2:1 or 3:1 as indicatives of an acceptable fit between the hypothetical model and the sample data. Also, a comparative fit index (CFI) <0.9 is usually accepted as supportive of the model (Bentler, 1990), which is the case in our hypothesized model (SME: CFI=0.915; LO: CFI=0.901). Finally, the baseline comparisons fit indices suggest that the hypothesized model fits the observed variance-covariance well, relative to the null or independence model (see Table 2).

### Results and Discussion

Table 2 and Figure 2 summarize the structural equation modeling (SEM) results in the relationships between human capital (HC), quality strategy (QS), and cost strategy (CS). For SME, there is a strong and positive relationship between HC and the two types of strategy (QS: b=0.42, p <0.001; and CS: b=0.39, p <0.001), thereby supporting hypotheses H1 and H2. Findings for LO were similar, also indicating a strong and positive relationship between HC and the two types of strategy (QS: b=0.58, p <0.001; and CS: b=0.34, p <0.001), thereby supporting hypotheses H1 and H2. Concurring results for SME and LO endorse the importance of implementing adequate human resources practices to ensure quality and cost management, regardless of firm size.

</table>

On the other hand, there is no effect of HC on outsourcing (OS), neither for SME (b=0.23, n.s.) nor for LO (b=0.16, n.s.), therefore rejecting hypothesis H3 on the positive effect of human capital on a firm’s outsourcing strategy. Hypothesis H4, that there is a positive relationship between a firm’s cost strategy and its outsourcing strategy, was also rejected for SME (b=0.02, n.s.). Note, however, that the results support H4 for LO (b=0.22, p < 0.005), which suggests that small firms do not seek cost efficiency by means of outsourcing activities, compared to larger firms (at least in the Valle del Cauca region). Hypothesis H5, which suggests that firms that prioritize quality strategies will tend to implement outsourcing initiatives, was rejected for both SME and LO. The findings showed a positive relationship between cost strategy and supply chain performance, for both SME (b=0.29, p <0.001) and LO (b=0.26, p <0.001), thereby supporting hypothesis H6. Hypothesis H7, that there is a positive relationship between quality strategy and firm performance, was rejected for SME (b=0.05, n.s.) and supported for LO (b=0.30, p <0.001). Finally, hypothesis H8, which suggested that firms will improve performance through the use of outsourcing practices, was rejected for both SME and LO. Figures 2, summarize the structural equation modeling results.
Conclusion
The findings from this research suggest that human capital strategies are essential for an effective deployment of quality and cost management strategies, which in turn impact positively on the supply chain performance. Furthermore, these results hold for both SMEs and LOs. Aligned with much of extant literature on human resources, human capital’s impact on firm and supply chain performance is therefore indirect, and results are rather attained by means of effective quality and cost strategies.

The relationship between such key drivers and supply chain performance, however, is not equally significant or as strong for SMEs as it is for LOs. Whereas cost strategy is indeed important for both SMEs and LOs to achieve competitiveness through superior supply chain performance, quality strategies seem to be related to supply chain performance only for LOs. Costly total quality management (and other, similar quality-related systems) could be the main reason.

Another interesting inference from our results pertains to the firms’ preferences towards outsourcing strategies. Contrary to widespread, international business sense, the firms studied seem to disregard outsourcing practices as a source of competitiveness. Indeed, the relationship between cost strategy practices and outsourcing strategies holds only for large firms. When SMEs outsource their activities, they are more driven by lack of access to the types of know-how, technologies, capital, and other resources that the bigger organizations enjoy. This could be explained by the notion that outsourcing decisions in Colombian SMEs may be made on the basis of a management team's skill level or personal interest. In comparison to LOs, the management teams of SMEs most likely already recognize the areas in which they have interest and ability and since they are small, it would easier for them to focus attention on those activities. As a result, the outsourcing decision may be made on the basis of talent, interest in performing an activity, or convenience rather than how it supports the whole organizations' strategy.

Similarly, it could be argued that Colombian SMEs are still in the process of establishing routines and hence lack competitive advantage as compared to larger organizations. It is therefore difficult for them to determine which functions are necessary to support the organization. In view of this, outsourcing decisions for SMEs would likely be premature and could result in the destruction of capabilities. In consequences, many SMEs would be less likely to pursue outsourcing for the many reasons global SMEs do it.
Taken together, our results hint that local companies should strengthen their alliances with third-party logistics (3PL) partners to be internationally competitive. The benefits usually associated with 3PL practices (e.g., service levels control, systems integration, access to a variety of specialized resources, cost reduction) are important for competition in a globalized marketplace. Such practices, however, do not seem to be the norm in the analyzed region. Organizational culture, national or regional culture, limitations in financial or human resources, and other factors could be hindering more proactive outsourcing strategies, especially amongst SMEs. This said, our study also shows that creation of firm value (i.e., performance) is indirect. That is, effectively implementing quality and cost strategies combines synergistically with outsourcing strategies to improve supply chain performance, perhaps compensating for the lack of other resources or capabilities.

Certainly, the key drivers studied are not the only ones affecting the performance of the supply chain. Beyond diving deeper into the nuances of the relationships hypothesized in this paper, future studies could also explore cultural or regional specificities that better explain the competitive drivers (or lack of them) amongst our local firms. For instance, local firms might lack the capability to obtain quality information related to 3PL’s best practices, and therefore ignore the strategic value of an effective supply chain partnership, the potential for risk reduction and risk sharing implicit in smart outsourcing strategies, and the synergies to be attained when important resources are freed—through 3PL—to be invested in other, core-related, valuable ventures.

Our contribution to the literature is threefold. Upon exploring the relationship between predictors and outcomes of supply chain performance through outsourcing, we are contributing not only to a more complete understanding of key competitive drivers, but we are also highlighting regional specificities that could help to bring these matters into the managers’ radars and help them consider more effective strategies. In addition, we are contributing to research methodologies by proposing a quantitative approach that helps to fill the numerical void common to many studies on competitiveness.

Abstract

To distribute high-quality fish throughout the food supply chain is a challenging task for the fishing industry. To deliver fish to the appropriate processors, in this work, we propose a decision support system (DSS) based on agent-based simulation and optimization for delivery of the right product to the right processor. The proposed DSS helps the organization in a) reducing losses in Whitefish supply chain, b) making a higher profit, and c) improving the supply chain performance.

Keywords: Vehicle routing, Agent-based simulation, Whitefish supply chain

Introduction

The fishing industry in Norway has significant contributions to their trade (SSB, 2018). In 2017, it contributed approximately 11% of their total export (OEC, 2019). However, the sector is experiencing declining profitability (Qualifish, 2018). Whitefish supply chains are complex in nature due to seasonal variations, high supply uncertainty and rapid quality deterioration due to handling and temperature variations. In Norway, catch volumes for whitefish including cod, saithe and haddock amounted to 721 525 tonnes in 2014. This included 473 478 tonnes of cod with a value of approximately 520 million Euros.

Most wild cod is exported as lower-value products preserved in salted, dried, and frozen forms. In season whitefish processors typically buy from coastal vessels that deliver fresh fish and in off-season, they mostly buy from sea-going vessels that deliver frozen fish. So, delays and inefficiencies in the distribution of whitefish from sourcing stations to appropriate processors after landing is cost-intensive and any delays in distribution can also contribute to food losses.
In this paper, dynamic pickup and delivery routing from different sourcing stations to the processors is investigated in the whitefish supply chain based on the quality of fish. We have limited our study to cod (*Gadus morhua*) which provides the most value among the wild caught fish in Norway (NSC, 2017).

The fish arrives at the sourcing stations in bulk mostly by coastal vessels that deliver fresh fish in season or seagoing vessels that provide fresh and/or frozen fish in off-season (Thakur, 2017). The arrival times of coastal and seagoing vessels at sourcing stations are uncertain, and for the most part this is also true for the quantity and quality of whitefish on the vessels. After the arrival of fish at the sourcing stations, each batch of bulk whitefish is marked with a current quality. The remaining shelf-life of that batch represents the condition of the fish, or the current quality in days until the fish can no longer be transported to appropriate processors. It is assumed that the processors prefer receiving the fresh fish, i.e., with maximum remaining shelf-life and that the sourcing stations have full knowledge about the quality of each batch of whitefish that arrives in bulk. Over time the quality of fish deteriorates based on the temperature and its intrinsic characteristics. We have considered three different temperatures in this study, namely, at sourcing stations, during the loading and unloading process, and on the vehicle during transportation.

**Problem Description**

In this study, we have considered two types of processors based on the capacity and products at different locations:

1) primary processors that produce packed fresh and frozen whole fish and fillets,

2) secondary processors that mainly produce a mix of consumer products such as ready meals, sushi, etc.

Processors place an order to the nearest sourcing stations based on their demand and processing capacity. Each requested order has to be served by the sourcing stations as early as possible to maintain the freshness and the quality of the fish. Fish from the sourcing stations is transported by trucks to different processors based on the quality. Availability of vehicles at each sourcing station varies over the day depending on the transporter preferences. Transporter has to select the pickup location (i.e., sourcing stations), and routing of the trucks based on the order, to minimize total travel distance and maximize the remaining shelf-life of fish at delivery to the processors. The focus of these objectives is to reduce the cost and maximize the customer satisfaction by the processors respectively. Therefore, an optimal solution needs to be found as per the requested order from a set of available solutions with a combination of the accessible vehicle route, the limited number of trucks in the fleet, and the current locations of each truck in the supply network.

Figure 1 describes the problem settings as investigated in this paper. To fulfil an order requested by the processors, the sourcing station manager or transporter has to make the following decisions:

(i) which type of vessels are delivering the fish to the sourcing stations;

(ii) which sourcing station should serve a requested order; and

(iii) selection of the vehicle route.
These decisions impact both objectives, i.e., fish quality and travel distances. Additionally, processors get a competitive advantage by delivering fresher products to their customers.

Figure 1 Delivery of whitefish under consideration of fish quality and available vehicle routes

Design of the decision support system
To investigate the problem described in this paper, we introduce a DSS based on agent-based simulation and optimization. This system combines the Geographic Information System (GIS) data from OpenStreetMap, (2018) with vehicle routing procedure, based on the existing architecture described in Fikar, Gronalt, & Hirsch, (2016). Figure 2 depicts the overview of the developed DSS. The user sets the input parameters and data and further defines the study region.

Figure 2 A DSS to investigate dynamic vehicle routing in whitefish supply chain
Once sourcing stations receive an order from a processor, it sends fresh or frozen fish available at the sourcing stations via truck. In this study, we consider that each sourcing station has a cold storage facility to reduce losses. Transportation states can be depicted in Figure 3, diagrammed in AnyLogic 8.3.2. Initially, a truck located at the sourcing stations waits for a shipment request sent by the processors. Once it gets the request, it loads fresh or frozen fish as per the order and delivers them to the appropriate processors. Travel time between sourcing stations is computed based on driving speed. We considered the speed of a truck is 60 Km per hour (60 Km/Hr) and distance is given by GIS module in AnyLogic 8.3.2. The truck unloads the fish at a processor and returns to the sourcing station. Finally, a truck is located at sourcing stations and waits for the next order. The advantage of the proposed agent-based simulation model is that it accurately estimates the dynamic ordering process between sourcing stations and processors.

Selected candidate sourcing stations, primary processors, and secondary processors sites in AnyLogic simulation software are in a wide range of locations in Norway.

Results

To study the defined problem setting in the above section regarding whitefish delivery to processors from sourcing stations in Norway, we implement the proposed DSS with AnyLogic 8.3.2. An overview and description of the parameters used in the DSS are given in Table 1. Further, we have set the value of the parameters used in this DSS simulation modeling based on literature and the secondary sources. The remaining shelf-life of the whitefish is calculated by Arrhenius equation (Laidler, 1984). The route from the sourcing stations to processors are taken from the OpenStreetMap (OpenStreetMap, 2018), and the shortest routes are calculated based on the GraphHopper features of AnyLogic 8.3.2. The visualization of the DSS is done based on GIS.

The performance of the DSS is shown in Table 2. We can see that the waiting time of the vehicle at sourcing stations is about 13 hr which is maximum as compared to processors. The average time to complete a tour from the sourcing stations to the processors is approximate 8 hr and the average distance travelled by a vehicle is approximate 473 Km/day in our setting. So, we can make changes in the strategies to minimize the waiting time of the vehicle at sourcing stations. The limitations of our study are that we have not considered the congestion on the route and also the working timing of the drivers.

Conclusion

In this paper, we proposed a decision support system (DSS) based on agent-based simulation and optimization to the delivery of the right product to the right processor basically regarding the whitefish delivery from sourcing stations to the processor in Norway. The main focus is on the quality of whitefish which is the influencing factor in
the dynamic vehicle routing. It will help the decision makers in the vehicle routing by consideration of the quality of whitefish which is not the case in traditional vehicle routing. Future work can focus on extending this model by including traffic congestion on the route.

Abstract

In the modern era of e-grocery, attended home delivery (AHD) has been identified as a crucial problem for the last-mile delivery problem (LMD). This paper deals with a real-life LMD problem in the context of Indian public distribution system (PDS). In this study, we propose a meta-heuristic algorithm based on iterated local search (ILS) to obtain a routing solution. By computational experiments, we show that the proposed approach performs significantly well for large size problem instances, and can be implemented to solve delivery problems faced in Indian PDS.

Keywords: Indian PDS, attended home delivery, iterated local search

Introduction

In recent years, last mile delivery has drawn significant attention in research and real-world practice, due to its importance in the modern era of e-commerce. The last mile delivery problem is a variant of the vehicle routing problem (VRP). This problem is well known for being NP-hard and extremely difficult to solve optimally. Attended home delivery is the most challenging part of the last mile delivery problem. In the modern society, this class of problem has substantial importance to several real-world problems ranging from drug companies and home health care services to telecommunication sector, e-grocery, and online retail (Campbell and Savelsbergh, 2005).

For a typical case of attended home delivery (AHD) under the last mile delivery (LMD) problems, the customer must be present to collect the delivery item. The presence of the recipient may be required due to several reasons, say for payment, security issues, or difficulties with leave the parcel unattended. In the present study, we consider a unique AHD problem faced by the Government of India, Delhi, to aid a problem of door-step delivery of rations under the Indian Public Distribution System (PDS). According to a proposal made by the Department of Food, Supply and Consumer Affairs of the Government of Delhi, PDS beneficiaries of Delhi can now opt for doorstep delivery of monthly ration. This action is hugely beneficial for the persons
of old age and with a physical disability (Botekari 2017). However, as discussed before, real-life doorstep delivery problems are NP-hard and extremely difficult to solve optimally. Thus, to aid the real-life problem of door-step delivery of rations in India, we formulate a multi-objective mathematical model and design a meta-heuristics algorithm to solve it.

**Literature review**

The work by Dantzig, Fulkerson, and Johnson (1954) was one of the first literature discussed on the VRP, followed by the work by Clarke and Wright (1964), where they incorporated more than one vehicle in the mathematical formulation. Since then, several other versions of VRP emerged. To name a few, one can see the paper by O’Connor & De Wald (1970) on transportation network design, work by Levin (1971) on fleet routing problem, and the study on distribution management by Eilon, Watson-Gandy, & Christofides (1971). The concept of time-window was later introduced by Solomon (1983) to the classical VRP problem. After 1990, researches on VRP accelerated rapidly, mostly due to the availability of computational resources. During this era, a number of search algorithms evolved as meta-heuristics to aid VRP and several other NP-hard combinatorial problems (Eksioglu et al., 2009). Since 1990, researchers discussed several meta-heuristics algorithms to solve VRP problems. To discuss a few, Renaud et al. (1996) were one of the first to propose a meta-heuristic for the VRP problems. Filipec et. al (1997) first proposed a genetic algorithm for the travel distance minimization. Later, Vianna et al. (1999) incorporated an evolutionary algorithm in iterated local search framework to minimize the total cost. Wu et al. (2002) proposed a simulated annealing approach and Polacek et al. (2005) proposed a variable neighbourhood search procedures for the capacitated VRP. Maya et al. (2012) adopted a greedy randomized adaptive search procedure to minimize travel distance and cost. Alaïa et al. (2016) combined clustering algorithms with genetic algorithms to optimize a pick-up and delivery problem. Cai et al. (2018) adopted an iterated local search based meta-heuristic for solving a real-life last mile delivery problem of an express delivery company in China.

All the above mentioned literature discuss the single-objective variant of VRP. However, literature on multi-objective VRP are relatively scarce. Montoya-Torres et al. (2015) pointed out that among the substantial literature on VRP, less than fifteen present was on multi-objective VRP. To highlight a few, Lin and Kwok (2005) studied a location routing problem considering simultaneous decision making on the location of depots, vehicle routing and assignment of routes. Tan et al. (2006) studied a truck and trailer vehicle routing problem (TTVRP) to minimize routing distance and the number of vehicles by a hybrid multi-objective evolutionary algorithm (HMOEA). Weise et al. (2010) presented an interesting real-life VRP problem involving the maximization of resource utilization and minimization of travel distance. They used an Evolutionary algorithm to solve the multi-objective problem. Dharmapriya and Siyambalapitiya (2010) considered a multi-objective VRP with time windows and split delivery, and adopted an artificial intelligence based computational technique to optimize the problem. A hybrid electromagnetism algorithm for multi-depot periodic vehicle routing problem was proposed by Mirabi (2014) to minimize travel distance and customer waiting time. Finally, the concept of carbon emission reduction in a multi-depot VRP was discussed by Rodrigues et al. (2014).
Problem Formulation
In the present scenario of Indian PDS food grains and other essential commodities are distributed to its beneficiaries via Fair Price Shops (FPS). As per the calculation of Chakraborty and Sarmah (2019), each FPS is on an average associated with about 500 families. As per the proposal of the Delhi Government, the households entitled for their monthly food grains under NFSA 2013 Act can now choose to get their ration delivered at their doorstep at an additional service charge. Figure 1 shows a general framework for the aforesaid problem.

![Diagram of door-step delivery problem](image)

**Figure 1: Framework of a door-step delivery problem of Indian PDS**

Here, the beneficiary initiates a delivery request through a mobile application or voice calling. In the process, the beneficiary also chooses a time slot for the delivery request. Upon receipt, the fair price shop processes the order and attempts to deliver the grains in the aforementioned time slot to avoid failed delivery due to non-availability of the recipient. This kind of problem can be broadly identified as single-depot capacitated vehicle routing problem with time windows (SDVRPTW). The provision to let the recipients choose the delivery time slot is one major aspect of SDVRPTW. Thus, the major challenge of the problem lies in the framework of the door-step delivery model (Agataz et al. 2011), as it is extremely important to minimize the randomness and no-show probability of the beneficiaries by abiding the time slot selected by the beneficiary. The nature of this kind of problem is NP-hard (Cai et al., 2018) and is extremely difficult to solve optimally. Therefore, in this study, we formulate the problem as a multi-objective mathematical programming model and solve by using the iterated local search (ILS) framework (Lourenço et al., 2003).

Mathematical model
Given a set of beneficiaries \( V = \{1, 2, \ldots, n\} \) with known demands of \( q_i \) for any \( i \in V \). The maximum vehicle capacity is \( Q \). The FPS is considered to be a source node and marked as 0. The directed graph can thus be noted as \( G = (V^+, A) \), where \( V^+ = V \cup \{0\} \) is the set of nodes and \( A \) is the set of arcs. Each arc \( (i, j) \in A \) is associated with a travel time \( T_{ij} > 0 \). Each customer is subject to a service time \( s_i \). The preferred time window in hours opted by a beneficiary is defined as \( m_i \) and \( n_i \). The formulation of the problem is as follows.
Minimize

\[ Z_1 = \sum_{i,j \in V} T_{ij} x_{ij} \]  
\[ Z_2 = \sum_{i,j \in V} (\max[(m_j - t_i),0]) + (\max[(t_i - n_j),0]) \]

Subject to:

\[ \sum_{j \in V} x_{ij} = 1 \quad i \in V \]  
\[ \sum_{j \in V} x_{ih} - \sum_{j \in V} x_{ij} = 0 \quad h \in V \]  
\[ q_i \leq u_i \leq Q \quad i \in V \]  
\[ u_i - u_j + Q x_{ij} \leq Q - q_j \quad i, j \in V \]  
\[ t_i + (t_j + s_j) x_{ij} - N(1 - x_{ij}) \leq t_j \quad i, j \in V \]  
\[ x_{ij} \in \{0, 1\}, \quad i, j \in V^+ \]  
\[ u_i, t_i \geq 0 \quad i, j \in V^+ \]

\(x_{ij}\) is 1 if arc is included in any route, otherwise 0; \(t_i\) is the time at which delivery is made for every node \(i\). \(N\) is a very large number and \(u_i\) is the accumulated demand for node \(i\). Equation 1 minimizes the total travel time, equation 2 minimizes the deviation of the actual delivery time from the beneficiary specified delivery time. Equation (3) and (4) ensures every route to begin from the depot and the visit of each customer to be exactly once. Equation (5) and (6) is the route capacity constraint and ensure that the amount of delivery on a route has to be less than vehicle capacity \(Q\). Equation (7) ensures that the route schedule remains feasible for every route.

**Proposed solution methodology**

An iterated local search (ILS) has been employed as the algorithm framework to solve the aforementioned problem of SDVRPTW. Initially, we use the weighted sum approach to convert the multi-objective problem into a single objective problem. The ILS framework consists of three major components, namely initial solution generation, improvement and the perturbation. At the beginning of the process, an initial feasible solution is generated for the problem. This method relies on traditional hill climbing algorithms as given in algorithm 1.
Algorithm 1: Initial Solution generation

Initialize an empty route r;
for all days
    current time ← 0;
    Initialize current node I ← 1;
    for each node
        Calculate time required to reach all other nodes from current node A;
        for all nodes accessible from current node
            calculate the time deviation B;
        end for
    end for
Find minimum of feasible weighted sum of A and B;
i ← new node the vehicle goes to;
Insert newly found node to node in route r;
Assign the column of time for that node to zero;
end for

In the improvement phase, several relocate and exchange operators are used for generating a better solution. In the relocate function, one or two vertexes is removed from the initial route and compared from the original solution. In the exchange operator, on the same route, two orders are interchanged. The solutions are discarded whenever they lead to infeasible solutions and the steps are shown in algorithm 2.

Algorithm 2: Solution Improvement

Use route to generate initial solution S₀
Set Sᵢ ← S₀
for all days
    Employ improvement operators;
    if f(Sᵢ) > f(S₀)
        Sᵢ ← Sᵢ
    else
        Interchange by and update solution Sᵢ;
        if f(Sᵢ) > f(S₀)
            S₀ ← Sᵢ
        end if
    end
end
Repeat same process by interchanging nodes for 2 random days
S₀ is now the optimized solution

In the perturbation phase, we employed a large neighbourhood search algorithm to explore the solution space. Several removal and insertion operators are used in this process. The removal operators included in the process are consists of Random removal (Random removal of some orders of a route), Worst removal (Remove highest cost order) and Route removal (Remove a complete route) from the solution. The Insertion operators are Random insertion (Random insertion of some orders of a route), Greedy insertion (Insert the smallest cost increment) and Route insertion (Random insertion of the removed route). The perturbation algorithm is shown in algorithm 3.
Algorithm 3: Perturbation

Find a solution that has to be perturbed;
Find a removal operator to be used;
Find a insertion operator to be used;
Generate solution $S_p$
Apply solution optimization on $S_p$

if $f(S_p) > f(S_o)$
    $S_o \leftarrow S_p$
else
    Accept original solution $S_o$
end

When a better solution is generated in the process, the previous solution is discarded and the new solution is stored. We run the operation for a pre-specified number of iterations, the program is terminated and the best solution is reported.

Computational Results

Here, in this section, we discuss the computational results for the aforesaid problem. The ILS was encoded in MATLAB 2015b on an Intel Core-i5 processor with 8 GB RAM and Windows 7 Professional edition. We applied IBM CPLEX Optimization studio on the same platform with a run-time limit of one hour to compare the solution gap for the mathematical programming problem. We have assigned equal weight of 0.5 for both the objective functions for the weighted sum average method. This converts the multi-objective model into a single objective optimization problem.

Two test instances were randomly generated considering a planning horizon of five days and seven days. Each instance was run for five different random scenarios. All the input parameters were randomly generated and the time window was considered to be of two hours. Vehicle capacity was assumed to be of 500 KG and service time was considered to be random numbers within $[10, 20]$ minutes. Customer demand was calculated as per NFSA 2013 (Chakraborty & Sarmah, 2019) and family size was considered to be random within $[1, 6]$.

To calculate the solution improvement, we compare the best solution reported by CPLEX after one hour of runtime. From table 1, it is seen that ILS performed better than CPLEX in one-hour time limit for almost all scenarios. It is also seen that, although CPLEX failed to solve the problem instances optimally for both the five and seven-day scenarios in the one hour time, the optimality gap shown by CPLEX was much lesser for the five-day instances, than the seven-day instances.

In order to compare the solution improvement, we use the following formulation:

$$\text{Improvement} = \frac{\text{CPLEX solution value} - \text{ILS solution value}}{\text{CPLEX solution value}} \times 100$$ (10)

### Conclusions

In this paper, we investigate a real-life SDVRPTW problem faced by the Government of India. An iterated local search (ILS) approach integrated with an adaptive large neighbourhood search has been proposed to solve the problem. The effectiveness of the algorithm has been evaluated through a set of randomly generated instances. We show that the ILS approach can effectively aid the door-step delivery problem in the Indian PDS. In this scope of work, the present research only explores a real-life door-step-delivery problem of Indian PDS. However, this study, by its nature, is generic and can be extended to many real-world SDVRPTW problems.

Truck sharing in the spotlight of current research streams - a literature review

Victor B. Wildhaber (victor.wildhaber@unisg.ch)
Institute of Supply Chain Management of the University of St.Gallen

Abstract

The road freight transportation-industry in the German speaking countries (Germany, Austria and Switzerland [GAS]) faces high margin pressure (resulting from the competition pressure) on the one hand and empty capacities on the other hand. The ecological pressure from e.g. regulatory measures, competition or public due to reputation reasons should not be under-estimated. The market for road freight transportation, however, lacks possibilities to foster utilization of physical resources through a sharing approach such as truck sharing that would lower costs and enable logistic service providers (LSP) to achieve higher margins.

Keywords: Truck sharing, road freight transportation, literature review

Motivation

The road freight transportation-industry in the German speaking countries (Germany, Austria and Switzerland [GAS]) faces high margin pressure (resulting from the competition pressure) on the one hand and empty capacities on the other hand. The ecological pressure from e.g. regulatory measures, competition or public due to reputation reasons should not be under-estimated. The market for road freight transportation, however, lacks possibilities to foster utilization of physical resources through a sharing approach such as truck sharing that would lower costs and enable logistic service providers (LSP) to achieve higher margins.

Applications of the sharing economy can be found in various areas such as accommodation- and car-sharing (NYT, 07.12.2018; NYT, 31.05.2018). As the sharing economy offers various advantages such as fostering utilization of idle capacities or the reduction of the ecological footprint (higher utilization of trucks leads to a reduction of total distance driven and trucks needed to carry out the same volume of shipments), these should be levered. The road freight transport-industry is an eligible field for truck sharing, as trucks not seldom run empty or not fully loaded. However, literature regarding some forms of sharing economy-applications in the road freight transportation is marginally available (i.e. best practices and challenges in resource sharing in [multimodal] hinterland transportation) and a literature review considering truck sharing could not be determined.

The above given information shows that the truck sharing can benefit the distressed

1 Truck sharing can be defined (working definition) through the following constitutive attributes: 1) provides the possibility to share, 2) underutilized trucks (as a physical asset), 3) that are owned by logistic service providers, 4) via a community-based (digital) platform and 5) with other logistic service providers (Botsman, 2015 & Zervas et al., 2016). For further information, see Stölzle & Wildhaber (2019).
through a higher truck utilization and that the research field still lacks in maturity. The literature review provides the truck sharing fertile soil by giving a comprehensive overview about relevant literature to the field. The latter can e.g. highlight research gaps and determine approaches that support (future applications of) resource sharing.

Methodology
This paper's literature review methodology is based on the systematic literature review that follows a set of transparent and reproducible steps and thus improves the quality of the review process (Crossan & Apaydin, 2010). The approach chosen follows the steps covered by Tranfield et al. to select, extract, analyze and synthesis data (2003). As it covers resource sharing in the road freight transportation that still is an emerging field of study, the author considered peer-reviewed journal papers and conference proceedings published until 2019, regardless their impact factor (Seglen, 1994). The articles were retrieved via a structured key word search performed on major databases and published websites like Ebsco ECONLIT, Elsevier SCIENCEDIRECT, ProQuest ABI/INFORM COLLECTION, Thomson Reuters WEB OF SCIENCE. The goal of the review was to capture the research addressing resource sharing in the road freight industry.

As it is still an emerging field of study the author choose to cover major research streams that matter to sharing logistic resources and not only apply a common systematic literature review as suggested e.g. in Tranfield et al. (2003). However, the research streams are understood as accesses to literature that layer-per-layer provide important insights and are bundled in the following sections appropriately. To cover the major research streams, major composites of the sharing logistic resource-concept, e.g. important constitutional definition elements set the cornerstones. The three most important research streams therefore are

• ...the horizontal logistic cooperation, that provides the environment, where
• ...utilization advancements can be achieved via
• ...the (digital) platform to connect the logistic service providers and thereby
• ...foster sustainability, where economic and environmental factors be paramount.

Therefore, the following keyword structure was applied:
• “logistic*” AND “horizontal cooperation” (for the horizontal logistic cooperation)
• “logistic*” AND “utilization” OR “optimization” (for the utilization)
• “logistic*” AND “exchange platform” OR “sharing platform” (for the digital platform)
• “logistic*” AND “sustainability” OR “economic improvements” OR “sustainable developments” (for sustainability)

After the preliminary identification and an initial filtering (only articles in English published in peer-reviewed journals), the subsequent steps were followed (to be continued):

1) selection according to inclusion and exclusion criteria (removed were *qualitative step*),
2) coding (research purpose [descriptive/normative], research nature [conceptual/empirical], research method [case study/literature review/quantitative modelling/survey/theoretical and conceptual]) and

---

2 The paper follows the bag of words approach in combination with a forward and backward search that was performed on WEB OF SCIENCE.
4) supplementary web and hand searches on thematic areas.

Bibliometric analysis (year, publication type, geographic regions, [authors and networks], [most referenced literature], synthesis of bibliometric analysis)

In the following the paper presents the bibliometric analysis in form of the distribution of articles over time, publication type, geographic region and other relevant aspects.

Content analysis (theoretical underpinning, methodological basis, road freight industry and physical resources, synthesis of content analysis)

In the following the paper gives insight into the content analysis by highlighting the research streams’ common motivation, barrier, facilitators and further relevant information towards truck sharing.

Respective literature streams:

- Horizontal logistics cooperation

  The area of horizontal logistics cooperations has been thoroughly studied and widely discussed (Caputo & Mininno, 1996; Schmoltzi & Wallenburg, 2012 – H5) and is a critical factor in a LSPs’ performance (Naesens et al., 2009).

  o Motivations (Cruijssen et al., 2007 – H2)
    - Improving cost and productivity through e.g. joint planning and the use of more skilled/more efficient use employees
    - Increasing customer service through complementary services, comply with higher SLAs or specialization
    - Improving the market position by penetrating new markets, serve larger clients, protecting the market share or the faster speed to the market

    - The aims of horizontal logistic cooperation’s are cost reduction, customer service, increased responsiveness, social relevance (especially environmental), value creation, improved productivity, growth, innovation, etc. (Pomponi et al., 2015 – H5).

  o Barriers (Cruijssen et al., 2007 – H2)
    - System partners with difference in interests, high coordination cost or the search cost to find a trusted party
    - Determining and dividing the gains: fair distribution also of work
    - Negotiation in case of a disagreement over decision
    - Coordination and high indispensable ICT-costs

  o Facilitators (Cruijssen et al., 2007 – H2)
    - Information sharing e.g. information integration or sharing performance data
    - Incentive alignment e.g. trust, common interests, mutual help
    - Relationship management and contracts e.g. clear expectations, strategic fit
    - Information technology e.g. data interfaces or collaborative planning. Also Özener et al. (2011 – H4) mentions that information sharing is beneficial since it permits carriers to identify the best possible collaboration opportunities on the basis of
anticipated order or capacity offers from partners.

- **Order sharing**
  - The form of order sharing depends upon the
    - Approach (Verdonck et al., 2013 -> H4)
      - the industrial context – FTL/LTL
      - the willingness to share information
    - Joint route planning
      - The key impact factor in the horizontal logistic cooperation is the joint route planning through reducing inefficiencies, redundancies and overlaps allowing cost savings up to 30 percent by improving the load factor, pooling, fleet reduction (Cruijssen et al., 2007b; Krajewska et al, 2008 – H1). To get the trade-off between waiting for a more affordable collaborative capacity and incurring higher holding cost, the reliable and sufficient exchange of data is necessary (Cruijssen et al., 2007a – H1). Through the joint planning and scheduling, operating cost can be reduced and profits increased (Yan & Chen, 2007 – H1). According to Bilotkach (2007 – H1), cooperating in cost-structures and scheduling leads to lower prices, higher quality (SLAs).
      - Another important within a horizontal logistics cooperation is a fair benefit allocation in terms of distribution of realized cost savings and profit gains (Cruijssen et al., 2007b; Krajewska et al., 2008).
- **Capacity sharing (verdonck et al., 2013 -> 2013)**
  - The capacity sharing has strong interaction with the route planning

- Through order and capacity sharing enhanced technologies in planning and auction-based matching, as well as load swapping, shipment dispatching policies can save significant transportation costs (Verdonck et al., 2013 -> H4).

- Schmoltzi and Wallenburg (2010 – H3) describe the horizontal logistic cooperation as follows: bonded through a contractual agreement, having a multilateral organizational scope, a quasi-concentration (of shared production, marketing/sales and supply), having a nation-wide or international geographical scope, focusing mostly on the road freight industry and operating with similar resources. There similarities are performed in market competence and at times in market penetration.

- **Utilization**
  - **Cornerstones**
    - The use of optimization techniques is constantly gaining importance (Volland et al., 2017 – U1).
    - Outsourcing logistics activities to third party logistic providers can generate significant efficiency advantages for both parties due to economies of scale and scope, fixed cost reduction and focus on core competencies (Azzi et al. 2013; Iannone et al. 2014).
    - In all cases, where the planning and use of a resource is not happening in the same time, a certain form of forecasting is useful
to achieve an accurate picture of what has to be ordered (compare Volland et al., 2017 – U1)

- Various technologies come into play when optimizing: a platform (with central functions such as matching or where further applications such as a geographical information system or routing are run on), localization sensors (e.g. GPS) and intelligent load carriers (e.g. RFID) (Mar-Ortiz et al., 2011; Kinobe et al., 2015; Lee & Chan, 2009; Gamberini et al. 2009 – U4)
- Optimizations are mostly based on mathematical optimization such as routing, location or networks (Banyai et al., 2019 -> U4).
- A SLR-solution (decentralized perspective) is required to improve the utilization (incl. truck appointment system). If one would take in the centralized perspective only the optimization of resources remains (Islam et al., 2013 – U5)

- To reduce the emissions various means to optimize can used: transportation mode (Hoehn et al., 2014 – U3), freight size (Rudi et al., 2016 – U3), routing (Validi et al., 2014 – U3), transport consolidation (Loon et al., 2015 – U3), location analysis (Musavi & Bozorgi-Amari, 2017 – U3) or energy conservation (Müller et al., 2014 – U3).

- Optimization of routing and loading operations
  - Time and distance are meant to be minimized (Vega-Mejia et al. 2019; Kramer et al., 2015 – U6).
  - Minimize waste (Vega-Mejia et al., 2019 – U6)
  - Minimize over-costs such as late deliveries by complying with time windows to ensure a high service level (Yang et al 2015a; Zhang, et al., 2016 – U6)
  - Proper weight distribution to improve fuel efficiency (Liu et al., 2008 – U6)

- Platform
  - Multi-sided digital platforms emerged as a business model innovation in the past two decades through advances in ICT and changes in the user-demand and expectations towards the digital offerings. Research on platforms has generally focused on technology management rather than assessing the implications of platform-based businesses for platform users and business managers. Platforms have evolved from identifying competitive strategies over conventional business models (Eisenmann, 2006 – P1) to improve platform management strategies trough envelopment and mutation (Tiwana, 2014; Mukhopadhyay – P1). Whereas platforms were understood as dynamic, co-creating value, platforms have become ecosystems that include more stakeholders (e.g. owner, complementors and users) (Smedlund, 2012; McIntyre & Srinivasan, 2017 – P1).
  - Even though there are more and more platforms coming up and these deserve attention and have importance, the level of penetration of these solutions is still limited to well-established technologies, whereas web-based systems and mobile/wireless solutions are still scarce (marchet et al., 2009 – P4)
  - Among others, platforms offer/advantages
    - real-time visibility, efficient data exchange and better flexibility to react to unexpected changes during shipment (Durr & Giannopoulos, 2003; Coronado et al., 2009; Prajogo & Olhager,
2012 – P2).

- Real-time oriented control approach to improve load consolidation, vehicle utilization and handle dynamic disturbances (Bock, 2010 – P2).

- Freight resource management systems supports the efficient and effective use resources. By this function matches between supply and demand should optimally created at minimum cost of information consolidation between the dispatcher and the order-to-vehicle-allocation (TAP, 2000 – P2).
  - Improved operational efficiency, route planning, utilization of transport infrastructure, customer satisfaction, overall cost (vehicle optimization)

- Integrated operational/information exchange platform enables a seamless and secure information system as well as an integrated platform to like actors creating important information streams (GIFTS, 2004 – P2).
  - Electronic one-stop-shop for all parties
  - Allow all related authorities to interact with operators and exchange

- Cost/time savings and service level improvements – improved operation cost and time, accuracy, data quality and facilitated payments (Button et al., 2001; Pokharel, 2005; Piplani, 2004 – P4)

- Increased efficiency of operations, better use of resources (Kia et al., 2000 – P4)

- Barriers
  - User-related: economic (e.g. financial) reasons (Hollenstein, 2004; Zeimpekis et al., 2006 – P2), operations-related barriers (Hollenstein, 2004; Zeimpekis et al., 2006 – P2), management-related barriers (Evangelista & Sweeney, 2006 – P2)
  - Policy-related: Lack of related policies (Tsamboulas et al., 2007 – P2), coordination and harmonization (INTEGRITY, 2011 – P2), standardization (PROMIT, 2009 – P2)

- Internal barriers:

- Sustainability
  - Initiatives:
    - First, sustainable transportation execution with the objective to reduce the emissions through technological innovation (such as cleaner vehicles and alternative fuels) and management strategies are widespread (Lieb & Lieb, 2010 – S1).
Second, in the last three decades reverse logistics have become another means to reduce emissions, to which LSPs have become committed by offering services to capturing goods after their point of consumption and returning those for proper disposal (Murphy et al., 1994; Lieb & Lieb, 2010; Meade & Sarkis, 2002 – S1).

Third, internal management initiatives aim to involve employees to develop an organizational sensitivity towards environmental sustainability issues through personnel training (Lieb & Lieb, 2010; Jumadi & Zailani, 2010 – S1).

Fourth, cooperation with customers reach out to involve the shipper to collaborate and engage with the sustainability offerings of the LSP (e.g. reverse logistics) (Lieb & Lieb, 2010 – S1). Web-portals can be used to share and visualize the emission-impact of the shipper (Cholette & Venkat, 2009 – S1).

Fifth, external collaborations address the LSPs’ suppliers, such as the sub-contractor. The latter can be selected e.g. by applying certain emission goals apart from economic factors (i.e. price) regarded (Humphreys et al., 2003; Bai & Sarkis, 2009 – S1). According to Vachon and Klassen (2006 – S1), it is important to integrate technology to monitor the collaboration goals, also to report these to the shipper.

- **Motivations to adoption**
  - External factors can be reaching an intended signaling effect using environmental audits (Darnall et al., 2009) or pressure from e.g. regulation, customer, competition or public, or (Azzone et al., 1996; Hervani et al., 2005; Lieb & Lieb, 2010 – S1).
  - Internal factors aim to improve the LSPs reputation through environmental improvement or increasing efficiency resp. reducing cost (McIntrye et al., 1998a; Wolf & Seuring, 2010 – S1). The LSPs most often perform the environmental actions via e.g. the improvement of the vehicle efficiency, applying environmental collaboration, waste reduction (incl. reverse logistics) or intermodality. In the micro level of the vehicle efficiency the focus lays on eco driving and the vehicle efficiency (Evangelista et al, 2018 – S2).
    - Reduction of distance leads to a reduction in emissions (Garren et al., 2011).

- **Criticalities and barriers to adoption**
  - Internal barriers are related to economic risks (e.g. investment risk), the long implementation period or trained personnel that is required (McKinnon, 2010; Lieb & Lieb, 2010; Hervani – S1).
  - External barriers that primarily addresses uncertainty about evaluation and measurement of the environmental initiatives (Wolf & Seuring, 2010 – S1).

- **Evaluation and measurement of environmental initiatives**
  - Measuring sustainability efforts has become more and more important in the recent years. Several kpi-sets based on energy consumption or pollutant emissions to measure sustainability efforts have been defined (McKinnon, 2010; Geens-Leenes et al., 2003; Schvaneveldt, 2003; Hilty et al., 2006 – S1). In most cases, the KPI-sets focuses on the economic or environmental impact at
the LSP and just in some cases the focus lays on environmental measures (e.g. emissions) (Evangelista et al, 2018 -> S2).

Capacity sharing:
- In case of enhanced utilization through capacity sharing besides less fuel consumption per shipment, also the driver cost accrue to the cost savings (Audy et al., 2007; Jacobson & King, 2009).

However, as premises on logistics resource sharing such as the mindset of LSPs, data security and legal liability still constitute barriers and functioning sharing economy-applications are not available, the potentials cannot be levered.

Future agenda
The section future agenda brings together insights from the before analyzed research streams with an impact on truck sharing and respective important emerging trends. Therefore, the paper distinguishes between market-level and firm-level trends.

Draft mode / non-finished
- Market-level trends
  - Technological trends:
    - Even though technologies such as transport management systems form the core of current ICT applications used in the field of transportation (ENABLE, 2010a – P2), there are important future trends of rapid development such as (Harris et al., 2015 -> P3)
      - Cloud computing: offering greater flexibility, also through
      - Wireless communication technologies (smartphones, qr-code, rfid, telematics): increasing use and capabilities – also computing power is increasing exponentially – devices getting smaller/more affordable – people more connected (ubiquitous) -> extends visibility in transportation
    - Big data and decision support systems with the aim of real-time, dynamic and integrated enable sophisticated analytics that improve decision-making. (Harris et al., 2015 -> P3)

- Firm-level trends
  - In terms of the economic sustainability and its impact on financial performance sustainable road freight transportation can have several cost benefits (Carter & Rogers, 2008 – S3). Similar to these cost benefits, from the perspective of container freight transportation, there are several advantages of truck sharing to achieve economic sustainability. Other than with the utilization improvement when distributing operating costs to more shipments in the case of freight capacity sharing (compare Islam, 2016 -> S3), the truck sharing for example allows the distribution of fixed costs such as truck amortization among more than one shipper.
  - Regarding the environmental sustainability, truck sharing can be attributable to a reduction in traffic movements due to fewer trucks being on the road (compare Islam, 2016 -> S3). The decrease of trucks also means, that there is less congestion (compare Baldacci et al. 2004; Noland et al., 2006; Bento et al., 2013 - S3).
  - When considering social sustainability as the sustainable management of social resources (Ashby et al., 2012 – S3), the LPS’ sustainability efforts
also affect employment stability what refers to good welfare of employees (Gladwin et al., 1995 – S3). Comparing to Islam and Olsen (2014 – S3) and Lynch (2001 – S3), truck sharing would also contribute social benefits through lower cost per truck and thus lessor turnover per driver required. Besides the driver has a higher job security (induced through lower cost-pressure and the LSP being more competitive through the possibility to enable lower prices)

- According to Midoro and Pitto (2000 – H1), horizontal logistics cooperations should develop the capability to enable leveraging the system partners resources and competences pooled within the horizontal logistics cooperation and orchestrating effectively the acivities.

- Comparing Verdonck et al. (2013 – H4), mathematical programming and negotiation protocols enable (truck) sharing in the most efficient way.

- According to Mehmood and Graham (2017 – U2),
  - Resource sharing uses technology such as localization sensors, a connecting platform, supported by mapping, coordinating and payment infrastructure. The first two technologies are used to enable visibility among the partitioning LSPs.
  - Big data and collaboration applications enable decentralized transport optimization and therefore are in many cases better organized.

**Results**

Based on the before mentioned analyses, market-level and firm-level trends the paper found that …

**Draft mode / non-finished**

Through first indications, the author presumes that the relevant research streams regarding truck sharing could lead, among others to the following areas: 1) governance, 2) business models and 3) platforms.

**Conclusion, limitations and outlook**

The paper concludes that …

**Draft mode / non-finished**

The paper among others, faces the following limitations:

- Thanks to the multi research stream and layer-per-layer approach the paper presents a literature review on truck sharing. However, the chosen approach does not fully fit with common approaches, what makes the robustness of the literature review critiziable.

**Draft mode / non-finished**

The literature review shows, what research streams support truck sharing to which extent. However, the author aims to depict and concretize further research areas regarding the research project “Towards the Use of Truck sharing in the Road Freight Transportation-Industry”.

The results, however, could be limited by little sources available in the road freight transportation and research streams provided by accompanying fields (transportation [in general], environmental and computational research).

Abstract

Considering the challenges LSPs are facing, the state of logistics services in the mainstream service literature, its fragmented nature, and provider-centric service classifications in the logistics literature, the purpose is to develop a new classification of logistics services in order to understand their evolution in relation to servitization that takes place in the customer’s supply chain. The study uses generic service frameworks and servitization criteria to illustrate how logistics service providers move towards advanced services.

Keywords: Logistics service providers (LSPs), Advanced services, Service supply chains

Introduction

Trends such as sustainable development and digitalization give rise to disruptive changes in logistics industry as a service business (Cerasis, 2017; DHL, 2018; Logistics Bureau, 2016). For LSPs, this reflects in the form of new logistics services and new ways of servicing customers, which in turn facilitates their own customers in transforming their business models to respond to challenges by advancing their aftermarket offerings and increase focus on in-use phase of their products. Such transformation of business models requires a response from LSPs that support or enable the change.

Whilst this development has led to an emergence of new perspectives in service management (inclusive operations and marketing), the literature on logistics services has not responded accordingly. Extant literature has provided a list of logistics services described with respect to logistics capabilities (Lai, 2004), industry characteristics (Berglund et al., 1999) or value creation patterns (Berglund et al., 1999; Prockl et al., 2012). Logistics services are though more commonly referred in terms of type of providers (e.g. Berglund et al., 1999; Lai, 2004; Prockl et al., 2012; Scarsi & Spinelli, 2017).

Service markets have moved towards a service-dominant logic (Vargo & Lusch, 2004; 2008), and customer offerings have been transformed through servitization, commonly described as a process of transformation from a product-centric mindset to a service-centric mindset (Kowalkowski et al., 2017). As offerings advanced, the need for service classifications is widely acknowledged (Jaakkola et al., 2017; van der Valk & Axelsson, 2015). Interestingly, in the service literature, logistics services are regarded as routine-intensive services (Jaakkola et al., 2017), instrumental services (Wynstra et al., 2006) or
consumption services (van der Valk & Axelsson, 2015), associated with a single activity such as transportation or warehousing. Neither dated (Fitzsimmons et al., 1998; Judd, 1964; Lovelock, 1983) nor more recent classifications (Jaakkola et al., 2017; Mathieu, 2001a; van der Valk & Axelsson, 2015; Wynstra et al., 2006) acknowledge the multifaceted and dynamic nature of logistics services or the transformation in the industry’s offerings as a response to changes in demand from supply chains.

Considering the challenges LSPs are facing, the state of logistics services in the mainstream service literature, its fragmented nature and provider-centric classifications in the logistics literature, the purpose of this study is to develop typology of logistics services in order to understand their evolution in relation to servitization that takes place in the customer’s supply chain. The study adopts generic service frameworks (Cova & Salle, 2008; Mathieu, 2001a) and operationalizes the purpose through two research questions: (1) How can logistics services be classified in relation to services supporting the products (SSPs), services supporting the customers processes (SSCs), services supporting the network (SSNs) and services supporting the end-users (SSU)? (2) How do logistics services evolve from the perspective of servitization?

Theoretical Framework

Firm vs. supply chain level of servitization

Organizational change and new market offering: In manufacturing, servitization entails offering advanced rather than basic services (Baines & W. Lightfoot, 2013) where the mindset of organizations shift from product-centric business models to service-centric business models (Kowalkowski et al., 2017). Extant literature focuses on forms of servitization (e.g. Gebauer et al., 2008; Oliva & Kallenberg, 2003) and drivers of servitization (e.g. Mathieu, 2001b; Wise & Baumgartner, 1999) such as achieving income stability, competitive advantage or extended marketing opportunities (Baines et al., 2009). Both early (Mathieu, 2001a; Oliva & Kallenberg, 2003) and recent studies (Story et al., 2017) illustrate how the types and scope of market offerings change when manufacturing organizations servitize. Whilst often addressed from a firm-level perspective, the implications of servitization reach beyond the boundaries of the provider’s organization by changing e.g. the firms position in its value stream, types and scope of its market offerings, and even structures, relations or capabilities within the organization or its networks (Brax & Visintin, 2017).

Supply chain level: To achieve their servitization goals organisations must enter new supply networks and service networks. This can, however, change the firm’s position within its value stream in that an integrator may take over the supplier’s role in having direct contact with the customer (Finne and Holmström, 2013). The supply chain level of servitization has been investigated with respect to supply network structures (e.g. Chakkol et al., 2014; Finne & Holmström, 2013), practices and technologies (Baines & W. Lightfoot, 2013), customer-supplier relationships (e.g. Selviaridis & Norrman, 2014).

Relevance of logistics services: Much servitization literature concerns the context of technology-oriented manufacturing firm (Eloranta & Turunen, 2015) and its supply network. However, servitization of manufacturing is not achievable without a similar transformation of the service network of which it depends on (Gebauer et al., 2013). Service network actors face unique challenges while trying to support the servitization of manufacturing firms (Gaiardelli et al., 2014; Reim et al., 2019), which has though primarily concerned downstream linkages of distributors. Hakanen et al. (2017) justify this with the resonance between servitization and marketing discipline. However, by extending this down-stream focus to towards the wider supply chain provides further insights for understanding the servitization of service networks.
**Logistics services: Evolution and existing typologies**

Logistics has a long history of engaging with the concept of service in various ways; as a performance measure, e.g. “customer service” and “quality” (Mentzer et al., 2001), as an activity (Autry et al., 2008), as an integrated service offering (Lieb & Lieb, 2010; van Laarhoven et al., 2000), and in relation to actors, i.e. providers of freight transport and logistics services (Lieb & Lieb, 2010; Persson & Virum, 2001). However, not much literature focuses particularly on logistics services with a service management lens. Several definition and classification efforts have taken different perspectives but in common state that TPL is composed of either simple or complex service bundles (Prockl et al., 2012) that require tangible asset base or knowledge resources (Muller, 1993; Sheffi, 1990) which try to satisfy a large portfolio of service needs (Autry et al., 2008) ranging from simple transactions to integrated solutions (Berglund et al., 1999; Hertz & Alfredsson, 2003).

Classification efforts focusing on the type of logistics services provided distinguish between services providers and solutions providers (Berglund et al., 1999) where mostly solutions are required as the complexity of the market offering and asset specificity increase (Persson & Virum, 2001). For this latter category, LSPs build on problem-solving abilities where LSPs might need to be service developers or even customer developers (Hertz & Alfredsson, 2003).

LSPs operate in triads where they link buyers and sellers in supply chains (Bask, 2001). Connecting actors between supply networks and logistics service networks (Andersson et al., 2014) and LSPs act as a support supply chain where product flow is facilitated through information or finance (Carter et al., 2015). The distinct supply chain role of LSPs refers to them as external logistics process integrators (Bolumole, 2003) or even fourth-party logistics service providers (4PL) (Sagietto, 2013). Considering the changes in requirements of the buyer market with servitization, it is of importance that LSPs as a service network transform their capabilities to meet the demand.

**Synthesis and framework**

Understanding the dynamics and evolution of service definitions in logistics has been called up for (Selviaridis & Spring, 2007). Servitization literature underlines that there is a need to transform the mindset of the service network in line with the servitizing supply network to achieve success (Reim et al., 2019). A framework of servitization of logistics services has the locus of service effort as focal point.

Mathieu (2001a) describes SSPs as services that enable proper functioning of or customer’s access to the product. Logistics services such as transport and warehousing support the exchanges between a seller and a buyer by providing an access to a product. When logistics services “advance the mission” (Mathieu, 2001a, p. 40), they act as SSCs. When they extend their scope to supplier or customer networks they function as SSNs (Cova & Salle, 2008). In addition to those, some logistics services extend beyond industrial markets and support end-users (SSUs) or consumers with suppliers’ products like last-mile or waste collection services which might be labelled as SSUs.

This study adopts the view of servitization as a continuum perspective to indicate the transition of manufacturing into services (Kowalkowski et al., 2017; Oliva & Kallenberg, 2003). On the one side there are logistics services offered with a productization mentality. These are highly standardized services offered to price-competitive markets. On the other side there are highly servitized offerings that fulfill one or more of the four servitization characteristics proposed by Brax and Visintin (2017) mentioned above. Figure 1 presents a continuum where relative importance of SSPs are higher on the productization end, a
transition takes place through SSCs in the middle and SSNs and SSUs reflect advanced, servitized logistics services.

![Figure 1- Servitization of logistics services – a continuum](image)

**Methodology**

**Sampling and data collection**

A qualitative research design approach is adopted to address the exploratory nature of the study. A content analysis is applied on the web pages of top 50 global LSPs to map logistics services and categorize with respect to servitization. Content analysis enables making “replicable and valid inferences from texts (or other meaningful matter) to the contexts of their use” (Krippendorff, 2004, p. 18). Web pages as secondary evidence have been used in logistics and supply chain management research (e.g. Bask & Kuula, 2011; Martinsen & Huge-Brodin, 2014). They describe services that are promised to customers, however, it has been noted that this material has been prepared for marketing communications purposes and might not provide an in-depth understanding of company behavior or action (Bryman & Bell, 2011).

The process from Weare and Lin (2000) is followed for the content analysis. For reliable sampling, several industry and consultancy reports were investigated. Taking a global perspective improves the generalizability of the findings, a publicly available ranking list of top 50 global LSPs that is based on logistics gross revenue was used for sampling (Armstrong & Associates, 2018). The global web pages of these LSPs were visited between December 2018 and April 2019. The unit of analysis in this study is the services that are provided by the sample. Following Weare and Lin’s (2000) unitization process the context units were selected as the market offerings of these LSPs which were labelled differently such as “products”, “services” or “solutions”.

**Data analysis**

Data was categorized based on cases; each LSP was treated as an individual case in order to monitor for potential patterns within LSPs. A deductive coding approach (Crabtree & Miller, 1999) was adopted where generic service frameworks from Mathieu (2001a) and Cova and Salle (2008) were used. In addition, four servitization criteria were borrowed from Brax and Visintin (2017) to divide the services between the main categories of productization and servitization. At the end of the deductive coding process, findings were exhibited on a comparison table together with illustrative service definitions. Then emergent coding approach (Boyatzis, 1998), was adopted to code various services that were classified at different sections of the table.

**Findings**

The categorization of logistics services with respect to levels of servitization results in a typology of four distinct levels: Offerings supporting customers’ products, their
processes, their networks or the final users. Table 1 presents examples of offerings for each of the four categories and illustrates what servitization feeds into logistics and how logistics responds to servitization.

_A new classification of logistics services_: Logistics services as **SSPs** focus mainly on enabling of access to a product that is exchanged between a customer and a supplier. These services consist to a large extent of physical resources and are to a large extent transactional since they are bought as a discrete purchase along with physical products. **SSC** entail a more longitudinal focus and an extended scope since they help customers with their processes of deciding, buying, preparing and executing logistics services have a more longitudinal focus and an extended scope. In addition, providing access for customers, **SSC** support their actions in relation to logistics services. Here the focus is
either on characteristics, inputs or outputs of logistics service provision process or it is on internal processes of a customer. These internal processes could be part of a function of a customer organization or an entire process that the customer organization chooses to outsource.

**SSN** carry SSC characteristics but provide value for not only a single customer but also for a customer’s customer network or a customer’s supplier network. They are integrative in nature, collecting and managing information flows between multiple actors, and even combining and sometimes distribute resources from and to a selected set of actors. The buyer of such services is a single organization, the value proposition is directed to a network. Accordingly, the service encounter is with multiple actors of this customer’s network, either upstream or downstream, who also evaluate the service outcome.

Majority of the logistics services that are analyzed are exchanged between business organizations. They facilitate the flow of goods and services between supply chain members. However, some of these offerings provide value for the final users (**SSU**) of these products and services. Final users can be consumers or users in the buyer’s organization.

**Servitization of logistics services**: Traditional logistics services that a large part of the market offering is composed of the services provided by physical assets such as trucks, shelves, facilities carry a product mindset, i.e. these build upon a product-centric business model. The value is based on specific inputs such as ton/kms travelled or cubic meters that are stored. Majority of these services carry the characteristics of SSPs where a slightly smaller portion of them are classified as SSCs.

Findings indicate that advancement of logistics services can take place in at least four ways. First, **LPSs servitize** by changing or extending their core offering and hence their position in their value stream by offering of e.g. financial services. **LSPs** can also overtake a specific function of their customer and by doing so they occupy an additional stage in the supply chain. A good example is managing packaging or inbound flows at a customer organization. A second way of servitization is changing the types and scope of market offerings by e.g. offering management of multiple flows with the combination of multiple resources besides basic transportation services. Here, traditional logistics services are customized for specific industries such as energy, mining, textiles, and retail. Service types are extended by reconfiguration of existing services with new services as well. Carbon reporting in transportation services, innovative combination of transportation modes for better transit times are examples to such reconfigurations. Such market extensions provide sector-specific solutions that are highly heterogenous. A third way of servitization takes place with a change in business model, shifting to a service-centric mindset. **LSPs** extend their value proposition to their customers’ value-in-use phases, concerned with outcome such as better process performances or improved availabilities either for a single customer or for a network of customers. Supply chain wide solutions such as inbound flows management, production logistics solutions, transportation network management services are examples for this type of servitization. Performance-based offerings include temperature stability and high visibility for sensitive products. Finally, a fourth way is changed capabilities or structures within **LSPs or their networks**. Digital logistics services such as high-end tracking and tracing allow **LSPs** to connect to and align with new networks and develop environmental performance monitoring capabilities. In this work, **LSPs** may become asset-free but that rely upon network-management capabilities and gain access to capabilities needed through strategic alliances with different partners in different markets such as quality assurance companies, certification companies, life-cycle assessment companies,
information technology companies besides their traditional partners such as carrier operators.

These findings also indicate that some types of services are relatively dominant in LSPs servitization strategies. Majority of productized services are SSPs. SSCs play a transition role. Some of them just support productized SSPs where some are offered in a completely changed business mind-set. SSNs and SSUs are mostly observed in relation to servitization strategies. This is expected because such services focus on the value in use phase of the market offering and extend the offering’s scope to a group of actors.

**Discussion**

This study aimed to provide a new classification for logistics services with a servitization perspective. While doing so, the study used the generic service frameworks to classify the highly diversified portfolio of logistics services that are offered to global markets. Findings point towards at least three main contributions. First, current servitization studies are highly focused on the technology-oriented manufacturing firm (Eloranta & Turunen, 2015) and how manufacturing companies transform into service-oriented organizations with and advanced portfolio of service offerings. Whilst, literature acknowledges the importance of having a supply chain perspective to understand this transformation (Bustinza et al., 2013; Finne & Holmström, 2013; Lockett et al., 2011), studies of logistics providers that engage in services that enable a supply chain perspective is scarce. Recent studies recognize the importance of service network’s alignment with servitizing companies, but focus mostly on the downstream flows, distributor networks (Hakanen et al., 2017; Reim et al., 2019). Manufacturing companies operate in supply chains that require service networks that support them both in upstream and downstream flows. LSPs are one of those service suppliers and understanding how they are servitizing is of importance for both supply chains and their service networks. LSPs servitize together with supply chains and in this process, they tend to change their mindset towards services supporting the network of their customers.

Second, servitization provides a great opportunity to LSPs to diversity offerings, and in that work, a multi-actor perspective on customers must be taken. Unlike the current perspective that relates logistics services with a single service category (Jaakkola et al., 2017; van der Valk & Axelsson, 2015; Wynstra et al., 2006), results show that logistics services provide value in many ways. LSPs servitize through sustainability (e.g. Centobelli et al., 2017) by providing eco-efficient services, through digitalization (e.g. Hofmann & Rüsch, 2017) by providing end-to-end visibility services, through customization and understanding the business customers’ context (e.g. Hakanen et al., 2017) by providing sector-specific solutions or through reconfiguration of existing or new resources, capabilities or structures (e.g. Kowalkowski et al., 2017; Prockl et al., 2012) by taking over an entire process at their customers. To this end, service lens towards logistics needs to adopt a multi-dimensional and multi-actor perspective.

Finally, this study complements the current logistics literature on provider-centric classifications where asset ownership (Sheffi, 1990), service orientations (Prockl et al., 2012) or capabilities (Lirn et al., 2014) determine how to classify LSPs. Since “the service environment may not allow completely separating the outsourced services” (Prockl et al., 2012, p. 557) classification based upon provider type is difficult; the same provider, despite having a basic orientation, might offer multiple types of services that capture the properties of multiple provider types. The results illustrate that global providers offer both productized and servitized versions of SSPs, SSCs, SSNs and SSUs to their markets. In particular, SSCs support their transition to servitization and there are many opportunities in terms of SSNs and SSUs for the logistics industry. Furthermore, such servitization
mechanism in logistics industry supports service-led growth in supply chains. Today’s competitive global markets continue facing strong service-led growth, but logistics services are still treated with a product-based mindset by mainstream service literature. Therefore, mapping logistics services with a service-based mindset provides the new vocabulary that both scholars and practitioners need.

**Conclusion**

The dynamics of service-led growth that is taking place in global markets must be understood by providers offering logistics services to their customers supply chains. Whilst servitization has influenced in particular the manufacturing industry for over three decades, the explanatory power of that concept is not limited to that sector. This study shows that the offering of LSPs can be understood in these terms, both with respect to diversifying their offerings and for providing value to their servitizing customers, global supply chains. This study initiates a discussion on the servitization journey of logistics services, however, such an approach has its limitations. More knowledge is needed through in-depth studies of servitization as a process, revealing servitization mechanisms, drivers and challenges of LSPs. In addition, knowledge on resource acquisition, resource generation for servitized logistics offerings is expected to provide evidence on new actors in logistics service supply chains and valuable skills and capabilities that are required for successful servitization. Finally, whilst this study argues for a supply chain level of analysis, further studies at the levels of dyads, triads and network-level would aid understanding of how such servitization strategies are structured, what types of capabilities and resources are needed, how do servitization with logistics services enable competitive advantage for supply chains and how does value co-creation process take place in a servitized environment with logistics services could provide important insights to servitization research.

With respect to practical implications, the results enable managers in logistics industry to evaluate their service portfolios with a servitization perspective. During the analysis it was interesting to observe that LSPs label their market offerings as ‘products’ frequently. However, in an era where their customers are heavily servitizing, it is essential for LSPs to understand this service-based mindset and develop their business in an aligned manner with supply chain members that they target.

Managing proximity in a period of discontinuity: an opportunity for Industry 4.0

Paul Coughlan (coughlnp@tcd.ie)

Abstract

In this paper, we examine the impact of Brexit as a discontinuity in the logistics and physical distribution of products between EU member states and the UK. We propose that Industry 4.0 technologies have the capability to mitigate the impact of Brexit on supply chain coordination and proximity. Through secondary data analysis, we analyse logistics service providers and port operations. We find that elements of Industry 4.0 can restore or enhance proximity and impact on generic performance metrics.

Keywords: Industry 4.0, Brexit, Proximity, Operations Performance

Purpose

This paper explores the challenges to supply chain integration arising from Brexit as a discontinuity. The research question posed in this paper is as follows: how can the application of Industry 4.0 by firms dealing with Brexit foster de-territorialisation of closeness (Gertler, 2003) in logistics management and physical distribution? Said differently, how can firms and suppliers coordinate their actions by means of digitization and re-create a sense of proximity regarding major processes, routines and procedures in the context of Brexit?

Research motivation

Brexit represents a significant challenge for firms and individuals in Europe and in the UK. As of the time of writing, the shape of a withdrawal deal or the possibility of no deal is unclear. What is clear though is that the implications for the movement of goods and of people will be disruptive. The nature of that disruption will come from a need for increased border checks in the context of mis-alignment of standards and tariffs. The implications will be particularly evident in flows of goods and materials between the UK and other EU members, and also the flow of goods and materials between EU members which transit through the UK. The resulting challenges to manufacturers, logistics companies and customers will include additional shipping time and cost. These implications will be particularly severe in the case of time-sensitive goods such as food,

Writing in 2003, Coughlan et al noted that the then recent slowdown in the global economy had been a trigger for discontinuous change, prompting many organisations to re-examine their collaborative strategies. The article focused on the management of collaborative relationships in a period of discontinuity and examined different choices faced by systems integrators in their management of collaborative relationships with their supply bases. In 2018, a new discontinuity has emerged – Brexit, which we explore in this paper.

Nadler describes two basic types of change, incremental and discontinuous (Nadler, 1998). Incremental or continuous change refers to the type of change which ought to go on all of the time. Such continuity helps in the generation of continuous improvement. In contrast, complex, wide-ranging changes brought about by fundamental shifts in the external environment lead to radical or discontinuous change. Here, there is a complete break with the past and a major reconstruction required of the organisation. An important element of leadership activity is whether it anticipates change or reacts to it (Nadler, 1998). In this respect, anticipatory changes are made early in the disequilibrium cycle and often before a period of industry upheaval has even begun. Reactive changes come either in response to some strategic initiative by a competitor, or when the organisation has its back against the wall. Combining these dimensions of scope and timing of change, Nadler (1998) presents a four-quadrant schema that plots anticipatory and reactive timing of change against incremental and discontinuous scope of change respectively and describes four responses to change:

- Tuning: the firm anticipates a change in conditions and takes incremental action
- Adapting: the firm reacts to a change in conditions and takes incremental action
- Redirecting: the firm anticipates a change in conditions and takes radical action
- Overhauling: the firm reacts to a change in conditions and takes radical action

Industry 4.0 represents the second conceptual strand of this research. In 2013, Acatech, the German National Academy of Science and Engineering, developed an initial description of Industry 4.0. Also referred to as “Industrie 4.0” in German, it was described as the technical integration of human-machine connections through Cyber Physical Systems (CPS), into manufacturing and logistics and the use of the Internet of Things (IOT) and Services (IOS) in industrial processes (Henning, 2013). This advanced digitalization of manufacturing facilities, incorporating internet technologies, smart machines and products was considered to be a new paradigm shift in industrial production, so much so that it would lead to a 4th industrial revolution, hence the term “Industry 4.0” (Lasi et al, 2014).

Tjahjono et al (2017) outline four principal features of Industry 4.0:

1) Vertical networking of smart production systems.
2) Horizontal integration via global value chain networks
3) Through-life engineering support across the entire value chain
4) Acceleration through exponential technologies

Industry 4.0 is a set of automated self-configuration, self-adjustment and self-optimization capabilities that allows for more agile and cost-efficient processes (Asdecker & Felch, 2018). While there is no conclusive definition of Industrie 4.0 or its features (Tjahjono et al 2017), Dallasega et al (2018) have categorised a range of elements as follows (Table 1).

Tjahjono et al (2017) assess the impact of specific digitalization and automation technologies on Key Performance Indicators (KPIs) for elements of the “Supply Chain 4.0”, focusing on procurement (“buying”), production (“making”), warehousing...
KPIs for each of these supply chain functions were identified, one of which was proximity. By analysing the impact of Industry 4.0 technologies on the KPIs, the implications for each supply chain function can be assessed.

Table 1 - Categorisation of elements of Industry 4.0 (Dallasega et al, 2018)

Dallasega et al (2018) explored challenges in Construction Supply Chains (CSCs) relating to distance between actors in the supply chain. Motivation, commitment and engagement were found to be influenced by proximity to the decision-making unit. Similarly, communication barriers, or exclusion from information flows, negatively impacted commitment and involvement in solution finding. They noted, however, that many concepts have emerged to bridge objective geographic distance since the advent of Industry 4.0 and digitization technologies. They include organizational, cognitive, social, cultural, institutional, and technological proximities. By drawing on proximity theory, Dallasega et al (2018) showed that Industry 4.0 concepts fostered what Gertler (2003) calls “de-territorialization of closeness” where construction firms and suppliers coordinated their actions by means of digitization, creating a sense of proximity regarding major processes, routines and procedures.

Conceptual framework
Based on the literature, we outline the framework in Figure 2 to guide the analysis of our study. It reflects the research question and proposes that, in the context of Brexit as a discontinuity, firms and suppliers can coordinate their actions by means of digitization to re-create a sense of proximity regarding major processes, routines and procedures.
**Design/Methodology/Approach**
This paper explores the challenges to supply chain integration arising from Brexit as a discontinuity. We develop a current case (Voss et al., 2016) focusing on the prospective experience of logistics services providers, exploring the operational context within which services are provided and the associated challenges to integration. We look specifically at two EU countries, Ireland and Spain, that trade with and through the UK. Applying the tests proposed by Miles and Huberman (1994) to the case selection: the case is relevant to the exploration of the research question, the phenomenon of interest is evident and, while generalisability is not of concern, it may be possible. Finally, the case is feasible with access to both archival and historical data.

We employ two data gathering methods to collect case narrative and historical and archival data. We are accessing the data by drawing from publicly available data sources, including published case histories, government agency guidance and commentary. Reflection on these data is undertaken from the authors’ perspectives as operations and supply chain management researchers located in different member states of the EU. As such, we engaged in a shared reflection on the emerging challenges faced by logistics providers in the context of Brexit.

**Findings**
The findings are presented in terms of the nature of the logistics processes and physical distribution of goods through ports in Ireland and Spain, destined for the UK, or which pass through the UK to another EU country.

**Ireland**
Ireland has a particularly close trading relationship with the UK. A briefing for participants at the British Irish Chamber of Commerce Infrastructure Committee/ Welsh Government Roundtable with the First Minister of Wales, Mr Carwyn Jones AM, on Monday 12 February 2018 noted that 11% (£13.3bn) of all Irish goods exports went to the Great Britain in 2016 while a further 40% (£46.3bn) went to the EU. Similarly, 22% (£15.5bn) of goods imported came from Great Britain with the EU accounting for 38% (£26.5bn) of imports. Over 80% of Ireland’s trade with mainland Europe transits as road freight through the UK. This is principally perishable or other time sensitive trade. Over 40% of Ireland’s seaborne traffic is through UK ports while 36% of container movements to/from the island of Ireland go through Northern Ireland. 80% of freight trade into Ireland...
enters via Dublin Port - 400,000 trucks use the Dublin-Holyhead route every year to transport exports to the UK and on to Europe.

The dominant mode for transporting goods is RoRo (roll on/roll off) and there is unlikely to be any realistic alternative for this trade other than the UK landbridge. After Brexit, this trade will have to exit and re-enter the EU with potential customs and border inspection implications which it does not face at present. Taking Diageo as a practical example, their trucks make approximately 13,000 border crossings each year. So, a customs check could potentially delay each truck by between 30 minutes to one hour resulting in additional costs of approximately €100 per journey or €1.3m per annum. Finally, should customs barriers be introduced for trade with the UK, an estimated 60,000 traders will be dealing with customs for the first time.

The Irish Government, through the state agency Enterprise Ireland has designed a Brexit Scorecard to assist Irish based firms prepare for Brexit and to develop a robust Brexit plan. This covers six key areas of business, one of which is “Operations”, which assesses how prepared firms are for the delivery of products and services. Readiness questions focus on increasing efficiencies, reviewing supplier vulnerability, logistics processes and increased administrative resource requirement. A joint report by Chartered Accountants Ireland and The Institute of Chartered Accountants in England and Wales (2018) outlined the supply chain issues facing UK and Irish businesses. These issues include customs checks, new trade tariffs and laws, and increased lead times. It is suggested that border technology could play a role in mitigating some of these issues, including automated number plate recognition, barcode scanning, smart seals on containers, enhanced driver’s licences and smartphone applications.

Spain

Spain is in a related but different position to Ireland in its exposure to Brexit. In anticipation, the Spanish authorities have developed a range of guidelines for all products and for specific categories including pharmaceutical, agri-food, and intellectual and industrial property. In the context of UK exit from EU with "no agreement", goods will be subject to customs supervision and control, which will entail:

- application of the corresponding tariffs
- prohibitions or restrictions on certain goods
- compliance with customs formalities
- customs authorisations issued by the United Kingdom shall cease to be valid in the EU.

In addition, non-customs controls may be applied for including agri-foodstuffs, cosmetics, pharmaceuticals, footwear or furniture. Such non-customs controls may be physical, depending on the risk assessment carried out by the different inspection services and the nature of the product. This physical control requires time spent at the border for the goods, which does not occur in the internal market.

Case Example

In November 2018, Simon Carswell of the Irish Times newspaper travelled with 1,400 kilos of high-value pharmaceuticals from Dublin to Wiesbaden, Germany. The resulting report illustrated how customs checks could impact upon Irish truckers in a post-Brexit context (Carswell, 2018). Carswell accompanied lorry driver John Carroll on his 41 hour, six-country journey to Germany, travelling by ferry from Dublin to Liverpool, driving 1100 kilometres across England to Dover and onto another ferry to Calais in France, through Belgium and The Netherlands to Germany. The pharmaceuticals he was carrying had to remain chilled until they reached their destination in a German factory at a pre-
defined delivery time slot. All this means that the refrigerated trailer, running on a diesel engine, had to be kept running and this could only be, for safety reasons, on the open top deck of the ferry where spaces are limited and in demand. This landbridge through the UK is currently the fastest route to Europe and is a preferred route for transport companies carrying loads like Carroll’s because of the shorter transit times that minimise inventory costs and other working capital requirements. The industry anticipates that Brexit could put days onto journeys, putting logistics back to the 1980s.

Figure 3 illustrates the route taken by Carswell and associated timings. In a post-Brexit scenario with border checks, the M20 from London to Dover, a vital artery in the Ireland-to-continental Europe landbridge, may bring delays, the length of which will be unpredictable. This route connects the M25, 26 and M20 motorways to Dover. In anticipation of delays, the UK authorities are considering using this 16km M26 link road and 21km of the M20 as a temporary lorry park. This plan, called Operation Brock, would create up to 2,000 on-road lorry car parking spaces on the M20. In October 2018 and under no-deal Brexit contingency planning, the M26 in Kent was shut down overnight to assess how it could be used as a “parking lot” for lorries.

One way of guaranteeing Irish trucks fast passage through Dover would be to secure international transit paperwork known as TIR or “Transports Internationaux Routiers”. This would allow approved hauliers traverse non-EU countries, as the UK will be, without stopping repeatedly for customs checks. However, this initiative could see tensions flaring as Irish lorry drivers drive by rows of parked-up UK lorries on the M20.

However, post-Brexit, the customer will still want a definite timeline and it may be that direct sailings become the only feasible option. There are alternative routes avoiding the UK by taking direct ro-ro ferries, from Rosslare to Le Havre or Cherbourg or “lo-lo” (lift-on-lift-off) freight routes such as the CLdN Cobelfret ferries from Dublin to Zeebrugge and Rotterdam where containers have to be loaded off and onto lorries. However, these direct sea routes to continental ports take longer, carry higher costs and have less capacity than the landbridge ferries. Ro-ro, drivers would still have long hours on the road to get to Benelux countries. As lo-lo ferries can take only a handful of drivers at a time, this creates another capacity problem.

In a subsequent article, Carswell (2019a) spent a day reviewing the operations and the preparations underway at Dublin Port (described as “Ireland’s Ground Zero for Brexit”) which will be the country’s busiest location for customs checks and inspections. 90% of roll-on, roll-off (“ro-ro”) freight arriving to and leaving from Ireland passes through Dublin port, with most containers leaving the port within minutes of arriving, including those carrying perishable foodstuffs such as sandwiches destined for the shelves of Marks & Spencer stores around Ireland. On average, there are 48 ship movements in the port each day. Four vessels arriving within one hour carry trucks adding up to thirteen lane-kilometres in length. The port is investing €10m for primary inspection posts and another

---

**Figure 3 – Journey from Dublin to Germany (Carswell, 2018)**
€20m for secondary inspection posts for state agencies including Department of Agriculture. It is expected to undertake up to five-fold increase in the number of inspections post-Brexit.

After Dublin port, Rosslare is the second busiest port in Ireland, handling 100,000 road freight units per year going to and arriving from Britain, mainly through two ports in Wales - Pembroke and Fishguard. Rosslare will be designated as a border inspection post. In anticipation of a no-deal Brexit, a set of virtual traffic lights has been developed 11km offshore Rosslare, at Tuskar Rock. Truck drivers boarding ferries in Wales will upload their cargo details to Irish Customs. As the ferry approaches Tuskar Rock approximately 3 hours later, a customs app (yet to be launched) will indicate if they are to go through a red, orange or green channel on arrival in Rosslare. Green means they can leave the port on arrival. Orange means their paperwork is not complete and they have to go to a newly opened trade facilitation counter in the port's terminal building to resolve any issues. A red light means they must proceed to the central control compound where their goods may be unloaded and inspected (Carswell, 2019b).

Analysis
The results show that, post-Brexit, there are critical vulnerabilities in the supply chain connecting EU states with each other. We return to the research question, how can the application of Industry 4.0 concepts by firms dealing with Brexit foster de-territorialisation of closeness in logistics management and physical distribution. Said differently, how can firms and suppliers coordinate their actions by means of digitization and re-create a sense of proximity regarding major processes, routines and procedures in the context of Brexit?

The basic argument that we wish to make is as follows: Brexit impacts on operations performance metrics – quality, speed, dependability, flexibility and cost. However, it is a fundamental challenge to proximity with implications for logistics and flow of goods. For example, because of Brexit, geographical proximity remains unchanged, while regulatory proximity disimproves. Then if the discontinuity of Brexit impacts negatively on operations performance, how can Industry 4.0 mitigate? Industry 4.0 offers generic potential for integration, data sharing and real-time control. Application may change and overcome some of the challenges to proximity. Attributes of Industry 4.0 may be linked directly to problems caused by Brexit and to proximity. Some of these metrics and dimensions of proximity may change for the better.

Three scenarios are explored: before Brexit, after Brexit, and after Brexit with the application of Industry 4.0:

Scenario 1
Before Brexit, the dominant proximity is geographical. In this single market and customs union context, technical proximity, though important, is predictable as regulatory standards are common within the EU. Institutional and organisational proximities are predictable.

Scenario 2
After Brexit, geographical proximity remains unchanged – the countries are still located where they were. However, technical and regulatory proximity have disimproved, given now separate regulatory regimes. Cognitive proximity has disimproved also as, from an EU perspective, the UK is seen as a 3rd party country.

Scenario 3
Underpinning scenario 3 is the proposition that, post-Brexit, Industry 4.0 can impact proximities. What can Industry 4.0 do to mitigate the negative impacts of Brexit, restore proximity and improve measures of operations performance? The attributes and
functionality of Industry 4.0 can combine to restore confidence in the supply chain and improve cognitive proximity – the UK is not so far and the barrier is not so high. To achieve this improvement in cognitive proximity requires that technical proximity through data sharing in real time improves to give a sense of physical progress of goods and materials through the logistics system. If it works, actors in the system have evidence-based choices where alternative routes, modes and delivery details are needed. With Industry 4.0, actors will deploy capabilities differently to locate a shipment through GIS, track it through RFID, integrate and share the information with other key actors to build/maintain confidence that a reliable performance is observable or latent.

Visualising these three scenarios in relation to the cases of the Dublin-Wiesbaden route, and the Dublin and Rosslare ports described earlier, we apply HACCP-like thinking to these operations. Here, the focus is on hazards to proximity and to each of the operations performance metrics at border crossings as Critical Control Points. So, post-Brexit, cognitive proximity has shifted due to UK barrier. Actors need to overcome that barrier. At the heart of the delay is the technological proximity. Previously what was an acceptable regulatory standard and tax regime no longer exists and, so, inspection is required resulting in delay. Application of Industry 4.0 can support electronic certification and speed up processing across critical control points. However, it requires data integration and access, elements of organisational proximity. So, in the context of Brexit as a discontinuity, there is a proposed hierarchy in the impact on dimensions of proximity and operations performance associated with an Industry 4.0 intervention. Post-Brexit (and before Industry 4.0), the hierarchy could be: geographical proximity remains unchanged, cognitive proximity disimproves, technological proximity disimproves, and organisational proximity is unchanged. With Industry 4.0, technological proximity is latent through existing systems but requires institutional and organisational proximity to improve. As a result, cognitive proximity improves back towards the original pre-Brexit level. Tables 2 and 3 reflect the argument:

How can Industry 4.0 mitigate the impact of Brexit in support of both of these propositions? Tables 2 and 3 outline elements of Industry 4.0, linked to the each category of proximity and to the five generic performance objectives. Arising from Tables 2 and 3, three propositions emerge:

- There is a sense of hierarchy among the types of proximity.
- Brexit will impact proximity and Industry 4.0 can mitigate this.
- Brexit will impact on the generic performance objectives. Industry 4.0 can mitigate this impact.

Conclusion

The research question posed in this paper asked how can firms and suppliers coordinate their actions by means of digitization and re-create a sense of proximity regarding major processes, routines and procedures in the context of the discontinuity that is Brexit.

Similar to Dallasega et al (2018), we find that that elements of Industry 4.0 foster “de-territorialization of closeness” where our this case, logistics firms, supported by port operators can coordinate their actions by means of digitization, creating a sense of proximity regarding major processes, routines and procedures. The expectation is that application of Industry 4.0 forms the basis for a technical proximity solution. “Control Tower” is an integration concept and implementation of Industry 4.0 requires institutional and organisational integration linking supply chain actors such as shippers, customers and customs bodies. Targeting the application of Industry 4.0, using HAACP-like thinking, can improve time losses and help to maintain quality. So, if that technological and organisational proximity can be improved in this way, then all dimensions of operational performance can be improved.

Based on our findings, we update our original conceptual framework from Figure 2. We now introduce a new category of proximity (i.e. regulatory proximity) and enable interplay between this and the pre-existing categories of proximity. Our overall conclusion is that Industry 4.0 technologies enable coordination of product and information, thereby restoring or enhancing categories of proximity, impacting on the generic performance metrics.

This Brexit situation is ongoing. Over the coming months (maybe years), the discontinuity will evolve, practice will be challenged and a research-rich environment will emerge. We plan to continue our analysis as the Brexit situation unfolds and through primary data collection via semi-structured interviews with key personnel in logistics providers as well as port and government agency bodies.

Abstract

In freight transportation, logistics service providers guarantee to deliver the orders of their industrial customers within specified time-windows. However, in some cases late deliveries occur resulting in an increase in overall costs, decrease in customer fill rate and bring penalties accordingly. In this study, we used interview technique by adopting a dyadic approach for examining late delivery problems from the perspectives of business buyers and logistics service providers. The research, herein, revolves around “on-time delivery” also by including penalties and recovery actions in case of delivery failures.

Keywords: Service failures, Late deliveries, B2B approach

Introduction

As service failure is an unavoidable reality due to the unique nature of the services (Hart et al., 1990), understanding service failures and developing effective recovery strategies are crucial both for service providers and business buyers. From the point of Exchange Theory, service failures and recoveries are part of special exchange processes. In this regard, customers who suffered from a service failure feel a certain degree of injustice and service providers offer service recoveries in order to compensate this feeling (Qin et al., 2012). In addition to this, Equity Theory posits that individuals in social exchange relationships benchmark the ratio of their inputs with the ratio of their outcomes within the exchange process. Inequity occurs when perceived inputs/outcomes are inconsistent with the actual
inputs/outcomes (Huppertz et al., 1978). In line with these theories, recovery strategies in B2B environment come into prominence and they have been studied mainly in relation with customer satisfaction, timeliness, apology and compensation, e.g., discount, free products (Davidow, 2000; Hess and Ganesan, 2003; Hübner et al., 2018).

Delivery performance can be defined as the level up to which products and services supplied by an organization meet the customer expectation (Rao et al., 2011). In this regard, business buyers often attach particular importance to delivery performance. On the other hand, logistics service providers (LSPs) attempt to reduce transportation cost and to increase customer service level simultaneously. Herein, compatibility to time windows by providing “on-time delivery” is considered as the focus of our study. The purpose of this study is twofold. Firstly, we aim to figure out the attributes of on-time delivery. Secondly, we try to find out the penalties charged and recovery actions offered in late deliveries.

Although service failures and recoveries are well studied in B2C environment, more work is needed in B2B area. In this regard, the study reveals the importance of timely deliveries and it points out must-have on-time delivery attributes. In addition to this, the research demonstrates which penalties are particularly implemented for late deliveries on business buyers’ side and which recovery strategies are offered by service providers in return. This research addresses three broad research questions:

1. How service providers and buyers evaluate delivery performance attributes?
2. What kind of penalties charged by business buyers in case of late deliveries?
3. What kind of recovery strategies pursued by service providers for compensating on-time delivery failures?

**Literature Review**

In service failures literature, two types of service failures take place: outcome failures and process service failures. While outcome failure is realized when customer cannot receive the service which he/she pays for, process failure occurs when there is a disruption in the service received (Nyugen and McColl-Kenedy, 2003). In this regard, process failures are more likely to occur in B2C market while outcome failures are mostly experienced in B2B environments. Most of these outcome failures are related with the transfer of products to customers including late delivery, documentation failure, information/communication failure, operational or booking failure (Özaydın et al., 2015). In B2B markets, failures create domino effects by effecting multiple parties. When service providers cannot meet delivery deadline, the clients of the customers of service providers are also jeopardized and this cause dissatisfaction in a wider network (Zhu and Zolkiewski, 2015). Therefore, it can be seen that the timeliness of delivery has a direct effect on the customer relationship. If service providers cannot perform on-time, this puts business buyers into trouble in terms of lost sales or bureaucratic processes to correct it (Özaydin et al., 2015). Looking at the consequences of service failures in B2B, it causes reduction in repurchase intention and deterioration of long-term relationships (van Doorn and Verhoef, 2008; Harrison and Walker, 2012); complaints (Hübner et al., 2018); decline in trust (Tronvoll, 2011); and increase in costs (Komunda and Osarenkhoe, 2012). Customer dissatisfaction and negative word-of-mouth are other endemic reactions that are experienced in B2B marketplace (Zeithalm et al., 1996; Davidow, 2000; Hübner et al., 2018;). In literature, these consequences of service failures are defined in general. Therefore, we aim to shed light on how these penalties differentiate in the context of “late deliveries”. As there are only a few studies on penalties and recoveries in B2B
context, we aim to investigate on-time delivery related penalties and recoveries more specifically.

**Research Methodology**

*Data Collection*

In this study, we used purposive sampling method. In purposeful sampling, sample members are selected based on their knowledge and expertise regarding the research subject (Palinkas et al., 2015). We selected companies from manufacturing and logistics sectors to address the late delivery problem in a more comprehensive way (Table 1). Through conducting face-to-face semi-structured interviews, we aimed to get a comprehensive insight in a dyadic way. All interviews were audio-recorded with permissions.

Themes of semi-structured interview are as follows: key attributes for on-time deliveries, consequences of late delivery, and recovery actions after late deliveries. Within this context, the participants of this study are representatives of 14 well-known companies. Due to confidentiality, company names are shown as “M” referring manufacturing firms, and “SP” for service providers.

*Data Analysis*

In order to develop a better understanding, we conducted a content analysis by basing on the methodology suggested by Strauss and Corbin (1998). We conducted open, axial and
selective coding in order to analyse the gathered data, and created main and sub categories accordingly.

Regarding open coding, company interviews were read line by line several times and divided into smaller discrete ideas, events or experienced moments. Then, tentative labels were created accordingly, which summarize the data extracted from the interview. Once some categories emerged, relationships among the open codes were identified and data were linked via a combination of inductive and deductive thinking through axial coding. Then, we identified the core variable that includes all of the data with selective coding, which involved integration of the categories in the axial coding model.

Regarding validity, a pilot preliminary test was done in order to ensure the clarity and accuracy of interview questions. In line with data saturation logic, process of gathering and analysing data lasted until the point where no new insights were observed in data.

In terms of reliability, we made meticulous record keeping through demonstrating a clear decision trail and ensuring that interpretations of data were consistent and transparent. After analyses completed, three authors conducted coding separately for ensuring inter-coder reliability.

**Findings**

**Key Attributes in On-Time Delivery**

The following attributes are seen as important indicators for on-time deliveries both for service providers and business buyers. Flexibility is defined as the ability of a system to change or react with little penalty in time, effort, cost or performance (Naim et al., 2006). Business buyers expect service providers to perform mode changes with flexibility in order to speed up the operations for being on time.

“*Most forwarders do not want to deal with changing modes. I say that 'I want you to turn the mode to the air right now based on the mail that I received from my client!' The forwarder needs to be able to change modes.*” (M6)

Accessibility in delivery problems is another concern for both parties. This concept is defined by Litman (2017) as person’s ability to reach services and opportunities as needed. Business buyers seek for authorized employees in delivery problems. Therefore, service providers should be reachable at all times to provide expected service level in delivery and they should inform their customers on timeliness.

“...in delays sometimes we cannot reach them for hours and we call thousands of people from the company.” (M1)

“*Business buyers complain about logistics companies. They say that they cannot find any respondent and cannot get info about their product in case of late delivery.*” (S4)

Consistency of service refers to a continuous operational process which is far from deviations (Knott et al., 2008). In this regard, consistency in delivery times is seen as a fundamental feature for business buyers. They expect service providers to set certain transit times and serve in certain standards.
“Most of service providers are certain in terms of transit time. However, their consistency is so important. In order to be consistent, they need to be serving in certain standards.” (M6)
“Except weather conditions, being consistent is an important factor for customers. It also brings credibility.” (S7)

Traceability of load and vehicle become more important in late deliveries both for service providers and business buyers because tracing enables a correct and up-to-date information transfer among business players.

“There are some companies that do not inform customers. In these companies, customers try to get information. These firms say ‘I will call you in 3 hours’ and they try to reach your truck.” (S1)
“Nowadays, we can see what the driver is doing and where the truck is with the help of vehicle tracking systems.” (S2)

Findings revealed that, trustability is an important indicator of customer satisfaction. If service providers do not meet the promised transit times, their image in their clients’ eyes will be affected negatively. From the point of service providers, being reliable is important for satisfying their customers, maintaining their brand image and increasing profit.

“If providers give us incorrect transit times, their image get worse in our eyes.” (M5)
“Customer chose us because of our delivery performance, if I did not give them the service that I promised before, and then I lost my credibility.” (S3)

Delivery tolerance intervals refer to upper and lower bounds of delivery lead times. Both business buyers and service providers agree that business type and stock keeping strategy (make-to-order/make-to-stock) in which the business buyers engage affect delivery tolerance intervals. For instance in JIT based automobile industry, production plan is done based on zero inventory logic and the delivery must be on time. Similarly, in textile industry, due to fast changing trends or fashion seasons they have some lead-time obligations that service providers have to comply with it.

“As we are a fashion company, we race against time. There is no tolerance for late deliveries.” (M2)
“There may be no tolerance if buyers’ production band works as just in time.” (S2)
“For example, even if we send some loads 10 days later, some companies do not say anything because they do not work on a JIT basis, and they already have enough material in their stock.” (S4)

Herein, weight/value ratio is another important criterion for determining tolerance level for business buyers, if products are light in weight but heavy in value, tolerances are low.

“Our tolerances are low because we send loads that are light in weight but heavy in value.” (M7)

Moreover, power relations among business players are important.
“Tolerances are related to the degree of the buyer's power on their customers.” (S7)

Regarding lower and upper bounds of tolerances for late delivery, two days of delay are acceptable.

“You will tell one day delay in a certain way, but the second day the problem must be solved because customer cannot wait you anymore.” (S5)
“We usually talk with their customer representative and ask them to solve this problem by 2 days because a delay of 2 days on road is a compensable delay.” (M6)

Consequences of Late Delivery
When service providers breach the standards, business buyers employ a “stick approach” (Porteous et al., 2015). In this research, service providers are subjected to penalties in case upper bound for delivery is exceeded. However, these penalties vary by the consequences of delay. Reducing business volume seems to be the most frequent penalty employed by transferring a portion of business to other carriers in order to penalize them.

“We lowered the amount of load that we used to give to ABC provider after late deliveries. We were giving 350 tons of cargo monthly but it fell by 70-80 tons currently.” (M4)

As a natural consequence of reducing the business volume, sales performance of the service providers is affected and it causes to lose their competitive advantage in the market.

“We started to fall to undesirable level and lost freight because the goods were not delivered on time.” (S3)

Termination of business and being put into black list occur to be as the other penalties charged by business buyers.

“When we started our business, we were working with ABC Logistics. We worked with them in both partial and complete truckloads. After serious customer complaints came about late delivery, we terminated our relationship.” (M4)

Switching service providers is another type of penalty implemented by business buyers.

“If you are constantly late, following the end of the contract customer says that he is going to try another firm and punish you with this way.” (M2)

Apart from those, business buyers may reject the late shipment or keep late arrived vehicles waiting (vehicle retention) as a penalty.

“If you send the load after three days with delay, the customer may say I reject the load because it is useless.” (S7)
“If our trucks do not go to Brand P’s gate on time, they make us wait because they give a certain time to other vehicles, too.” (S1)
Furthermore, if the subcontractors of service providers cause the delay situation, business buyers apply management intervention and use their influence to force service providers to work with their chosen carriers.

“Our sanction right is generally high in big companies. If subcontractors of service providers cause delay, we have the right to eliminate who we don’t want to work with.” (M3)

Initially, warnings and requests for official letters take place in case of late delivery.

“If the delay occurs, we apply pressure by asking official letters, warning them in the presence of a notary public.” (M7)

Interestingly, similar to B2C context, negative word of mouth (NWOM) and complaints to third party mechanism are common penalty practices in B2B environment.

“In case of late deliveries, we absolutely transmit it to the central company in Germany. Their warning is more serious and sanctioning than ours.” (M2)

“In the event of delay, end user complains to the business buyers and writes on internet blogs. This falls our score.” (S4)

“In case when we do not send their orders on-time, they complain about us and spread NWOM” (S6)

Business buyers keep scorecard records to evaluate the performance of service providers. As on-time delivery is one of the most weighted performance indicators of service providers, they reduce the score as a punishment.

“Providers get a lower score on their score card because of late delivery. They are evaluated by such categories...” (M2)

In some cases, penalty fees charged. In case of band/production halts and extra labour costs, business buyers charge these fees to logistics service providers. Moreover, there may be some cost of reclamation and cost of unsold goods that arise from late deliveries. Herein, responsibility of paying these types of costs belongs to the service provider as a penalty.

“If we do not comply with the contract then we will be obliged to pay the worker’s wage per hour. This is our liability.” (S5)

“When you are late it means that the products are not going to be on-time in the stores. Then business buyers reflect the rate of loss to us as reclamation expenses.” (S6)

**Recovery Actions**

Late deliveries occur inevitably and service providers attempt to compensate these failures. The recovery actions including distributive, interactional and procedural dimensions play a mediating role between prior satisfaction and satisfaction with recovery (Siu et al., 2013). Distributive justice actions are associated with the outcome of the recovery actions. It includes discounts, coupons, refund, free gift, repairs and replacement with the aim of compensating the service failure (Blotgett et al., 1997).
In order to compensate late delivery, service providers offer discounts or extend payment terms.

“Certain concessions can be made for not losing the customer for example payment deadlines can be extended.” (S2)

“In case of late delivery, we make gesture to the customer. We offer 200 euros discount.” (S1)

If delivery date exceeds the due date, service providers burden the cost of air cargo. In addition to this, service providers carry the loads of their customers free of charge due to being late. The aim of this action is to avoid losing customers and ensure continuity of good relations with their customers.

“If it is necessary, we send the load by air without demanding cost. We bear the cost and it is strongly related with the relationship with our customer.” (S2)

“In case of late delivery, we do not take cost of freight to show that we are in good faith.” (S6)

In some cases, service providers make unexpected service recovery offerings by providing a storage service to business buyers with the aim of improving their image in their customers’ eyes.

“Carrier provides us a storage service as a side service in order to fix their image.” (M5)

Interactional justice actions refers interpersonal treatments including explanation, politeness, honesty, effort, apology and empathy as the manner of the operation of the recovery process (Siu et al., 2013). In case of late deliveries, sending delay notice and providing timely information as well as providing explanation for delay become important for business buyers.

“Even if it was late, I could reach every time I called. Both sales and customer service shared delay details and reasons.” (M2)

“We inform our customers every day. When the ship does not arrive to destination on time and we say that it will arrive tomorrow and after unloading, deadline info is shared with you immediately.” (S1)

“It is very important to inform customers about late delivery because it allows the customer to foresee and take action accordingly.” (S6)

Apologizing is another important thing to overcome consequences of late deliveries. In this sense, service providers organize customer visits and they look for the other ways to apologize as a constructive action.

“We tell the customer that we will be more careful in the future. We organize customer visits. We say that this was our fault, sorry.” (S1)
Procedural justice actions concern the fairness of policies, procedures and criteria used by decision makers (Blotgett et al., 1997). It includes process and decision controls, accessibility, flexibility and speed. In some business relations, service providers are obliged to prepare process improvement report and proactive action plans after late deliveries. By this way, procedural improvements are achieved for ensuring on-time delivery.

“We prepare a CAPA (Corrective and Preventive Action) form after late deliveries. Then providers have to develop a project and heal themselves.” (M1)

Conclusion
In this research, we addressed the key attributes of on-time delivery such as flexibility, accessibility, consistency, traceability, trustability, creating sustainable value, performance evaluation, tolerance levels, weight/value ratio and power relations. Accordingly, we aimed to find out the penalties charged as well as the other consequences when the upper limits were exceeded such as reducing business volume, termination of business, being put into black list, switching, rejection of shipment, vehicle retention, management intervention, warnings, negative word of mouth, complaints, reduction in scores, request of free freight, and handling variable costs.

In detail, the study examines the cases in which customers impose penalties and how these penalties are applied. Moreover, this study investigates the recovery options pursued by service providers for late delivery failures. We have found that also in B2B context, distributive, interactional and procedural recovery actions exist.

The scientific contribution of this research is to lay emphasis on the penalties and recovery actions within the framework of “on-time deliveries”. We employed a dyadic approach embracing manufacturing companies and service providers. In practical sense, the study contributes for developing a deeper understanding for penalty and recovery actions in B2B context.

Abstract

In this study, we explore the factors that facilitate or hinder the deployment of emerging technologies in the logistics and warehousing industry in Australia. We conducted interviews with representatives of organisations in the logistics value chain in Australia. Based on our initial findings, interviewees generally agreed that there is greater pressure now to adopt newer technologies and alter their practices and business models or risk losing existing and new customers. Speed of change, cost and standardisation of data are three key considerations highlighted for the implementation of emerging technologies in logistics to facilitate efficiency and sustainability of supply chains.

Keywords: emerging technologies, logistics, warehousing.

Introduction

Emerging technologies such as Internet of Things (IoT), data analytics, artificial intelligence and machine learning, intelligent robotics, and blockchain have the capacity to transform industries offering substantial benefits to users (Fonseca, 2018; Posada et al., 2018). However, the factors that affect the deployment of these technologies are not well understood. Some of these include regulatory barriers and policy inconsistencies, cost, skills shortages and failure to understand the opportunities that new technologies offer (Schelechtendal et al., 2015; Fagnant and Kockelman, 2015).

In the context of Australian logistics, warehousing and supply chains, improving efficiencies and safety remains a high priority. Emerging technologies offer substantial improvements not only in productivity and safety but also in terms of flexibility,
transparency and interoperability (Tu, 2018). Hence, developing deployment strategies that address the needs of all types of businesses as well as large organisations and SMEs is essential.

The purpose of this study is to explore the factors that facilitate or hinder the deployment of emerging technologies in establishing world class logistics infrastructure in Australia and ultimately develop a decision-making framework that can be utilised for designing and operating logistics and warehousing infrastructure that meets the needs of the future.

Specifically, this study explores the following research questions: (1) What are organisational and industry level drivers for deploying emerging technologies in logistics and warehousing?; (2) What are the factors that affect deployment of emerging technologies and what impact do these have on outcomes?; and (3) What are the key actions necessary to be undertaken by organisations and industry for realising the capabilities of emerging technologies?

In order to address these research questions, this study will involve a review of the literature, logistics industry stakeholder interviews and qualitative case study analysis.

**Literature Review & Theoretical Background**

**Drivers for deploying emerging technologies in logistics and warehousing**

In order to understand the organisational and industry-level drivers for the implementation of emerging technologies in logistics, it is important to refer to the literature to understand the logistics function in supply chain management (SCM).

Logistics refers to “managing the flows of goods and information from a point of origin to a point of consumption” (Murphy and Wood, 2011). According to the Council of Supply Chain Management Professionals (CSCMP), “logistics management is that part of SCM that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers’ requirements”. Logistics management is usually divided into materials management and physical distribution management (Fernie and Sparks, 2014). Logistics-related activities within the firm may include the following: customer service; demand forecasting; facility location decisions; order management; inventory management; procurement; materials handling; packaging; transportation management; reverse logistics; international logistics; warehousing management. Any implementation of emerging technologies by the logistics operations of the firm may impact these other functional areas as well. In Australia, international technology start-ups are already disrupting the logistics industry by implementing emerging technologies in the areas of supply chain and logistics management. These include last-mile autonomous vehicle drones, trucking marketplace and fleet management and e-commerce logistics.

Warehousing is the storage of inventory or that part of a firm’s logistics system that stores products (raw materials, parts, goods-in-process, finished goods) at and between points of origin and point of consumption” (Douglas et al., 1998). Warehousing management has an increasingly important role in logistics and supply chain systems due to the changes in other functional areas as a result of implementation of technologies and contemporary management strategies, such as lean inventories. (Murphy and Wood, 2011).
Warehousing has a significant relationship with transportation sometimes referred to as “transportation at zero miles per hour” (Murphy and Wood, 2001). There is a trade-off between warehousing and transportation, as the presence of a warehousing facility closer to a producer generates shorter-haul transportation routes, but this is more costly per mile than long-haul routes. However, this cost may be offset due to the possibility of transporting larger volumes of weight along the short-haul routes. The implementation of emerging technologies in warehousing management has been identified as having a major impact on logistics operations, particularly with regards to automated warehousing (Wang, McIntosh and Brian, 2010).

The implementation of emerging technologies within the logistics function facilitates the effective forward and reverse flow and storage of goods and services. There is an increasing need for logistics management to take into consideration the need for flexibility and real-time responses to the changes in market demands (Uckelmann, 2008). Customers of logistics service providers, such as manufacturers, have adopted new strategies such as agile manufacturing and mass customisation, which have transformed these organisations into integrated networks in which core competencies are aligned with those of other organisations in the supply chain. The development of new technologies, such as the Internet, has facilitated the virtualisation of inter and intra-company operations, which has enabled data, e.g., about production and products, to be exchanged autonomously with the embedding of systems throughout the entire value chain (Brettel et al., 2014). As a result, industrial production has globalised into an open supply chain network characterised by short-term business connections and cooperation between stakeholders. The technology required by this open supply chain network is made available by the concept of “Industry 4.0” (Vogel-Heuser and Hess, 2016), which is referred to as the 4th industrial revolution (Fonseca, 2018). Industry 4.0 is characterized by the advanced digitalisation and integration of industrial manufacturing and logistics processes, and the use of internet and “smart” objects (machines and products) and merging the physical and the virtual worlds by the adoption of information and communications technology (ICT) (Posada et al., 2015).

**Barriers to the implementation of emerging technologies**

In a partially-automated warehouse, emerging technologies are causing disruptive changes in warehousing strategies. For example, the development of advanced robotic systems which use digital add-on systems to transform forklifts. The brewing company, Carlsberg uses such forklifts to move up to 500 pallets per hour around one of its Swedish distribution centres. Even people are being displaced from the warehouse environment by emerging technologies, due to the speed and efficiency with which robotics and machines can pack goods. However, in a partially-automated warehouse, people still play a substantial role in its operations. In contrast, in a fully-automated warehouse, the implementation of emerging technologies means there is little need for people to conduct traditional warehousing tasks. For example, such a warehouse could house an automated storage and retrieval system (AS/RS), where the centre’s Warehouse Management System (WMS) could be linked to cranes on rails, which move up and down aisles of racks that extend from the floor to the ceiling of the warehouse. Such a warehouse would offer high levels of productivity (due to the efficiency and being able to operate 24 x 7 365 days a year), and offsetting some of the power they use by operating in an unheated or un-cooled environment, with little if any need for artificial lighting, leading to savings on energy costs.
However, even a fully-automated warehouse requires people to manage it operations. Amazon, which has more than 100,000 robots inside its warehouses across the world, still has 500,000 human employees on its payroll worldwide. This is because the company claims that “robots do not have the ‘common sense’ or ‘dexterity’ needed for the job”. Also, while almost half of jobs in the transport, postal and warehousing sectors are within road transport, i.e., freight (Australian Industry Standards, 2017), presenting a huge opportunity for the implementation of autonomous vehicles, it would be hard to imagine replacing such a large number of workers right now. However, in future, this may be a possibility if the costs involved in using autonomous vehicles are reduced.

**Theoretical Framework**

The dominant theoretical approach to SCM and logistics research has been the systems approach (Lambert et al., 1998). This is because the systems approach recognises the interdependence of the major functional areas of the firm, including logistics (Murphy and Wood, 2011). It has been argued by academics that the systems can be used to understand SCM and logistics, which requires a holistic perspective, consideration of total cost and avoiding sub-optimisation (Grant et al., 2005; Bechtel and Jayaram, 1997). However, one logistics system does not fit all companies because goals and objectives vary from one firm to another (Murphy and Wood, 2011, p27). Although systems analysis is useful for describing and modelling the movement of goods, inventory data and demand patterns, there is an element of interaction between people in logistics management that is too complex for the systems approach to be applied (Rigby et al., 2000). Therefore, models and theories that are applicable to complex situations and contexts are more suitable for logistics management (Nilsson, 2006). The application of models and frameworks based on complexity theory has become more common given the increasing complexity of logistics management due to shortened product lifecycles, decreasing time to market, emerging technologies, etc. (Nilsson and Gammelgaard, 2012). Several studies apply complexity theory to SCM and logistics (e.g., Ellram et al., 2007; Wysick et al., 2008; Holweg and Pil 2008; and Svensson, 2010).

However, the theoretical approach that provides an organisational-level perspective, as opposed to a systems or complexity approach, is the resource-based view (RBV). This theory can be applied more simply to explain the drivers for and barriers to the deployment of emerging technologies in logistics and warehousing because it proposes that a firm’s performance is governed by its internal processes and management of resources (Wernerfelt and Karnani, 1987). One of the key underlying assumptions of the RBV is resources are distributed heterogeneously amongst competing firms, such that those firms with lower cost of resources and capabilities for implementing a certain strategy gain competitive advantage over their competitors. (Barney, 1991).

**Overcoming barriers based on RBV**

One of the key barriers to implementation of Industry 4.0 is the high costs involved (Schelechtendal et al., 2015). Despite the benefits of fully-automated warehouses, the costs of establishing such facilities is very high due to the need for customisation and specialised infrastructure. Consequently, smaller supply chain firms are not able to make use of such emerging technologies. However, since industry 4.0 will be like an ecosystem, collaboration will be a key determinant of a firm’s competitive advantage (Reinhard et al., 2016). This is because, within the ecosystem, there will be clusters of firms which are
active along common value chains, including manufacturers, service providers, suppliers, primary customers, research institutes, universities, etc., which can realise synergistic benefits from being in close proximity to one another by sharing resources, skills, knowledge, and costs which generally leads to accelerated innovation (KPMG, 2016). In this way, firms within the logistics and warehousing industry can compensate for a lack of resources and capabilities to implement emerging technologies for mutual benefit, including optimisation of the supply chain network.

Therefore, based on the RBV, we propose that resources such as emerging technologies provide firms in the logistics and warehousing industry with capabilities that provide them with a competitive advantage. However, as indicated by the literature review, firms struggle to gain access to the necessary resources (including both emerging technologies and human capital), infrastructure and services required at affordable prices. We expect to see this identified as a key barrier in our case studies. The purpose of this study is to explore the factors that facilitate or hinder the deployment of emerging technologies in establishing world class logistics infrastructure in Australia and ultimately develop a decision-making framework that can be utilised for designing and operating logistics and warehousing infrastructure that meets the needs of the future.

Research Methodology

This study employs a qualitative approach in addressing the research questions presented above. Interviews are more appropriate in cases where new/emerging issues are to be explored and the views of many different stakeholders are to be captured (Sofaer, 1999). Hence, we conducted a number of face-to-face interviews with senior executives and relevant mid-level managers working for different types of organisations providing logistics and warehousing services. Other interviewees included users of logistics and warehousing services, officers representing logistic and warehouse councils, regulatory bodies and policy making entities. The interviews were audio recorded and transcribed, with analysis conducted using the qualitative analysis software NVivo.

Results

Drivers for the implementation of emerging technologies

Customers are the drivers for the strategies of many companies now, as they demand certain products or services within certain short timeframes now. For example, a store manager at a local store wants a delivery to occur at a certain time of the day when they are not busy with customers. These technologies are enabling visibility to allow everyone along the supply chain to be efficient in what they do.

Companies need to understand the order, the customer, and then be flexible to meet demands of the customer. Companies need to recognise that their business models might be partly effective, e.g., regional distribution centres, but also recognise the need to create new models to achieve flexibility in supply chains. As the supply changes, companies need to know who they need to engage with to meet demand. This is a new trend in the industry. For example, a number of retailers or FMCGs are examining their supply chains and realising that the market is changing and that they may need to change their business models to perhaps take care of their own logistics, etc. Do they now remove the middle part of the supply chain and go direct to the end-user? However, these companies have never had any visibility of who these end users are in the past. Now that business models
are moving from a B2B to a B2C model, there may be a need to look at technologies that would support this shift.

Consideration of the “last mile” is crucial. For example, if a product is ordered at one location but delivery is required at another, it is possible to arrange for the delivery if a mobile truck has the stock and is close to that new location. Solutions are now emerging for this sort of demand. Toll was recently awarded a contract by Telstra for the provision of a last mile solution which is automated and has the ability to allow for moving delivery locations, real-time alerts, etc. In the past, Telstra used a solution called Brightstar for around 10 years to do this but it had no visibility of its customer base. The reason for this new tender was to provide Telstra with this visibility so it could market its products more effectively to the correct target markets with the most appropriate marketing materials, etc. This also facilitates packaging which is also targeted to specific customer segments. This sort of B2C activity is gaining momentum in the Australian industry.

There is a need to develop a generic framework for the implementation of emerging technologies across the supply chains, driven by e-commerce. Apart from efficiency, sustainability also has to be considered. For example, companies, such as CC-Amatil are thinking about how to reduce the use of single-use plastic bottles.

Gaining access to resources and capabilities through collaboration

The case studies revealed that implementation of emerging technologies is driven by the need for network assurance (operational efficiency) and cost. In order to achieve supply chain network optimisation, CC-Amatil is looking outside its traditional network of partners and going outside of the industry to find potential non-competitive complimentary partners who have similar needs, such that they can share transport and warehousing, etc. On one hand, they could look to do consolidated loads, e.g., CC-Amatil could align itself with a chips company to transport both its drinks and chips to the same destination, e.g., vending machines location. This means customers would have to hold less inventory and it would be fresher. On the supplier side, CC-Amatil could be more responsive to changes in demand and make more frequent deliveries. CC-Amatil could also look at collaborating with non-competitive partners for reverse network distributions. CC-Amatil has spoken to Toll to identify other Toll customers and see where synergies exist, e.g., where the networks are shared such that trucks could be used to move stock from point A to B for one company and then B to A for the other. This is more efficient use of trucks hence reducing traffic congestion, emissions, etc.

For many 3PLs, short-term contracts mean that relationships are also short-term, so then 3PLs are not willing to invest in new solutions. 3PLs and also retailers have low margin gains, so they are in a different situation to the NBN, which focuses more on being able to provide spare parts to the network to ensure it operates no matter what the cost is. On the other hand, 3PLs and retailers are not able to spend as much to solutions. Therefore, the major 3PLs can play a key role in providing a platform for collaboration to implement new technologies and optimise the network. For example, they should be able to transport goods for various suppliers using the same trucks, in order to optimise the use of their fleet of trucks across the network. It shouldn’t be an issue for these suppliers as long as their goods are segregated and data is not shared.

Further, the interviews revealed that collaboration can facilitate the implementation of emerging technologies, e.g., collaboration between industry partners facilitated by GS1 (under guidance of the Australian Logistics Council) to conduct pilots. This enables
businesses to understand their supply chains better. Pilots are important in proving to businesses that solutions can work in real-life. Apart from efficiencies, other advantages partners can reap include greater visibility, shared data, etc. When companies operate in silos, there is not enough volume to make it cost effective to implement these new solutions, but eventually, if these companies, e.g., a group of FMCGs, which are not competing on supply chain but rather product, collaborate to reduce costs of logistics.

Lack of capabilities for implementation of emerging technologies in the industry

The biggest challenge for the industry right now is that there are many areas of technological innovation, from block chain to Big Data to IoT, but there is not a great understanding of many of these technologies and how they can or can’t be applied. Many companies do not know where to start, even though they might see IBM, for e.g., come and give presentations, they do not know how to implement the solution. This is the case with larger companies, such as NBN, which, despite having resources, are unsure of how to go about it. Digitisation is not a new concept, with some technologies being around for the last 30 years. The industry is on the verge of realising just how little it knows and how much potential there is for implementing emerging technologies. The industry has only touched on about 3% of Big Data, but there is potential for a much greater level of application of Big Data and IoT to supply chains. This is due to a changing market driven by consumers, e.g., customers want to receive more goods quicker.

Every organisation needs to understand its strategic landscape, i.e., what are the market forces that could lead to change or pose a threat are (SWOT). Businesses need to assess their current situation, where they want to be future, what path they need to take to get there, and what the potential forces (internal and external) that have to be overcome to achieve that. If they are focused on only one aspect of their operations, they will not be able to do this because they need to look at the bigger picture. It is important to realise that, although certain technologies can achieve certain results, not all businesses need to be looking to implement such complex technological solutions if they are not going to use them to their maximum capability because in reality on the ground, users are not able to use such sophisticated technology. The journey needs to be an evolution and different companies are at different stages of that evolution. For some organisations, current organisational structures and process are too deep-rooted to change and find solutions that can be implemented. If a technology provider can develop a platform that is simple enough to use, then this can be overcome. Organisations that have the design-thinking mentality are better positioned to be longer-term leaders in that field because they consider the end-user experience.

Role of government in facilitating access to resources and capabilities

The interviews reveal that Federal and State governments need to work together to link the various sea and inland ports together. They need to make inland ports stronger assets to reduce some of the pressure off the metropolitan routes by diverting traffic away from traditional seaports which are often located near growing metropolitan areas. Government can also play a role in protocol standardisation. In IT, standards are always sort after for interoperability. However, in terms of supply chains, there is massive fragmentation, and this is mainly driven by the fact that most supply chain systems require specialisation, or they are high proprietary. There have been attempts to implement this sort of
standardisation, such as supply chain-centric blockchains, etc. but a simple government-backed protocol would be very helpful.

Discussion

The landscape has changed such that 3PLs need to build assets with a view to the future, as B2C activity is gaining momentum in the industry. Some of these technologies will impact the way consumers order goods and their expectations of how quickly they will be able to receive them. Then there will need to be consideration given to how the supply chain will need to be flexible to meet this demand. This change is driven by consumer demand but also the underlying technology platforms that are being made available. One of the biggest barriers for large companies is that to add on other applications can be a complex process because it could impact a whole range of systems already being used which would need to be reconfigured. It is much harder to try a new technology and more expensive for larger companies for this reason. The other issue is that there is not a great deal of long-term thinking for e.g., in retail, there is a very short-term focus.

The industry in Australia is challenged by the high cost of labour and relatively expensive warehousing space (e.g., in Sydney). Within the area of automated warehouses, the major cost is labour. There are several relevant issues around labour that need to be considered: aging workforce, the need to attract a younger workforce, and the need to attract more females. Another challenge within the small Australian market is the current mindset. When a branded company sets up a solution, there is a thinking by competing companies that they should not share in the use of that solution. This is where universities could play a part in providing platforms to bring industry partners together to develop and apply new technological solutions for logistics. The major 3PLs could also play a key role in providing a platform for collaboration to implement new technologies and optimise the network. 3PLs could also lead the way in introducing new technologies and creating a culture of innovation.

Based on our initial findings, logistics and warehousing providers generally agreed that there is greater pressure now than before from users and customers on improving flexibility, timeliness and efficiencies. Providers are under great pressure to adopt newer technologies and alter their practices and business models or risk losing existing and new customers. For instance, a number of retailers in the FMCG sector are closely examining their supply chains and realising that the market is rapidly changing. Consequently, these retailers are considering the need to perhaps change their business models to the point of solely taking care of their own logistics. Speed of change, cost and standardisation of data are three key considerations highlighted for the implementation of emerging technologies in logistics to facilitate efficiency and sustainability of supply chains. The general consensus from stakeholders is that operating in silos does not enable companies to fully harness and nurture new technologies given that they lack sustainable volumes and that a joint effort amongst providers is perhaps more beneficial.

Providers and users also admit that even though digitization is not a new concept, there is still a lack of understanding of many of these technologies and its application. They assert that this void can be filled with greater awareness and support from government bodies and local logistics and warehousing councils. For instance, both parties need to work together to link the various sea and inland ports to reduce some of the pressure off the metropolitan routes by diverting traffic away from traditional seaports which are often
located near growing metropolitan areas and enforce protocol standardisation. in IT standards which are always sort after for interoperability.

**Conclusion**

In terms of contribution to literature, preliminary results of this study show how emerging technologies have the potential to create efficiencies. Providers of warehouse and logistics services including users admit that inefficiencies create unnecessary delays, affect service levels and unnecessary expenditures. However, all of these could be significantly avoided if stakeholders could embrace a more collaborative attitude rather than taking on a competitive disposition. The study brings to light a number of themes that suggest that emerging technologies needs to be consistently embraced and embedded within the company for sustainable growth. The findings of this study also allow the researchers to undertake a further in-depth inquiry to develop a decision framework that could be adopted by companies for the implementation of emerging technologies across the supply chains, driven by e-commerce. Despite the limitations of this study being conducted in the Australian context, the reasons highlighted and themes raised have been supported as important by other scholars (Koch et al., 2014) and with caution results can also be generalized to similar economies.

Abstract

Supply chain (SC) mapping is a stream of research as well as a managerial activity. It is also important in SCM teaching. Despite this importance, very little empirical research has addressed SC mapping and SC maps. Based on a qualitative case study in an industrial company, this paper gives evidence of the discrepancies between how managers define the outbound SC, the SC map they draw and what they say when mapping. It supports the underlying hypothesis about how individual mental representation of SC influences SC mapping. It opens avenues for further research about how using mapping and maps in SCM.

Keywords: Supply Chain Mapping, Outbound supply chain, Case study

Introduction

Since the 1990s, supply chain mapping has been a common practice and an important research topic (e.g. Lambert et al., 1998; Gardner and Cooper, 2003). Many different pictures of supply chains (SC) are made by companies, teachers and consulting firms. However, few studies question the role of these “pictures”, their use in companies and their usefulness for people involved in SC operations or management, as well as their influence on SCM concepts and practice. In line with Carter et al. (2015) or Fabbe-Costes (2017), we advocate that they are not neutral and could play a key role in SCM.

A supply chain map, like a geographical map, is supposed to represent the “territory”. Since no map can represent everything, people who map make choices, and, in particular when there is no mapping convention (Gardner and Cooper, 2003), often adopt personal representation codes, both of which reflect biases. Moreover, since a map is a “model”, it is “projective” (Le Moigne, 1990). Supply chain maps thus might reflect the viewpoint of the people drawing them, as well as their project or expectations related to SCM. Supply chain maps might also be influenced by people’s history, discipline, culture, experience of the territory, etc. They might also reflect the purpose of the mapping, being a sense-making activity (Henneberg et al., 2006)…
The purpose of this paper/research is to study supply chain mapping as a managerial activity and to question the impact of SC maps on SCM. In the literature review, we combine perspectives from SCM and from the ‘network pictures’ literature in industrial marketing (e.g. Henneberg et al., 2006) to ask the following: Do companies produce and use SC maps? Do managers’ individual SC maps reveal different “viewpoints” of/in the supply chain that could reveal different mental representations of what a SC is? When managers map a SC, what are the differences between what they draw, how they explain their mapping, and how they define the SC? The research design section details our qualitative case study focusing on the outbound supply chain of an industrial company. After presenting the empirical results of the research, we discuss their managerial and academic contribution before concluding.

Literature review

Supply chain management and the “images/pictures” of supply chains
Since the early 1980s, the study of SCM has involved the drawing of pictures of supply chains. Some famous figures are commonly cited. They show different aspects of what supply chains are. Stevens (1989) focuses on internal functions that have to be integrated with a linear representation of what an integrated chain is. Harland’s figure (1996) highlights the structure of the “chain” (from a line to a network) and the number of echelons. Mentzer et al. (2001) adds the types of actors participating in the chain. Some figures (e.g. Lambert et al., 1998) are clearly “centred” around a pivot with an upstream SC (up to initial suppliers) and a downstream SC (to end customers). In their framework, Cooper et al. (1997, p.10) identify actors, flows (information and product), business processes and SCM components. With the influence of the network approach (Haakansson and Snehota, 1995), supply chains are also seen as networks (webs) evolving through interactions of activity links, actor bonds, and resource ties (e.g. in Skott-Larsen et al., 2007). Consultants (e.g. Cohen and Roussel, 2005), who focus on the supply chain architecture, frame SCs around entities (actors), processes, data, applications, and infrastructure (IT and physical assets) referring to resources. The SCM literature review shows a variety of ‘pictures’ including different aspects depending on what message authors want to deliver about SCM. A cumulative list of categories of elements that figure on academic SC pictures can thus be established.

Supply chain mapping in SCM
SCM scholars have noted a “profusion of map styles”, with a variety of categories of elements figuring in academic SC maps, and suggesting the need for a supply chain mapping convention (Gardner and Cooper (2003, p.37). Hines and Rich (1997), who studied 7 mapping tools, point out they are contingent and address different objectives, which suggest taking care of the context when choosing one. Probably the best-known source on mapping for SCM is Lambert et al. (2008), which groups maps in two categories. The relationship-based maps often take the perspective of a focal firm, thus they “will look different depending on a company’s position in the supply chain” (ib., p.200). It points out the importance of the “viewpoint” and related “views”. Activity-based maps include: time-based process mapping (TBPM), pipeline inventory process mapping focusing on physical flows and steps in the logistics-production-distribution process, and extended value stream maps. For these maps, “the determination of the unit of analysis is critical to any mapping effort” (ib., p.212). The chapter concludes with: “Many managers believe that supply chain maps, whether they are relationship-based or activity-based are not worth the effort to prepare. However, once management has these maps in hand, they often report that they cannot think of a better way to understand the
nature of their supply chain” (ib., p.216). Maps are useful tools to better understand the “SC territory” and could also be considered as decision tools. Since there is no convention or set of conventions by which to represent SCs, SC maps are influenced by personal mental representations, the SC being a social construct (New, 2004). It is thus worth studying the individuals’ SC maps and the one(s) organizations provide to support SCM activities. It is also worth deconstructing SC mappings to unveil the implicit assumptions “behind” SC maps and the use of maps as tools of “power” in SCs.

Lessons from the network picture literature
Most contemporary SCs are named “networks” and SCM scholars refer to the IMP literature to better understand inter-organisational networks. Thus, the “network pictures” literature (in particular Henneberg et al., 2006 and 2010; Geiger and Finch, 2010 or Leek and Mason, 2010) is relevant to deepen the study of SC maps. In line with this literature, individual SC maps are the managers’ “theories-in-use about what the relevant business network looks like, and how it ‘works’” (Henneberg et al., 2010, p.356). Considering the variety of actors in a SC, these views could potentially be different, even between persons belonging to different functions in a company, and the mismatches could reveal important SCM issues.

To our knowledge, no empirical study has been done to question the making, use, usefulness of SC maps in companies and in SCs, as well as to question how mapping (as an activity) could reveal mismatch between mental representations of SCs and be useful for SCM. The research presented is an attempt to fill this gap.

Research design and methodology
We conducted a case study (Voss et al., 2002) in the downstream (outbound) car supply chain of Renault Group (RG), collecting data from December 2018 until March 2019. We gathered existing maps of the distribution chain – from the manufacturing plants to the end dealers – and analyzed their purpose (why do they exist?) and use (how are they used?). We conducted facilitated mapping exercises, combined with semi-structured interviews, with 18 RG managers involved in the management of RG outbound SC. To gather as many different “visions” as possible of the RG outbound SC, we interviewed key informants from different RG functions (manufacturing, logistics/operations, Supply Chain, quality, informatics, commerce), at different hierarchical levels (among the 18 persons, 8 are managers). Table 1 summarises the 18 informants, in 4 main categories. We also gathered many relevant internal documents from RG.

<table>
<thead>

<td>18</td>
</tr>
</tbody>
</table>

The interview guide was structured around 4 themes, always asked in the same order:
1. Interviewee’s profile (background, current position in RG, role in outbound SC);
2. Interviewee’s definition of the outbound SC of RG (how he[she] represents him[her]self the “territory” of the outbound SC);
3. Does the interviewee have ready-made maps of the outbound SC? If yes, does he/she use them in his/her work? If no, would a map be a useful device in his/her job?

4. Can the interviewee draw a map of the outbound SC? The facilitated mapping exercise was done on a paper sheet A4 format that was scanned at the end of the interview (Figure 1 shows an example map).

![Figure 1 – Respondent’s n° [1] map](image)

After recording and transcription, two of the authors coded separately the data collected and discussed and resolved any difference of their coding. This was done in four steps using a cumulative open coding: i.e. adding new items at each step. First, the collected maps were coded (what is drawn by respondents). Every piece of the drawings were named (*items*) and characterised referring to the *categories* found in the literature review. Second, the discourse of the respondents during the mapping (what is said during drawing) was coded in the same way, including new items if any was found. Third, the outbound SC definition (territory) was coded. Finally, the answers concerning the existence/usefulness of maps were analysed.

We used presence-absence matrices to produce results. At each step, we identified core items in SC maps (sum per line) and difference between respondents (comparisons of the columns). Table 2 shows the coding of the 18 maps (step 1). We then compared the tables produced at each step of the coding process. Appendix 1 shows the items found at each step. We also collected significant verbatim to illustrate some of the results. The internal documents of RG helped us to interpret some results. We split the respondents in 4 groups (cf. table 1) to explore the potential influence of respondent’s role in the management of RG outbound SC on mapping.

**Findings**

*About the company maps.* In fact, there are few maps of the outbound SC available in the company. There are two popular maps used in every presentation to sketch out the outbound SC. They are quite simplistic (linear and including few actors), mainly used for training new staff. They are so old that nobody can remember who drew them! They give a standardized representation of the SC from the moment cars leave the manufacturing plants, helping to develop a common vision and share objectives within
the company. In these maps, the plant, the customer (dealer) at an international level (geography), intermediary warehouses and logistics points, operations done on cars in warehouses, means of transport and the physical flow of cars are all represented. It is worth noting that, during the interviews, five participants (respondent [1], [5], [6], [15] and [16]) mentioned other maps. In the 2 extra maps provided, one is a geographical map of RG distribution; the other links the outbound SC with the overall SC of RG.

**About the 18 outbound SC maps.** The mapping exercise was not so easy for a lot of people, some respondents being at first reluctant to draw: “I am not good at drawing” (e.g. [E4], [E9], [E12], [E13]); “my picture is not clear” (e.g. [E11]), “have others made better pictures than mine?” ([8]). However, everyone produced a map. Table 2 gives the result of the analysis of the 18 maps. Thanks to the variety of respondents (different view points), we ended with 20 items in total, referring to 8 categories found in the literature.

**Legend:** (1) The items is represented on the respondent's map  
(0) The items is not represented on the respondent's map  
(+-_) The items is implicitly represented on the respondent's map

Three items are quite systematically represented (plant, warehouses, dealers) and four others are frequently present (means of transport, physical flow, points of tracking and the cars). Note that these items are the ones present in the official company map. The total per column shows a variety of richness of the maps. The individual maps confirm that every manager has his own supply chain vision. If the maps are not focused (centred) on the respondents’ activity, they seem influenced by their experience (e.g. figure 1 has been drawn by a logistics person). Most of the 18 maps are much more complex than the company maps. The richer maps were done by respondents [15], [1] and [12], who have more experience in the company, a transverse role (interacting with many people and functions) and with operational field contacts.

**About the 18 discourses during the outbound SC mapping exercise.** First, the analysis of what the respondents say while drawing the maps confirms the importance of the 20 items found at step 1. Second, it shows (see Appendix 1) some differences between discourses and pictures: 7 new items mentioned by respondents were not in the maps. The new items did not lead to add any new category of items. Third the comparison of matrices done at step 1 and 2 (see Appendix 2) shows that all items are more cited (step 2) than drawn (step 1). The discourse during mapping is richer than the map for every respondent and every item (except for 2 items) and it confirms that respondent’s experience of SCM influences his[her] way of mapping SC (e.g. [2] “since I am in the
export flow…”; [4] “you can have port or not, but since I like ports…”; [E17] “being in charge of quality, necessarily it is the vagaries that give us grain to grind”). Finally, like for maps, there is a difference in richness of the discourses of respondents (range from 17 to 4 items). The mapping exercise led some respondents to ask themselves some key questions regarding: SC perimeter (e.g. [E9] “does the outbound SC begin here or there? [...] for me it is a bit unclear”; [12] “the perimeter must go there [the dealer], but it should go further [the end customer]”), or how to represent some items ([E18] “there is also a kinematic part that seems to me to be missing from that representation. But on an A4 sheet I’m sure we can do better than that”).

About the 18 definitions of what the outbound SC is (territory). In line with the previous results, the analysis of the definition of outbound SC given by the respondents confirms the importance of the 27 items found at step 1 and 2. 7 new items mentioned by respondents were not in the maps and the discourse during mapping (see Appendix 1). The new items did not lead to add any new category of items. Comparison of maps and definitions (see Appendix 3) shows that all items are more present in definition (step 3) than pictures (step 1). If most definitions clearly mention that the outbound SC begins “when the car comes out of the plant” ([E1]), it is less clear where it ends. In line with the company maps some persons mention the dealer as the end point of the outbound SC, while most (10 out of 18) clearly go up to the end-user. Most definitions (13 out of 18) mention the performance objectives related to the management of the outbound SC that were not much present in maps (5 out of 18). Some respondents go into detail in some aspects of the outbound SC, in line with their experience or their responsibility (e.g. [E3] insists on the SC information system giving visibility to the commerce). Some definitions clearly state that the outbound SC is “complex” and some point out a fuzzy difference between the SC in terms of “physical operations”, “company function” and “company department” (e.g. [E14]).

About the use and usefulness of outbound SC maps. Appendix 4 sums up every point gathered in interviews concerning use, usefulness, existence of maps, experience of mapping… The need for having maps is clearly mentioned by a majority of respondents, even if most of them say that they don’t use maps and do not map. Respondents express the need for mapping tools… Could this refer to the need for convention of Gardner and Cooper (2003)? Since SCs are complex (which is a problem for mapping them for a majority of respondents), maps are useful to visualise, represent and better understand the SCs. Respondents spontaneously mentioned 11 types of map usefulness and 7 sources of mapping difficulty. There is a controversy over whether a map should be as complete as possible or not. But some respondents insist on the need for maps to be as faithful as possible. [E13] states “I think for a long time the carmakers didn’t take care of the downstream SC because they didn’t really see the stakes”. Could this explain why there are so few outbound SC maps in RG?

Difference between the 4 groups of respondents. The analysis of the differences between the maps, discourses and definitions of the four groups of respondents, even if subject to caution due to the low number of respondent per group, gives support to the importance of the experience of the territory (company, automotive sector, logistics operations and SCM, etc.) on mapping.

Discussion
In our case study, the alignment between organisational and individual maps is good. The organisational maps of RG, used for training, are simple and so old that they probably influence employees’ representations. They include such basic and core elements of the outbound SC that it is not surprising they also figure in the individual
maps. The comparison of the individual maps reveals that there are mismatches (e.g. type of map, what is represented, perimeter...). All in all, the sum of what is represented on individual maps is not so different from what is represented in the collection of academic maps. The 18 maps (mailed by RG key informants) tell us about managers' visible horizon (Carter et al., 2015) of RG outbound SC.

The mapping of SC is not an easy task for managers who express the need to develop tool to map. None of the 18 maps refers to or looks like the mapping tools or maps found in the literature. However SC mapping is considered as useful for managers participating to the management of a SC. This encourages researchers to go on working on this aspect of SCM, and to better communicate their results to industry.

The comparison of the results obtained at each steps gives evidence of the varied and more or less complex SC maps, discourses and definitions. This variety confirms the subjective nature of mapping and probably reveals the variety of SC mental representation of managers. It suggests that sharing individual maps could be helpful to improve collaboration between SC actors and eventually to align representations.

The comparison of results from step 1 with step 2 as well as the comparison between the four groups of respondents supports the influence of individual experience and projects (and objectives) in the SC on the individual maps. It suggests, in case of dysfunctions in the management of the SC, that studying the mismatches between individual SC maps could help to better understand where problems come from and to solve them. In line with the network literature perspective, the interviewees’ discourses also suggest that drawing maps made them understand things differently i.e. drawing doesn’t just represent the world, it (re)constructs it.

The comparison of results from step 1+2 with step 3 attests that “the map is not the territory”. The overall list of 33 items and 8 categories obtained at the end of step 3 is a valuable output to discuss and build SC diagnosis tool.

Conclusion
Our research questions the “neutrality” of supply chain mapping and helps to better understand the mapping process at the individual level. It also improves our understanding of the role/usage of maps in SCM. Philosophically speaking, it points to the importance of revealing the underlying ontological and epistemological vision of SC managers and researchers, respectively. Maps objectivize but are not objective pictures! Companies need to be fully conscious of the power of SC maps and to take greater care with their mapping activities.

The collected data did not permit us to unveil the implicit assumptions “behind” SC maps and the use of maps as a “powerful” tool in SCM. To go further on this understanding, a focus group with the respondents and other SC actors could be organized to discuss differences between maps and discuss the result of the research. The focus group could also discuss the following two questions. Does a better understanding of the differences between individual SC maps could help explain and solve SCM dysfunctions?

Our data did not permit us to study the potential influence of SC maps and mapping activity on SCM. This could be the aim of the continuing research collaboration with RG, with an action research approach. Can maps be considered (or serve) as intermediary or boundary objects in multi-function SCM teams (Carlile, 2002)?

Since the focus of our case study was the outbound SC of RG, adopting the point of view of the industrial company and studying first the internal actors’ SC maps, further research could replicate the methodology to study the maps of ‘external’ actors such as suppliers (for transport, logistics and operations-on-car activities), dealers, etc.
Finally, the research questions the need for a company to spend time and resources to map its SC. It questions the kind of map to promote and the relevance to adopt a convention (Gardner and Cooper, 2003). Is it a good thing to standardize maps? It also questions the use of maps and mapping in industry as well as in academia. Can maps influence managers’, students’ and researchers’ mental representations of SCs? Do persons’ mental representations of SC influence their mapping of SCs? More generally, how can maps be used in SCM?

Acknowledgements

We thank Renault Group that supported this research and accepted to make data and persons available for this particular study that makes part of a larger research project.

Managing Change in Operations
Digital Strategy and Transformation: a Systematic Literature Review

Abstract

Nowadays, manufacturing companies have been facing a complex phenomenon of technological advance, often named Industry 4.0, that is reshaping companies’ strategy and organization, products and services, supply chains and operations. At the best of our knowledge, the academical panorama lacks an exhaustive literature review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems. Accordingly, this paper carries out a systematic literature review with the aim of mapping the publications and systematizing the often-fragmented literature on this field to propose directions of future inquire that could inspire scholars and support practitioners.

Keywords: Digital Strategy, Digital Transformation, Literature Review, Industry 4.0

Introduction

Nowadays technologies progress like a dense avalanche of advancements pouring into the environment (Brynjolfsson and McAfee, 2014). The rhythm of growth has been exponentially hastening in recent times indeed, and this has been provoking shocks in the realm of management (Westerman et al., 2014; Brynjolfsson and McAfee, 2017; Venkatraman, 2017). This complex phenomenon, often named Fourth Industrial Revolution or Industry 4.0, is reshaping companies’ strategy and organization, products and services, supply chains and operations (Porter & Heppelmann, 2014). The concept of Industry 4.0 (I4.0) was initially introduced in Germany in 2011 (Lu, 2017), referring to the integration of physical objects, human actors, intelligent machines, production lines and processes across organizational boundaries, with the aim of realizing a system in which all the processes are integrated and information is shared in real time (Hozdić, 2015).

This wave poses an important challenge to companies that more and more are required to deal with the opportunities offered by the digital technologies which are at the core of
the Fourth Industrial Revolution. Aware of both the limited financial resources as well as of their level of digital readiness, companies need to make some strategic choices, selecting and exploiting the set of digital technologies that better fit with their own context (Hess, 2016).

In other words, to remain competitive companies are called to strategically govern the digital change by formulating and executing a clear strategy to keep pace with the new digital reality (Matt et al. 2014).

Since the beginning of the 2010s, a large proliferation of papers on this subject matter has been observed, but often in a quite fragmented fashion and using an ample variety of terminology. At the best of our knowledge, the academic panorama lacks a complete and exhaustive literature review on how companies can strategically govern the digital change provoked by technology advancements and occurring in business systems. To date indeed, the newness of the topic and the wideness of the combined domains blur the knowledge on the company ground and torment researchers and experts across their affairs by creating overlaps between words and meanings, constructs and definitions, and by fostering useless varieties of vocabulary, and diverse perspectives on the same objects and phenomena.

Accordingly, this paper carries out a systematic literature review (SLR) on this field, with the aim of charting the map of the publications and systematizing the often-fragmented literature on this field into a comprehensive body of organized knowledge, underlining the different perspectives and proposing some directions of future inquire that could inspire scholars and support practitioners.

In pursuance of these targeted objectives, the SLR has been guided by the following research questions:

• RQ1: Which are the perimeter and the current state of the art in the field of research?
• RQ2: Is there a way to frame and organize the knowledge belonging to this field?
• RQ3: Which are guidelines to drive future researches on this field?

Findings of the research contribute to systematize the often-snipped literature on how to govern the change provoked in companies by digital technology advancements. Results of the literature review show that the field under investigation may be framed into four blocks, namely: Digital Transformation Strategy; Digital Transformation Execution; Leadership & Culture; and Models. Hence, our review will depict the nature and the main contents of these blocks, to what extent they are intertwined, and which are the levers managers may employ to govern the change. Along this line, in the final part of the paper, a discussion on the current detected gaps is carried out, and some avenues of future researches are spelt out.

Methodology
Towards achieving our aim and answering the research questions, a systematic literature review on how to strategically govern the digital change provoked by technology advancements occurring in companies has been carried out. The field under investigation, which concerns the process followed by companies to strategically select the most prominent digital technologies and then drive their implementation within the companies, revolves around two main key areas. From one side the opportunities offered to the companies by the set of digital technologies and the Fourth Industrial Revolution, and, from the other side, the strategic process they have to follow to govern within the company this change. Accordingly, two different groups of keywords have been selected to carry out the literature review on the ISI Web of Science Database (core collection):
• Group 1: it contains the keywords to intercept the papers referring to the Fourth Industrial Revolution (i.e. "Industry 4.0"; "Industrial Revolution"; "Smart Factory"; "Smart Manufacturing") and the ones referring to Digitalization or Digital Transformation (i.e. "Digital*").

• Group 2: it contains the keywords related to the investigation of how firms can strategically cope and manage these digital technology advancements which is the baseline of the studied field. The focus has been given to the governance of this kind of transformation ("Strateg*"; "Transformation*"; "Change"; "Roadmap"; "Cultur*").

We combined a) the terms belonging to group 1 and group 2; and b) the terms belonging to group 1 with each combination of two terms belonging to group 2. a) and b) where searched respectively in titles and topic (i.e. abstract, title and keywords). In this way, we were able to capture most of the papers covering the field under investigation.

The queries that were accomplished on the 12th of March 2019, returned 10,114 results at first, reduced to 508 by applying some basic filtering options proposed by ISI as the research area (i.e. Management, Business, Operations Research Management Science), the English language, and the document type. Duplicates have been subsequently removed. The application of these criteria provides us with 459 papers, that were subsequently analyzed by the authors.

Consequently, in order to check the pertinence of these papers with the field under investigation (e.g. how to strategically govern the digital change provoked by technology advancements occurring in companies), we read the abstracts of these articles and we excluded those articles that were not pertinent, and 168 relevant articles remain. The reading of the full articles made it possible to identify the 59 most pertinent articles.

At the end, after 16 papers and 8 books have been added via a snowball process, the final dataset was composed by 83 contributions. It may be argued that the final database is made up in most part by ISI ranked journals (i.e. the queries searched on ISI-WoS Database), while the snowball process added mostly practitioners’ articles. We believe that this balance is valuable, bearing in mind the topicality and the hype of the theme discussed.

Finally, all the selected articles have been carefully mapped in a structured spreadsheet with different dimensions, namely: - the field, - the topic and the purpose of the article, - the construct/s under investigation and its definition (when provided), - the description of the theoretical ground, - the methodology, - the main findings. The analysis of this spreadsheet made it possible to develop a framework that organizes the contributions of the literature on the field and sheds some light on the state of the art on the theme as well as on gaps and avenues for further researches.

Field of research
Giving a general overview of the papers, the overall counter of publications per year on the field has been growing exponentially and the curve has just reared in the last three years (max[1996-2015]: 5; 2016: 8; 2017: 10; 2018: 28). The mounting interest around the topic witnesses its relevance and renews the necessity of this work.

The large part of the publications empirically test their arguments on real cases (Figure 1), interviews and surveys, secondary data analysis or action research, but the analysis of the papers also shows the presence of a consistent set of papers (i.e. “Opinions”) which expound findings without the backing of a proper scientific methodology – and this principally happens with the articles dealing with strategical matters.
The deep analysis of the papers shows that the articles on the field are quite fragmented and they deal with different aspects of the phenomenon, thus making it difficult to get a clear picture of it. To try to systematize the variety of these contributions, we develop a framework meant to integrate the different dimensions that shape the research field on how to govern the transformation provoked in companies by digital technology advancements. This framework (see Figure 2) is composed of four blocks.

The first two blocks – Digital Transformation Strategy (DTS) and Digital Transformation Execution (DTE) - constitute the backbone of the field and describe the process of digital transformation process (DT) triggered by the injection of digital technologies into companies. The second two blocks instead revolve respectively around the technical skills, Leadership and Culture companies need to be equipped with to be successful in the change process, and the Models literature supplies to comprehend these kinds of transformations. In this view, these latter two blocks sustain the field’s backbone providing knowledge and tools to the people enlisted in the digital transformation process.

---

![Figure 1: Publications per year and methodologies employed](image)

Figure 2: The architecture of a Digital Transformation Process

![Figure 2: The architecture of a Digital Transformation Process](image)
The Digital Transformation

The backbone of the field describes the process of governing the transformation of the company triggered by the injection of digital technologies. This process may be broken down into two diverse blocks, referring respectively to its strategical conception (i.e. Digital Transformation Strategy) and its execution (i.e. Digital Transformation Execution). More neatly, inside the concept of Digital Transformation there is one set of papers that concern Digital Transformation Strategy (DTS), where a company needs to explore the opportunities offered by technology (Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Konlechner et al., 2018) to select which to invest on (Mithas et al., 2010; Ardolino et al., 2018; Ghobakhloo, 2018; Pappas et al., 2018; Ross et al., 2018) and how to organize and control the strategical change (Tichy, 1983; Bharadwaj et al., 2013; Andriole, 2017; Davenport & Westerman, 2018). DTS papers conceptualize the path to be executed, argued in the second group of papers, which instead deal with the practical deployment of strategy into actions to transform the business model (Ross et al., 2016; Gobble, 2018) or with the management of the business-system-technology integration (Woodard et al., 2013; Agarwal & Brem, 2015; Teubner, 2018; Gastaldi et al., 2018). Consequently, as Digital Transformation Strategy lies in abstraction by the very nature of strategies, as its operations are made in the land of representations and models of reality (Gavetti and Levinthal, 2000), it has concrete effects on reality only through the Digital Transformation Execution (DTE) block (Gavetti and Rivkin, 2007). The proposed distinction comes out by the analysis of the aim and main constructs presented in the analyzed papers and will be clearly described in the subsequent sections.

Digital Transformation Strategy

Papers within this block deal with how to strategically address the opportunities and risks that originate from digital technologies, planning the company journey towards being digitally transformed (Singh & Hess, 2017). In order to refer to this concept, authors often employ different labels (i.e. digital transformation strategy, digital strategy, digital business strategy). A part from the different labels, the common features, which delimitate the boundary of the concept, relay on the fact that it governs the digital transformation: a) by defining objectives and priorities to provide directions (Mithas et al., 2010; Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Ardolino et al., 2018; Ghobakhloo, 2018; Konlechner et al., 2018; Pappas et al., 2018; Ross et al., 2018); b) by organizing the structure to enable the execution of digital initiatives (Agarwal & Brem, 2015; Hess et al., 2016; Sia et al., 2016); and c) by gauging progress to reroute efforts or investments when required (Sebastian et al., 2017).

Moreover, authors who use the label digital business strategy (Mithas, 2010; Kettinger, 2011; Bharadwaj et al., 2013; Grover and Kohli, 2013; Markus and Loebbecke, 2013; Mithas et al., 2013; Woodard et al., 2013; Sia et al., 2016) emphasize the integration between information technology (IT) function strategy and business strategy, which has its root in the need to achieve a peaceful and effective co-existence between IT and business strategy, thus suggesting a juxtaposition of their purposes and plans (Henderson & Venkatraman, 1992).

Beyond the definition of the concept of DTS, papers show that firms might craft their digital strategy to achieve two main objectives:

Value Propositions. A company can transform its value proposition to elevate “the performance implications of IT strategy beyond efficiency and productivity metrics to those that drive competitive advantage and strategic differentiation” (Bharadwaj et al., 2013). Ross et al. (2017) draw how companies use to pursue either a Customer
Engagement Strategy, whether they decide to focus on boosting their customer experience (Lanzolla & Giudici, 2017; Haenninen et al., 2018; Kotarba, 2018; Subramaniam et al., 2019), or a Digitalized Solution Strategy, if they bet on R&D chances to innovate their value proposition by combining products, services and available data (e.g. new smart and connected product, platform, analytics service-based) (Woodard et al., 2013; Porter and Heppelman, 2014; Echterfeld and Gaumeyer, 2018).

Processeses. A company, pursuing an Operational Excellence Strategy (Ross et al., 2017) may decide to transform its processes. The matter is how to invest on the redesign of the way activities to deliver value propositions are performed, taking advantage of technology to generate more outputs employing less inputs (Zuehlke, 2010; Erol et al., 2016; Dremel et al., 2017; Sanders et al., 2016; Szozda, 2017; Gastaldi et al., 2018; Kaidalova et al., 2018; Mittal et al., 2018). Moreover, authors sustain companies are required to consider adapting their processes whenever a change in their value propositions occur (Benner, 2009; Ross et al., 2016; Dremel et al., 2017; Lanzolla and Giudici, 2017; Ross et al., 2017).

Digital Transformation Execution

Digital Transformation is the product of the execution of a Digital Transformation Strategy (i.e. Digital Transformation Execution - DTE), where strategies transform the reality towards their exploitation by mean of actions (Gavetti and Rivkin, 2007; Ross et al., 2016). Accordingly, the overall subject matter of the second block is how to exploit the strategical transformations of value propositions and/or processes by leveraging on technologies (Day-Yang, L. et al., 2011; Gastaldi et al., 2018; Wagner et al. 2018; Weill and Woerner, 2018). Comparing to the previous block, here the knowledge is much more fragmented due to the absence of a referential theory and also because researches mostly and simply describe use cases of technology and how they have just been implemented (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018). Despite the complexity in navigating the knowledge of this block, the analysis on the research aims and the findings of each paper contained into the dataset allowed us to identify three patterns on DTE, regarding Industry 4.0, Lean Management and Project Management.

DTE & Industry 4.0. As salient detail, the contributions referring to the construct Industry 4.0 (i.e. The Fourth Industrial Revolution) mainly focus and prioritize the digital transformations of manufacturing operations and supply chains, and the way an Operational Effectiveness strategy (Ross et al. 2017) may be executed. (Hozdić, 2015; Lee, et al., 2015; Lu, 2017; Bienhaus & Haddud, 2018; Yin et al. 2018).

DTE & Lean Management. Going inside the contributions referring to the digital transformation of Supply chains and Operations, we notice a niche of contributions inquiring the relationship between Lean Management (LM) (Womack and Jones, 1997) and Digital Transformation, and we can outline two outlooks. On one side, Bortolotti et al. (2014) claim the effective execution of a Digital Transformation cannot avoid laying on already efficient and streamlined processes. This is the reason why tracking LM may lead to an operational readiness to change (Sanders et al., 2015; Mrugalska and Wyrrwicka, 2017; Besser Freitag et al., 2018). On the other side, Kolberg and Zühlke (2015) overturn the concept, arguing that LM is enabled by Digital Transformation, because technology is broadening the chances for manufacturing and service companies to reinforce their efficiency by solving problems in ways afore unthinkable.

DTE & Project Management. Indeed Digital Transformation Executions are often described as a package of digital coordinated projects, (Erol et al., 2016; Goelzer and
Fritzsche, 2017; Dremel et al., 2017; Singh & Hess, 2017; Bertoncel, 2018), and this opens a question on the role of Project Management in the Digital Transformation process, although few publication refers explicitly to the issue (Schüritz et al., 2017; Teubner, 2018).

**Leadership & Culture**

The third block considers the academical interest on the impact of the organizational and cultural variables into a Digital Transformation (i.e. DTS and DTE). Compared to the rest of the papers, this block presents a dissonant peculiarity on the methodologies employed by scholars, that is the preponderance of hypotheses tested by surveys and statistic techniques, while case studies are the rule in the other papers. In this niche of knowledge results figure out two main topics discussed by scholars: technical skills, leadership, and cultural background requirements.

From the analysis, these requirements seem a prerogative to make a Digital Transformation effective, mainly for two reasons: first, they must to be fostered whatever the DT will be (Ross et al. 2016; Sia et al., 2016; Westerman, 2016; Dremel et al., 2017); second, it is “difficult, rather impossible, for a network of typical manufactures to achieve them in a short run” (Ghobakhloo, 2018)

**Technical skills.** Some publications claim that a Digital Transformation to survive in time without having a negative impact on performances need people to be equipped with some technical skills (Weizi et al., 2016). These are required to understand, deploy and manage the opportunities offered by technologies and the dynamics of the change their introduction involves Sia et al., 2016; Davison and Ou, 2017; Ross et al. 2017). Such skills are hybrid skills (Weizi et al., 2016; Schwarzmueller et al., 2018), for example, the ability to perceive week signals of disruption (Bertoncel, 2018) or to handle the analysis and conversion of big amount of data to make decisions above valuable information (Davenport and Patil. 2012; McAfee, Andrew, et al., 2012; Schallmo et al., 2017).

**Leadership.** Literature maintains the central role leadership plays in the Digital Transformation process, and in particular the interaction between leadership and technology advancements that is baptized as e-leadership (Avolio et al. 2014). Weizi et al. (2016) divide the construct of e-leadership in two layers, where at micro level it deals with the abovementioned skills requirements, and, at a macro level, e-leadership challenges the redesign of company’s governance to allocate responsibilities to tackle a DT. On this account, the analysis on the dataset pinpoints a stream of research on the relationship between Chief Information Officers and Chief Executive Officers (Weizi et al., 2016; Hansen et al., 2011; Oberer & Erkollar, 2018), and the opportunity/possibility of introducing a new referential profile the Chief Digital Officer – CDO to supervise the DT (Singh & Hess, 2017).

**Cultural Background.** Some contributions address the theme of which kind of organizational culture is more suited to engage a Digital Transformation. From the analysis, two significant features emerge: agility and innovation (Ross et al., 2017; Dremel et al., 2017). In particular, Schwarzmueller et al., (2018) state “organizational culture should be transformed to a culture of involvement, in which decisions are taken together, a culture of innovation, that ensures agility based on the acceptance of suggestions, and a culture of training, in which staff is constantly developed (Patterson et al., 2005).” Furthermore, other authors hint companies need to pursue openness to change (Ghobakhloo, 2018) to adapt more quickly and shorten adaptation time to new working habits (Weizi et al., 2016), and, eventually, create a culture of decision making based on data instead of experience and intuition (McAfee et al., 2012; Dremel et al., 2017).
Models
The Models block collects the contributions which provide knowledge on the opportunities offered by technology advancements and on guidelines companies may follow to implement a Digital Transformation. They are divided into three different groups: Frameworks, Roadmaps and Methodologies, and Assessment Tools.

Frameworks. As defined in the introduction of the paper, Digital Transformation is a consequence of the technological evolution which companies wrestle along their journey. Literature maintain diverse publications that try to build knowledge around this phenomenon (Porter & Heppelmann, 2014; Romety, 2016; Westerman et al., 2014), inquiring how technologies progress, and/or their social impact, and/or the types of mutations they are provoking on companies (Brynjolfsson and McAfee, 2014; Porter & Heppelmann, 2015; Weill and Woerner, 2015; Brynjolfsson and McAfee, 2017; Venkatraman, 2017).

Roadmaps and methodologies. In this group are contained all the contribution referring to methods (i.e. standards and steps) (Bibby & Dehe, 2018; Mittal et al., 2018), guidelines, roadmaps and tools (Westerman, 2016; Andriole, 2017; Gobble, 2018) which a company could use for architecting and standardizing its Digital Transformation (Liu, Day-Yang et al., 2011; Porter & Heppelmann, 2015; Matt et al., 2015; Erol et al., 2016; Parviainen et al., 2017; Dremel et al., 2017; Gobakhloo, 2018; Weill and Woerner, 2018). Methodologies can be applied to any type of digital transformation, and their focus ranges from the entire company to a specific project. Literature is rich of anecdotal cases of successful integration of technologies towards a digital transformation (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018), but a thorough reference methodology to handle the problem of Digital Transformation still lacks (Nwaiwu, 2018).

Assessment tools. This stream of papers provides contributions on instruments which support managers or companies in measuring and evaluating the degree of technological integration into company’s processes. This results in a seminal provision to position companies into a reference system that can better drive the digital transformation process (Plomp and Batenburg, 2010; Bibby & Dehe, 2018; Heavin & Power, 2018; Kontic & Vidicki, 2018).

Conclusion
Although this is a preliminary review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems, some contributions to both research and practice have been provided. On the academic side, the paper systematizes the knowledge on the field and provides a framework to orient future researches. On the managerial side, our research offers some insights on the strategic aspects of the digital transformation that endeavour and supports organizations and managers that are tackling the challenges offered by the new digital era.

The paper has also some limitations, that can drive further developments. Results maintain that literature on the field is still in its infancy, suggesting that future research should go more in depth in comprehending how digital transformation can be developed and executed. The performed queries are more focused on the digital strategy conceptualization rather than its exploitation. So, additional research could be performed through a wider sample to validate and enrich the considerations addressed on Digital Transformation Execution subgroup.

Abstract
The potential of digital innovations is clearly recognized. However, its implementation within manufacturing companies seems to be more difficult. Considering that digital innovation within manufacturing companies are a combination of digital and physical assets, it seems plausible that the consideration of information systems related governance mechanism may support the digital innovation management within manufacturing companies. We derive six propositions which give insights into which dimensions are relevant for digital innovation management in manufacturing companies.

Keywords: Digital Innovation Management, Digital Technologies

Introduction
The diffusion of digital technologies into the manufacturing industry creates new opportunities. These opportunities may arise from improvements in efficiency and effectiveness (i.e. smart factory) or through the offerings of new products, services or even business models. The combination of digital technologies such as sensors, actors and cloud computing with non-digital products and services provide significant opportunities but capturing the value of the digital transformation has proven to be challenging to firms in traditional industries (Henfridsson et al., 2018; Svahn and Henfridsson, 2012). Whereas the innovation potential of digital technologies is widely recognized, few studies address the management of digital innovations (Abrell et al., 2016). We aim to enhance the understanding of how to manage digital innovations in manufacturing companies. To do so, we relate to IS literature and derive insights from software development projects and compare these with the activities and challenges of eleven Industrial Internet of Things (IIoT) projects of three manufacturing companies.

Digital Transformation
Digital transformation describes how companies need to change their processes and the company’s way to compete in the digital age. There exist different terms describing the changes, such as information age, industrial internet or industry 4.0. The information age started with the third industrial revolution, also known as the digital or ICT revolution, at the end of the twentieth century (e.g., Castells, 2011; Dosi and Galambos, 2013). The technologies, mainly
ICT, lay new foundations for companies, economies and societies. In addition, Musso (2013) concludes that the information age has sped up the transition from manufacturing to services, highlighting the influence of the technological changes on business models.

In industrial companies, these changes are labelled as industrial internet, industrial internet of things (IIoT) or Industry 4.0. The main approach of the industrial internet or industrial internet of things (IIoT) is to bring software and machines together (Bruner, 2013). The term stems from the US and was first introduced by General Electric. IIoT enfolds initiatives belonging to a higher degree of intelligence with the power of advanced computing, analytics, low-cost sensing, and new levels of Internet connectivity (Posada et al., 2015). Posada et al. (2015) highlight three key elements of IIoT: (1) intelligent machines, (2) advanced analytics and (3) people at work.

Industry 4.0 belongs to a similar initiative, mainly pushed from Germany. The core elements of Industry 4.0 are embedded systems, smart objects, cyber physical systems (CPS), the concept of a Smart Factory, robust networks, cloud computing, and IT-security (Bauer et al., 2014). The coexistence of the physical and virtual worlds, with the use of emerging ICT, opens possibilities such as “enhanced human-machine cooperation (including human interaction with robots and intelligent machines), connected machine networks that follow paradigms of Internet connectivity and social networks, improved human-in-the-loop interaction between the cyber and physical worlds, networked and decentralized value chain transnational scenarios, and emergence of product-service networks based in intelligent, smart products, and associated services” (Posada et al., 2015, p.27).

Whereas Industry 4.0, IoT, IIoT and digital manufacturing focus on the changes of digital technologies in industrial companies, the term digital transformation is industry independent and analysed based on the perspective of different research streams. Vial (2019) defines, based on a comprehensive literature review, digital transformation as “a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies”.

Although avoiding the term “digital technologies” in his definition, Vial (2019) highlights that that most of the digital technologies mentioned in the literature review fit with the popular SMACIT acronym, referring to technologies related to social, mobile, analytics, cloud, and the internet of things. Furthermore, it’s the combination of technologies that are particularly relevant in the context of digital transformation (Bharadwaj et al., 2013). For example, the use of social media on the mobile phone may be the prerequisite for gathering and storing big data and to perform analytics.

Others, in addition, highlight the merge of the physical and digital world, enabled through IoT sensor and actuators and connectivity technologies (Fleisch et al., 2014; Yoo et al., 2010). Summarizing, the traditional processes of manufacturing companies focusing on physical products is challenged with the requirements to integrate digital aspects. How to cope with these new requirements is a challenging task for manufacturing companies. Hence, to get an understanding of the different requirements manufacturing companies are facing while developing digitally enhanced products, services or processes, we summarize the key aspects of the traditional innovation management and information systems (IS) related innovation management.

**Traditional Innovation Management: Insights from Business Management**

Managing innovation has traditionally focused on new product development (NPD) activities. Prerequisites for the development of products are the engagement in a bundle of activities that include the management and transformation of resources and information in order to create products that meet or create market demand (Wheelwright and Clark, 1992). Typically, in innovation management, four types of innovation exist: process, product, service and business model innovation (e.g., Teece, 2010). Considering key determinants of the traditional
innovation management, Damanpour (1991) highlights in his meta-analysis several factors that have a positive correlation with innovation: specialization, functional differentiation, professionalism, managerial attitude toward change, technical knowledge resources, administrative intensity, slack resources, and external and internal communication.

Johansson and Kullström (2018) argue that an innovation management, which has been dominated by structure and control, mirrors the circumstances where goals and objectives have been clear. Instead, innovation activities nowadays are increasingly confronted with fuzzy objectives and complex processes and traditional methods have been found lacking (Kapsali, 2013). Therefore, there is a need to find methods that suit more complex projects.

**Innovation management: Insights from IS literature**

Traditionally IS innovation research has focused on the adoption, diffusion, implementation, acceptance, and assimilation of IT in organizations (Fielt and Gregor, 2016). However, there is a growing interest on the paradoxes and dilemmas that digitization creates for organizations developing, deploying, and managing digital innovation (Nambisan et al., 2017). As Nambisan (2017) states: “This transition from innovation to digital innovation comes as a golden opportunity to be seized upon by information systems (IS) researchers. IS researchers have, for the last four decades, been at the forefront in observing the dawn and consecutive wakes of digitization in organizations and, broadly, in society, and explaining its repercussions.” Similar to the definitions in business research, IS scholars define digital innovation as the creation of (and consequent change in) market offerings, business processes, or models that result from the use of digital technology. Stated differently, in digital innovation, digital technologies and associated digitizing processes form the base for new ideas. Thus, digital innovation management refers to the practices, processes, and principles that underlie the effective orchestration of digital innovation (Nambisan, 2017).

Svahn and Henfridsson (2012) conclude that product innovation and IT innovation literature provide a different outlook on innovation. While product innovation cultivates firm-centricity and exercise of formal control, IT innovation builds upon network-centricity and the creation of digital options. Network-centricity introduces uncertainty that counteracts the traditionally exercised formal control over the product innovation process. The authors conclude that more research is needed on these seemingly opposing logics (Svahn and Henfridsson, 2012).

**Digital Innovation Management: Research Framework**

Different researchers argue that there is a need for new theories in this age of digital innovation and digital transformation (Hinings et al., 2018; Svahn and Henfridsson, 2012; Yoo et al., 2012). More specifically, Nambisan et al. (2017) say that “[t]here is a critical need for novel theorizing on digital innovation management” that deals more adequately with the rapidly changing nature of innovation processes in a digital world. Although the innovation process itself is crucial to understand, the management is important as well.

As the proportion of software within innovations of manufacturing companies is rapidly growing, manufacturing companies can profit from understanding the requirements to successfully manage IT innovations. However, as Svahn and Henfridsson (2012) highlight, there are differences between the management of product and IT innovations and hence, there is a need to get an understanding on how to incorporate both aspects.

To do so, we rely on the concept on IT governance. As Leonhardt et al. (2018) summarizes, newer research on IT governance mainly enfolds the governance mechanisms related to structure, process and relational mechanisms.

One key aspect to IT governance is the decision-making structure, implemented to define the locus of authority for IT activities (Sambamurthy and Zmud, 1999). Choices range from centralized to decentralized or hybrid decision-making. More specifically, a central decision architecture grants all decision rights to the IT organization, a decentralized one delegates
decision-making authority to the business units (Brown and Magill, 1994). Thus, we conclude that the locus of authority and its role in digital innovation management needs further research attention.

Horizontal coordination mechanism enfold informal and formal designs that focus on the interaction of individuals and the coordination of activities across units (Mintzberg, 1979). The mechanism aim at facilitating interaction and problem-solving across different departments (Brown, 1999). The formal coordination mechanism refer to steering committees or cross-unit integrators. Examples of cross-unit integrators are Chief Digital Officers.

Since digital innovation requires the combination of diverse knowledge across different departments (Yoo et al., 2010), interdepartmental dynamics and the respective horizontal coordination mechanism may be at the core of digital innovation management.

Although Yoo et al. (2010) focus on the internal cooperation relevant to acquire knowledge, Hildebrandt et al. (2015) highlight the growing importance of cooperation with external partners. More specifically, acquiring and integrating complementary and heterogeneous external knowledge on digital technologies is an important prerequisite for digital innovation (Hildebrandt et al., 2015). Thus, we add internal cooperation and external cooperation as two further dimension as being potentially relevant to understand digital innovation management.

As it is our goal to understand digital innovation management, we focus on the analysis of the innovation process itself and the four governance mechanisms as summarized in Figure 1.

Research methodology
We grounded our observations in data from a multi-case study with three multinational companies from the machine industry that face the diffusion of digital technologies. Each of the companies belong to a wider company network and reports to headquarters. In addition, company B acts as a national headquarter for further subsidiaries. Overall, we have analyzed eleven IIoT initiatives that are the unit of analysis for the study at hand. Because of the emergent nature of this topic, we apply an exploratory research approach. In addition, we analyze existing literature focusing on digital innovation and its management and derive a framework that guides our research (Eisenhardt, 1989). The goal is to match theory and reality in a nonlinear, path-dependent process that systematically combines empirical observations and insights from extant literature (Storbacka, 2011).

The exploratory research lasted from January 2016 to September 2017, with follow-up interviews in 2019. We accompanied the companies throughout the development process and conducted 12 to 16 meetings within each of the participating companies. The companies were part of a joint working group. Hence, there are activities that the companies conducted jointly (i.e. successful practice visits) or applied the same methods (i.e. evaluation of market trends). Other activities are company specific. The data gathering occurred through meetings within each of the three companies. During the meetings, we observed the activities and conducted
Idea Selection I

- Integration of 5 interviews. We wrote minutes for each meeting (observation and interviews), and compared them with literature.

We used Miles and Huberman’s (1994) four-step approach to analyze the collected data. First, we developed a contact summary sheet in which the main themes of each interview were recorded. One researcher identified the main themes, while the other two researchers checked these themes using the interview minutes. The themes covered, for example, the content of different IIoT initiatives and the measures to implement them. Second, a complete theme list was developed based on the contact summary sheet. Third, all interviews were coded using selective coding (Strauss and Corbin, 1990) to categorize the answers into the main themes. One researcher was responsible for coding the interview minutes, while the other researcher checked the coding. In the event of disagreement, the point was discussed until agreement was reached. If no agreement was reached, the point was referred to the interviewees for clarification. This procedure ensured a high level of inter-rater reliability (Voss et al., 2002).

Fourth, we wrote the case study and performed a final validity check, which was done by presenting the results to the interviewees and to the top management of the respective company.

Case study analysis

The three manufacturing companies developed nine IIoT ideas that focus on offering new services to the customers. Three initiatives focus on the digitalization of internal processes (i.e., digital working instructions, dynamic planning and production system (smart factory) and global service). Overall, the activities of the innovation process can be described according to the six generic dimensions: idea generation, idea selection (I), idea concretization, idea selection (II), development and dissemination. Table 1 and Table 2 summarize the main activities, separated into activities that each company conducted similar as well as company specific activities.

Table 1: Insights from the innovation process of 11 IIoT initiatives (I)

We conducted follow-up interviews in 2019 to derive the level of diffusion. Whereas company A achieved to implement three pilot tests with customers (Case A1, A2 and A3), company B is also able to cooperate with pilot customers for case B1. Only company C had to stop all of its activities.
Based on the research framework derived, next to the process, we focused on the governance mechanism. Whereas in some cases, the governance mechanism have been similar for the studied company, other mechanism differed depending on the initiative. Table 3 highlights the insights of the governance mechanism.

Discussion
The specific activities of company A and B at the beginning of the innovation process highlight the need to coordinate with other subsidiaries or activities conducted throughout the company. At company A, during the idea concretization phase, headquarters was involved to align the subsidiary activities with companywide initiatives. Although each of the four cases at company A was presented to headquarters, the “pay per use” initiative needed further alignment as the potential service offering influenced process steps covered from other subsidiaries and was clearly in the locus of authority of headquarters.

The interdisciplinary project team is a central part in traditional as well as digital innovation management and was present in each of the studied initiatives. Interdisciplinarity seems to be important, not only for the knowledge needed for the development of digital innovation but also for the strengthening of internal cooperation and thus the implementation of the digital innovation throughout the company. More specifically, the interdisciplinary teams helped to improve the attention throughout the company and, in addition, to integrate knowledge from other functions. In the case of company B, internal cooperation was strengthened through a mix of focused project developments and larger group meetings that involved up to forty employees from different functions and subsidiaries. Although company B’s project team consisted of internal members, there was a continuous possibility to take in additional knowledge from the network. Company A and B continuously harmonized their activities with other ongoing projects and hence, allowed to take in additional knowledge from the network. Thus, the insights suggest that besides the internal cooperation, digital innovation management is strengthened through collaboration with the company wide network.
**P1:** Internal cooperation through interdisciplinary project teams supports the knowledge intake from different functions and the knowledge diffusion throughout the company and hence, the digital innovation management.

**P2:** Cooperation throughout the company wide network supports the knowledge intake and hence, the digital innovation management.

</tr>
</tbody>
</table>

**Table 3: Insights from governance mechanism of 11 IIoT initiatives**

With focus on external cooperation, the eleven initiatives differed. The development activities of the four initiatives of company A are conducted internally or in cooperation with the company wide network. Company C had an even stronger focus on the knowledge of internal members. Only company B did involve external partners, exemplifying the agile development philosophy through an early involvement of customers and suppliers. Based on the follow up interviews, the management of company B highlighted that the early collaboration with partners (customers and technology suppliers) helped for the internal and external focused innovations. The digital transformation representative of company A confirmed, as he states: “We should have integrated the customer right in the beginning”.

**P3:** External cooperation with partners (customer, supplier, experts) is important for digital innovation management.

The initiatives of company A have been orchestrated by a specifically assigned digital transformation leader. His role was to coordinate the different initiatives and to integrate the various activities throughout the company. In addition, the CEO had a central role, showing the
importance of the digital innovations and fostering its implementation activities. Company B assigned one initiative to the leader of strategic projects (guaranteed machine availability) and the internal focused projects to the COO. Whereas the leader of strategic projects continuously involved employees from different functions and subsidiaries and actively strengthened the informal knowledge transfer, the COO did not install similar coordination mechanisms. At company C, one initiative (Global Service) was assigned to the head of global services. Even though there was a high involvement of the CEO in company C, horizontal coordination mechanisms were missing for the other initiatives.

**P4: Formal and informal coordination mechanism are important to consider for the digital innovation management.**

The analysis of the locus of authority within the cases leads to different insights. In company A, the initiatives are highly linked to headquarters as the offerings of the services lies in the responsibility of headquarters. Being aware of this, the company tried to involve headquarters early and continuously. The locus of authority within company B changed during the innovation process. Whereas in the beginning, the company had the authority to decide, there was a development stop ordered from headquarters. Only after the company achieved a buy-out a restart of the innovation processes were possible. After that, Swiss headquarters was officially assigned to be the locus of authority and, in the case of case B1, successfully continued the project. Similarly, based on headquarters orders, company C was not allowed to invest in the development of digital innovations as headquarters wanted to integrate the initiatives network. Since they were driven from the Swiss site alone, headquarters did not allow continuing with the initiatives before analyzing which other sites from the company wide network needs to be integrated into the development process.

Each of the analyzed initiatives had issues with the locus of authority. It seems that the primary prerequisite is to have it defined and second, to handle changing locus of authority and to adapt the management of digital innovation.

**P5: The definition of the locus of authority is a requirement for digital innovation management. If new requirements lead to a change in the locus of authority, digital innovation management needs to be adapted.**

Only one of the studied initiatives (B1) did integrate the agile development philosophy. The follow up interviews with the leader of the strategic development projects supported the importance of this philosophy, while contrasting the success of the digital innovation (B1) with the two other projects (B2 and B3). Similarly, company A highlights retrospectively that an earlier involvement of customer needs (and pains) and a more agile development process would have helped to speed up the development process.

**P6: An agile innovation process with an early involvement of customers and suppliers as well as iterative phases supports digital innovation management.**

**Conclusion**

The analysis of the management of eleven IoT initiatives exemplifies the difficulties of managing digital innovations within manufacturing companies. We add to literature as we compare the micro-level activities of the development of the IoT initiatives with the relevant dimensions derived from the IS literature on digital innovation and its management. First, we show that a linear development process, as implemented from the manufacturing companies, does not respect the complexity of digital innovations. As suggested from the IS literature on digital innovation, an iterative and agile approach helps to get a better understanding of the
underlying interdependencies. Another influencing factor is the interdisciplinary of teams, which need to be visible throughout the company and act as intermediaries between their functions and the project team (internal cooperation). Third, external cooperation is not only needed in the idea generation phase but during all the development stages. The development of digital innovations is complex and often, there is a lack of knowledge and experience which needs to be incorporated from external partners. Forth, in addition to internal and external cooperation, the cooperation within the company wide network is another important dimension for knowledge intake and diffusion. Fifth, changing locus of authority led to project stops and hence, exemplified its importance. The sixth dimension, horizontal coordination mechanism, shows the need to have defined responsibilities, which covers the interdisciplinary nature of digital innovations.

The exploratory research approach and the comparison with insights from IS literature allows to expand our understanding of digital innovation management. All derived dimensions need to be considered to successfully manage digital innovations within manufacturing companies. Limitations occurs as the development activities are still ongoing. In addition, more cases are needed in order to understand if one of the derived dimensions do have stronger impacts on digital innovation management than others.

Nevertheless, the derived proposition provide a starting point for further research. For example, the locus of authority needs further research attention as despite the clear finding of its importance, it remains open, how subsidiaries need to operate within the realm of headquarters.

Managing change in operations: The case of the wire stripping machine in Agbogbloshie, Ghana

Alice Frantz Schneider (alicefr@ifi.uio.no)
University of Oslo, Norway

Abstract

This paper investigates the cable processing in Agbogbloshie, Ghana, one of the best-known informal electronic waste management sites worldwide. Wire stripping machines have been installed on site, but are scarcely used. Instead, environmentally eroding and health hazard inducing, open-air burning continues in order to extract metals from the cables. To investigate the machines’ lack of use, the theory of constraints is applied to empirical data collected in Agbogbloshie in 2017. Financial, policy, and market are identified as the system’s constraints. The subsequent suggestions aim to increase the use of the machines, which would ultimately lead to environmental and socio-economic improvements.

Keywords: E-waste management system, Informal recycling, Theory of constraints.

Introduction

The electronic waste (e-waste) management in Ghana is a complex system comprised of a variety of processes and agents. Agbogbloshie – a scrap metal yard located in Accra – is an important part of such system, and is among the main sites for informal e-waste processing in the world (Akormedi et al., 2013; Daum et al., 2017; Oteng-Ababio et al., 2016). The scrap metal yard has drawn attention to many challenges that accompany such e-waste management within environmental, social and economic spheres (Akormedi et al., 2013; Grant and Oteng-Ababio, 2016).

Processes such as the manual dismantling of electric and electronic appliances, as well as the cable processing, are among the ones that are performed in Agbogbloshie. The cable processing, in particular, is responsible for one of the main environmental exposures in the area (Akormedi et al., 2013). This is conducted mainly through open-air burning, which causes substantial pollution in the region, and threatens both the environment and society (Tue et al., 2016). Different types of wire stripping machines have been installed on the site between 2014 and 2016, which are capable of processing a wide range of cable sizes. However, the burning of cables persists.

This paper investigates the reasons for the lack of use of the wire stripping machines. Qualitative approaches have been used to collect data, such as on-site observations, interviews, and photo documentation. The Theory of Constraints (TOC) is used in the analysis. The TOC has a systemic perspective and understands the system as a network of chains that is as strong as its weakest links – denoted the system’s constraints.
In order to be able to suggest improvements for the processing of cables, it is important to first identify the constraints of the system.

The case of cable processing is part of a larger research project that analyses e-waste management systems in different countries. Sustainability is the main guiding-lenses, with the basic understanding that these systems should aim to meet “the needs of the present without compromising the ability of future generations to meet their own needs” (World Commission on Environment and Development, 1987, p. 41).

The paper is structured as follows: the next section describes the data collection, followed by a brief discussion of the TOC. Next, I present the case of the cable processing by discussing the burning of cables, the implementation of the wire stripping machines, and the challenges regarding the change in operations. In the discussion section, I apply the TOC to the case of the wire stripping machines. In this context, the focus is on the two first focusing steps of the theory, namely to identify the system’s constraints and to decide how to exploit the constraints (Goldratt, 1990). The last section concludes with remarks on the application of the TOC to the case.

**Research design and situated context**

The e-waste management in Ghana is understood as a complex system with several types of agents that interact with one another, each one performing different processes. This paper addresses two types of agents: the workers processing cables in Agbogbloshie, and the local non-governmental organization (NGO) that assisted in installing the wire stripping machines. The primary agents of interest are the workers who perform the cable processing.

Data were collected in Ghana during a period of two weeks in September of 2017. Several points of interest and organisations were visited in Accra and in adjacent cities. These visits enabled to better understand the challenges of e-waste management in the country. The Agbogbloshie site was visited seven times during the stay. Data were gathered through a mixed methods approach that combined observations, interviews, photography, and videos.

In Agbogbloshie, I engaged in conversations with 10-15 workers, while observing the activities performed by them and by other workers in the area. In addition, longer periods of observation on the e-waste processing, performed by different workers, have strengthened the data collection. Semi-structured interviews were conducted with the Greater Accra Scrap Dealers Association (GASDA) in Agbogbloshie, and with the NGO Green Advocacy Ghana (GreenAd) in Sakumono.

**Theory of constraints**

The TOC is a management theory, developed by Eliyahu Goldratt in the mid-1980s, that understands an organization or setting as a system (Rahman, 1998). This system takes inputs from the outside environment, acts on them through several processes, and produces outputs that go back to the outside environment (Schragenheim and Dettmer, 2000). The TOC defends the statement that “any efforts to improve a system’s output must consider the effects of these efforts on the whole system (Schragenheim and Dettmer, 2000, p. 14)” due to the interdependent nature among variables in the system. Therefore, improvements should aim at optimizations to the whole system, instead of only individual processes.

The theory considers that the system’s performance in achieving its goals is limited by one or more factor(s), referred to as the system’s constraint(s) (Puche et al., 2016; Rahman, 1998). To improve performance, the TOC focuses on these constraints. Allocating efforts to improve processes that are not one of the system’s constraints is
considered as a waste of resources since doing so would not affect the overall performance of the system.

The TOC has several tools that aim to understand and analyse a system, in order to provide suggestions for improvements. Tools include the current reality tree that is applied to identify the core problems and the future reality tree that aims to establish the future goals and ways of achieving them (Chou et al., 2012). Nevertheless, the TOC is more than a set of tools: “It is more fundamentally a paradigm shift which demands that we think about our problems, our goals and objectives, policies, procedures and measures, in a different way” (Mabin and Balderstone, 2000, p. 1).

According to Simatupang et al. (2013), the TOC comprises three different, yet interrelated, areas: logistics, performance measurement, and logical thinking; each one applying different methods. This paper focuses on the area of logical thinking, which primarily comprises the five focusing steps and the thinking process.

The five focusing steps
When seeking to make systemic improvements, Goldratt (1990) points out that it is fundamental to understand that every system was built for a certain purpose. Therefore, before any improvement is sought, it is necessary to first define the overall purpose of the system, and the factors that will be used to access the impact of any local decision on the global goal (Goldratt, 1990).

Once these are clearly defined, a series of steps may be used to aim for systemic improvements. Elaborated by Goldratt (1990), the five focusing steps are:

1. Identify the system’s constraints.
2. Decide how to exploit these constraints.
3. Subordinate everything else to exploiting the constraints.
4. Elevate the constraints.
5. Return to step one, while preventing inertia to become a constraint.

Chou et al. (2012) explain the focusing steps in detail: Step one consists of identifying those processes in the system that have a capacity which is lower than the overall system’s demand. Step two focuses on maximising the efficiency of such processes, based on the existing resources of the system. Step three comprehends the synchronization of the other processes in the system to the constraints. Step four targets on the acquisition of additional resources, in order to increase the constraints’ capacity and eliminate them as constraints.

The five focusing steps are meant to be a cyclical process, and this is evidenced by step five. By exploiting and elevating the existing constraints, it is natural that other factor(s) – which previously had no impact on achieving the system’s goal – become the new constraint(s). The search for improvements should be a continuous process because a system will always have at least one constraint.

Types of constraints
The factors restricting the achievement of goals within a system can vary substantially. Depending on the type, they might require different management approaches. For this reason, identifying the type of constraint enables a better understanding throughout the focusing steps. These constraints are categorized by Schragenheim and Dettmer (2000) as market, resources, material, vendors or suppliers, financial, knowledge or competence, and policy (cf. figure 1).

Resources and material are typically physical constraints. While the first comprehends internal sources (e.g. equipment, machines, people), the latter refers to external sources (e.g. raw materials, supplies), which are not enough to respond to the market’s demand.
The TOC recognizes that most constraints in a system are not physical, but managerial-policy related (Rahman, 1998). According to Schragenheim and Dettmer (2000), the reason for this is because almost all physical resources are dependent on some kind of policy. Managerial-policy constraints are often the most difficult to identify and require cooperation among functional areas (Rahman, 1998).

Market, financial, vendors/suppliers, knowledge/competence, and policy are all managerial-policy constraints. Schragenheim and Dettmer (2000) explain them in detail: The market constraint refers to the case in which the system’s capacity is more than the demand. The financial constraint comprehends the lack of financial resources to meet the system’s obligations. Vendors/suppliers refers to the case in which the lead-time of supplies is either too long or not reliable, to the extent that it affects the market demand. Knowledge/competence is a constraint when the lack of either hinders the achievement of goals in the system. Lastly, the policy constraint refers to cultural mores and ways of thinking: These appear either through explicit knowledge, such as written documents or through tacit knowledge, such as values.

The cable processing in Agbogbloshie
A multitude of processes is performed at the scrap metal yard of Agbogbloshie. The cable processing is one of these, and it has severe impacts in the area. In this section, I present my findings, focusing on the following points and their impact:

1. The burning of cables,
2. The implementation of the wire stripping machines, and
3. The challenges regarding the change in operations.

GASDA is the association of scrap dealers located in Agbogbloshie: It is responsible for organizing the activities, as well as granting permission to the ones who want to visit, or to work at the scrap metal yard. In an interview, the head of the association pointed out that the association has between 3000 and 4000 members and that everyone needs to become a member prior to working on the site. Amankwaa (2014) conducted a survey in Agbogbloshie, and the findings showed that the majority of workers are of young age – in the range from 15 to 30 years old – and that many have no formal education.

The e-waste that arrives in Agbogbloshie is first manually dismantled. The activity is often organized in groups, and the tasks are either performed in shelters or in the open air. Next, the cables are gathered in separate piles to be further treated (see figure 2). The most common practice to quickly remove the plastic insulation is to burn the cables. This process is assigned to a different group: often to the youngest men (Amuzu, 2018) as new members of the GASDA, to be accepted as workers on the site.
The burning of cables
For the burning activity, workers use an area further away from the dismantling area (see figure 3). They perform the activity primarily with shorts and t-shirts, leaving parts of their bodies directly exposed to the toxic emissions. Sandals are also more common than closed toe shoes, and the workers’ feet often have direct contact with the polluted soil. Cables are transported in and out of the burning area with a wheelbarrow. The cables are fuelled with petrochemical products (e.g. insulation foam from refrigerators, old tires), and burnt with the help of long sticks. The e-waste activity is male-dominated (Amankwaa, 2014). Throughout this process, women go around the area – some accompanied by children – to sell food and water in plastic sacks.

The environmental NGO GreenAd conducts, among other activities, research on e-waste management in Ghana. During an interview, GreenAd mentioned that, on a health education campaign, they gave around 300 gloves and 300 masks to different workers in Agbogbloshie. The findings of this study revealed that workers did not want to use the Personal Protective Equipment (PPE) provided: Instead, they argued that the masks were uncomfortable and that it was easier to work with bare hands than wearing gloves.

The large amount of metal wires from the burning process is sold to intermediates – the scrap metal dealers – who then sell the material to smelting industries. Spread across Agbogbloshie are weighing scales, used to assess the value of the extracted metals.
The cable burning results in the emission of toxic gases and other dangerous species, which causes substantial pollution of the soil, water, and air in the region. The emissions can cause severe health problems; in particular, for the workers involved in the burning process and directly exposed to the toxins. Common health problems that have been observed include high concentrations of heavy metals in blood samples, and pulmonary issues (Daum et al., 2017). Even though a series of health initiatives have been implemented by NGOs trying to raise awareness among workers, many of the risks are not yet understood by them. As GreenAd explained in the interview:

“We've heard stories of people falling sick and they think it's malaria. They keep on taking medication, it doesn't work [...]. It's all about education and people making an effort to help them out, to understand the various issues they are dealing with.”

When talking with workers, some stated to know about the risks involved. However, they would emphasize that the e-waste is their business and a way of safeguarding their own families’ livelihoods. This has been reinforced by GreenAd, which also pointed out to indirect risks unknown by workers:

“They feel they're making a living, that's the whole idea [...]. But they don't know it's coming back to them [...], cause these metals can also be found in the food chain. You have cattle eating there, people sell food [...]. Before they eat it sometimes they don't even wash their hands. So they're earning money to buy medication, that's how it is.”

Evidently, these overall negative impacts go beyond the workers who are directly involved with the e-waste processing. For instance, I could observe goats and cattle close to the cable burning area, which showed open wounds throughout their bodies. Food markets are focus points for further dissemination of the toxins to the greater community: For instance, the onion and yam market, located between Agbogbloshie and the urban slum of Old Fadama.

The implementation of the wire stripping machines

In 2014, the international organization Pure Earth opened the Agbogbloshie Scrap Metal Recycling Center. Funded by the United Nations Industrial Development Organization and the Global Alliance on Health and Pollution, this pilot project was implemented with the local partners GreenAd and GASDA (Pure Earth, 2016). The centre started its operation with four wire stripping machines (Pure Earth, 2014) capable to strip large coated cables of different thicknesses, down to a certain diameter. One of these machines is shown in figure 4.
