Restricting to two hypothesized factors, we first checked for factorability by different means. The overall Kaiser-Meyer-Olkin (KMO) criterion of sampling adequacy yielded 0.72 which is above the recommended threshold (Hair et al., 2014) (Kaiser, 1970). Bartlett’s test of sphericity was highly significant (p<0.001) indicating adequate correlations among the variables (Bartlett, 1950) (Hair et al., 2014). Next, principal component analysis with oblimin rotation was performed for the 14 items. We iteratively eliminated five items due to high cross or low factor loadings less than the recommended 0.65 (Hair et al., 2014). Interestingly, Market-Info 1 loads highly into Resource-Info, which is contrary to the hypothesized loading. This is addressed in the CFA. The remaining two sets of items have an Eigenvalue of at least 1.9 and explain 50% of the total variance, which is lower than the recommended value (Hair et al., 2014). With nine items and 44 observations, the observations-to-item-ratio is 4.9:1.
which is marginally below the recommended 5:1 rule of thumb (Bryant and Yarnold, 1995) (Hair et al., 2014). However, this ratio can be seen critically (Arrindell and Van Der Ende, 1985). Inter-item-correlations and item-to-total-correlations range between 0.3 and 0.62, exceeding the suggested threshold of 0.3 (Hair et al., 2014). Finally, Cronbach’s α ranges from 0.79 to 0.81, which is above the required value of 0.7 (Nunnally, 1978). In conclusion, all of the above provides evidence that the items are reliable and that the constructs developed are internally consistent.

Analogous to the first model, we conducted an EFA with the second (market-source and resource-source) as well as the third model (functional and cross-functional). The results are briefly summarized in the following. In the second model values for the KMO (0.71) were again acceptable and so was the measure for sampling adequacy (Bartlett’s test highly significant at p<0.001). Restricting the model to two factors lead to consistent loadings. We eliminated seven items due to high cross- or low factor loadings. Interestingly, resource-source 6 (quality management) loaded into market-source rather than its hypothesized construct. People seem to understand quality management not only as a source of information about the product’s quality but also as a function translating quality requirements from the market into product requirements. We address this item specifically during the CFA. With seven remaining items, the observations-to-item-ratio was above the recommended 5:1 threshold (Bryant and Yarnold, 1995) (Hair et al., 2014). Inter-item-correlations and item-to-total-correlations are between 0.3 and 0.6 and therefore acceptable (Hair et al., 2014). Model three shows consistent and high factor loadings. No items were eliminated. With KMO at 0.66 and Bartlett’s test highly significant (p<0.001) factorability and sampling adequacy is supported. Inter-item and item-to-total-correlations range between 0.54 and 0.89. Observations-to-item-ratio exceeds the recommended cut-off-value (Hair et al., 2014). However, the Eigenvalue of the second construct is relatively low (0.8) and Cronbach’s α (0.67) is just below the threshold (Nunnally, 1978). This indicates issues with the second factor. Nevertheless, we decided to proceed with the two-factor-solution in the second model, due to consistent and high loadings.

In order to assess construct validity and confirm the factor structure resulting from the EFA, we conducted a CFA. We employed a structural-equations-modelling-approach using SPSS AMOS 24. CFA demonstrates that collapsing all items into one construct is empirically less sound than the respective a priori structure of a model. Construct validity is usually measured through convergent and discriminant validity (Campbell and Fiske, 1959). Convergent validity describes the degree of convergence of a set of items. Discriminant validity assesses if items, which are intended to measure different latent variables (constructs) actually do so (Bagozzi and Yi, 2012). We conducted three CFAs – one for each model with two latent variables and the respective indicator variables. The first model (market- and resource-info) was entered with nine items (five for market- and four for resource-info) resulting from the EFA. The first iteration showed relatively low loadings with market-info 6 not loading significantly. Moreover, the a priori model still had market-info 1 loading into the latent variable resource-info. We therefore decided to eliminate both items during a second iteration. This led to highly significant factor loadings (p<0.001) with average loadings per factor above 0.7. As can be seen in table 3 construct reliabilities (CR) are above the recommended 0.7 and the average variance extracted (AVE) are above 0.5 suggesting convergent validity. The maximum shared variance (MSV) and the average shared variance (ASV) for the two constructs is below the AVE, strongly indicating discrimination between them (Hair et al., 2014) (Fornell and Larcker, 1981). Further exploring discriminant validity, we calculate the inter-construct-correlations and
compare to the square-root of the AVE. Inter-correlation marginally exceed the square-root of the AVE in the second decimal. In sum, all measures support that the two constructs are valid and capture unique aspects. To analyze the a priori specification of the resulting model, we compared several goodness of fit indices (Edwards, 2001) (Hu and Bentler, 1999). SPSS AMOS automatically calculates numerous indices, however, we focused on those most affected by sample size (Fan et al., 1999). The root mean square error of approximation (RMSEA) has a recommended value below 0.06. The comparative fit index (CFI) as well as the Tucker Lewis index (TLI), sometimes also referred to as the nonnormed fit index (NNFI), both have acceptable values larger than 0.95. These values are conservative, which addresses our relatively small sample size (Hair et al., 2014)). As shown in table 3 our final model meets these values.

Notes: n=44

Hence, the first model showed a remaining seven items for the two constructs. Similarly, we conducted the CFA for models two and three. For Model two (market- & resource-source) we received low and non-significant loadings in the first iteration using the initially hypothesized structure. In the second iteration, we opted for the structure resulting from the EFA which meant that we linked resource-source 6 (quality management) to the market-source construct. Furthermore, we deleted another item due to low and non-significant loading. This improved factor loadings with all of them being significant at p<0.05 as well as CR and AVE. Merely the first construct indicated issues with convergence at an AVE of slightly below 0.5. Model-fit-indices were all above thresholds. Finally, model three (functional and cross-functional) was assessed using the structure provided by the EFA, resulting in overall acceptable values for validity and model-fit. Only the relatively high value for MSV and ASV indicate potential problem for discriminant validity. However, with AVE of both constructs still exceeding them, we argue this scale still captures sufficiently unique aspects.

Discussion
To conclude, our scale development approach resulted in six constructs with a total of 17 items (~40% of the initial pool). Figure 2 summarizes quantitative part of the scale development. The scales at hand have several limitations that the researcher needs to be aware of when using the scales for further analysis. First, due to low maturity of the subject, there is only a narrow range of literature available for the definition of constructs and generation of items. Second, we operate based on a convenience sample not a randomized sample representing all manufacturing or automotive companies in Germany. The robustness of scales needs to be validated based on a larger, randomized sample. Third and probably linked to the previous points, we do encounter minor issues, particularly with discriminant validity. This needs consideration in the interpretation of further analysis based on these scales. Despite all these limitations, we argue that we have developed first constructs to capture a potential reconciliation process rigorously and empirically supported. All threshold values are chosen conservatively to combat doubt regarding our sample adequacy and our scales meet these recommended values. Finally, we argue that the contribution of these scales also lies in their simplicity and
relatability for practitioners. All items used as indicator variables are practical realities strategists are confronted with regularly.

Figure 2 – summary of quantitative part of scale development. Own illustration based on (DeVellis, (2016))

**Outlook**

The contribution of our study is twofold. First, we contribute methodologically, by developing a sound and easily reproducible scale for measuring some aspects of the OS-process in general and the relevant aspects of the reconciliation process in particular. Second, the presented scale-development serves as a first step in a larger work empirically testing the concept of reconciliation more extensively. Slack & Lewis claim that companies ought to pursue a harmonization of market- and resource-based perspectives. In other words, they posit that successful companies balance both elements, consciously and deliberately weighing them against each other. Based on our work, the next step is to conduct a statistical analysis, e.g. hierarchical cluster analysis, to empirically test whether companies in fact address the goal of a reconciled strategy in their strategy-process.

Abstract

Supply chain disruptions (SCDs) remain one of the most significant threats to firms’ performance. In this study we investigate chief executive officer (CEO) stock options as an antecedent of SCDs. Based on an eleven-year sample of more than 2,000 disruptions in U.S. S&P 500 firms we conceptually and empirically explain an inverted U-shaped relationship between CEO stock options and SCDs. We contribute to research the investigation of a previously neglected antecedent of SCDs, a more nuanced view on the strategic impact of CEO stock options, and insights on the moderating effect of relative chief operating officer (COO) power.

Keywords: Supply chain disruptions, CEO stock options, COO power

Full Paper

Introduction

Business interruption risks remain a significant threat to firms’ performance. Despite the high importance of SCDs for academia and practice, their causes are neither conclusively identified nor empirically well understood. Moreover, even though their decisions directly influence the supply chain, the impact of decision makers in charge of operations management is also neglected in operations management research (Hendricks, Hora, & Singhal, 2014). In this context, stock options are supposed to evoke more aggressive risk-taking by otherwise rather risk-averse executives in alignment with the shareholders’ interests. The concept of stock options allows executives to participate from the potential upsides of high-risk decisions with limited downside risks due to their optionality. This also comprises an increased willingness to take risks with regards to supply chain
management. Recent studies are ambiguous regarding the effectiveness of CEO options and call for further research on contingency factors impacting managerial risk taking (Benischke et al., 2019; Wowak, at al., 2015).

By contrasting agency and behavioral agency theory, we investigate the impact of CEO options on SCDs and the moderating effects of relative COO power and market uncertainty (see figure 1). We draw upon a unique, hand-collected sample of more than 2,100 firm-year observations over the years 2006 to 2016 with more than 2,000 SCDs in 223 S&P 500 firms. To support our manual sampling process, we used a machine learning algorithm to identify potentially relevant SCDs from more than 450,000 press announcements.

Our study contributes to operations management research in multiple ways. First, we identify and empirically investigate CEO options as a widely neglected organizational antecedent of SCDs. Second, we establish an inverted U-shaped relation between CEO options and SCDs enhancing research on CEO options with a more nuanced perspective on the effects of CEO options. Third, our study highlights the importance of having a powerful COO in the top management team with regards to supply chain stability. Fourth, we emphasize the necessity of adopting a contingency perspective when assessing CEO options and SCD risks. Finally, we introduce machine learning as a supporting technique to empirical secondary data research in operations management.

**Theoretical background**

**SCDs**

Prevailing research on SCDs emphasizes their harmful consequences: Hendricks & Singhal in several studies found, that SCDs diminish stock returns, market and shareholder value, and reduce sales over several years following a disruption (1997, 2003, 2005). In line with Hendricks & Singhal (2003) we define SCDs as unexpected events in the supply chain or its environment that threaten the normal business operations of a firm. Existing studies on SCDs vary strongly in the events being considered. Based on related supply chain risk literature, we use a dichotomous classification to cluster the SCDs used in our study. First, we separate micro- and macro-SCD-risks being in- and external to the organization (Wu et al., 2006). As we in this study investigate the effects of CEO stock options on SCDs, we exclusively focus on micro-disruptions which can directly be influenced by the firms. Loosely following the meta-analysis by Ho et al. (2015), we consider the following micro-disruptions in our study: demand and supply mismatches, delays, outages (of machinery or production), strikes, product quality issues, recalls, infrastructural problems, and issues of adverse business conduct. In line with Hendricks
& Singhal’s understanding of supply chain management and its subsystems, we assume that executives either indirectly (through negligence of important operations processes) or directly (through active strategic decisions or conscious misconduct) effect SCDs (2014).

(Behavioral) Agency Theory and CEO Options
The basis of agency theory and research on CEO options is the separation of ownership and management in firms, leading to potentially diverging interests between shareholders (principals) and managers (agents) (Jensen & Meckling, 1976). Principals delegate the management of the business to the agent (i.e. the CEO), who is assumed to act in their best interest. In this context, agency theory assumes, that agents are risk-averse. Stock options are supposed to reduce the CEOs’ risk-aversion by offering the CEO the opportunity to profit from firm success while not suffering from potential loss (Wiseman & Gomez-Mejia, 1998). Since CEO options are meant to influence a CEO’s behavior, behavioral agency theorists pronounce the need to combine agency with behavioral decision theory to fully explain its effects (Martin et al., 2016). Behavioral agency theory enhances agency theory by prospect theory to explain managerial risk-taking (Wiseman & Gomez-Mejia, 1998). Prospect theory postulates that managerial decision behavior depends on individual valuation of potential gains and losses to the personal wealth (Kahneman & Tversky, 1979) with wealth being understood as current, just-received, and fully anticipated wealth. Accordingly, agents weigh anticipated future wealth against declines in current endowed wealth (Benischke et al., 2019).

Development of hypotheses
CEO options and SCDs
If not in charge of operations themselves, CEOs have a strong impact on strategic decision-making regarding initiatives that affect company operations, such as cost-reduction programs, process-oriented programs (e.g. quality management, working capital management), or budgeting (e.g. R&D spending) (Wowak et al., 2015). Overly risky decisions in pursuit of stock performance optimization, thus, have the potential to evoke SCDs. Whereas agency theorists postulate a linear relation between CEO options and managerial risk-taking, based on the behavioral agency theory we assume that the relation between stock options and risk-taking is more nuanced and driven by two latent interacting forces: the perceived benefits in case of success and the perceived costs in case of loss associated with higher risk-taking by the CEO. CEOs with a low stock option share have little incentive to take risky decisions, as they only limitedly benefit from increasing share prices if the high-risk initiative achieves anticipated results. However, they have much to lose in terms of non-financial wealth or imminent penalties. With an increasing but still moderate CEO option share, the financial incentive to take risks increases, as the fully anticipated wealth assigned to high-risk initiatives becomes more compelling. As risk-taking preferences of an agent vary depending on the executives’ framing of the situation and anticipated effects on the personal wealth (Sitkin & Weingart, 1995), the CEO will constantly weigh benefits and costs of risky decisions against his current endowed wealth. Up to a certain point depending on the personal risk-taking preference, the incremental benefits of taking additional risks will overweigh the perceived incremental costs and will cause CEOs to ignore indications of project failure, to be negligent about risk mitigation, or to ignore downside risks of their decision (Wowak et al., 2015). As a consequence, we assume SCDs to increase. Following our logic of decreasing marginal benefits and increasing marginal cost of taking high-risk
decisions, we argue that with a high option share relative to the CEOs total compensation, risk-taking decreases as the CEO considers a large part of his prospect wealth at risk.

**Hypothesis 1 (H1):** CEO options exhibit an inverted U-shaped relationship to the frequency of SCDs, such that firms with low and high CEO option shares will experience fewer SCDs than those with medium CEO option shares.

**CEO options, market uncertainty, SCDs**

When analyzing managerial risk-taking behavior, market uncertainty being defined as the extent to which a CEO faces an unpredictable and unstable environment (Finkelstein & Boyd, 1998) is arguably of special interest. Uncertain markets are characterized by constant variations in customers, preferences, and competition and increased supply chain risks per se (Trkman & McCormack, 2009). This will enhance the perceived costs of additional risk-taking by the CEO. Moreover, research suggests that with increasing market uncertainty firms face higher complexity in their task environment and an increased need to review and adjust strategies continuously (Miller & Friesen, 1983). This increases the alignment efforts within the top management team (TMT), which restricts the CEO in making high-risk decisions. Finally, with less predictability of the market and a growing amount of personal wealth being linked to firm performance, CEOs tend to become increasingly risk-averse and seek to preserve personal wealth (Wiseman & Gomez-Mejia, 1998). As the marginal costs increase as compared to the marginal benefit related to additional risk-taking, the U-shaped relationship between CEO options and SCDs is flattened, thus SCDs decrease.

**Hypothesis 2 (H2):** The inverted U-shaped relationship between CEO options and SCDs is (a) flatter in markets where uncertainty is high and (b) steeper in markets where uncertainty is low.

**CEO options, relative COO power, SCDs**

Past research suggests that the increasing marginal cost curve counteracting the marginal benefits of CEO options might increase in the presence of a powerful COO. Power is defined as the extent to which the COO can influence the behavior of others and has the discretion to shape and implement strategic decisions in his interest (Finkelstein, 1992). The COO frequently is delegated responsibilities usually held by the CEO. He, thus, reduces power distance in the TMT and constrains the power otherwise centralized in the position of the CEO (Worrel et al., 1997). With increasing power of the COO, the CEO needs to more closely involve him when initiating strategic changes in a firm’s operations. By creating a task-oriented conflict between CEO and COO, decisions are made in a process of social interactions that reveals differing assumptions and expectations (Marcel, 2009). This alignment process will arguably constrain the CEO’s tendency to disproportionally focus on upside potential of high-risk decisions with regards to operations and, in turn, increase the CEOs perceived risk to be blamed with a negative outcome of a high-risk initiative if pursued against opposition. Second, power structures in TMTs can create conflicts among executives. By contending the power of the CEO, the COO takes a monitoring role towards the CEO. This is based on an inherent competition between the CEO and COO and the fact that a weak performance of the operations function being visible to the external labor market might harm future employment opportunities of the COO (Fama, 1980). Third, the functional backgrounds represented in the TMT influence the salience of certain organizational objectives and performance drivers (Marcel, 2009). While Hayward & Hambrick show that CEOs – a
role rather focused on output-oriented than internal processes – tend to be more risk-seeking with higher individual power (1997), COOs will presumably act in the foremost interest of their functional responsibility and, thus, will challenge overly risky decision based on a profound understanding of the operations function.

Hypothesis 3 (H3): The inverted U-shaped relationship between CEO options and SCDs is (a) flatter, when the relative power of the COO is high and (b) steeper, when the relative power of the COO is low.

Data and methods

Sample
To empirically test our hypotheses, we gathered more than 2,000 SCDs from PR Newswire press announcements in the Factiva database from 223 publicly traded S&P 500 firms in the U.S. between 2006-2016. Based on the taxonomy developed above, we identified key search terms to identify first relevant disruption announcements per category, following the procedure of Hendricks & Singhal (2005). To handle the number of announcements and support our manual coding process, we developed a supervised machine learning algorithm, using python 3.6 & scikit-learn libraries, to automatically identify potentially relevant announcements based on both, title and body of the announcements. We re-read all announcements tagged as potentially relevant by the algorithm to judge the appropriateness, discussed unambiguous announcements. We then, clustered the announcement into the SCD categories introduced above, using triple coding technique and regularly testing for intercoder reliability (Daniel & Harland, 2018). We then merged this SCD sample with TMT data from S&P Capital IQ’s ExecuComp and firm characteristics from S&P Capital IQ’s Compustat.

Measures
We operationalized our dependent variable (DV) supply chain disruptions as count variable (i.e. the number of recalls of firm i in year t), ranging from 0 to 8 in our sample. Our independent variable (IV) CEO options was operationalized as the share of stock options granted relative to the total compensation of the CEO as reported by ExecuComp. Following prior research, we calculated this variable as a two-year weighted average (Wowak et al., 2015).

With regards to our moderating variables, we put our focus on the presence of the COO role rather than on the title as such, following Hambrick & Canella (2004). We operationalized COO relative power as the COO’s total compensation relative to the total compensation of the highest paid TMT member (the CEO). This definition implies that higher relative compensation ratios indicate higher power in the TMT (Daily & Johnson, 1997). We operationalized market uncertainty as the coefficient of variation of sales per industry on four-digit SIC code level in a given year (Tosi et al., 1973).

To increase robustness of our research model we included multiple control variables on firm-, industry- and TMT-level. On firm-level, we controlled for firm size, financial slack, operating performance, past financial performance using Tobin’sQ, R&D intensity, and capital intensity. On environmental-level, we controlled for market uncertainty, technological turbulence, and technological sophistication. On TMT-level we considered TMT size, TMT ownership structure, CEO duality, and COO relative power.

Since firms with a history of SCDs may be more likely to subsequently encounter problems, we included lagged DVs in all models. Finally, all research models contain year and industry dummies. We lagged all variables in our model (except for the DV) by
one year to account for the fact, that strategic decisions based on information in a given year, will take time to become effective (Souder & Bromiley, 2012). All continuous variables are winsorized at the 1.0% level to avoid bias from outliers.

**Model**

We use STATA’s generalized estimating equation (GEE) model to analyze our unbalanced and pooled cross-sectional time-series data, following structurally similar studies based on longitudinal data (Wowak et al., 2015). GEE measures the effect on the DV “population-averaged” across all units in the data set, thus, considering both, within- and between-unit variation. Unlike alternative approaches (e.g. random- or fixed-effect models), GEE can handle with potential heteroscedasticity and serial correlation as it accounts for both inter- and intra-firm variations (Shah et al., 2016). Moreover, GEE does not (wrongfully) omit “zero SCD” firms (Sine et al., 2003).

**Results**

Table 1 provides descriptive statistics (unstandardized) and correlations (standardized) for all variables used in our models. The top right part of the matrix shows Spearman’s rank-order correlations, the bottom left values show Pearson’s product-moment correlations. The fact there is no significant correlation between CEO options and SCDs might be a first indication that the relationship might indeed not be rather curvilinear / U-shaped.

**Table 1 – Descriptive Statistics and Correlations**

As we have COO presence in only 53.6% of all firm-year observations we shrink our sample size by 990 observations with the inclusion of the COO power moderator and control variable. Accordingly, we tested hypotheses 1 and 2 ex ante in separate models without the COO power variables. We repeated the tests in a second group of models including the COO power moderator and variables to test hypothesis 3. This approach allowed us to test hypotheses 1 and 2 without a potential COO presence selection bias.
(which we separately tested for as described below) and served as a first robustness test for the effects investigated in hypotheses 1 and 2. Table 2 exhibits the results of the regression analysis. Model 1-1 contains control variables only. Model 1-2 tests the main effect and model 1-3 includes the main and the first interaction effect without the COO power variables. Models 2-1 to 2-3 are identical in structure to models 1-1 to 1-3 but include the COO power variables. Model 2-4 additionally contains the second interaction term. Model 2-5 is the full model with the main and both interaction effects. All models are highly significant (p<0.01) and show increasing Wald χ² statistics with inclusion of the IV and additional moderators. Despite the drop of 999 firm-year observations between model 1 and 2 all results remain constant for both, the main and interaction effect, indicating a high robustness.

Hypothesis 1 theorized an inverted U-shape relationship between CEO options and supply chain disruptions. Necessary condition for such a curvilinear relationship is a negative second-order effect of the IV in our regression model. In support of Hypothesis 1, model 1-2 shows that CEO options have a highly significant effect on supply chain disruptions and the second-order effect is significantly negative. In hypotheses 2 and 3 we theorized a flattening in the inverted U-shape relationship between CEO options and supply chain disruptions by our interaction effects. A flattening (or steeping) of a quadric relationship requires the regression coefficient between the interaction effect and the squared IV to be significant and positive (Haans et al., 2016). As depicted in our full model 2-5 the coefficients of both interaction terms are significant and negative, with their corresponding second-order effects being significantly positive. H1, H2, and H3, thus, are strongly supported. Given the stable results of the main and the first interaction effect in both the model with the COO variables (N = 2,134) and the model without the COO variables (N = 1,144), our estimations show high robustness. Still, we conducted multiple additional checks to ensure a high robustness of our findings. Our main analysis was conducted using a
negative binominal distribution best fitting our count data DV. To ensure our results are not driven by model specifications, we reran the analysis with an ordinary least square (OLS) random effects model with robust standard errors (model 3-1) and with Driscoll-Kraay standard errors to rule out cross-sectional correlation (model 3-2) (Shah et al., 2016). Both models confirm the results presented above. Next, we reran our main model with two different specifications of our IV using an unweighted average in model 3-3 and annual values in model 3-4. Again, our estimations are confirmed.

Firms with COOs might be substantially different from firms without COOs. Unobserved factors (e.g. operations management experience of the CEO) might influence both, the decision to have a COO and supply chain related outcomes and bias the results of our study. To test for this potential sample selection bias, we applied a Heckman two-stage selection model (1979) in line with prior TMT research (Kim et al., 2016) and included an inverse Mills ratio (IMR) predicting COO presence in all our models 2-1 to 2-5. As the IMR is insignificant and all other results remain robust, our analysis does not suffer from a sample selection bias. The results including the IMR are shown for the full model in model 3-5. Moreover, we drew on multiple means to lower the risk of potential endogeneity in our study. Among other measures, we created an endogeneity control by regressing CEO options in $t - 1$ on eleven of its potential firm-, industry-, and TMT-level antecedents in $t - 2$ and including this predicted IV as endogeneity controls in our models 2-1 to 2-5. Again, the results remained robust in all models. We show the results for the full model in model 3-6. Given the results of the tests above, reverse causality and endogeneity do not appear to be a problem in our study.

**Discussion**

*Theoretical Implications*

Our findings have important implications for research on SCDs and the extensive literature on the impact of CEO options on executive behavior. First, we extend operations management research by investigating CEO options as an organizational antecedent of SCDs. We empirically show, that CEO options – especially at medium levels – increase the frequency of SCDs. Second, we contribute to strategic management research which investigates the effects of executive stock options. While research on this topic has long been dominated by two schools of thought – agency theory expecting more risky decisions and behavioral agency theory expecting less risky decision as consequences of stock options – our research conceptually and empirically adds a more nuanced assessment of CEO options to prevailing literature. Third, this study identifies both organizational and environmental factors that have significant impact on CEO option-induced risk-taking. Both, market uncertainty and relative COO power have a flattening effect on the relationship between CEO options and SCDs, thus, diminishing the CEOs willingness to take disproportionate risks with regards to operations management. As of today, research on performance effects of COOs is ambiguous (Hambrick & Cannella, 2004; Hendricks et al., 2014). Our findings underline the importance of a COO at equal terms with regards to supply chain stability and further confirms research underlining the importance of operations capabilities in the TMT as a source of competitive advantage.

Finally, our study advances strategic and operations management research from a methodological standpoint. As the algorithm is not limited to a predefined dictionary of relevant terms but constantly evolves based on the growing training data set, this approach might be an interesting alternative to dictionary-based approaches. Especially in times of “big data” that can hardly be managed manually anymore and for relatively new areas of research where no established dictionaries exist, this approach can become increasingly relevant.
Practical Implications
Our findings bring about two important implications for decision makers. First, we advise decision makers to carefully select and combine different tools of executive compensation. Whereas CEO options might not be the best incentive used by itself, they still might be a valuable tool to induce additional risk-taking if required. However, this decision needs to be made very deliberately, keeping in mind potential risks. We, thus, recommend decision makers to balance CEO options with other means of executive compensation such as stock that also have a downside potential and reward sustainable decision making. Second, if using CEO options, we advise decision makers to embed their usage in an organizational setting that either does not facilitate strategic individual actions by the CEO or, as this study has proven, has a relatively low power distance in its TMT to enable mutual control among executives.

Limitations and Avenues for Further Research
Our study is subject to certain limitations that provide interesting avenues for further research. First, while our study focuses on the effects of CEO options, future research should investigate the interplay of CEO options with other prevailing means of executive compensation (e.g. stock ownership) in predicting supply chain stability. Second, whereas we focused on CEO compensation, it might be of interest to investigate effects of additional TMT characteristics on supply chain stability. Third, research has a strong focus on the CEO when investigating the effects of stock options. Future studies could expand this scope to other TMT members’ roles and strategic outcomes in their areas of responsibility to better understand potentially diverging interests between different functional strategies.

**Abstract**

This study analyses the impact of internal and external mechanisms on the process of operational capability development. While internal mechanisms comprise a set of operational resources used by companies in order to improve their performance, external ones refers to the influences coming from external players. High Performance Manufacturing database composed the sample with 263 companies from fifteen countries. The results suggest that internal mechanisms influence positively operational capabilities development. Furthermore, external aspects like supplier development and customer alignment create a feedback process nurturing organizational knowledge.

**Keywords:** Operational Capabilities, Coevolution, Operational Performance.

**Literature Review**

**Operational Capabilities**

Operational capabilities have been understood also as a set of interrelated routines of companies for performing through their resources base (Peng et al., 2008), including the role of external players, such as supply chain partners (Raddats et al., 2017; Vanpoucke et al., 2014), and professional network (Zhang, Gregory, and Neely, 2016). Beside a conceptual convergence of the prior literature, prior studies present an absence of consensus of the antecedents of operational capabilities, because it has been understood as a phenomenon composed by multiple elements (tangible and intangible). Capability development has been studied from two main approaches. Some authors have pointed out organizational knowledge as an intangible element of the organizational capabilities regarding their value for decision-making, and identifying new opportunities and threats (Grant, 1996). Similarly, a body of empirical studies shed light on the role of tangible factors, such as operational practices and new technologies on capabilities development (Wu et al., 2010).

As one of the most important internal resource of companies, organizational knowledge has internal and external perspectives. While internal knowledge is considered as a way in which companies explore their internal resources, external knowledge refers to identify a set of opportunities and threats in the market (Paiva, Roth, and Fensterseifer,
Previous studies have pointed out market knowledge as a way to detect proactively changes in the market (Alfalla-Luque et al., 2018; Lee, 2004). Thus, we may state that market knowledge is one of the sources that influence companies’ operational activities adaptability (Alfalla-Luque et al., 2018; Paiva et al., 2008).

We combine internal and external mechanisms in our proposed framework. Therefore, we consider customer and supplier market knowledge, effective process implementation, continuous improvement, and anticipation of new technologies as antecedents of operational capability. On the other hand, operational capability influences positively operational performance. In the sequence, customers and suppliers adapt their processes according to the performance target defined by the company. Finally, both customers and suppliers influence company’s organizational knowledge in a looping process. The same looping is identified between operational performance and internal mechanisms of effective process implementation, continuous improvement, and anticipation of new technologies.

**Co-evolution theory**

Co-evolution theory is originally from Biology. Ehrlich and Raven (1964) demonstrated a joint evolution between butterflies and some species of plants. This approach was brought to Social Sciences by Lewin and Volberda (1999) for mentioning simultaneous interactions among managerial actions, industry, and institutional and government environments. Currently, co-evolution in Social Sciences is a macro-theory that integrates several theoretical approaches. It is considered as a promising theory to reduce the dichotomy between determinism and voluntarism view in management studies. Thus, while determinism emphasizes external factors as determinant of the company’s adaptation, voluntarism covers factors from managerial action (i.e., internal scope) (Abatecola, 2012).

Five properties support co-evolution theory: multilevelness and embeddedness, multidirectional causalities, nonlinearity, positive feedback, and path and history dependence. In order to characterize a co-evolutionary phenomenon, all properties should meet together at the same time (Lewin and Volberda, 1999, 2009).

**Hypothesis development**

Paiva et al. (2008) empirically found a positive impact of external knowledge on value creation resulting from manufacturing resources. Considering that external knowledge enable proactiveness, Alfalla-Luque et al. (2018) found a positive effect of adaptability capacity of companies on the operational and financial performances. Those studies suggest that market knowledge influence internal processes and thus companies may adapt to continuous changes in the environment. Based on these arguments, we hypothesize:

Hypothesis 1 – Market knowledge influences positively companies’ internal processes.

Resources and operational practices are accessible for the companies, but there are idiosyncrasies related to how to evaluate and reconfigure those practices over time. Teece (2007) proposed the ‘seizing’ and ‘reconfiguring’ mechanisms to identify opportunities and threats, and to implement them in companies’ activities. We argue that continuous development of the internal factors by companies lead to operational capability development.
Hypothesis 2 – Internal processes positively influence operational capability.

Operational capabilities has been defined from different perspectives, such as based on trade-off concept (Boyer and Lewis, 2002), cumulative capabilities (Ferdows and De Meyer, 1990; Schroeder et al., 2010), and combinative capabilities (Rosenzweig and Roth, 2004; Roth and Miller, 1992; White, 1996). All of them understand operational performance related to the company’s heterogeneity. Prior studies have also emphasized the positive effect of operational capabilities over performance, measured by quality, delivery, flexibility and manufacturing costs (Peng et al., 2008, 2011; Schoenherr and Narasimhan, 2012; Tan et al., 2007; Wu et al., 2010). Thus, we hypothesize:

Hypothesis 3 – Operational capability influences positively operational performance.

Regarding the process of operational capability development, we consider that companies influence external players through their performance, which characterizes an external adaptation. Empirical studies have used co-evolutionary theory to illustrate this aspect. For example, Dieleman and Sachs (2008) showed political changes in the Indonesian institutions caused by Indonesian Salim group. Braguinsky and Hounshell (2016) highlighted the influence of Osaka company’s performance on industrial policies changes in the Japanese textile industry, as well the competitors’ efforts in order to keep in the market. From this, we hypothesize:

Hypothesis 4 – Operational performance of companies influences positively interactions with external players.

Fifthly, according to the internal feedback mechanism from co-evolutionary theory, the company’s operational performance may help managers to adapt their manufacturing tasks. Therefore, we argue that operational performance influences positively internal factors of companies: effective process implementation, continuous improvement, and anticipation of new technology. (Peng et al., 2008, 2011; Schoenherr and Narasimhan, 2012; Tan et al., 2007; Wu et al., 2010)

Hypothesis 5 – Operational performance positively influences tangible internal factors.

We state that companies develop their operational capabilities within a dynamic process, in which the companies and other players exert influence and are influenced by each one other continuously. Based on previous studies, we hypothesize that when the
company’s market knowledge is influenced by external actors, it adapts its internal factors (Alfalla-Luque et al., 2018; Paiva et al., 2008). Based on this argument, we present the last study’s hypothesis:

Hypothesis 6 – Higher the integration with external players, higher the market knowledge of companies.

Methodology

This study uses data from the fourth round of the High Performance Manufacturing (HPM). The fourth round data collection started in 2012 and it contains 330 respondents at the moment from fifteen countries: Brazil, China, Finland, Germany, Israel, Italy, Japan, South Korea, Spain, Sweden, Switzerland, Taiwan, United Kingdom, United Stated, and Vietnam. These countries were selected due to the composition of high performance and traditional manufacturing companies, and its distinct institutional characteristics, such as cultural, industrial politics and economic development. Additionally, the project contains data from machinery, electronics, and transportation components industries to cover distinct contexts – stable and dynamic environments (Schroeder and Flynn, 2001).

All measurement items in this study are from the HPM database. Nine latent variables and forty-four items with a five-point Likert’s scale were used in this study. As the first step, we cleaned data for checking missing values. Full data with 330 respondents presented 9.43% of missing values. We removed incomplete responses until to reach 263 useful respondents (2.53% of missing values). As an acceptable condition (less than 5%), we proceed with a mean replacement according to the most appropriate treatment suggested by experts.

The nine scales of this study are: customer market knowledge, supplier market knowledge, effective process implementation, continuous improvement, anticipation of new technology, operational capability, operational performance, customers and suppliers. Customer and supplier market knowledge states an ability of companies to detect trends or changes from the market in which they operate (Alfalla-Luque et al., 2018). Effective process implementation refers to the ability of companies to develop and implement new processes (Huang et al., 2008). While continuous improvement scale seeks to provide a set of proactive adaptation ability of companies (Bortolotti et al., 2015; Peng et al., 2011), anticipation of new technologies scale evaluates the ability for moving technological structure early than rivals (Garrido-Vega et al., 2015). Operational capability scale refers to a broad ability of companies for performing their full manufacturing task (Wu et al., 2010). In turn, operational performance is measured by the traditional OM variables: cost, quality, delivery, and flexibility (Bortolotti et al., 2015; Peng et al., 2008). Finally, customer alignment and supplier development scales refer to external players that may influence and be influenced by the focal company; therefore, both scales seek to measure interactions level in their processes and services.

In order to analyse common method bias, we used procedural and statistical remedies (Lee, and Podsakoff, 2003). First, we got data from five distinct respondents for the dependent and independent variables. Secondly, personal identity of respondents were not revealed. Thirdly, respondents answered self-administered questionnaires without any external influence. Fourth, data matches the perception of two respondents per company. Fifth, Harman’s one-factor revealed no emergence of a single factor with variables used in this study, in which the first factor represented just 17% of the whole variance. These results suggest no concern about common method bias in the study.
**Data Analysis and Results**

Followed two stage analytical procedures of structural equation modelling; we treated measurement model (reliability and validity tests), and then a path analysis model for testing the hypotheses. Table 1 provides a descriptive analysis of the latent variables, including means, standard deviations, correlations, and square roots of AVE in diagonal (remaining data after model purification).

Initially, we analysed validity and reliability. Standardized indicators loading and p-values were used as criteria to remove items with low loadings. Remaining items presented a satisfactory composite reliability, and convergent and discriminant validities. Firstly, the values of composite reliability ranged from .799 to .848, showing an adequate fit (>0.7). Secondly, convergent validity was addressed by the average variance extracted (AVE), which ranged from 0.538 to 0.716, higher than the recommended value (>0.5). Thirdly, discriminant validity also is identified because squared root of AVE are higher than constructs correlations (Hair Jr. et al., 2014). Overall, the overall results suggest a good internal consistency of data.

We ran a path analysis with the Amos18 software. The indices for goodness fit of the structural model are highly satisfactory (table 2).

Results from the structural model indicate a positive relation among customer market knowledge and supplier market knowledge with effective process implementation. Only Effective process implementation did not present a statistically significant result. Nevertheless, considering the positive relation between Anticipation of new technology and Effective process implementation, the results support hypothesis one.

Regarding hypothesis two, we found a positive relation among effective process implementation, continuous improvement, and anticipation of technology and operational capability. However, only one presented a statistically significant result. Thus, hypothesis two was only partially supported. We also found support to confirm third hypothesis, in which operational capability has a positive influence on operational performance of companies. (See table 3)

2255
Our results indicate that operational performance positively influences customers and suppliers interactions. Therefore, it confirms the fourth hypothesis. The fifth and sixth hypothesis tested the feedback effect on the internal mechanisms. In this case, operational performance is positively related only to anticipation of new technology and negatively to effective implementation. Thus, the results only confirm partially the fifth hypothesis. The sixth hypothesis evaluates the influence of external players on the organizational knowledge. The results showed a positive result between customer interaction on customer market knowledge and supplier interaction on supplier market knowledge. Therefore, these results confirm the last hypothesis.

**Discussion**

The results found indicate that customer and supplier market knowledge positively impact internal mechanisms (Alfalla-Luque et al., 2018). It refers to checking opportunities and threats present in the market. Furthermore, internal resources when related to effective processes implementation (Huang et al., 2008; Morita and Flynn, 1997), continuous improvement (Bessant and Francis, 1999; Colman and Devinney, 2013), and anticipation of new technology (Matsui, 2007) strengthen operational capabilities.

Also, the results suggest that companies with stronger operational capabilities may achieve higher operational performance including costs, quality, delivery, and flexibility. In addition, operational performance is considered a ‘managerial control point’ in which managers define their functional targets. At the same time, operational performance works an internal feedback process that positively influences the internal mechanisms (antecedents of operational capabilities). This aspect present a clear connection to the co-evolutionary theory, which considers feedback effect as a property that lead companies jointly evolve over time (Lewin and Volberda, 1999).
On the other hand, operational performance may influence changes in external environment, influencing external players and partners. Our results indicate that higher operational performance increase customers and suppliers interactions. This result is in consonance with previous studies that have showed a joint evolution between companies and industry players (Braguinsky and Hounshell, 2016; Chen et al., 2017; Raddats et al., 2017; Rodrigues and Child, 2003). Changes in the external environment or companies lead to a new organizational forms or to the adaptation of existing ones, according to the basic premise of co-evolutionary theory (Lewin, Long, and Carroll, 1999). Based on that premise, our results indicate a positive influence from customers and suppliers’ interactions on the market knowledge. This result suggests that adaptations in the resources portfolio caused by external influences at the end influence the process of operational capability development.

Table 4 indicates three main mechanisms identified by this study. The internal factors are related to the influence of tangible and intangible resources on the operational capabilities development. Furthermore, internal factors receive influences from operational performance (named as internal feedback) and external players (named as external feedback) mechanisms. Internal feedback refers to the causal effect of an outcome reached by managers; in other words, regarding the outcome achieved, it provokes internal adaptations in order to achieve managers’ goals. In turn, external feedback represents the effect of adaptation of external players on companies’ internal

factors; it implies an internal adaptation to improve companies’ processes. Consequently, companies will be able to develop their operational capabilities through a cyclical process for monitoring external players. Therefore, there is an ‘interactively developed capabilities’ (Raddats' et al., 2017) between dyads based on internal and external mechanisms simultaneously.

### Conclusions

This study brought new insights to the process of operational capability development. For doing so, we underline co-evolutionary theory as the support for our analytical framework. The framework considers capabilities development as a cyclical process among internal and external mechanisms. Thus, the results suggested a direct influence of internal mechanisms on operational capabilities. In turn, operational performance and external players influence companies’ internal resources, and, at the end also influence operational capabilities.

More than theoretical implications, this study provides some managerial contributions. First, managers should pay attention to the company’s strengths, monitor and manage internal and external sources in order to respond to the changes in the environment. Second, managers should monitor the external environment (players and partners) constantly in order to adapt their internal resources when looking for developing their capabilities. Third, as a cyclical process of operational capabilities development, managers should pay attention to what aspects from the environment and external players are more relevant.

We may list some limitations present in this study. Firstly, we used only customers and suppliers as external actors to analyze the co-evolution process among companies, however, according to the theory many others external players should be considered, such as competitors, consumers, entities, institutions, among others. We also used cross-sectional analysis but co-evolutionary processes also needs a longitudinal research approach to be fully analyzed (Breslin, 2016). Future studies can extend this debate by analyzing the effect of other set of external players, as well as considering a longitudinal approach in order to understand distinct effects along the time.

Developing problem-solving capabilities for sustainable solutions: A dynamic capabilities approach

Matin Mohaghegh (matin.mohaghegh@phd.unipd.it)
Department of Economics and Management, University of Padova

Andreas Größler
Department of Operations Management, University of Stuttgart

Abstract

Continuous improvement is a premise for a firm’s competitiveness over time. Problem-solving activities are a way to continuously improve the operations of a firm. However, not every problem-solving activity leads to sustainable improvements. The problem-solving literature promotes systematic behavior to cope with problems (systematic problem-solving or SPS). Although the effectiveness of SPS is well-documented in the literature, many firms fail to fully reap the benefits of this behavior or struggle to sustain its outcomes over time. Motivated by field work at a manufacturing firm, this study aims at understanding the major reasons of failures for SPS-based programs, from a dynamic capability perspective.

Keywords: Systematic problem-solving, dynamic capabilities, case-study

Introduction

In today’s fast-moving and global business environments, characterized by unpredictable changes and uncertainty, creating new capabilities by which organizations approach and respond to problems seems necessary to achieve continuous improvement and stay competitive in the long-term (Helfat & Peteraf, 2015; Teece, 2007). However, not all problem-solving activities result in sustainable outcomes. The literature on problem-solving promotes a systematic approach to deal with problems (e.g. Choo et al., 2015; Repenning & Sterman, 2002), called systematic problem-solving (SPS). SPS is a multistage process encompassing different activities (i.e. problem definition, problem analysis, and solution design) before a final decision is reached whose main objective is to constantly improve operational processes (Repenning & Sterman, 2002). Although many firms implement improvement-oriented programs (e.g. Lean, Kaizen, Six Sigma DMAIC), they cannot fully reap the benefits of SPS-based opportunities or struggle to sustain the outcomes over time (Netland & Ferdows, 2014; Bateman, 2006).

This study addresses the need for long-term and sustainable success in the context of operational problem-solving. We propose that the theory of dynamic capabilities (DC) sheds light on the major reasons of failures in SPS-based programs. Teece (2007) defines DC as the firm’s capacity to (1) identify opportunities (sensing), (2) make investments to
seize those opportunities (seizing), and (3) reconfigure enterprise’s assets and capabilities to maintain competitiveness (reconfiguring). DC theory indicates that solving problems fundamentally with the help of structured actions, i.e. SPS, requires continuously and systematically developing sensing, seizing, and reconfiguring capabilities.

Based on insights from a case-study company, we identify different modes of problem-solving behavior. Accordingly, we propose that not every problem-solving behavior could be considered as a DC and hence contribute to sustainable improvements. Then, we identify and discuss two groups of impediments for successful SPS adoption. One is a cognitive bias defined as a natural tendency of problem-solvers to jump to a solution. The second one is a set of organizational impediments for SPS adoption namely: (a) time pressure, (b) resource constraints, (c) individual problem-solving and lack of collaborative culture, and (d) insufficient leadership practices. We demonstrate how these factors curb problem-solver’s capabilities for sensing, seizing, and reconfiguring as three components of the DC.

This study contributes to a body of literature where a systematic approach is emphasized for dealing with complex problems and decisions. Despite all the attention to design SPS and promote techniques for this mode such as lean manufacturing and Six Sigma DMAIC in the operations management literature, a clear picture of the conditions by which SPS-based programs succeed or fail is missing. The theory of DC sheds light on realizing behavioral and organizational impediments of SPS.

This work also has considerable implications for managers. It provides insightful information to address the circumstances through which problem-solving activities pay off successfully.

**Design/ Methodology/ Approach**

To understand problem-solving activities in companies, we conducted a case-study. The research site was a manufacturer of gardening equipment and supplier of agricultural products. This setting is of particular relevance for two reasons. First, operational problems related to cost, quality and delivery of the products occurred frequently and we could realize how different problem-solving behaviors contribute to sustainable development. Second, the plant manager of the firm started emphasizing improvement-based programs (e.g. lean manufacturing and its bundles such as JIT or TQM) due to an increasing trend of customer complaints together with reports about the low efficiency of the assembly line (e.g. a high defect rate and warehousing problems). Therefore, it is assumed that the firm previously faced difficult times fundamentally solving problems.

All in all, the case-study company provided a good opportunity to observe problem-solving activities (before and after the implementation of improvement-based activities). We gathered data, over a period of three months, on the actual problem situation. This included several days shadowing the managers and roaming the shop-floor employees as well as conducting semi-structured interviews to understand how problems were overcome in the company. We also relied on the memory of interviewees to provide historical information concerning different problems, their frequency, and the problem-solving actions.

Data analysis began with reviewing the observational data and analyzing the notes recorded during the interviews. We identified a sample of problems that were resolved differently. Hence, different levels for problem resolution and their potential impacts on operational performance are highlighted. In order to ensure having a comprehensive
understanding of problem-solving activities and sharpen its generalizability, we double-checked the proposed levels and their effects to see whether, or not, they are also supported by the literature, i.e. theoretical triangulation (Eisenhardt, 1989).

Explication of Building Blocks

Based on insights from the case-study and in line with the literature, we propose three levels for problem-solving and present the main characteristics of each.

Level 1: Intuitive Problem-Solving (IPS)

Level 1 occurs when problem-solvers employ prompt remedies to temporarily solve the problem. In the literature, it is interpreted as jumping to a solution where intermediate steps of comprehensive problem-solving such as problem definition, problem analysis, and solution design are skipped or abbreviated (Baer et al., 2013). Adopting the cognitive perspective of the dual-processing theory (Evans & Stanovich, 2013), this level could be labeled intuitive problem-solving (IPS) as it relies on heuristic reasoning of problem-solvers while confronted with complex problems. Although IPS results in short-term and minimal improvements as problems are temporarily solved, there is a high likelihood for problems to recur. Moreover, it might lead to type III errors, i.e. solving the wrong problem because IPS is a solution-mindedness behavior mode and problem-solvers work around the problems by focusing just on problem symptoms rather than its major causes (Smith, 1989). A sample problem from the case company is briefly explained in Table 1 and it is highlighted why the problem-solving efforts represent IPS adoption.

<table>

| In many cases, front-line employees are behind the defined schedule to meet the daily production target. | • **Temporary Solution:** Low productivity is mostly covered by a high rework rate.  
• **Operational Performance:** Although this solution is helpful in the short-term as the production target is met, the same problem occurs again as insufficient attention is put on a root-cause analysis. | |

Level 2: Semi-Structured Problem-Solving (SSPS)

Level 2 problem-solving, from dual-process theory (Evans & Stanovich, 2013), could be interpreted as a rational reaction to fundamentally solve the problem. Problem-solvers, on this level, are required to go through a set of steps (i.e. problem detection, problem formulation, and solution design and implementation) to take structured actions (Baer et al., 2013). Although, deliberate and reflective efforts are employed to link the observed problem to a diagnosis, and eventually an appropriate solution, it fails to produce a positive change in production processes. Activities of level 2 are limited to an action, although helpful to solve the problem, cannot contribute to sustainable and long-term...
developments. Indeed, a problem is solved but the effects are still short-lived and hence radical improvements in operational processes are less likely to occur. This level is called semi-structured problem-solving or SSPS. Table 2 summarizes the main characteristics of SSPS based on our data.

**Table 2: SSPS Adoption (Level 2 Problem-Solving)**

<table>

| Unbalanced workloads | • Root-Cause Analysis:  
  ▪ Production planning is not based on customer demand.  
  • Solution:  
  ▪ To balance the production line, production planning is taken as an action to collect rich information regarding the most (least) demanded products.  
  • Operational Performance:  
  ▪ Problem-solving activities end with the proposed solution. However, solutions do not lead to positive change. In this case, production planning is done whenever assembly line is either over-utilized or under-utilized.  
  ▪ Improvements are still short-lived and mostly incremental in nature. | • Problem-solving should be stressed in such a way that problems remain solved with a low probability of recur (Argyris, 1976). This should be done through constant monitoring and standardization of the operational processes.  
  • Process changes should be routinized for further improvements (Anand et al., 2009). Otherwise, problem-solvers are less likely to establish repeatable processes in order to prevent re-occurrence. |

**Level 3: Systematic Problem-Solving (SPS)**

In essence, level 3 problem-solving corresponds to a situation where problem-solvers rely on rational reasoning and employs a systematic approach to deal with problems. Similar to level 2, it begins with problem detection, goes through problem formulation and analysis and concludes with the best applicable solution. However, in contrast to level 2, level 3 is more complete and leads to the modification of production processes. We label this level as systematic problem-solving (SPS). The problem-solving literature promotes SPS as a behavior mode that is more likely to create and retain a positive change in operating routines (Itabashi-Campbell et. al, 2011; Tucker & Edmondson, 2003). Indeed, SPS is not limited to the right problem to detect and the best solution to take based on root-causes. Standardization or routinization (i.e. systematically incorporating positive changes) also matters for sustainable solutions. Once the fundamental solution is identified and the positive change is implemented as a result of cyclical investigation through (formal) improvement initiatives, there is a lower likelihood that problems recur. Table 3 summarizes SPS adoption in the case-study company.

| High Holding Cost | • **Root-Cause Analysis:**  
  - Warehousing is limited to just counting stocks.  
  - Lack of a plan to store and to move stocks in a structured way (products are not positioned in the right place at the right time). This causes inconsistencies when counting the products and also when sending them out to end-users. |  
| | • **Fundamental Solution:**  
  - Just In Time (JIT) to reduce the high dependency on the warehouse.  
  - The layout manager together with the warehouse manager start attempting to improve the warehouse (spacing and timing).  
  - Inventory management techniques such as LIFO (last in first out) and FIFO (first in first out) are suggested under different conditions. |  
| | • **Positive Change:**  
  - Fundamental proposed solutions are incorporated within production process in form of positive changes (e.g. appropriate stocking becomes routinized and part of warehousing operations). |  
| | • **Operational Performance:**  
  - Problems are fundamentally solved with lower probability to recur.  
  - Lower cost is imposed to the system in the long-term after incorporating the solutions in operational processes. |  
| | • **Positive Change:**  
  - Fundamental proposed solutions are incorporated within production process in form of positive changes (e.g. appropriate stocking becomes routinized and part of warehousing operations). |  
| | • **Operational Performance:**  
  - Problems are fundamentally solved with lower probability to recur.  
  - Lower cost is imposed to the system in the long-term after incorporating the solutions in operational processes. |  

**Characterizing level 3 as a dynamic capability (DC)**

As described earlier, Teece (2007) defines DC as the capacity (1) to sense and shape opportunities and threats, (2) to seize opportunities, and (3) to maintain competitiveness through enhancing, combining, and reconfiguring the business enterprise’s assets. DC is linked to human cognition by Helfat and Peteraf (2015) where managerial dynamic capabilities of sensing, seizing, and reconfiguring are recognized as necessary elements that lead to a change and an amelioration of firm-level performance. Along with this definition, Zollo and Winter (2002) propose DC is “a learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness” (p. 340). In the context of operational problem-solving, to constantly modify and update existing routines and implement positive changes in production processes seem to be substantial characteristics of a DC in order to seek continuous improvement (Eisenhardt & Martin, 2000).
Building on proposed definitions for DC, we claim that just level 3 problem-solving or SPS could be considered as a DC, necessary to achieve sustainable solutions and address continuous improvement. We stipulate that SPS not only highlights the right problem to detect (sensing), and emphasizes a course of actions to appropriately respond to the problem (seizing), but also should lead to the constant modification of operating routines and implementation of positive changes in production processes (reconfiguring). Figure 1 shows that the main activities for SPS match sensing, seizing, and reconfiguring capabilities.

Table 4 - SPS Impediments

<td>Cognitive Bias</td>
<td>SPS Behavioral Impediment</td>
</tr>
</tbody>
</table>
Relying on just previous personal experiences leads to heuristics and shortcuts associated more with irrational sphere of making choices. Firm and its managers mostly care about tangible outcomes (e.g. financial indicators, production capacity and sales). Hence, the attention is moved from problem and its causes to problem symptoms, i.e. IPS.

Problem-solvers mostly adopt level 1 problem-solving or IPS due to an extreme time pressure (e.g. Crisis or customer’s pressure). “Sometimes, we must immediately react to a problem” (Plant manager) as a sense of urgency overtakes comprehensive problem formulation (e.g. to keep the production running). Increasing pressure to front-line employees (e.g. assembly line is over-utilized in some cases; rework) seems to be common to reach the daily production target.

Lack of valid information regarding the problem structure derives problem-solvers to rely just on pre-existing hypotheses to jump to a solution. Although the effectiveness of SPS is well-realized by the plant manager, he claims that “improvement activities are costly”. Without organizational resources (i.e. information, money, and human resources), SPS is less likely to succeed.

Even after emphasizing the improvement-based activities and encouraging team-work, in many cases, errors in shop-floor are rarely reported to the assembly line supervisor. Therefore, problem status becomes hidden and information is not shared across different levels (Still, in some cases, individual problem-solving is dominant rather than team-work). One employee highlights dysfunctional conflicts based on personal relationships during the problem-solving sessions. Participation of lower-level employees is rarely observed (group problem-solving sessions is mostly limited to upper managers sessions). Hence, shop-floor employees as the important problem-solving informants are neglected.

“I only inform my supervisor about a failure when I cannot solve it by my-self” (a front-line employee). One potential reason could be that employees are afraid to be blamed by supervisors. Upper-level managers are responsible for resource allocation, training problem-solvers, encourage team-work and participation of employees, and establish collaborative culture for group problem-solving. Upper-managers also are required to provide an environment where SPS can flourish (i.e. culture for continuous improvement, organizational learning, and change). Lack of attention from top managers for aforementioned tasks prevents level 3 and leads to levels 1 or 2 problem-solving.

Based on insights from the case-study, this study discusses two aggregate themes for the failures of SPS-based programs: (a) behavioral and (b) organizational impediments. We claim that both groups prevent level 3 problem-solving, i.e. lead to level 1 or level 2.
and hence can be considered the major factors by which sustainable problem-solving outcomes are less likely to achieve.

The behavioral theme refers to a cognitive bias of individuals while confronted with problems. Drawing from the idea that humans are cognitive misers, Evans and Stanovich (2013) argue that most of human behavior is controlled by rapid autonomous responses (intuitive mode) unless reflective reasoning (systematic mode) is triggered. This natural and instinctive tendency to jump to solutions limit sensing, seizing, and reconfiguring capabilities of problem-solvers. The sensing capability is limited as problem-solvers focus on a wrong problem that is more likely to recur and hence cannot contribute to sustainable development. Quick recognition of the problem which is not based on adequate problem analysis and employing workarounds based on subjective prior beliefs is a result of the inability of problem-solvers to interpret problem-structure data. Therefore, seizing and reconfiguring capabilities of problem-solvers are distorted, problems cannot be appropriately responded to, and long-term success seems difficult to be achieved.

For the second aggregate theme, organizational impediments, we identify four factors namely (a) time pressure, (b) resources constraints, (c) individual problem-solving and lack of collaborative culture, and (d) insufficient leadership practices.

**Time pressure:** SPS takes time and becomes effective only with a delay (Repenning & Sterman, 2002). When time pressure is high (i.e. either external pressure such as intense competition and customers’ pressure or internal pressure from top managers for “Don’t bring me problems, bring me solutions” type of culture), problem-solvers act as quick satisfiers by just eliminating problem symptoms. Rushing into solutions prevents problem-solvers to get involved in SPS (Tucker et al., 2002) and limit sensing, seizing, and reconfiguring capabilities of problem-solvers.

**Resource constraints:** knowledge-based theory (KBT) proposes that information is the main dimension of SPS (Nickerson & Zenger, 2004). When problem-solvers fail to obtain the relevant information, they just rely on their knowledge on prior successful solutions that are devised according to their personal experience. However, information gathering is costly and requires a considerable investment on organizational resources (Mintzberg et al., 1976). From a DC perspective, identification of a right problem (sensing), making investment to transform it into an opportunity to grow (seizing), and adopting positive changes based on rich information (reconfiguring) seem difficult when either organizational resources (strategic such as information or other resources such as money and human resources) are not available or a firm’s understanding is limited on potential resources to invest on.

**Individual problem-solving:** the problem-solving literature promotes team-work to facilitate SPS (Morrison, 2015). Individual problem-solving, compared to group-problem-solving with heterogeneous team members where a problem could be viewed through multiple perspectives with different cognitive structures of participants, is less effective (Baer et al., 2013). From a DC perspective, when the problem and its structure are not perfectly shared, problem-solvers are less likely to shape a problem as an opportunity to learn from and to employ a course of actions to fundamentally overcome the problem.

**Insufficient leadership practices:** senior executives play the most critical role not only for resource allocation and training problem-solvers, but also to create a supportive context
where SPS can fully flourish. Leaders should emphasize team-work and encourage front-line employees to participate in SPS by making incentives, create commitment, and trigger the culture of continuous improvement, change and learning (Bruccoleri et al., 2019). This type of leadership is known as transformational leadership in the literature (Lopez-Cabrales et al., 2017). Transformational leadership is concerned with the encouragement of SPS adoption through exploring new ideas (sensing), establishing an environment where problem-solvers can formulate the problem faced (seizing), and constantly improving the operational processes (reconfiguring) for the successful SPS adoption.

**Discussion and Conclusion**

First, we demonstrated that not every problem-solving behavior serves as a DC. We illustrate that, among identified levels, level 3 problem solving or SPS could be considered a DC to improve and maintain operational performance over time. The main activities of SPS match sensing, seizing, and reconfiguring capabilities. Problem detection refers to the sensing capability as it includes the detection of a value-creating opportunity or addressing a right problem. Problem-solving activities should focus on the problem that brings value and leads to the opportunity to learn from. Problem formulation (i.e. problem definition, problem analysis, and solution design) emerges as the seizing capability which means to invest on organizational resources to fundamentally respond to the problem. Finally, routinization is recognized as the reconfiguring capability to constantly refine and make positive changes in operating routines of the firm.

Second, we also show that activities for level 1 and level, although helpful for short-term improvement, might undermine level 3 or SPS and usually fail to result in sustainable outcomes. This study also determines two themes as the major reasons of failures for improvement-based activities. One is a behavioral factor that refer to a cognitive bias, i.e. a natural tendency of problem-solvers to jump to a solution. This, indeed, leads to levels 1 and 2 problem-solving with tangible and certain outcomes. The second theme is a set of organizational impediments in particular time pressure, resource constraints, individual problem-solving and lack of collaborative culture, and insufficient leadership practices. We claim that these factors distort sensing, seizing and reconfiguring capabilities of problem-solvers where DC cannot be developed and SPS adoption is less likely to take place or its effect is minimized in long-term.

Implications of production movements on manufacturing firms’ financial performance

Jussi Heikkilä (jussi.heikkila@tuni.fi)
Tampere University

Teemu Laine
Tampere University

Mohammad Moshtari
Tampere University

Abstract

This paper examines the effects of production relocations on manufacturing firms’ financial performance, by employing survey data and financial statement of 229 Finnish manufacturing companies. Comparison groups are built of companies that have relocated their production and those that have not done so. The paper employs information directly from the financial statements to understand real performance implications. It was found that labor intensity is not always related to production movements, and, significantly, companies that relocated their production maintained their profitability better than those that did not do so. This result implies further studies with both theoretical and practical relevance.

Keywords: Production, Relocation, Financial performance, Profitability

Introduction

Manufacturing companies have been actively looking for new manufacturing locations throughout the last decades in their search for lower production costs, new markets and customers, and best capabilities for future success. The importance of manufacturing industries for national economies is significant because of jobs and tax incomes. Therefore, there have been increasing concerns among policy makers to re-attract production that has been moved abroad. Relocation of production has been extensively studied from different perspectives during recent years (the most recent ones being Baraldi et al., 2018; Barbieri et al., 2018; Bailey et al., 2018; Di Mauro et al., 2018; Heikkilä et al., 2018a and 2018b; Johansson et al., 2018). However, there are not many studies available (cf. Stentoft et al., 2018) in which the performance effects of production relocations are directly studied. This study aims to contribute to this research by analyzing the financial implications of production movements. The data used for the analysis combines survey data and financial statement data of 229 Finnish manufacturing companies during the time period of 2010 to 2015.

Several studies examine the objectives and expected benefits of the production
relocation. However, these studies typically exclude the actual outcomes of the relocations from the studies or they use survey instruments to examine perceived performance outcomes. Stentoft et al. (2018) are among the few studies that address the performance outcomes of the production relocations, with their focus on cost performance and operational performance, and also cost accounting capabilities, which can be considered as a prerequisite for anticipating and managing cost-related performance outcomes. Their study was based on Danish survey data which was collected at the same time as our data in Finland, using the same survey instrument.

In order to provide more support to the findings on the production relocation performance, Stentoft et al. (2018) mention use of return on capital employed (ROCE) figures (as averages) from the studied companies. However, they do not report any significant associations or influences of the production relocations to those figures. In other words, as a clear motivation for this study, despite the highlighted need for understanding the production relocation performance, as perceived by the managers or reported as financial performance, the extant literature has not been able to provide evidence on such a link.

Indeed, thorough understanding of the companies and their production relocation cases is required for unveiling production relocation performance, in contrast to similar companies that did not make production relocations. In order to enable such comparison, one has to be careful in designing the research setting accordingly. Wagner (2011) is among the very few who have compared the performances of the relocating and non-relocating firms. He used propensity scoring to establish a sufficient basis for the comparisons. As Wagner (2011) argued, there is no data available about the same companies both relocating and not relocating under the same circumstances, and therefore, one has to find matches of similar companies to enable comparisons. Wagner (2011) reports his analysis on the relocating company characteristics and relocation performance effects in the German context, but the examination in his surveys is limited to the effects on human capital intensity and productivity, with only small or not significant performance effects.

In this study, we argue that understanding the effects of relocation on firm performance would require an extensive analysis of the production relocation decisions, compared with non-relocation and supplemented with an analysis of longitudinal performance data from the financial statements. Such analyses need to be conducted by matching the relocating companies in sufficient detail with those companies that did not relocate their production (Wagner 2011). These analyses would help in unveiling the possible differences between the actual performance outcomes, i.e. the long-term profitability of the companies, in the companies that did make production relocation decisions and those that decided to stay at home. Such possible differences have not been empirically examined, thus outlining the contribution potential of this study.

In order to examine the production relocation performance, it is important to analyze the conditions under which the production relocations could be more likely done. Overall, cost benefits are desired in offshoring decisions, and thus cost accounting capabilities are associated with offshoring, as was found in the study by Stentoft et al. (2018). Such capabilities both enable analyses prior to production relocation and unveil potential for savings and other financial benefits from production relocation. If the cost accounting reveals potential for labor cost savings, this could support production relocation considerations. More broadly, the labor intensity, or human capital intensity, as Wagner (2011) described, could encourage companies to continuously analyze production location and their effects on firm performance and profitability.
**Design/methodology/approach**

The premise for this study is to find an objective view on the performance of companies relocating their production. The following two propositions were addressed, grounded on earlier research:

- Proposition 1: Lower capital intensity (higher labor intensity) supports production movements (cf. Canham and Hamilton, 2013; Dachs et al., 2006).
- Proposition 2: Production movement activity has a positive effect on financial performance (cf. Bertrand, 2011; Jiang et al., 2007; Lu and Beamish, 2001; Massini et al., 2010; Moser et al., 2009; Wagner, 2010).

The empirical analysis consists of two parts. First, the production movement activities were studied using logistic regression. Second, the effects of production movements were analyzed using propensity score method. Two groups were formed to control the influences of the production movements. The first group consisted of companies that had made production movements and the second group was a control group with similar characteristics but with no production movements. The groups were compared for production movement activity and characteristics, financial performance and operational working capital.

The study combined two data sources. The data regarding manufacturing relocations came from a survey consisting of manufacturing offshoring and backshoring by Danish, Finnish and Swedish firms during 2010-2015, collected in the autumn of 2015 (Heikkilä et al., 2018a, Heikkilä et al., 2018b, Johansson et al., 2018). The second data source was the financial statements of all the 229 Finnish firms that responded to the survey, for the years 2010-2015 (six years), providing a view on the evolution of the financial figures.

**Literature on production relocation performance**

Only few articles have studied the actual performance effect of the production relocation (Stentoft et al., 2018). Surprisingly, relocation in general associated with firm performance has not been extensively studied either. Knoben and Oerlemans (2005) analyzed firm relocation research and concluded that research on the effects of the relocation decisions remained scarce, despite the interest in the relocation decisions and their antecedents. More particularly, some research on the relocation outcomes focused on stock prices (e.g. Brandon-Jones et al., 2017), possibly neglecting profitability effects at multiple performance effects on business operations, measured by return on assets and its components, as well as the effects on the innovation possibilities.

Since then, Wagner (2011) has explicitly studied the relocating firm characteristics, as well as the effects of those relocations. Similarly to this study, Wagner also used propensity scores on his survey data, in order to find a comparison group for the relocating companies among those companies that did not relocate their production. In his study on German manufacturers, Wagner (2011) concluded that relocating firms are “larger and more productive, more human capital intensive, and have a higher share of exports in total sales”. Regarding the performance effects of the production relocations, Wagner (2011) focused on the employment and productivity effects of the relocations, and found only small negative effects to the employment and positive effects on the productivity, the latter limited to the companies that had long experience on offshoring relocations. In contrast to Wagner (2011) study, uniquely, this study supplements the survey data with financial statement analyzes, to analyze the effects of relocations to the financial performance of the firms by employing return on assets and its components.

The advantage of this approach is to provide the overall performance effects, neither limited to the effects related to the labor and costs nor to the effects perceived by the survey respondents. Instead, the approach enables the view on the broader competitiveness of the
companies under examination.

*On decision-making and performance*

Overall, managers tend to assume rational decision-making, based on the financial figures and forecasts available. However, financial information often fails in actually supporting decision-making, which may hinder the performance effects of those decisions. Wouters and Verdaasdonk (2002) argue that managers find financial information useful “(1) when they must make a significant, new or rarely taken decision, (2) when they must take new considerations into account, and (3) when operational knowledge is distributed across various people from different parts of the organization”. All these characteristics tend to apply production relocation decisions, which should then benefit from financial information available before the relocation decisions. Indeed, financial information would be needed to understand the decision-making situation and thus support the decision-making process. More particularly, cost accounting capabilities may help making relocations decisions (Stentoft et al., 2018), but it is noteworthy that the companies need to understand if they seek to keep their current performance with the relocation or improve it from certain perspectives. This requires more extensive analyses than cost accounting on the labor-intensive operations, and thus support the choice of analyzing long-term profitability and its trend over time, in contrast to the comparison group.

Bals et al. (2016) outlined a theoretical framework on different options of production relocation decisions. They also highlighted the need for understanding the decision-making processes of production relocation and eventually the performance outcomes of those decisions. In their agenda for further studies, they brought up the distinction between the strategic relocations and reactions to earlier relocation failures. Indeed, seeking for cost savings, for instance, may be in these two cases a remarkably different issue. Besides, they placed an emphasis on the organizational readiness for production relocation decisions (also well beyond the cost accounting capabilities) and the need for examining units of analysis on different levels with respect to the production relocation decisions. In response to this need for understanding production relocation decisions, the present article examines long-term profitability outcomes of the production relocations in contrast to similar companies that did not make production relocations, which provides an overview of the outcomes that could be thus detailed from different perspectives of the framework of Bals et al. (2016).

**Analysis**

Logistic regression analysis is performed to find out if capital intensity is connected with relocation activity. Respondents in our survey research stated that savings in labor costs were the most important reason to offshore (Heikkilä et al., 2018a and 2018b; Johansson et al., 2018). This would imply that labor costs are significant part of companies cost structure and savings in there would be significant enough to justify production movements. Finding out if more labor and less capital-intensive companies move production more often would be in-line with survey results.

Analysis is performed using SPSS binary logistic model. The chosen explanatory variables are total assets to revenue for capital intensity. The financial indicators from the beginning of the examined period (2010) are used. The assumption is that bigger companies and companies in certain types of industries move production more often. Controlling effects of industry and company size is done using control variables from the survey data. Companies answered to which industry their focal plant primary belongs. The industries are classified into a 1-5 scale based on the technology intensity. The total number of employees in companies operationalizes the company size in the analysis.
The production movements are separated into three different analyses. Table 1 presents the sample data for the analyses. The probability for offshoring, backshoring and any production movement are compared to no-movement group of companies. The limit for the sample sizes is often 50 or 100 with minimum observation-to-predictor ratio of 1:10 (Peng et al., 2010). All of the analyses fulfill the criteria of 50 observations with adequate observation-to-predictor ratio. The requirement for logistic regression analysis is that the conditional mean of the binary outcome is binomially distributed (Peng et al., 2010). It is assumed that the production movements are independent of each other, even if it is possible that some companies follow the example of others when making production movements. Thus, the assumption of the binomial distribution is robust (Peng et al., 2010).

</tbody>
</table>

Overall, the prediction of production movement is difficult with the use of logistic regression and the information from the chosen financial measures. The evidence on the effects of labor intensity to production movement activity is not clear (Proposition 1), so the model does not support the survey results. The number of employees and the technology-intensity of a company seem to be relatively good predictors for production movement activities. Companies with higher number of employees and companies in industries with higher technology-intensity seem to move production more often than others do.

**Propensity score analysis for financial performance**

When analyzing effects of production movements, it is not possible to examine the same company with and without production relocations using the same time period. Therefore, companies with production movements are compared to companies with no production movements. The problem is that companies who are active in production movements tend to have certain characteristics more often than others, as was seen in the results for the logistic regression analysis. Bigger companies and companies in higher technology-intensive industries seem to relocate production more often. This often leads into research settings where groups of companies in the comparison are different, and these differences are not controlled for analysis of, e.g., differences in performance.

The situation in which uneven selection of the participation makes the focused group and control group different is called selection bias. In this study, the companies that have moved production tend to be bigger and they are not evenly distributed across industries. The bias rises from the possibility that size and industry type affect the financial performance of companies. To control the effects of industry and size the control group needs to be as similar as possible compared to the focused group of companies, i.e., in our study those companies that have done production movements. To do this, each company that has moved production need to be matched with a similar non-moving company (ideally identical) at the time of production relocation (Caliendo & Kopeinig, 2008).

Production movement companies can be matched to its no-movement pairs by using the propensity score method (PSM). It has become a popular approach to examine effects
in situations where selection bias is a potential problem. Moser et al. (2009) and Wagner (2010) have analyzed the effects of offshoring using PSM and focusing on the effects in employment and productivity.

Taking into account relevant differences between units when selecting the control group can yield an unbiased estimate of the treatment impact. According to Caliendo and Kopeinig (2008), PSM should include the following five steps:

1. Propensity score estimation
2. Choose matching algorithm
3. Check overlap/common support
4. Matching quality/effect estimation
5. Sensitivity analysis

Step 1 includes choosing the propensity score model that calculates probabilities for the units to be selected in the treatment group. When the final purpose of the product is to select a suitable control group, not to estimate accurate structural coefficients, the given models yield similar results (Caliendo & Kopeinig, 2008). In this study, the chosen statistical computing program (SPSS) is used to calculate propensity scores. Variables that affect simultaneously the selection and the outcome should be chosen and only the variables that are unaffected by the participation should be included (Caliendo and Kopeinig, 2008). In this study, the chosen variables are company size (number of employees) and industry (two-digit SI-codes). The attempt is to keep the number of variables as low as possible due to the small sample size and to minimize the variance in propensity scores.

In Step 2, after the estimation of propensity scores, the actual matching of the treated and untreated units takes place. One of the most common and straightforward ways of matching, also used by Wagner (2010) and Moser et al. (2009), is to use the nearest neighbor matching method (Thoemmes 2012). The decisions can be considered as trade-offs between bias and efficiency. In here, due to the relatively small sample size but still sufficient number of untreated control units, one-to-one matching was applied. The caliber shows how far the nearest neighbor is from its treated pair. Increasing caliber adds chance for weaker matches. Increasing caliber causes bias but choosing small caliber can cause units to be excluded from the analysis. Here, the analysis was performed using different calibers to validate the sensitivity of the results.

The purpose of Step 3 is to ensure that for each treated unit a close untreated unit can be found. This is called common support. In a lack of common support, observations can be discarded if the chosen caliber is small, resulting in some regions of the propensity score distribution consisting of only treated or non-treated units. When the number of discarded units is increasing, it raises the question if the remaining units represent the sample well enough.

In Step 4, matching quality is verified by comparing distributions of the selected variables and means of estimated propensity scores. Independent t-test is performed in order to compare the difference between the means of the estimated propensity scores for the production movement and control groups. There should not be found any statistically significant differences in the mean after the matching is done or otherwise the matching quality is inadequate. At this point, it is still possible to go back and try different variables or matching methods. If the matching quality is sufficient, it is possible to calculate average treatment effect on treated (ATT). The treatment effect is here considered as the difference of the arithmetic means using independent t-test. When using matching method without replacement and the amount of discarded units is small, we assume that p-values from the t-test are approximately correct.

The objective of Step 5 is to verify assumptions that all the covariates are taken into
account and the results are not sensitive to discarded units because of lack of common support. The first assumption is strong and difficult to test. The rest of the analysis assume that all of the relevant covariates that affect matching are taken into account. The assumption of common support is tested by including also bigger calibers in matching (if possible) to ensure that discarded units do not significantly affect the results.

*Testing proposition 2 with the propensity score method*

The effects of production relocations were tested for financial effects of any relocation decision (offshoring or backshoring) against companies with no movements. Any production movement group and no-movement groups both had 55 companies in the analysis. Table 2 below shows the distribution of company size for the two groups and Table 3 shows the distribution of industries in the two groups.

</tbody>
</table>
The overall distributions are relatively even for both groups and matching was, therefore, considered successful even with the low number of no movement firms and electrical industry (SI code 27) being over-represented in the any movement group and fabricated metals (SI code 25) and computer, electronic and optical products (SI code 26) being over-represented in the no movement group. Analysis of means of discarded variables in Table 4 support that matching quality is sufficient even for the variables that were left out of the matching. No statistically significant differences between the groups were found, even if any movement companies are bigger in terms of revenue.

Table 5 presents the results for effects of any production movements in terms of profitability and operational working capital. The difference between the comparison groups (ATT value) for change of OROA (4.30 percentage points) imply that any movement group has been able to maintain the profitability much better than the no-movement control group. Therefore, proposition 2 is supported with 5% risk level in one-way testing (p < 0.023). As OROA can be calculated as gross profit multiplied by asset turnover, the relocating firms have performed better especially regarding the profits (income statement).

</table>

The effects in operating working capital are seen in the absolute change of operating working capital (-5.88 %, with no statistical significance) but the effect disappears when the change in revenue is taken into account in the net trade cycle. The change of inventories shows a statistically significant change in the ATT. The results for the change of inventory are more reliable in terms of more companies included in the analysis.

Findings and conclusions
The paper examined the effects of production relocations on manufacturing firms’ financial performance, by employing survey data and financial statement data of 229
Finnish manufacturing companies. Uniquely, the study employed financial information directly based on the financial statements, to understand the overall financial performance implications in a longitudinal manner (2010-2015 in this study).

Regarding proposition 1, the findings of the study suggest that labor intensity does not always predict production movements, although a weak relationship between less capital-intensive companies and production movement activity was identified.

Regarding proposition 2, the most important finding of the study is a positive relationship between the production movement activity and the financial performance. A statistically significant difference of 4.30 percentage points in the change of OROA was found between the comparison groups, especially due to the better maintained gross profits of the relocating companies. Indeed, companies with movement activities were able to maintain their profitability better than companies in the control group with no movements, during a weak economic cycle.

The contribution of the paper lies only partly in the identified effects on the financial performance. Besides, the approach of the paper provides the following benefits to the scholarly discussion in this area, to be further examined and tested in the forthcoming studies:

- The article addresses directly the performance effects of the relocation to provide a operationally solid basis for comparisons.
- This article, quite uniquely, brings up the profitability to the discussion (cf. Stentoft et al., 2018), and can show an effect of the relocation on the profitability, to foster discussion on the actual performance effects of the production movements.
- This article is among the very few articles that is able to compare the effects of the relocation with the companies that did not relocate, with a methodology suggested and used by Wagner (2011).

It is noteworthy that in its analyses on the financial performance effects, this study included long-term profitability and profitability trend in the analysis and was thus able to show the companies’ ability to maintain the profitability (in contrast to non-relocating companies, in response to the challenging economic situation). This is a relevant approach also for the further studies. One should not only focus on the financial performance positive or negative trends in the pure numbers, but the analyses should enable recognizing the possible negative effects of not making any decisions about the production locations.

Finally, production movements are in an important role in the strategy and profitability of manufacturing firms. Investigating more specific mechanisms behind the positive effects offer interesting opportunities for future research. As a limitation, the article, of course, cannot state that maintaining the profitability was only due to the relocation. Instead, relocating companies might be more active also in their other choices and decisions in managing their profitability. Thus, in-depth cases studies are suggested to unveil these dynamics underlying the positive financial performance effects.

Acknowledgements
We gratefully acknowledge the financial support received for this research from Tekes – the Finnish Funding Agency for Innovation, through the research project “Reshoring of Manufacturing (ROaMING): Disruptive Technologies, Business Ecosystems and Performance Information as Key Enablers”. We thank MSc Samuli Kinnunen who supported in collecting and analyzing the data for this research, and all the members of the ROaMING research team.

Abstract:

Ship-Breaking Industry is contributing to the Development of Bangladesh since the 1960s. This research argues that theories of Operations management would help this industry not only to manage in a better way but also to overcome the criticism about this sector around the world. Grounded Theory as the methodology has been adopted with Negotiated Entry into three Ship-breaking Yards. Having analyzed the fictitiously named cases, Hill Model and HW Model emerged instrumental to explain the operations activities of the ship-breaking Industry. This finding may be considered as an extension of the Operations Management theory. Future researches can be directed to the path of Supply chain management, Financing, and recycling of product of ships.

Keywords: Ship-breaking; Operations Management; Circular Economy; Hill Model and HW Model

Background:

Although there has been enough attention on Ship-breaking Industry in Bangladesh by the Environmental activities, Non-governmental organization (NGO), legal practitioners and journalists (Print and Electronic), academic and research attention is relatively inadequate to this growing and important sector of Bangladesh. Ship-breaking industry possesses economic importance and peril to the environment at the same time as previous researchers noted. Most of the ship breaking yards are situated in Sitakund by the side of Bay of Bengal. The location and the availability of cheap labor rate have acted as the biggest competitive advantage to establish itself as one of the biggest ship scrapping market (Zakaria, Ali & Hossain, 2012).

Ship breaking industry has enjoyed subsistent growth over the years in Bangladesh. This industry was found to be the unique source of scraps for small rerolling industries in Bangladesh for years. Their output in 2008 rose to become more than doubled as compared to that in 2005 (Sujauddin et al., 2015). Ship breaking industry helps to meet 60% demand for the raw materials required by the local steel industry. Around 1.5million tons of scrap steel is produced from ship breaking. This contributes to national steel production to 50% and contributes to national steel consumption to as much as 25%. Domestic vessels are mostly made out of steel and equipment from the dismantled ships in Bangladesh (Hossain, Iqbal, Zakaria, 2010). These findings align with the thinking of circular economy which is based on the idea of “the economy being restorative and regenerative” (McDonough & Braungart, 2010). Ship breaking industry also contributes to a huge extent for the national economy. Around 10 billion Taka of import duty, yards tax, and other taxes are earned by the government. Also, the ship breaking industry creates employment for a large number of people (Rabbi & Rahman, 2017). According to the World Bank, around 1.5million new jobs have to be created for the next 20 years (Rahman, 2017).

Disassembling of ship bears great economic value, but grave environmental concerns (Talukder, Fakhruddin & Hossain, 2015). Pollution of environment by emitting toxic materials, being cause of different diseases of the workers, causing death of workers although the most is occurred by the carelessness of the workers- could be stated as the major adverse impacts of ship-breaking in Bangladesh (Rahman, 2017; Jobaid, Khan, Haque & Shawon, 2014; Muhibullah, 2013; Sikder, Bhuiyan, Ghosh & Rabin, 2016).

The Environment Conservation Rules, 1997 requires that each ship breaking yard must develop an environmental management plan. Then a clearance certificate from the Department of the Environment, Ministry of Forest and Environment is required. The new rule states that the exporter has to certify that the ship to be disposed of in Bangladesh has to be environmentally safe. Although it is hard not to pollute the environment around ship breaking yards, the impact on the environment can be minimized by adhering to international conventions (Rabbi & Rahman, 2017).

Though every organization posits various prescriptions to make the ship-breaking industry less detrimental for the environment and people, very less has been talked about how the process of ship-breaking can be carried out complying with the well-proven theories of operations management. This paper particularly focuses on the process choice and infrastructural part of the process of breaking the ship into useful pieces. This research argues that theory and Concepts of Operations management would help this industry not only to manage in a better way and become competitive but also to overcome the criticism about this sector in Bangladesh and around the world.
CHOICE OF FRAMEWORK OF OPERATIONS MANAGEMENT

Skinner’s (1969) idea on manufacturing strategy has been developed and extended by a number of researchers and among them two frameworks have provided ‘real alternative emphasis’ to the original idea (Anderson, Cleveland and Schroeder, 1989:137). One is Terry Hill’s framework (1985) and the other is the Hayes and Wheelwright (1984) stages of developing a manufacturing strategy. Although these models are regarded as classic models, they were chosen because of their relevance to this study. The discussion begins with the Hill framework named the 'Hill Model' and is followed by the Hayes and Wheelwright Model that is titled as the 'HW Model'.

HILL MODEL OF OPERATIONS MANAGEMENT

Terry Hill (1985) gives attention to the strategic and contingency issues of manufacturing policies. He put forward a framework of Manufacturing Strategy (Figure 1). This model is widely recognised both by academicians (Anderson et al., 1989; Adam and Swamidass, 1989; Ward, Leong and Snyder, 1990) and by practitioners (Voss, 1992). There are five steps in this model. These are: Corporate objectives, Marketing strategy, Order winning criteria, Process choice and Infrastructure. This model is relevant to this study because of its special attention to the organisational and HRM issues in developing a manufacturing strategy. The main advantages of this model are: identification of strategic role played by manufacturing, links between the marketing and manufacturing, identification of order winning criteria and the separate steps of developing a manufacturing strategy.

Figure 1: Hill Model of Manufacturing Strategy; Source: Hill (1985:41)

However, there are some weaknesses in this model. First, there is inadequate attention to the implementation of manufacturing strategy. Voss (1990) suggested a three-phase model of manufacturing strategy development. The first phase is equivalent to Hill's first three steps and the second phase is equivalent to Hill's last two steps. The third phase is the implementation. Although implementation is considered as those activities undertaken after setting the strategy, it clearly shows the inadequacy of the Hill Model on the implementation.

Second, there is incomplete consideration of the organisational and human resource management issues. The relationship of these issues with manufacturing strategy has received attention in some studies in the recent past. For example, Misterek and his colleagues (1990) examined the links between manufacturing strategy and organisational culture, Tranfield and his colleagues (1990) examined the relationship between the manufacturing strategy and organisational design. The importance of human resource issues in manufacturing strategy was highlighted by some researchers (for example, Goodridge, 1986; Oliver, 1990; Prabhu, 1990).

Hill (1985:158) believes that all these issues are part of the manufacturing 'infrastructure' that comprises 'the controls, procedures, systems and communications combined with the attitudes,'
Hayes and Wheelwright's (1984) stages model of manufacturing strategy has attracted the attention of academicians and practitioners around the world (e.g. Anderson et al., 1989; Adam and Swamidass, 1989; Ward et al., 1990; Misterek et al., 1990; Schroeder et al., 1992; Mills, Platts and Gregory, 1995). This notional framework has particular relevance to the present research. The HW model has highlighted the progression of developing manufacturing strategy and the present research has adopted a comparative case study on Ship breaking Industry in Bangladesh. Figure 2 shows the HW Model of manufacturing strategy.

### HW Model of Operations Management

**Stage 1: Internally Neutral**  
(Minimise Manufacturing's negative potential)

- External experts are used in making decisions about strategic manufacturing issues.
- Internal management control systems are the primary means for monitoring manufacturing performance.
- Manufacturing is kept flexible and reactive.

**Stage 2: Externally Neutral**  
(Achieve Parity (Neutrality) with competitors)

- "Industry practice" is followed.
- The planning horizon for manufacturing investment decisions is extended to incorporate a single business cycle.
- Capital investment is regarded as the primary means for catching up to competition or achieving a competitive edge.

**Stage 3: Internally Supportive**  
(Provide Credible Support to the Business Strategy)

- Manufacturing investments are screened for consistency with the business strategy.
- Changes in business strategy are automatically translated into manufacturing implications.
- Longer-term manufacturing developments and trends are systematically addressed.

**Stage 4: Externally Supportive**  
(Pursue a Manufacturing-Based Competitive Advantage)

- Efforts are made to anticipate the potential of new manufacturing practices and technologies.
- Manufacturing is centrally involved in major marketing and engineering decisions.
- Long-range programs are pursued in order to acquire capabilities in advance of needs.

The HW model has a number of advantages. These are: it identifies the four roles that manufacturing can play in achieving competitive advantages; it suggests a continuum that contains four stages for developing manufacturing strategy; it highlights the growth and incrementalism for developing manufacturing strategy; it shows the influence of contextual factors, both internal and external, on manufacturing strategy.

However, certain comments can be made on this model. First, it gives inadequate attention to the infrastructural and organisational issues for developing manufacturing strategy. A number of researchers have highlighted the importance of these issues in developing manufacturing strategy. Akkermans and Aken (1991:9) mention that 'so-called "soft" issues like organizational culture, organizational politics and organizational learning are often not seen as essential for the operations manager's job. Yet they constitute the major challenge in developing a successful operations strategy'. Secondly, it appears that the process of implementing manufacturing strategy has received inadequate attention in this model. Although Hayes and Wheelwright (1984:30) believes that the development of a manufacturing strategy is an interactive process of planning and execution, a good number of researchers have highlighted the need for separate research attention to the process of implementing manufacturing strategy (Voss, 1988; Leonard-Barton, 1988; Miller and Hayslip, 1989; Barker, 1990;
Marucheck et al., 1990; Kinnie and Staughton, 1991). Finally, the HW model has considered the corporate and business level of an organisation but did not consider the plant level for developing manufacturing strategy. All these observations on the HW Model will be pursued in this research.

**Method:**
Ship breaking activities appears to be very restrictive and very difficult to get access in to the yard. The main focus of this study is to understand the ship breaking activities. Without having knowledge of how ship breaking activities are taking place, it would be difficult to conceptualize the problem & suggest any advice for the problem. The nature & realities of field indicates the appropriateness of research methodology to be adopted (Denzin 1978; Glaser and Strauss 1967).

Considering this realities, research team decided to adopt naturalistic paradigm (Lincoln and Guba, 1985) for this research. Moreover, in order to get access, the lead researcher had to use official position (Director, Government Bank of Bangladesh). The lead researcher had to visit all three ship yard as a part of a “Negotiated Entry” into the yards. In addition, research team had to explain the academic rationale of this study & this help the research team to establish trust between the owner & researchers. It took more time to apply this approach and access was negotiated and only for academic purposes. The problems associated with gaining access and developing trust are well established in the research methodology literature (Bogdan and Taylor, 1975; Whyte, 1984; Lincoln and Guba, 1985: Johnson, 1975). Then a detail discussion broadens our understanding about the phenomenon of ship breaking activities & becomes difficult to concentrate on one particular area. Based on the observed realities, research team discussed & concentrated on operations management. From ground of ship yard, we gradually move upward, ship broker & finally to the highest level of the relevant authorities of Government of Bangladesh.

The Methodology adopted was qualitative and Grounded theory (Glaser and Strauss, 1967) approach. On Grounded theory, Discussion meeting, Observations, Open ended questions, access to the documents and recording some the discussion and allowed to take photo of work activities. Once the owner trust the research team, everything become open and very elaborate and the meeting times of 10 minute becomes 2 hours. The nature of ship –breaking activities in the Yard indicates the Grounded Theory Methodology is appropriate in this research (Rahman, 2016). The duration of this research project is about six months from July 2018 to December 2018. Three field visits took place during this period. After the successful key informant interviews, the research team reviewed necessary documents and found out the parameters on which the comparisons among the three shipyards can be made.

*The Naturalistic Paradigm:*
The naturalistic paradigm is the alternative way of understanding the organisation from the social perspective. Its focus is to get insights into the social processes of an organisation. A number of researchers have highlighted the theoretical and substantive dimension of the naturalistic paradigm (Bogdan and Taylor, 1975; Lincoln and Guba, 1985; Denzin, 1978; Morgan and Smircich, 1980; Walker, 1985; Reason, 1988). Its main assumptions are: multiple realities, interaction between the researcher and subject, generating hypothesis, use of qualitative research techniques such as observation, in-depth open-ended interviewing, ethnography, holistic view of the organisation and the subjective interpretation of the experience. As Walker (1985:13) mentions 'there can be no absolute objectivity but only agreements on truth and validity shared by people who hold the same meaning'.

*The Grounded Theory:*
Glaser & Strauss (1967) mentioned in their classic book on “The Discovery of grounded Theory” that in order to understand the realities, an inductive research methodology in particular 'Grounded theory Approach' (Glaser and Strauss, 1967) has been deployed. This method is appropriate because some of the theories are 'too remote or abstract to offer much detailed guidance and assistance' (Martin and Turner, 1986:142). On Grounded theory Glaser and Strauss (1967:6) mention that "Generating a theory from data means that most hypothesis and concepts not only come from the data, but are systematically worked out in relation to the data during the course of research". Turner (1983) has applied grounded theory approach in the organisational behaviour area. On the use of this research approach in organisational research, Martin and Turner (1986:143) mention that "An emerging
grounded theory primarily justifies itself by providing a detailed and carefully crafted account of the area under investigation. The theoretical account not only aids the investigator's understanding, but provides a means of communicating findings to those in the area studied, either as a basis for discussion or as a vehicle for implementing change”.

Furthermore, it is almost established phenomenon that use of voice-recorder during interview greatly beneficial for the researcher (Whyte, 1984). Lead author of this paper has used voice-recorder elsewhere to conducting a field work (Rashid, 1997). Now-a-days, with the development of technology, in many organisations' videos is being used to examine the movement of people and parts within the studied area. Video can provide the details of movement along with the descriptions though it is very expansive mechanism. It can provide an insight into the shipbreaking processes of an organisation without physically visiting that particular plant. Moreover, observation and document review technique of data collection were used to study the ship-breaking in the yard. All the collected data were systematically analysed to make sense about the ship-breaking activities. On the basis of field work, this framework has been developed.

**Framework Emerged from Fieldwork**

**International:** International Maritime Organization (IMO), Basel Convention-1989, United Nations, Hong Kong Convention 2009- European Ship.

**National:** Bangladesh Bank, Bangladesh Government, NGO, GOB, Environmental activities, Legal aspect, Tax, Ministry of Shipping, ministry of Environment, Ministry of Commerce, Ministry of Industry.

**Apex Body:** Bangladesh Ship Breaking Recycling Association (BSBRA).

**Plant Level:**

```
| Ship Selling | Ship Breaking | Ship Recycling | Customer |
```

```
| Structure | Infrastructure |
```

**Source:** The Authors

**Interview:**

Interview is one of the important techniques for collecting data (Yin, 1984). It may take various forms and can be placed on a continuum with unstructured interviews at the one end the semi-structured interview in the middle and the structured interview at the end (Berg, 1989; Robson, 1993). The unstructured interview is free from scheduling of questions but controlled through the researcher's interview framework (Burgess, 1982). It may be used to validate the observation and also to develop trust with the key informants. The semi-structured interview comprises pre-determined lists of questions using the words familiar to the subject. It allows the researcher to understand the subject's view and this can be accomplished through the unscheduled queries that arise during the interview process. The structured interview is the fixed schedule of questions developed by the researcher. It may be used to validate researchers 'ideas about the subjects' actions (Berg, 1989; 16).

The researcher was allowed to use a voice-recorder during the interviews. It is a symbol of a high level of trust (Whyte, 1984) in the researcher. The length of interview varied from manager to manager and also between levels of managers. The average length of recorded interview was one and one quarter of an hour.
The Document Review:

The document review is another technique of collecting data. It is an acceptable technique in qualitative research (Marshall and Rossman, 1995; Lincoln and Guba, 1985). This technique may be used to get information on the historical background of the field, to broaden understanding about the nature of the business, and also to validate the observation. In addition, it can be used to resolve differences of opinion that are generated through the interview. The documented sources can also help to reconstruct the past activities. The documents are classified into two categories such as primary and secondary (Yin, 1984). The primary document is a document on which decisions are taken and most often it contains financial and personal information.

Comparative Case Study:

Turning to the comparative case study, a large number of researchers have used this method. This method helps to develop a new theory or a model (Walton and Susman, 1987) and also provides the opportunity to test findings of one case against other cases (Leonard-Barton, 1988). It reveals that multiple data collection techniques, such as observation, interview and document review, have been commonly used in comparative case studies. Wilkinson (1983) is the exception who has provided a detailed description of research method and also pointed out some of the problems relating to the access to some of the sources. The review of comparative case studies reveals that time frame has not been considered. The main advantages of this method are that it provides the basis for comparison of data and also the opportunity to demonstrate the similarity and differences of the findings (Voss, 1992). The main disadvantages of this method are that it fails to capture the process of change and also the depth of all the cases may not be the same. Level of access to the data sources in all the studied cases may vary. In addition, this method requires more funding than a single case study.

Brief Case Descriptions:

In order to maintain the anonymity as agreed with the owner of shipyard, Case-1, Case-2 and Case-3 has been used. Moreover, all case materials have been presented in a tabular form instead of descriptive format.

Case -1 is a small Yard and mostly manual system operating system. Yard appears to be not well structured. In the process of breaking a ship, it was identified that there are some hazardous materials inside the ship and overall quality of the ship was poor. Cleaning the hazardous materials from the ship was difficult task and took long time, although there was no major accident. As a result owner has failed to pay bank loan on time and become bank defaulter. Owner has to close down the yard.

Case-2 is a medium sized yard. This yard is primarily manual system with some automated equipment. This yard is in running condition but no attention to improve and follow the compliance issues. International price fluctuations put this yard in a losing condition. Moreover, big tidal wave has put huge raw materials into the sand. Taking out all those material and selling is a very difficult and long term task. Little employee accommodation was found.

Case-3 is a medium sized yard and growing at a faster rate. This yard is a mix of manual and automated. This Yard is following all the rules and regulations of the Government of Bangladesh. Moreover, new automated structure will be developed soon to satisfy international compliance. Regarding employees separated multistoried dormitories with all facilities has been developed. This Yard is operating round the year.

DISCUSSION AND IMPLICATION:
Ship breaking industries in Bangladesh started its voyage in Bangladesh in 1960s when Chittagong Steel House brought and scrapped “MD Alpine”, a cyclone-struck ship stranded in the shores of Sitakund, Chittagong (Hossain, Iqbal & Zakaria, 2010). In 2014-15, there were around 150 registered ship breaking yards, some of which has a capacity of scrapping 4 ships simultaneously. A significant number of ship breaking yards are ISO and other quality management certified, and many others have applied for it (Shameem, 2012). According to Greenpeace (2005), cheap labor cost, frail environmental regulations and weak safety issues are the main reasons behind pursuing ship breaking in Bangladesh. In 2015, there were around 80 companies were operating, with around 200000 workers working in this industry (Dunn, 2015). Maximum numbers of ships are scrapped in Chittagong,
Bangladesh and Alang-Sosiya, India. These are also known as capitals of the ship breaking. However, they are also known as sacrifice zones or toxic hot spots (Steve, 2010). The sub-continental ship breaking yards use beaching method for disassembling ships, as this region has huge tidal range and extensive mudflats (Pasha, Mahmood, Rahman, Hasnat, 2012). Bangladeshi ship breaking yards are not different from this. The ships are cut at small pieces using gas cutting. Bangladesh recently has scrapped some of the biggest deactivated ships of the world. Bangladesh scrapped around 30% of the world’s LDT from 2000 to 2010. According to www.shipbreakingbd.info, Bangladesh held the first position in scrapping the highest number of ships from 2004-2009, and still holds a top position in ranking.

From the comparative case study, it can be easily extracted that the yard with automated structure is growing rapidly in terms of business volume. This very yard, namely KRSY, is providing better facilities for the employees and has a First-aid room with enough equipment. KRSY operates its business round the year with activities more regular compared to its counterparts. Moreover, KRSY is resistant to the volatility of International Market Price of Steel and not a loan defaulter. KRSY conforms more to the theories of operations management i.e. Hill’s Model and HW Model than the other yards. Thus the general conclusion can be drawn that the yard which breaches itself more to the theories of operations management, will enjoy more success than others who remain far from the textbook operations theory.

On the basis of this study, the government of Bangladesh is financially benefited by getting tax and socially this industry will be contributing for the infrastructure development of the country. Theoretical implications are that Terry Hill (1985) model and Hayes and Wheelwright (1984) Model can help to explain the development of ship breaking industry of Bangladesh. Practically, the managers can get better insights by using these two models for their work and can also satisfy international compliance relating to this industry. At a higher level, this study contributes to the theory of circular economy.

Abstract

Operations strategy deals with tasks that manufacturing function has at the strategic level. Our purpose was to answer a classical question in a novel way: How corporate strategy can be translated into implications and terminology that are meaningful to manufacturing? A qualitative research perspective was followed, prompting to emerging results that follow an inductive approach. A Colombian manufacturing company participated in this project. OS representation was proposed by the participants through an “Operational Excellence Tree” to answer de question. We found that this novel result could be called bio-inspired solution and bio-inspired strategies is a good opportunity for further research.

Keywords: Operations strategy, bio-inspired strategy.

The knowledge gap and research question

This investigation contributes to research in operations strategy field. Operations strategy (OS) deals with tasks that manufacturing function has to fulfill in order to meet current and future challenges of the company (Slack and Lewis, 2011). According with Hayes and Wheelwright (1984, p. 398), companies that provide significant and credible support to their overall competitive strategy: “Translate the business strategy into implications and terminology that are meaningful to manufacturing”. How to do it is a classical problem that remain open in the literature (Vivares, 2017) because there is not a universal OS that is good for all the companies (Miltenburg, 2009).

To verify the knowledge gap around this topics, a systematic review was performed (Bartels, 2013; Kitchenham, 2004). 395 references were found using two search equations. After their analysis, it can be concluded that there is a novel contribution to answer the following research question:

How corporate strategy can be translated into implications and terminology that are meaningful to manufacturing?
**Design/methodology/approach**

A qualitative research perspective was followed, prompting to emerging results that follow an inductive approach. An action research (AR) process was carried out to answer the research question. AR should contribute both to academic and practical fields (Avella and Alfaro, 2014). AR can be considered experimental research (Styhre and Sundgren, 2005). In this investigation, the experiment can be described as follows: 1) designing a procedure to guide the discussion required to answer the research question; 2) application of the procedure, and, 3) evaluation of results to validate the contribution to the OS.

A Colombian manufacturing company participated in this project. A group of 14 employees related to the production system administration participated in a workshop aimed at providing the structural bases to translate the company corporate strategy (CS) into the OS. The workshop followed the procedure in Figure 1, using open questions and discussion among the participants.

![Figure 1- General procedure to identify the structural bases of OS](attachment:image)

Question [1] was related to the company strategic needs. Questions [2], [3] and [4] were oriented on guiding the participants towards understanding the importance of translating the CS into OS, and question [5] on how to do it. Finally, the question [6] aims to define the specific application in the company.

**Findings**

As an emergent result from the process a bio-inspired solution was proposed by the participants. Specifically, OS representation was proposed through an “Operational Excellence Tree” (Figure 2), which contains the precise terminology for the company OS.
Analog to the biological process, the roots support the whole tree and keep it erected, while absorbing water and nutrients from the soil, as OS is supported and nurtured by principles. The trunk holds the crown and keeps it firm, so, it allows connecting the OS with the company business strategies (BS). Branches represent each of the different BS, which helps to provide the fruits expected by the CS. Finally, sap circulates through the entire tree, being defined, in this case, as a renovating and revitalizing energy that keeps people motivated inside the company.

To test the suitability of the resulting tree as a tool to translate CS into OS, the workshop participants and the company management team were asked separately (Table 1), obtaining a high level of agreement and good acceptance by the management.

Discussion
A bio-inspired approach to OS alignment with CS and BS was obtained to answer the research question, specifically by analyzing the behavior of the trees. According to Vivares et al. (2018, p.1): “Bioinspiration is to solve problems taking lessons inspired by the behaviors of nature”. The systematic literature review performed allowed us to confirm novelty of this approach since few articles were found regarding bio-inspired strategies, and none of them studied the problem addressed in this research.

From the reviewed works in the state of the art, some works have made bio-inspired contributions. For example, Peralta et al. (2017) presented a bio-inspired framework for sustainable fractal manufacturing, Kuznetsova et al. (2016) adopted the concept of industrial symbiosis to improve an Eco Industrial Park performance, while McCullar et al. (2016) propose bio-inspired design as a strategy to enhance sustainable products development. However, none of these contributions are however related to OS or CS.

For this reason, we state a novel hypothesis for further research:

*Bio-inspired solutions are meaningful to translate corporate strategy into OS implications and terminology.*

Furthermore, the aforementioned reasons suggest a more extensive field for research: bio-inspired strategies or bio-inspired management. This is a kind of framework in which we have an entrepreneurial problems and researchers can look for lessons from the behaviors of the nature to solve them. This approach has been used in other sciences but is not used yet in the OS field.

Conclusion
A bio-inspired approach to OS alignment with CS and BS was obtained to answer the research question, specifically by analyzing the behavior of the trees. The systematic literature review performed allowed us to confirm novelty of this approach since few articles were found regarding bio-inspired strategies, and none of them studied the problem addressed in this research. From a practice perspective, the proposed approach was well evaluated, and accepted by the company as a valuable contribution to translate CS into OS, in a didactic and easily understandable way to all levels of the workforce. Action research was a useful paradigm.

Abstract

This paper investigated the role of the absorptive capacity and management cost control in the relationship between operational capabilities and business performance. We conducted a survey in the automotive and food industry and ran a structural equation modeling as analysis method. We found that different nature of operational capability impact on different type of performance. Additionally, we found that traditionally advocated benefits of management cost control on performance is mediated by operational cost efficiency. Finally, our results suggest investigations of some other potential capabilities that could mediate the absorptive capacity and performance.

Keywords: Capabilities, performance, practices

Introduction

The relationship between organizational capabilities and performance has been a lot studied, however, there are still plenty more to be done since this relationship could be analyzed from different dimensions of the performance (Kafetzopoulos et al., 2014). In addition, different assumptions while building the theoretical mechanism relating capabilities to performance also made this topic still open for research. For some scholars, operational capabilities are antecedents of performance (Wu et al., 2010), while others suggest differently (Jansen et al., 2005; Fosfuri and Tribó, 2008).

Schroeder and colleagues (2002) advocated that operational capabilities are positively related to manufacturing performance when incorporating both external and internal learning. Therefore, we started our study by adopting a similar rationale. In our manuscript, we operationalized information and knowledge acquisition and incorporation as absorptive capacity (Zahra & George, 2002).
Based on the literature of management control and practiced based view (Bromiley & Rau, 2016; Chenhall, 2003), we hypothesize that management control process might mediate the relationship between absorptive capacity and operational capabilities. Then, the latter might manifest on business performance. Among several operational capabilities, we explored the flexibility and operational cost efficiency and we adopted both financial and non-financial performance (Tatikonda & Montoya-Weiss, 2001)

From our results, we reinforced some of the existing studies about operational capabilities and performance. However, our results also suggested some controversial insights regarding the antecedents of these capabilities and the role of managerial cost control with performance.

Our research aimed to contribute in three big points. First, to improve the understanding of the impact of operational capabilities on the business performance. Second, to determine impact of absorptive capacity on the business performance and operational capability development. Third, to evaluate the role of managerial control on business performance and capabilities development.

Next, this work is structured in the following way: in section two we present a literature review on capabilities, absorptive capacity and management control. In section three, we described the research methodology. In section four, we present and discuss the results. And in section five, we conclude the paper.

Theoretical background
Capabilities
The study of the company's capabilities is a recurrent theme in the operations literature, as well as in strategy. The definition of capability is still a subject of study due to the profusion of is meanings and the most recurring conceptualization of capabilities relies on ideas of resources, routines, and skills. Pandža et al., (2003) and Amit and Schoemaker (1993) defined the capabilities as the idiosyncratic processes arising from tangible or intangible knowledge developed through the interrelationship of company resources and history. More specifically, some other authors suggested that capability is as bundle of the repetitive organizational routines and procedures and it represents a pattern of an organization behavior to solver problem and achieve a certain pre-defined goals (Dosi et al., 2000; Winter, 2003; Ray et al., 2004; Peng et al., 2008). Wu et al., (2010) propose capability as a set of skills, processes, and routines aiming at the alignment of resources in response to specific problems. These routines represent the strength or proficiency of a set of skills and competencies to manage resources for task execution.

Flexibility, cost efficiency and performance
There are several types of organizational capabilities, such as production, logistics, R&D, continuous improvement, project management, among others (Schmenner and Vastag, 2006). In the literature, the capabilities are often used as synonyms of how well organizations is performing in cost, quality, flexibility, deliveries (Ferdows and De Meyer, 1990; Flynn and Flynn, 2004; Rosenzweig and Roth, 2004; Schroeder et al., 2011; Skinner, 1969), or "environmental protection" (Avella and Vázquez-Bustelo, 2010).

By studying capability and performance, Swink et al. (2005) observed that cost efficiency and flexibility influence business performance through strategic integration of operational processes. However, some other studies demonstrated cost efficiency and flexibility might not impact in the same manner on all the business performance. For example, Rosenzweig, Roth, and Dean (2003) have argued that process flexibility has a positive influence on customer satisfaction, but did not confirm the same impact on sales.
As for the leadership in cost, they observed a positive relationship in sales, but did not ratify the same direction in customer satisfaction.

By turning the attention to the capability of cost efficiency, it is almost straightforward to infer that this capability is positively related to the organizational performance (Peteraf and Barney, 2003). Thus, while observing the role of cost efficiency in the supply chain, we can infer that cost efficiency creates values, but the value generated could be appropriated either by the supplier or by the customer depending on the power of these agents in the chain (Brandenburger and Stuart, 1996). Therefore, based on the rationales above, we declare the following hypotheses:

**H1:** Operational capabilities have a positive relationship with business performance.
- **H1a:** Cost efficiency has a positive relationship with financial performance.
- **H1b:** Cost efficiency has a positive relationship with customer satisfaction.
- **H1c:** Process flexibility has a positive relationship with financial performance.
- **H1d:** Process flexibility has a positive relationship with customer satisfaction.

**Absorptive capacity**

The seminal articles by Cohen and Levinthal (1989, 1990, 1994) described that the prior knowledge and relevant skills of a company are those that enable the assimilation of new knowledge and, in a way, do things in other configurations. In order to express this ability, Cohen and Levinthal (1989, 1990, 1994) proposed the term absorptive capacity (AC), which represents the ability of a company to recognize the value of new information and then to assimilate it and apply it for business purposes.

Based on the similar rationale, Zahra and George (2002) emphasized the dynamic aspect of this capacity and advocated that AC corresponds to the set of routines and processes of the company, which allows the acquisition, assimilation, transformation, and exploitation of external knowledge aiming to the generation of a dynamic organizational competence. Narasimhan, Rajiv, and Dutta (2006) also corroborate the dynamism of AC. These authors suggest that the process of absorption of know-how is essentially one of the most valued and uses a series of knowledge assets, which are sometimes not structured.

To better structure the AC as organizational routine, Tu et al., (2006) suggested AC as a set of organizational mechanisms that enable the identification, communication, and assimilation of relevant external and internal knowledge. They suggest four dimensions of AC such as relevant prior knowledge, communications network, communications climate, and exploration. By noting the dependency of the new knowledge on the previous one, Tsai (2013) emphasized on the cumulative characteristic of AC, then on the routines of prolonged process of accumulation of investment and knowledge.

**Potential and realized absorptive capacity**

Zahra and George (2002) proposed two complementary dimensions of AC: (a) Potential Absorptive Capacity (PAC) that is based on acquisition and assimilation; (b) Realized Absorptive Capacity (RAC) based on transformation and exploitation. According to these authors, these two dimensions when properly managed, companies might experience superior performance, since it can change and reshape the base of the resource to fit to the market demand.

According to Zahra and George (2002), PAC provides the company’s flexibility and freedom to adapt quickly to the environment. This capacity provides an increase in the company’s ability to exploit the relevant external information (Fosfuri and Tribó, 2008). However, Jansen et al., (2005) also suggest when the firm focuses on PAC, it continually refined the knowledge stock, but increases its costs in order to reach a new level of...
learning, therefore the decreasing its marginal contribution to performance (Brettel et al., 2011).

On the other hand, some studies suggested that RAC is the primary source of performance improvements, which means when the company focuses on RAC, it tends to make a profit in the short term (Jansen et al., 2005). RAC captures the new insights and results from the combination of current and newly acquired knowledge in operations and employ it to improve the organizational practices, routines and capabilities (Leal-Rodríguez et al., 2014). In other words, it represents the capacity to leverage acquired knowledge and transform it into innovation results (Zahra and George, 2002; Fosfuri and Tribó, 2008). According to Zahra and George (2002), these two subcategories (PAC and RAC) have complementary roles. Considering the discussion pointed out in the literature, we declare the following hypotheses:

H2: Absorptive capacity is positively related to organizational practices and capabilities;
   H2a: Absorptive capacity is positively related to cost management control of the organization;
   H2b: Absorptive capacity is positively related to cost efficiency capacity of the organization;
   H2c: Absorptive capacity is positively related to flexibility capacity of the organization;

H3: Absorptive capacity is positively related to organizational performance
   H3a: Absorptive capacity is positively related to financial performance
   H3b: Absorptive capacity is positively related to customer satisfaction

Management control system – Cost control
The literature defines management control system (MCS) as the control process in which companies execute to implement and support their business strategies (Otley, 1994; Simons, 1994; Langfield-Smith, 1997). Therefore, we could infer that MCS has a close relationship with performance.

Similar to organizational capabilities, MCS could also be seen as routines and procedures to maintain or adjust the organizational activities, such as planning, budgeting, cost control, environmental analysis, competitive process analysis, performance evaluation, resource allocation, and incentives (Simons, 1987). Moreover, Henri (2006) understands that MCS acts as an antecedent of the organizational capabilities, that is, it represents the mechanism of influence of the company's competencies. In this sense, Henri (2006) suggests that the MCS impacts, through the diagnostic and interactive tools, on the generation and maintenance of organizational capabilities. Following this line of reasoning, it is observed that the literature presents evidence of the positive influence of the management control tools on capabilities and performance (Govindarajan and Gupta, 1985; Marginson, 2002; Chenhall, 2003; Nisiyama et al., 2016).

Additionally, Merchant and Otley (2007) advocated that the control systems is a broad process that comprises the strategic development, strategic controls, and learning processes. These controls contribute to achieving organizational goals, consequently, impacting positively on organizational performance.

Malmi and Brown (2008) when analyzing MCS as a package of managerial artefacts, they argue that these artefacts can contribute to the understanding of how the definition of control systems can support organizational activities. In a complementary manner, Chenhall (2003) points out that the control systems are more related to the set of activities inherent to the processes, for example, statistical quality control, just-in-time system,
among others. Consistent with this view, (van Veen-Dirks, 2005) argues that management accounting and the control system support managerial behavior to meet the production strategy.

Based on this rational, we suggest that:

\[ H4: \text{The cost control has a positive relationship with operational cost efficiency.} \]

From another perspective, the cost control could be seen as a set of processes that is part of the MCS that aims to identify, control and reduce the organizational expenses based on a given budget (Langfield-Smith, 1997). Therefore, in several occasions, it is possible to observe a positive impact of this managerial tools on business performance measures captured by ROI, ROA, market share, among others (Ketokivi and Schroeder, 2004).

However, by observing the supply chain configuration, the bargaining power of the customer and/or supplier could impact severely on the business performance of the focal firm (Porter, 1992). Therefore, we could expect that even having a significant cost control process in the organization, if the supplier and/or the customer has a greater bargain power than the focal firm, then, the value created might be appropriated by these other agents, consequently not manifesting on the focal firm’s performance. In other words, the cost control is a sine qua non condition for the firm to compete; consequently, Thus, we declare the following hypotheses:

\[ H5a: \text{The cost control does not impact on the financial performance for companies in the industries that suppliers normally have greater bargain power than the focal firms.} \]

\[ H5b: \text{The cost control has a positive relationship with customer satisfaction for companies in the industries that suppliers normally have greater bargain power than the focal firms.} \]

The figure 1 could summarize our theoretical discussions and hypothesis.

**Survey Methodology**

We designed our questionnaire by adapting from existing literature in operational capabilities, absorptive capacity, management control and performance. The questionnaire was first designed in English, then translated to Portuguese. The
questionnaire was first assessed by academics and practitioners to correct problems concerning distortions (problems with assertive, lack of objectivity, among others). They suggested small corrections that were done for the final questionnaire. After that, we ran a pre-test with a small sample from the target industries, and we found no major issues.

The questionnaire has four main blocks. The first block collected data regarding the operational capabilities (cost efficiency and process flexibility). The second block gathered the info concerning management control (cost control). The third block aims to evaluate the absorptive capacity (potential absorptive and realized absorptive capacity). And finally, the fourth block seeks to assess business performance (financial performance and customer satisfaction).

We conducted our study in São Paulo (Brazil) from April to December 2017. We successfully contacted 387 firms from a random sample of 449 companies of the National Association of Auto Parts Manufacturers and 924 companies of Brazilian Association of Food Industries. From those contacted companies, 299 accessed the questionnaire, and we obtained 161 valid answers (81 food sector, 61 auto parts, 19 did not indicated the sector). As part of common method variance mitigation strategy, we maintained the confidentiality of the respondents and companies’ names.

Variables description

Operational capability – Cost efficiency
We used two 7-points scale items to assess it where we asked respondents to indicate how cost-efficient operational practices are executed in the organization. From the scale, the higher the rating, the more intensive are the practices in the company. The three items were adapted from Boyer and McDermott (1999) and Swink et al. (2005).

Operational capability – Process flexibility
We used four 7-points scales items to assess it where we asked respondents to indicate how flexible operational practices are executed in the organization. The higher the rating, the more intensive are those practices in the company. The questions were based on the existing studies of Boyer and McDermott (1999), Machuca and Álvarez-Gil (2003) and Rosenzweig et al., (2003).

Absorptive capacity
This variable was measured as second order latent variable that was composed by the Potential absorptive capacity and Realized absorptive capacity. This first dimension was measured by three 7-points scale items based on the study of Leal-Rodriguez et al (2014) and Jansen et al. (2005). The latter was also based on the same literature and it was measured with five 7-points scale items.

Performance
The literature characterizes the performance as multidimensional construct (Kafetzopoulos and Gotzamani, 2014) and it could be analyzed from financial and non-financial measures (Kaplan and Norton, 1992, 2001, 2007, van Veen-Dirks, 2005, 2010). A set of dimensions to measure the performance could be used such as return on investment (ROI), profitability, sales, market share, contribution to technological leadership, contribution to the retention of employees, and the degree of customer satisfaction. From this perspective, our study assessed the business performance construct based on two dimensions: customer satisfaction and financial performance.

Financial performance
This variable is measured by four self-evaluated items where we asked respondents to rate how the company performed in the last fiscal year in each of the financial dimensions. We employed a 7-point scale where higher the rating, better the performance. These items were based on the existing studies of Tatikonda and Montoya-Weiss (2001), Swink et al. (2005).

**Customer satisfaction**

This variable was based on the study of Shenhar et al., (1997). We used four items to assess it where we asked respondents to indicate how the company positions itself about its customer satisfaction. We employed a 7-point scale where the higher the rating, the higher is the customer satisfaction.

**Measurement and construct validation**

We performed the confirmatory factor analysis to assess the reliability and validity of our variables. All the constructs demonstrated reliable (CR>0.7; AVE>0.5) and discriminant validity (square root of AVE > correlations of each pair of variables – See Table 1). Our CFA model demonstrated a regular fit given the sample size (χ²=476.89; DF=282; p-value=0.000; CFI=0.913, RMSEA = 0.067) (Hair et al., 2014, p. 584). Regarding the common method variance, we assessed its impact using unmeasured latent method factor (Podsakoff et al., 2012). This common method factor is equally loaded on all the observed variable. Then we computed the chi-square difference between the CFA model and the common method variance method and no statistically difference was found between the both models (p=0.16). Therefore, we inferred that the common method variance is not a concern in our study. However, for our hypothesis assessment, we computed the composites using the factor scores obtained from the CFA model with the unmeasured common latent factor. Hence, our composites could be considered as been common method variance adjusted. To assess our hypothesis, we ran the structural equation modelling (SEM) using the composite calculated previously.

**Results and discussions**

By observing the significant regression coefficients in the Table 2, we noted that absorptive capacity is necessary to develop operational capability, more specifically, the process flexibility. The absorptive capacity is also positively related to the management cost control process, which supports our hypothesis H2a. The absence of the relationship between absorptive capacity suggests this direct relationship might be mediated by the management cost control.

Surprisingly, observing the effects of our variables on the business performance, we could note that the management cost control process did not impact on the performance, which is counter intuitive. According to the literature mentioned in the theoretical section, the management cost control impacts positively on the performance, however,
the absence of direct effect on financial performance suggested in the H5a is supported, and could be caused by the bargain power of the customers. However, the absence of effect on customer satisfaction did not support the hypothesis H5b. The impact of management cost control process on financial performance seems to be mediated by operational capability, more specifically, the cost efficiency capability. This finding suggested that by practicing cost control process, it will not necessarily manifest in performance, but it will impact positively if it develops cost efficiency capability, consequently, on the performance. This rationale could be support by the concept of cumulative capability (Ferdows & De Meyer, 1990) and support our hypothesis H4.

We observed that different nature of operational capabilities can impact on business performance in a different manner. While flexibility is positively related to customer satisfaction, operational cost efficiency affected positively on financial. This finding suggested that industries that suffer cost reduction pressure such as food and auto parts, the operational cost efficiency might be necessary but not enough to satisfy the customers (Spring & Boaden, 1997). We also noted that absorptive capacity is positively impacting on financial performance, this result support our hypothesis H3a, but not the H3b.

**Final considerations**

Managerially, we demonstrated that effect of management cost control process on process might be mediated by the capacity of operational cost efficiency. This finding made us believe that simply implementing the cost control process will not improve the business performance, unless, this control process develops the cost efficiency capacity. If the organizational objective is the long-lasting operational cost efficiency, then sand cone model might be considered.

Theoretically, we contributed by demonstrating the different operational capabilities can bring different type of contribution to the business performance and the role of absorptive capacity as antecedent of these capabilities.

Our results suggested that absorptive capacity could improve the flexibility capability of the company, since, this capacity could reconfigure the company and adapt it to the external environment. However, to exploit the company, the effect of the learning on cost efficiency capacity is mediated by the management cost control.

Our study did not fully and exhaustively explore the effect of absorptive capacity on performance. We found that there is a direct relationship between these two concepts, hence suggesting that there might be some other capability that could mediate the learning towards the business performance. We also suggest studies using other industries, since we focused on two ones that are known by great customer bargain power.

Abstract

Nowadays, manufacturing companies have been facing a complex phenomenon of technological advance, often named Industry 4.0, that is reshaping companies’ strategy and organization, products and services, supply chains and operations. At the best of our knowledge, the academical panorama lacks an exhaustive literature review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems. Accordingly, this paper carries out a systematic literature review with the aim of mapping the publications and systematizing the often-fragmented literature on this field to propose directions of future inquire that could inspire scholars and support practitioners.

Keywords: Digital Strategy, Digital Transformation, Literature Review, Industry 4.0

Introduction

Nowadays technologies progress like a dense avalanche of advancements pouring into the environment (Brynjolfsson and McAfee, 2014). The rhythm of growth has been exponentially hastening in recent times indeed, and this has been provoking shocks in the realm of management (Westerman et al., 2014; Brynjolfsson and McAfee, 2017; Venkatraman, 2017). This complex phenomenon, often named Fourth Industrial Revolution or Industry 4.0, is reshaping companies’ strategy and organization, products and services, supply chains and operations (Porter & Heppelmann, 2014). The concept of Industry 4.0 (I4.0) was initially introduced in Germany in 2011 (Lu, 2017), referring to the integration of physical objects, human actors, intelligent machines, production lines and processes across organizational boundaries, with the aim of realizing a system in which all the processes are integrated and information is shared in real time (Hozdić, 2015).

This wave poses an important challenge to companies that more and more are required to deal with the opportunities offered by the digital technologies which are at the core of
the Fourth Industrial Revolution. Aware of both the limited financial resources as well as of their level of digital readiness, companies need to make some strategic choices, selecting and exploiting the set of digital technologies that better fit with their own context (Hess, 2016).

In other words, to remain competitive companies are called to strategically govern the digital change by formulating and executing a clear strategy to keep pace with the new digital reality (Matt et al. 2014).

Since the beginning of the 2010s, a large proliferation of papers on this subject matter has been observed, but often in a quite fragmented fashion and using an ample variety of terminology. At the best of our knowledge, the academic panorama lacks a complete and exhaustive literature review on how companies can strategically govern the digital change provoked by technology advancements and occurring in business systems. To date indeed, the newness of the topic and the wideness of the combined domains blur the knowledge on the company ground and torment researchers and experts across their affairs by creating overlaps between words and meanings, constructs and definitions, and by fostering useless varieties of vocabulary, and diverse perspectives on the same objects and phenomena.

Accordingly, this paper carries out a systematic literature review (SLR) on this field, with the aim of charting the map of the publications and systematizing the often-fragmented literature on this field into a comprehensive body of organized knowledge, underlining the different perspectives and proposing some directions of future inquire that could inspire scholars and support practitioners.

In pursuance of these targeted objectives, the SLR has been guided by the following research questions:

- RQ1: Which are the perimeter and the current state of the art in the field of research?
- RQ2: Is there a way to frame and organize the knowledge belonging to this field?
- RQ3: Which are guidelines to drive future researches on this field?

Findings of the research contribute to systematize the often-snipped literature on how to govern the change provoked in companies by digital technology advancements. Results of the literature review show that the field under investigation may be framed into four blocks, namely: Digital Transformation Strategy; Digital Transformation Execution; Leadership & Culture; and Models. Hence, our review will depict the nature and the main contents of these blocks, to what extent they are intertwined, and which are the leverages managers may employ to govern the change. Along this line, in the final part of the paper, a discussion on the current detected gaps is carried out, and some avenues of future researches are spelt out.

**Methodology**

Towards achieving our aim and answering the research questions, a systematic literature review on how to strategically govern the digital change provoked by technology advancements occurring in companies has been carried out. The field under investigation, which concerns the process followed by companies to strategically select the most prominent digital technologies and then drive their implementation within the companies, revolves around two main key areas. From one side the opportunities offered to the companies by the set of digital technologies and the Fourth Industrial Revolution, and, from the other side, the strategic process they have to follow to govern within the company this change. Accordingly, two different groups of keywords have been selected to carry out the literature review on the ISI Web of Science Database (core collection):
• Group 1: it contains the keywords to intercept the papers referring to the Fourth Industrial Revolution (i.e. "Industry 4.0"; "Industrial Revolution"; "Smart Factory"; "Smart Manufacturing") and the ones referring to Digitalization or Digital Transformation (i.e. "Digital*").

• Group 2: it contains the keywords related to the investigation of how firms can strategically cope and manage these digital technology advancements which is the baseline of the studied field. The focus has been given to the governance of this kind of transformation ("Strateg*"; "Transformation*"; "Change"; "Roadmap"; "Cultur*").

We combined a) the terms belonging to group 1 and group 2; and b) the terms belonging to group 1 with each combination of two terms belonging to group 2. a) and b) where searched respectively in titles and topic (i.e. abstract, title and keywords). In this way, we were able to capture most of the papers covering the field under investigation.

The queries that were accomplished on the 12th of March 2019, returned 10,114 results at first, reduced to 508 by applying some basic filtering options proposed by ISI as the research area (i.e. Management, Business, Operations Research Management Science), the English language, and the document type. Duplicates have been subsequently removed. The application of these criteria provides us with 459 papers, that were subsequently analyzed by the authors.

Consequently, in order to check the pertinence of these papers with the field under investigation (e.g. how to strategically govern the digital change provoked by technology advancements occurring in companies), we read the abstracts of these articles and we excluded those articles that were not pertinent, and 168 relevant articles remain. The reading of the full articles made it possible to identify the 59 most pertinent articles.

At the end, after 16 papers and 8 books have been added via a snowball process, the final dataset was composed by 83 contributions. It may be argued that the final database is made up in most part by ISI ranked journals (i.e. the queries searched on ISI-WoS Database), while the snowball process added mostly practitioners’ articles. We believe that this balance is valuable, bearing in mind the topicality and the hype of the theme discussed.

Finally, all the selected articles have been carefully mapped in a structured spreadsheet with different dimensions, namely: - the field, - the topic and the purpose of the article, - the construct/s under investigation and its definition (when provided), - the description of the theoretical ground, - the methodology, - the main findings. The analysis of this spreadsheet made it possible to develop a framework that organizes the contributions of the literature on the field and sheds some light on the state of the art on the theme as well as on gaps and avenues for further researches.

Field of research
Giving a general overview of the papers, the overall counter of publications per year on the field has been growing exponentially and the curve has just reared in the last three years (max[1996-2015]: 5; 2016: 8; 2017: 10; 2018: 28). The mounting interest around the topic witnesses its relevance and renews the necessity of this work.

The large part of the publications empirically test their arguments on real cases (Figure 1), interviews and surveys, secondary data analysis or action research, but the analysis of the papers also shows the presence of a consistent set of papers (i.e. “Opinions”) which expound findings without the backing of a proper scientific methodology – and this principally happens with the articles dealing with strategical matters.
The deep analysis of the papers shows that the articles on the field are quite fragmented and they deal with different aspects of the phenomenon, thus making it difficult to get a clear picture of it. To try to systematize the variety of these contributions, we develop a framework meant to integrate the different dimensions that shape the research field on how to govern the transformation provoked in companies by digital technology advancements. This framework (see Figure 2) is composed of four blocks.

The first two blocks – Digital Transformation Strategy (DTS) and Digital Transformation Execution (DTE) - constitute the backbone of the field and describe the process of digital transformation process (DT) triggered by the injection of digital technologies into companies. The second two blocks instead revolve respectively around the technical skills, Leadership and Culture companies need to be equipped with to be successful in the change process, and the Models literature supplies to comprehend these kinds of transformations. In this view, these latter two blocks sustain the field’s backbone providing knowledge and tools to the people enlisted in the digital transformation process.
The Digital Transformation
The backbone of the field describes the process of governing the transformation of the company triggered by the injection of digital technologies. This process may be broken down into two diverse blocks, referring respectively to its strategical conception (i.e. Digital Transformation Strategy) and its execution (i.e. Digital Transformation Execution). More neatly, inside the concept of Digital Transformation there is one set of papers that concern Digital Transformation Strategy (DTS), where a company needs to explore the opportunities offered by technology (Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Konlechner et al., 2018) to select which to invest on (Mithas et al., 2010; Ardolino et al., 2018; Ghobakhloo, 2018; Pappas et al., 2018; Ross et al., 2018) and how to organize and control the strategical change (Tichy, 1983; Bharadwaj et al., 2013; Andriole, 2017; Davenport & Westerman, 2018). DTS papers conceptualize the path to be executed, argued in the second group of papers, which instead deal with the practical deployment of strategy into actions to transform the business model (Ross et al., 2016; Gobble, 2018) or with the management of the business-system-technology integration (Woodard et al., 2013; Agarwal & Brem, 2015; Teubner, 2018; Gastaldi et al., 2018). Consequently, as Digital Transformation Strategy lies in abstraction by the very nature of strategies, as its operations are made in the land of representations and models of reality (Gavetti and Levinthal, 2000), it has concrete effects on reality only through the Digital Transformation Execution (DTE) block (Gavetti and Rivkin, 2007). The proposed distinction comes out by the analysis of the aim and main constructs presented in the analyzed papers and will be clearly described in the subsequent sections.

Digital Transformation Strategy
Papers within this block deal with how to strategically address the opportunities and risks that originate from digital technologies, planning the company journey towards being digitally transformed (Singh &Hess, 2017). In order to refer to this concept, authors often employ different labels (i.e. digital transformation strategy, digital strategy, digital business strategy). A part from the different labels, the common features, which delimitate the boundary of the concept, relay on the fact that it governs the digital transformation: a) by defining objectives and priorities to provide directions (Mithas et al., 2010; Hansen et al., 2011; Mithas et al., 2013; Ross et al., 2016; Ardolino et al., 2018; Ghobakhloo, 2018; Konlechner et al., 2018; Pappas et al., 2018; Ross et al., 2018); b) by organizing the structure to enable the execution of digital initiatives (Agarwal & Brem, 2015; Hess et al., 2016; Sia et al., 2016); and c) by gauging progress to reroute efforts or investments when required (Sebastian et al., 2017).

Moreover, authors who use the label digital business strategy (Mithas, 2010; Kettinger, 2011; Bharadwaj et al., 2013; Grover and Kohli, 2013; Markus and Loebbecke, 2013; Mithas et al., 2013; Woodard et al., 2013; Sia et al., 2016) emphasize the integration between information technology (IT) function strategy and business strategy, which has its root in the need to achieve a peaceful and effective co-existence between IT and business strategy, thus suggesting a juxtaposition of their purposes and plans (Henderson & Venkatraman, 1992).

Beyond the definition of the concept of DTS, papers show that firms might craft their digital strategy to achieve two main objectives:

Value Propositions. A company can transform its value proposition to elevate “the performance implications of IT strategy beyond efficiency and productivity metrics to those that drive competitive advantage and strategic differentiation” (Bharadwaj et al., 2013). Ross et al. (2017) draw how companies use to pursue either a Customer...
Engagement Strategy, whether they decide to focus on boosting their customer experience (Lanzolla & Giudici, 2017; Haenninen et al., 2018; Kotarba, 2018; Subramaniam et al., 2019), or a Digitalized Solution Strategy, if they bet on R&D chances to innovate their value proposition by combining products, services and available data (e.g. new smart and connected product, platform, analytics service-based) (Woodard et al., 2013; Porter and Heppelman, 2014; Echterfeld and Gausmeier, 2018).

**Processeses.** A company, pursuing an Operational Excellence Strategy (Ross et al., 2017) may decide to transform its processes. The matter is how to invest on the redesign of the way activities to deliver value propositions are performed, taking advantage of technology to generate more outputs employing less inputs (Zuehlke, 2010; Erol et al., 2016; Dremel et al., 2017; Sanders, et al., 2016; Szozda, 2017; Gastaldi et al., 2018; Kaidalova et al., 2018; Mittal et al., 2018). Moreover, authors sustain companies are required to consider adapting their processes whenever a change in their value propositions occur (Benner, 2009; Ross et al., 2016; Dremel et al., 2017; Lanzolla and Giudici, 2017; Ross et al., 2017).

**Digital Transformation Execution**

Digital Transformation is the product of the execution of a Digital Transformation Strategy (i.e. Digital Transformation Execution - DTE), where strategies transform the reality towards their exploitation by mean of actions (Gavetti and Rivkin, 2007; Ross et al., 2016). Accordingly, the overall subject matter of the second block is how to exploit the strategical transformations of value propositions and/or processes by leveraging on technologies (Day-Yang, L. et al., 2011; Gastaldi et al., 2018; Wagner et al. 2018; Weill and Woerner, 2018). Comparing to the previous block, here the knowledge is much more fragmented due to the absence of a referential theory and also because researches mostly and simply describe use cases of technology and how they have just been implemented (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018). Despite the complexity in navigating the knowledge of this block, the analysis on the research aims and the findings of each paper contained into the dataset allowed us to identify three patterns on DTE, regarding Industry 4.0, Lean Management and Project Management.

**DTE & Industry 4.0.** As salient detail, the contributions referring to the construct Industry 4.0 (i.e. The Fourth Industrial Revolution) mainly focus and prioritize the digital transformations of manufacturing operations and supply chains, and the way an Operational Effectiveness strategy (Ross et al. 2017) may be executed. (Hozdić, 2015; Lee, et al., 2015; Lu, 2017; Bienhaus & Haddud, 2018; Yin et al. 2018).

**DTE & Lean Management.** Going inside the contributions referring to the digital transformation of Supply chains and Operations, we notice a niche of contributions inquiring the relationship between Lean Management (LM) (Womack and Jones, 1997) and Digital Transformation, and we can outline two outlooks. On one side, Bortolotti et al. (2014) claim the effective execution of a Digital Transformation cannot avoid laying on already efficient and streamlined processes. This is the reason why tracking LM may lead to an operational readiness to change (Sanders et al., 2015; Mrugalska and Wyrwicka, 2017; Besser Freitag et al., 2018). On the other side, Kolberg and Zühlke (2015) overturn the concept, arguing that LM is enabled by Digital Transformation, because technology is broadening the chances for manufacturing and service companies to reinforce their efficiency by solving problems in ways afore unthinkable.

**DTE & Project Management.** Indeed Digital Transformation Executions are often described as a package of digital coordinated projects, (Erol et al., 2016; Goelzer and
Fritzsche, 2017; Dremel et al., 2017; Singh & Hess, 2017; Bertoncel, 2018), and this opens a question on the role of Project Management in the Digital Transformation process, although few publications refer explicitly to the issue (Schüritz et al., 2017; Teubner, 2018).

Leadership & Culture
The third block considers the academical interest on the impact of the organizational and cultural variables into a Digital Transformation (i.e. DTS and DTE). Compared to the rest of the papers, this block presents a dissonant peculiarity on the methodologies employed by scholars, that is the preponderance of hypotheses tested by surveys and statistic techniques, while case studies are the rule in the other papers. In this niche of knowledge resultsfigure out two main topics discussed by scholars: technical skills, leadership, and cultural background requirements.

From the analysis, these requirements seem a prerogative to make a Digital Transformation effective, mainly for two reasons: first, they must to be fostered whatever the DT will be (Ross et al. 2016; Sia et al., 2016; Westerman, 2016; Dremel et al., 2017); second, it is “difficult, rather impossible, for a network of typical manufactures to achieve them in a short run” (Ghobakhloo, 2018).

Technical skills. Some publications claim that a Digital Transformation to survive in time without having a negative impact on performances need people to be equipped with some technical skills (Weizi et al., 2016). These are required to understand, deploy and manage the opportunities offered by technologies and the dynamics of the change their introduction involves Sia et al., 2016; Davison and Ou, 2017; Ross et al. 2017). Such skills are hybrid skills (Weizi et al., 2016; Schwarzmueller et al., 2018), for example, the ability to perceive week signals of disruption (Bertoncel, 2018) or to handle the analysis and conversion of big amount of data to make decisions above valuable information (Davenport and Patil. 2012; McAfee, Andrew, et al., 2012; Schallmo et al., 2017).

Leadership. Literature maintains the central role leadership plays in the Digital Transformation process, and in particular the interaction between leadership and technology advancements that is baptized as e-leadership (Avolio et al. 2014). Weizi et al. (2016) divide the construct of e-leadership in two layers, where at micro level it deals with the abovementioned skills requirements, and, at a macro level, e-leadership challenges the redesign of company’s governance to allocate responsibilities to tackle a DT. On this account, the analysis on the dataset pinpoints a stream of research on the relationship between Chief Information Officers and Chief Executive Officers (Weizi et al., 2016; Hansen et al., 2011; Oberer & Erkollar, 2018), and the opportunity/possibility of introducing a new referential profile the Chief Digital Officer – CDO to supervise the DT (Singh & Hess, 2017).

Cultural Background. Some contributions address the theme of which kind of organizational culture is more suited to engage a Digital Transformation. From the analysis, two significant features emerge: agility and innovation (Ross et al., 2017; Dremel et al., 2017). In particular, Schwarzmueller et al., (2018) state “organizational culture should be transformed to a culture of involvement, in which decisions are taken together, a culture of innovation, that ensures agility based on the acceptance of suggestions, and a culture of training, in which staff is constantly developed (Patterson et al., 2005).” Furthermore, other authors hint companies need to pursue openness to change (Ghobakhloo, 2018) to adapt more quickly and shorten adaptation time to new working habits (Weizi et al., 2016), and, eventually, create a culture of decision making based on data instead of experience and intuition (McAfee et al., 2012; Dremel et al., 2017).
Models

The Models block collects the contributions which provide knowledge on the opportunities offered by technology advancements and on guidelines companies may follow to implement a Digital Transformation. They are divided into three different groups: Frameworks, Roadmaps and Methodologies, and Assessment Tools.

Frameworks. As defined in the introduction of the paper, Digital Transformation is a consequence of the technological evolution which companies wrestle along their journey. Literature maintain diverse publications that try to build knowledge around this phenomenon (Porter & Heppelmann, 2014; Rometty, 2016; Westerman et al., 2014), inquiring how technologies progress, and/or their social impact, and/or the types of mutations they are provoking on companies (Brynjolfsson and McAfee, 2014; Porter & Heppelmann, 2015; Weill and Woerner, 2015; Brynjolfsson and McAfee, 2017; Venkatraman, 2017).

Roadmaps and methodologies. In this group are contained all the contribution referring to methods (i.e. standards and steps) (Bibby & Dehe, 2018; Mittal et al., 2018), guidelines, roadmaps and tools (Westerman, 2016; Andriole, 2017; Gobble, 2018) which a company could use for architecting and standardizing its Digital Transformation (Liu, Day-Yang et al., 2011; Porter & Heppelmann, 2015; Matt et al., 2015; Erol et al., 2016; Parviainen et al., 2017; Dremel et al., 2017; Ghabakhloo, 2018; Weill and Woerner, 2018). Methodologies can be applied to any type of digital transformation, and their focus ranges from the entire company to a specific project. Literature is rich of anecdotal cases of successful integration of technologies towards a digital transformation (Kohli and Johnson, 2011; Agarwal & Brem, 2015; Hansen and Sia, 2015; Oks et al., 2016; Dremel et al., 2017; Kaidalova et al., 2018), but a thorough reference methodology to handle the problem of Digital Transformation still lacks (Nwaiwu, 2018).

Assessment tools. This stream of papers provides contributions on instruments which support managers or companies in measuring and evaluating the degree of technological integration into company’s processes. This results in a seminal provision to position companies into a reference system that can better drive the digital transformation process (Plomp and Batenburg, 2010; Bibby & Dehe, 2018; Heavin & Power, 2018; Kontic & Vidicki, 2018).

Conclusion

Although this is a preliminary review on how to strategically govern the digital change provoked by technology advancements and occurring in business systems, some contributions to both research and practice have been provided. On the academic side, the paper systematizes the knowledge on the field and provides a framework to orient future researches. On the managerial side, our research offers some insights on the strategic aspects of the digital transformation that endeavour and supports organizations and managers that are tackling the challenges offered by the new digital era.

The paper has also some limitations, that can drive further developments. Results maintain that literature on the field is still in its infancy, suggesting that future research should go more in depth in comprehending how digital transformation can be developed and executed. The performed queries are more focused on the digital strategy conceptualization rather than its exploitation. So, additional research could be performed through a wider sample to validate and enrich the considerations addressed on Digital Transformation Execution subgroup.

Abstract

This paper describes how firms can develop Firm Supply Chain Agility (FSCA) and its benefits for operational performance (OP). The purpose of this research is twofold. First, to analyze the role of transactive memory system (TMS) and supply network flexibility (SNF) as potential antecedents of FSCA, also evaluating the moderating role of TMS; and, second, to evaluate the relationship between FSCA and OP, also examining the possible mediating effect of FSCA. The relationships are tested with survey data from 190 Spanish high-tech firms using structural equation and linear regression models.

Keywords: Firm’s supply chain agility, transactive memory system, supply network flexibility.

Main subject text

Theoretical background

Today’s hypercompetitive environment – characterized by demanding customers, short product life-cycles, volatile supply and demand, global supply chains, and rapid advances in technology – has pushed firms towards finding new ways of competing (Swafford et al., 2006; Chiang et al., 2012). Indeed, research suggests that developing a firm’s supply chain agility (FSCA) can be key to improving competitiveness in the current environment (Christopher, 2000; Gligor et al., 2015; Kim and Chai, 2017). FSCA has been conceptualized variously as a comprehensive strategy, a paradigm, a management system or practice, and even as a capability (Shin et al., 2015). In this study, we adopt
Braunscheidel and Suresh’s (2009, p. 126) definition of FSCA as “the capability of the firm, internally, and in conjunction with its key suppliers and customers, to adapt or respond in a speedy manner to a changing marketplace, contributing to the agility of the extended supply chain”.

Given the importance of FSCA, an investigation of how such a capability can be built and the performance outcomes is of utmost importance (Blome et al., 2013; Gligor et al., 2015). The literature has identified some antecedents of FSCA by recognizing, for example, that FSCA depends on: the flexibility of the procurement/sourcing, manufacturing, and distribution/logistics processes (Swafford et al., 2006); internal and external integration of the firm (Braunscheidel and Suresh, 2009); coordinating, cooperative, and communicative mechanisms in the supply chain (Gligor and Holcomb, 2012); and the development of supply- and demand-side competences (Blome et al., 2013). Research has also identified outcomes associated with FSCA. For example, FSCA enables a firm to be more market-sensitive, have greater capacity to synchronize supply with demand, better manage disruption risks, achieve shorter cycle times, ensure uninterrupted service to customers, and accelerate the introduction of new products (Braunscheidel and Suresh, 2009; Blome et al., 2013; Gligor et al., 2015). However, due to limited research in this field, there have been a number of recent calls to explore new antecedents of FSCA and to further scrutinize the effect of FSCA on performance (Chiang et al., 2012; Blome et al., 2013; Gligor et al., 2015; Chan et al., 2017; Fayezi et al., 2017). Swafford et al. (2006) indicated that agility requires competitive strategies based on both the development of knowledge and the generation of flexible processes so firms can respond to changing circumstances in the environment. Building on this, our study evaluates a variable related to knowledge – transactive memory system (TMS) – and a variable related to flexibility – a firm’s supply network flexibility (SNF) – as potential antecedents of FSCA.

Our first variable, TMS, “is the shared division of cognitive labor with respect to the encoding, storage, retrieval, and communication of information from different domains that often develops in close relationships” (Lewis and Herndon, 2011; p. 1254). This variable, related to the creation, maintenance, transfer, and coordination of knowledge in work teams (Argote and Guo, 2016; Heavey and Simsek, 2017; Huang and Cheng, 2018), has been applied to various types of dyadic relationships (Hammedi et al., 2013; Argote and Guo, 2016), work groups (Liang et al., 1995; Argote and Guo, 2016), organizations (Heavey and Simsek, 2015; Huang and Cheng, 2018), and even contexts that transcend organizational boundaries, such as the development of TMSs between supply chain partners (Obayi et al., 2017). Although TMSs have received little attention in the operations management field, this variable could contribute greatly to the development of FSCA. For example, it has been recognized that uncertain environments require the rapid generation and coordination of new knowledge (Gligor et al., 2015; Argote and Guo, 2016). Further, firms like Honda, Apple, Zara, and Amazon have all succeeded in developing supply chain agility because they have teams that are motivated to develop creative solutions to unexpected problems (Gravier, 2016).

Our second variable, SNF, is related to an organization’s ability to effectively and efficiently reconfigure its supply base (Liao et al., 2010), enabling the firm to maintain a sufficient set of alternatives and responses to possible changes in the environment (Liao and Marsilliac, 2015). Although the extant literature has recognized the importance of different types of flexibility in achieving FSCA (Chan et al., 2017), SNF is a relatively new concept that remains underexplored in the FSCA literature (Liao et al., 2010; Purvis et al., 2014; Liao and Marsilliac, 2015). As Lummus et al. (2003) argued, supply chain design must take change into account. When the market changes, competitive priorities
also change, making it necessary to find new supply chain partners with the required capabilities. Finding such partners is necessary for high levels of flexibility in supply networks (Purvis et al., 2014). Cisco, for example, uses three different supply networks to manufacture its products (depending on the type, volume, and customization required). When the need arises, it can switch manufacturing from one network to another, achieving rapid response to changes in the environment (Lee, 2004). It is thus reasonable to expect that having different strategic options for product supply would facilitate higher levels of FSCA.

Given the need to further evaluate the effect of FSCA on performance (Gligor et al., 2015), we also examine the relationship between FSCA and a firm’s operational performance (OP). Supply chain managers must know what results to expect from the implementation of FSCA-focused strategies, yet prior studies have evaluated only some measures of operational performance (e.g. Gligor and Holcomb, 2012; Blome et al., 2013; Eckstein et al., 2015; Gligor et al., 2015). Our study expands these measures by exploring the relationship between FSCA and OP in four specific areas – delivery, production cost, product quality, and production flexibility – that reflect the four key capabilities of a focal firm in responding to competition (Wong et al., 2011).

Based on the above, our study has two main goals. First, to analyze the role of TMS and SNF as potential antecedents of FSCA, evaluating the moderating role of TMS in the SNF-FSCA relationship; and, second, to evaluate the relationship between FSCA and OP, examining the possible mediating effect of FSCA on the relationship between SNF-OP. These goals are summarized in the following two research questions:

RQ1. What is the relationship between TMS, SNF, and FSCA?
RQ2. How does FSCA affect OP, either directly or by mediating the relationship between SNF and OP?

The relationships to be empirically investigated are illustrated in the theoretical model in Figure 1.

**Figure 1. Theoretical Framework of the Study**

**Design/methodology**

In order to provide empirical evidence for the proposed research hypotheses, Spanish companies belonging to the high technology sector were selected from the Iberian Balance Sheet Analysis System (SABI) database. Once the total population was defined, a survey was conducted to obtain specific information for our research, following Dillman’s (2000) prescriptions. The unit of analysis was the firm, and the preferred respondents were senior managers with knowledge of the processes and activities of the firm’s operations department and who had the capacity to make decisions in that department. The procedure for data collection was through the computer-assisted telephone interview (CATI) system. Finally, we obtained a final sample of 190 usable surveys and a final response rate of 12.45 percent.

The main constructs used in our model were: TMS, SNF, FSCA, and OP. The measurement scales for these variables were adapted from prior studies: TMS (Lewis,
A seven-point Likert scale survey was designed to capture managers’ perceived levels of these variables (1 = maximum disagreement; 7 = maximum agreement). Moreover, we considered other contextual factors that might have an influence on operational performance such as firm age and firm size.

We examined the reliability and validity of the measurement scales following the procedure developed by Kaynak and Hartley (2006). We also studied all indicators of the measurement scales’ goodness of fit by analyzing the absolute and incremental goodness of fit and the model’s parsimony. In all cases, the indicators are within the levels recommended as acceptable in the literature (Hair et al., 2010).

The theoretical model was tested using the methodology of structural equations and regression analysis. In order to test H1, H2, H4 and H5, we employed structural equation modeling (SEM) to estimate the proposed research model. Results indicate a good fit for the measurement model with a Chi-square of 862 and 549 degrees of freedom, CFI of 0.90, IFI of 0.90, BBNNFI = 0.90 and RMSEA of 0.05. The standardized coefficient weights for each causal path are provided in Figure 2 for the main effects, being all factor loadings significant. The analytical approach outlined by Hayes (2013) was used to test the hypothesis related to moderation (H3). A summary of the moderation analysis results is available in Table I. In addition, Figure 3 presents the moderating effect of TMS in the SNF-FSCA relationship, for low, moderate and high TMS values. The empirical evidence suggests FSCA achieves its optimum when companies have high values of TMS and SNF. However, higher values of TMS weaken the relationship between SNF and OP. In other words, the existence of a highly developed TMS leads to SNF becoming less important in the consecution of FSCA.
Findings

The study makes three important contributions to Operations Management research, Supply Management Orientation and the Resource-Based View (RBV). First, in response to suggestions by Swafford et al. (2006), it contributes to the literature on Operations and Supply Chain Management by evaluating the role of TMS and SNF as possible antecedents of FSCA. These antecedents have not been considered before in the literature on agility. On the one hand, finding evidence of a positive relationship between TMS and FSCA (H1) supports the conclusion that the presence of high levels of TMS in the operations department encourages FSCA. This is a novel contribution to the literature in the field. Although the benefits of TMS and the use of knowledge in other areas of the organization are recognized (Zheng and Mai, 2013; Peltokorpi, 2014; Argote and Guo, 2016; Heavey and Simsek, 2017), there has been almost no exploration of these benefits in operations management. Therefore, our study adds to pioneering studies like that of Obayi et al. (2017), which have begun to explore the role of TMS in the field of operations, supply chains and their role in OP. Obayi et al. (2017) considered the TMS generated among the partners in the supply chain. Our study extends the knowledge of the area, by considering the TMS in the firm’s operations department and exploring the benefits that this can have on the FSCA. On the other hand, evidence of a positive relationship between SNF and FSCA (H2) reinforces the need to reconfigure the supply
base in the face of changes in the environment. This finding is not only consistent with the operations management literature that recognizes the importance of different types of flexibility to achieve FSCA (Swafford et al., 2006, Swafford et al., 2008, Braunscheidel and Suresh, 2009, Chan et al., 2017), but also improves our knowledge on the flexibility-agility relationship, by exploring a particular type of flexibility, practically unexplored in this field: SNF. Firms that have different strategic options for product supply and can properly reconfigure their supply base will have a better position to develop the FSCA.

Both antecedents, in turn, highlight the need to develop intra- and inter-organizational competencies to achieve FSCA. FSCA depends on issues related not only to internal management of the firm (such as the presence of high levels of TMS in the operations department) but also to external management of the firm, such as relationships with suppliers (SNF). This need has been suggested by prior studies such as those performed by Braunscheidel and Suresh (2009), Gligor et al. (2015), and Fayezi et al. (2017). This study empirically confirms these assumptions.

Evidence of the moderating role of TMS in the relationship between SNF and FSCA (H3) is also important. In contrast to previous proposals, we find a negative moderating effect of TMS. That is, when the firm has high levels of TMS in the operations department, the relationship between SNF and FSCA weakens. One possible explanation for this finding may lie in the firm’s capability for internal management. A high level of TMS grants the firm greater internal management capability, which facilitates its adaptation or response to market changes using its own mechanisms. Thus, based on survey data collected from 137 start-ups in China, Zheng and Mai (2013) found that forming teams of start-ups that were operating in highly uncertain environments and that had high levels of TMSs did not have to resort to external sources when responding to surprises in their environments. Rather, they responded to surprises by improvising using their own knowledge. Improvisation requires integrating and applying new and preexisting knowledge in real time, and the existence of a high level of TMS in the team facilitated this task.

As a firm’s operations department develops its TMS, the probability of resorting to its supply base to improve FSCA decreases. In other words, the solutions for managing rapid changes can be forged internally. The ability to create, maintain, transfer and coordinate knowledge in operations departments with high levels of TMS enables the firm to draw on its own abilities instead of consulting external players to solve problems (Carney et al., 2008). Further, improving FSCA through the firm’s internal processes encourages quick response and eliminates the costs associated with seeking new suppliers and generating commercial transactions (Williamson, 1975). SNF involves finding the best strategic combination for product supply. Such searches require not only the presence of suppliers available on the market but also the time, cost and knowledge necessary to perform a search and to select suppliers effectively and efficiently. Firms with a high level of TMS in the operations department will thus be more inclined to invest in themselves to respond to uncertainty instead of delegating this responsibility to external agents.

Second, the study makes a key contribution to the agility literature by examining the association between FSCA and OP. The evidence of a positive relationship between FSCA and OP (H4) confirms the importance of developing FSCA to improve the firm’s operating measures. Consistent with prior research (Gligor and Holcomb, 2012; Eckstein et al., 2015; Gligor et al., 2015; Chan et al., 2017), this finding also enables us to extend knowledge in the field by considering four key dimensions of OP: delivery, production cost, product quality and production flexibility. To the extent of our knowledge, prior studies that explore the relationship between FSCA and OP have considered only some
of these dimensions (Blome et al., 2013; Eckstein et al., 2015; Gligor et al., 2015; Chan et al., 2017). Our study provides a more complete view of the operating measures improved by FSCA.

Finally, the study contributes to developing the literature supporting the relationship between flexibility and agility as a competency-capability relationship (Swafford et al., 2006; Braunscheidel and Suresh, 2009; Swafford et al., 2008; Chiang et al., 2012; Blome et al., 2013). However, this study extends past research considering an aspect of external flexibility, related to supply management. Normally, the studies have evaluated the flexibility relative to the internal processes of the firm. There is few research that extend the flexibility beyond the limits of the focal firm. Our findings suggest that the variable FSCA mediates the relationship between SNF and OP (H5). That is, while SNF is a competency, FSCA is a capability. According to the RBV, competencies in themselves do not lead to sustainable competitive advantage. Rather, they must be combined and managed to develop capabilities. Thus, SNF in itself does not generate greater OP per se, but requires FSCA to obtain operational benefits.

This study also has important implications for managers. The empirical evidence obtained highlights the value of investing in FSCA as a tool to build a sustainable competitive advantage. FSCA enables the firm to compete in an increasingly dynamic and changing environment by improving some of the firm’s operational aspects, such as increasing product quality, decreasing production costs, improving issues related to product delivery and/or encouraging production flexibility.

At the same time, the study allows managers to understand how FSCA can be strengthened. We stress that FSCA depends not only and exclusively on internal aspects of the firm but also on parties external to it, which involve different agents in the supply chain. Managers should thus develop both intra- and inter-organizational resources to encourage FSCA. First, managers could focus on the intra-organizational possibility of developing a solid TMS in the operations department. That is, they could build work teams that prioritize collaboration and trust among the group’s members, with members who specialize in a specific area and are willing to share and coordinate individual knowledge. Such teams not only enjoy greater response capability but can develop creative solutions to unexpected problems (Akgün et al., 2006) in the area of operations, increasing FSCA. Second, managers could develop the inter-organizational possibility of SNF by building a network of suppliers flexible enough to adapt to changes in the environment and thus able to respond quickly to new demands from the firm’s customers. For example, in environments with highly competitive and dynamic markets, short product lifecycles and rapid new product introductions, maintaining these flexible networks reduces the firm’s dependence on its suppliers and increases its capability to adjust supply and demand.

However, it should be noted, in the face of the need to prioritize one option over the other, investment in internal resources in the firm seems to be the more effective response when developing FSCA. Specifically, developing TMS in the operations department could be especially valuable when uncertainty is high as with the high-tech industry, because TMS provides a knowledge base that can be coordinated to better address uncertain conditions in the environment (Argote and Guo, 2016) without facing the costs associated with the search for new suppliers and the generation of new commercial transactions.

It is also important to note that while managers can develop SNF to strengthen FSCA, SNF does not improve the firm’s operational aspects directly. A firm that has different strategic options for product supply, has a greater capability to adapt to changing market conditions.
requirements which increases its FSCA. This FSCA will lead to improvements in operational measures.

Abstract

Smart product development (SPD) in industry 4.0 facilitates decision making during different activities involved in development process. Contextual evidence shows such activities are influenced by several factors; however there remains little understanding on factors influencing SPD from industry 4.0 in Indian context. Present study aims to identify and develop perception based prediction model to investigate critical factors influencing SPD. Two dimensions extracted viz. “technological” and “strategic” factors have significant positive impact while out of five identified critical factors three have significant positive impact i.e., technology & innovation, system integration and collaborative engineering. Thus, increasing quality of industry 4.0 can be accomplished with proper integration of technologies.

Keywords: Critical factors, India, Industry 4.0, Smart product development

Introduction

With the advancement of digital technologies and a paradigm shift to industry 4.0 manufacturing industries have been found to be in major transformation towards adopting smart manufacturing (Feeney et al., 2015). This new industrial trend affects organizational structure and customer’s demand (Gilchrist, 2016) which resulted into development of complex and smart products with new capabilities thus influence product life cycle that is somewhat different from conventional product development approach (Nunes et al., 2017; Ahmed et al., 2019). Industry 4.0 is an integration of “intelligent systems, machines, production and processes to form a well-defined network” (Kagermann et al., 2013, cited in Ahmed et al., 2019). It is a concept that involves combined components of “cyber physical systems (CPS)”, “internet of things
(IoT)” with cloud based models as disruptive technologies (Wang et al., 2015; Dalenogarea et al., 2018). It produces new types of products with intelligent systems embed in it. Despite the recognition of the term “smart” as extensively used by many organizations and researchers, still today there is no consensus of consistent definition. The concept of “smart product” is a network based integrated approach that spans entire manufacturing process and control production stages/processes autonomously (Nunes et al., 2017). It is characterized by its computation and data-storage facilities and its way of interaction with other objects. From developing economy like India manufacturing industry resembles high priority sector in terms of wealth creation and employment generation. However, such development initiative is still in its concept phase and has got immense potential to bring positive effects in terms of cost, quality, productivity, time, flexibility and innovation. Traditional product development approach consisting of multiple processes and sub-processes that interferes decision making information and knowledge capture (Ahmed et al., 2019) and hence real time decisions cannot be taken (Wasim et al., 2013). This becomes an imperative for development of frameworks for smart products so as to offer unprecedented customer insights. In-spite of several advantages in combining industry 4.0 and SPD, majority of the Indian industries are in state of dilemma with respect to its adoption and implementation. Contextual evidence indicates that factors that influence traditional product development approach may not be same as in case of smart product development. Thus the purpose of this paper is to identify the critical factor dimensions that affect smart product development from Indian industry 4.0 perspective. Accordingly the following objectives have been considered.

**Objectives:** (i) To identify and predict the influence of critical attributes or indicators on SPD; (ii) To identify critical factor dimensions and its influence on SPD.

**Hypotheses Development**

**Technology and Innovation**
With high-technology development influenced by innovation facilitates product design and development process. Such innovation led technological development engenders substantial changes in existing market that leads to successful product development. Quality of the product can be improved with technology intervention as organizations are moving towards digitalization in context of industry 4.0. Development process of smart product entails diffusion of advanced technologies and equipment, advanced production procedures with upgraded software and databases. Thus it is expected that ‘technology and innovation’ would increase the process flow by focusing on process innovation. Accordingly the following hypothesis is proposed.

H1: Technology innovation has positive influence on smart product development

**Collaborative Engineering**
Collaboration, in terms of human interface perspective, aids towards execution of series of activities which provides channel for team. Collaborative product development from
engineering perspective is a technology oriented process that is used to design innovative and improved products by exploring new markets so as to gain competitive advantage (Büyüközkan and Arsenyan, 2012). From the literature it is evident that collaborative process is followed in many industries those are involved in complex product and service development including research and development (Feller et al., 2005). Collaborative engineering also focuses in handling problems in relation to partner selection and evaluation which is critical for product development success. Thus following hypothesis is proposed.

H2: Collaborative Engineering has positive influence on smart product development

**System Integration**

Pertaining to SPD from Industry 4.0 perspective, SI refers to cyber physical systems that interconnect physical systems and communication infrastructure (Baheti et al., 2011). Integration of cyber technologies make products internet enabled that generates lots of data and communicates with other interconnected products. These facilitate product development process which can be achieved in cost effective and effectual manner. With system integration approach flexible operations could be performed by adjusting combination of standardized modules that speed up the product development process and reduces time to market. Thus following hypothesis is proposed.

H3: System integration has positive influence on smart product development

**Sustainability**

Sustainability is considered to be a critical attribute that strategically addresses the risk management in product development. With reference to environmental perspective issues pertaining to sustainability related to smart products focuses on reducing wastes, resources and energy thus moving towards green products. Reducing series of activities pertaining to traditional product development approach would eventually make the process efficient and eliminate any special causes of defects which ultimately lead to product development success. Moreover, economic sustainability facilitates agility and smooth flow in smart product development with objective to maximize profit and minimize costs. Thus the following hypothesis has been proposed.

H4: Sustainability issues have positive influence on smart product development.

**Lean Operating System**

Lean implementation is initiated by cyber physical system (CPS) which results in elimination of wastes by maximizing productivity. Such implementation produces products at low production costs, with good quality, better accessibility to market and customer satisfaction. Lean aspects of product development include knowledge based engineering focusing on smart technology, mistake proofing, and continuous improvement as core enablers for process development (Khan et al., 2013). Knowledge based platform proposed in work of Ahmed et al. (2019) demonstrates the influence of
advanced lean technology in product development process using knowledge-based engineering. Thus the following hypothesis is proposed.

**H5:** Lean Operating System issues have positive influence on smart product development.

**Methodology**

In order to address the research objective the present study adopts qualitative and quantitative approaches. A comprehensive search on related literature has been conducted to identify critical attributes of SPD in context of industry 4.0. To carry out qualitative based approach a semi-structured questionnaire was prepared in understanding the contextual attributes and accordingly an in-depth interview is carried out from ten manufacturing organizations where respondents were from top management and managers who have got experiences of working in domain of product development. Criteria for selecting respondents were such that they should have at least served for minimum of eight to ten years as senior manager category with respect to design, R&D, marketing aspects of product development. Organizations involved in manufacturing products that includes consumer based household appliances and intelligent medical devices are considered in this study. Overall five critical attributes have been finalized to be taken into consideration from industry 4.0 perspectives. With identification of critical attributes of SPD attributes a structured questionnaire is developed and respondents were asked to give their opinion for each attributes on 5 point Likert scale ranging from “5= strongly agree” to “1= strongly disagree”. A structured questionnaire was sent to around 250 organizations, out of which 200 organizations responded. Out of 200 questionnaires received 35 found to be with missing data thus total 165 questionnaires were taken into consideration for further data analysis. Overall 165 respondents’ opinion is finally captured for data analysis. SPD is taken as dependent variable in terms of product development success considering operational performance measures. To establish link between predictor and dependent variables proposition have been drawn considering literature and contextual understanding (Büyüközkan and Arsenyan, 2012; Hermann et al., 2014; Kiel et al., 2016; Jianfan et al., 2017; Mrugalska and Wyrwicka, 2017; Kamble et al., 2018). Thereafter, a step-wise multiple linear regression modelling is performed to study the influence of all the five models on SPD. Secondly, factor analysis with PCA (principal component analysis) is done on five attributes to extract and identify the critical dimensions. Third, the extracted critical dimension is further subjected to regression analysis to predict and understand the relationships between extracted factor dimensions and dependent variable (SPD success). In this study SPD is taken as dependent variable which is measured by both operational and quality performance.

**Data Analysis and Results**

This research is exploratory in nature. From quantitative perspective firstly a step wise multiple linear regression modelling is executed which shows all five models are statistically significant with positive and significant impact on SPD. The data being
captured were further subjected for corroboration to see whether it could be analyzed through factor analysis or not. Accordingly, we performed the following analysis: (i) Correlation Analysis: Correlations were high among the practices; (ii) stepwise regression model of critical attributes on SPD (iii) Bartlett’s Test of Sphericity: Found to be significant (p < 0.05), this shows the acceptability of data; (iv) Kaiser Meyer Olkin Test (KMO): KMO test has been found to be 0.752, which is well above cut-off range; (iv) cronbach alpha: overall is 0.791, F1 is 0.823 and F2 is 0.696. Therefore based on analysis it can be concluded it is appropriate to conduct factor analysis (Meyers, 2006; Pallant, 2007). Before conducting factor analysis we performed univariate and multivariate statistics of the variables and discovered no apparent outliers (Jun et al., 2006). To further confirm the existence of normality we conducted two tests i.e. Kolmogorov-Smirnov and Shapiro- Wilks tests, which shows p value to be greater than 0.05 and therefore revealed normal distribution.

**Note:** Dependent Variable is Smart Product Development (SPD); TI: Technology and Innovation; SI: System Integration; CE: Collaborative Engineering; LOS: Lean Operating System; SUST: Sustainability
Factor analysis is performed on five critical indicators as identified from review of literature and contextual understanding based on qualitative study. We conducted factor analysis on explanatory variables/indicators with objective to determine minimum number of factors that accounts for maximum variance in data. The factors were extracted using principal component analysis (PCA with varimax rotation). The objective of deploying PCA is to reduce the number of variables (Jolliffe, 2002). PCA is used to “extract maximum variance from the data set with each component thus reducing large number of variables into smaller number of components” (Tabachnick and Fidell, 2007), which facilitate easier interpretations. Table 3 exhibits rotated component matrix which shows all the five variables having factor loading of more than 0.5 and further could be reconfigured into two factor dimensions as being extracted. Factor dimensions extracted are labeled as “Technological” (F1) and “Strategic” (F2).

Note: Rotation Method: Varimax with Kaiser Normalization

The overall reliability analysis shows Cronbach’s alpha to be 0.791 which validates the reliability of the study. Further reliability analyses show Cronbach’s alpha values for factor dimensions F1 and F2 to be 0.823 and 0.696 respectively, which validates the reliability of the factors being extracted. Regression analysis is performed on two extracted factors. The model explains the variance ranging between 46.8% to 53.5% i.e. the predictors explains the variance in the dependent variable well which is more than the standard 40%. Durbin- Watson index suggests that there is no problem of autocorrelation in data. F-value and VIF indicates that overall model has no multicollinearity problem.

Overall, analysis (Figure 1) indicates the importance of technological factors which can be regarded as critical dimension for SPD. It is expected that from industry 4.0 perspective, IoT could have capability to offer transformational solutions for solving the complex digital issues in complex digital environment. In our opinion smart India in future would add value to realisation of industry 4.0 by deploying cloud manufacturing / manufacturing-as –a- service (Maas) which is gaining importance in manufacturing industry. Cyber-physical systems resemble a significant technological enabler for smart product development.

**Findings and Discussions**

The stepwise regression analysis reveals that attributes like technology and innovation (TI), system integration (SI) and collaborative engineering (CE) have significant positive impact on SPD whereas attributes like lean systems (LS) and sustainability (SUS) have insignificant impact on SPD. The impact analysis of technological innovation indicates that Indian industries are moving towards digital manufacturing where product development process will be executed through organised application of scientific knowledge and is consistent with Hecker (2005). With intervention of advanced technologies it is also likely that developmental process is driven by innovations that add value to the products which facilitates market demand. Here, SI resembles critical significance of cyber physical systems (CPS) where organizations would be able to generate large chunks of production data for real time analysis and decision making. Perception of respondent’s towards SI also confirms the rapid move of manufacturing organizations to adopt IoT (internet of things) based approach where objects/ entities are virtually interconnected with lots of data being generated. CE approach also shows the significance of concurrent engineering management on the developmental process of SPD. As SPD from industry 4.0 perspectives is in its stage of infancy thus it would take some time to apply lean systems management and to develop a sustainable framework. Although TI, SI and CE models have been found to be statistically significant however impact of TI, SI found to be strong and CE to be moderate. This shows the lack of prominence in teamwork and human resource
practices. Exploratory factor analysis extracted two factor dimensions which are referred to as constructs namely “technological” and “strategic” factors respectively. Based on analysis performed, automatic linear modelling shows that both technological and strategic factors have significant impact on SPD which is interesting and thus exhibits paradox. The paradox itself gives an impression that strategic factor alone could not significantly impact SPD when acting alone but can significantly influence when combined effect of each technological attributes (TI, SI and CE) is deployed which shows complementarity effect with other resources. The results indicate that Indian industries with respect to Industry 4.0 anticipate better digital adoption with reduced operational costs and productivity improvement. The significant influence of strategic factor indicates the importance of triple bottom line (3BL) with lean initiatives as critical strategic components towards successful SPD initiatives. The perceptual measures from technological perspective expected to exhibit digital automation with integrated sensor systems as one of the most implemented technologies. The results obtained based on analysis gives an overall impression that increasing quality of industry 4.0 can be accomplished with proper integration of technologies and strategy. The integrated application of technological and strategic factor dimensions indicates that when products embed with advanced technology it increase intelligence and play strategic role. From lean initiatives the results indicate the possible dominance of design engineers to hide unwanted and irrelevant features and reduce environmental impact of product. Findings exhibit an overall impression that strategic/ intelligent product information is likely to be utilized as part of user-centered design process, where industrial designers can take advantage of smart product’s life cycle management. Overall the perception based findings show that advances in semantic and sensing technology can change approach of user interaction with products which eventually leads to product development success.

Contribution of the Study
In this study attempt has been made to analyze the perception of Indian organizations which are involved in product development in order to measure the impact of factor dimensions on SPD in terms of expected implementation benefits. Since the concept of smart product development from industry 4.0 in Indian context is in its stage of infancy and the scarcity of literature available in the said context clearly shows the prominence of the present study and its contribution. Results demonstrate the emergence of two constructs (technological and strategic) which are positively associated to expected benefits in terms of SPD success. The main contribution of this paper is identification of emerging constructs (herein referred to as factor dimensions) of SPD and how these factor dimensions are seen in emerging economy context like India, since most of the studies have been done from developed nations perspective. In this regard the present study showed how technological and strategic factor dimensions are associated with projected benefits of SPD. The designated approach using quantitative model for industries 4.0 gives industries the opportunity to learn regarding solutions from techno-strategic aspect which may be deemed to be a novel contribution from Indian context since Industry 4.0 is still in concept development phase.
Conclusions
In this paper the current industrial development on smart products from industry 4.0 in Indian context has been represented. The attributes and factor dimensions influencing SPD gives a preliminary overview regarding developmental process based approach for smart products. SPD from industry 4.0 perspective in Indian context being relatively new thus there is always a possibility of high degree of uncertainty and technological know-how for real time implementation. Hence, present study would be beneficial for its application based findings which could be taken up by the industries as partial guidelines to undertake implementation procedures from both technology and strategic perspectives.

Practical Implications
Results derived from this study can be beneficial to operations manager and industry policy makers to execute decisions at all levels from strategic, tactical and operational aspects. From operational perspective the results exhibit which attributes are critical for successful implementation of SPD. Considering the present industrial scenario the results would provide partial guidelines to the industries who wish to adopt the strategy of industry 4.0 and think which attributes should be considered. Accordingly based on competitive priorities industries can develop and design their implementation strategies. On other hand industrial policy makers can use the findings of this study to initiate policy level decisions as to what technology and strategic dimensions need to be considered during developmental phases of smart products in order to achieve competitive advantage. For example technological attributes like TI, SI and CE could be strong trending patterns followed by strategic attributes like lean systems and sustainability. Results and findings derived from this study can be beneficial to operations manager and decision makers to design their implementation strategies.

Limitations and Future Scope
In this study five critical attributes of SPD have been considered and there is a scope to explore more number of attributes from industry 4.0 perspective. From statistical perspective the study has some limitations since we considered perceptual measures based on respondent’s opinion from industry 4.0 context, thus there may be possibility of respondent’s bias. Secondly, there is a scope to increase number of respondents to generalise the findings. Future research can incorporate multiple variables and attributes along with control variables for advanced statistical learning. Furthermore, advanced prediction modelling could be initiated in future to investigate the role of contextual variables. Researchers can even think of bringing design management aspects into the entire process flow methodology to make smart products highly flexible and quality oriented.

Abstract

A manufacturing process with two stages of quality control is considered. Initial screening is performed following some critical operations that generate a high proportion of defections. This allows us to discard the defective items at an early production stage and increases the productivity downstream in the production line. The initial screening cost, as well as the defect detection rate, depend on the screening speed. A mathematical model is developed and the optimal production parameters are analytically determined. We provide numerical examples and sensitivity analysis to illustrate the results and to derive managerial insights and implications.

Keywords: Optimal lot sizing, Screening time, Imperfect quality

Introduction

For many companies – e.g. those in electronics and semiconductor industries – it is reasonable to have an initial screening after some initial processing, especially, critical operations such as chemical or mechanical handling like chemical etching, drilling, etc. The reason for this is that the proportion of defections at that particular stage of the process is relatively high, and the remaining production steps are time-consuming and costly. Discarding the defective items at an early production stage increases the productivity downstream in production line and improves the overall performance measures of the system. Therefore, companies sometimes have even more stages of quality checking than one. Cao et al. (2012) provide methods for optimal allocation of inspection stations. Bouslah (2018) provide a model with two stages and joint control of production, inspection and maintenance. The reason for the two stages is the existence of two machine lines. Even though, adding initial inspection to the system might be reasonable for a company because they want to check the parts or input materials from their suppliers. Of course, the extra effort of initial screening has its own costs, and we aim to optimize the time spent with this activity in order to minimize overall costs. The optimization is carried out in the framework of the classical models of inventory analysis.
Cárdenas-Barrón et al. (2014) stated that Harris (1913) published the first inventory model. A special issue of the International Journal of Production Economics celebrated the hundred years’ anniversary of this seminal paper. Among the papers published in this issue, Cárdenas-Barrón et al. (2014) contains a broad overview of the extensions of the original model as well as an extensive bibliography. Andriolo et al. (2014) provide a comprehensive summary on papers in the field, followed by Glock et al. (2014) with a survey on literature reviews in the area of lot sizing. We restrict our attention here on the papers closely related to our topic.

Our model belongs to the extensions of the Economic Production Quantity (EPQ) model, originally developed by Taft (1918) which assumes that the production rate is finite. The other research field we would like to join is focusing on imperfect quality items. A related Economic Order Quantity (EOQ) model is proposed in Salameh and Jaber (2000). It assumes that every single finished item is screened, and the imperfect ones leave the system at the end of the screening period in a batch. The authors draw up the explicit formula to calculate the economic lot size quantity and found that it is increasing with the growth of the average proportion of imperfect quality items. Khan et al. (2011) reviewed the extensions of this model where none of them considers the speed of the screening as a decision variable. Additionally, our paper is adding another stage of quality control to the EPQ version of the model.

Al-Salamah (2016) states that inventory models with imperfect quality can be classified in two categories: predictable and unpredictable identification, the former one being more often found in literature. The author considers imperfect inspection, destructive and non-destructive acceptance sampling. Reviewing most cited papers in the stream of imperfect quality, we found that perfectly reliable quality control is more often assumed which is more or less equivalent to the assumption that every single item is checked at the end of the production process. Alamri et al. (2016) argue that exhaustive inspection may eliminate the return service cost caused by defections, and the impact of letting through defective items could be severe. Instead of sampling techniques, exhaustive screening is more commonly applied in the industries we would like to analyse in this paper. Based on Sahling and Hahn (2019), the biopharmaceutical manufacturing does also belong to the stream of the possible examples with their flexible flow and very strict quality check requirements.

Moussawi-Haidar et al. (2016) were the first who integrated screening time into their production model with rework. Previous literature assumed either that all items are perfect or that screening is carried out continuously, making it possible to rework imperfect items immediately after detection. The authors provide closed form expressions for the optimal production lot size in a framework where inspection is finished later than production, and all defections are repaired. Chiu et al. (2007) consider a proportion of defections to be repairable and the remaining ones to be scrapped, and investigate the joint effects of stochastic machine breakdowns, scrap, and rework on the optimal production run time.

The speed of screening was first considered as a decision variable in Hauck and Vöröš (2015). The authors built EOQ models to find the optimal lot size, screening speed, and level of investments to increase the speed of quality control. In this paper, we rather focus on the initial screening time. We assume that the defect detection rate depends on this time, i.e. the more time is spent on the screening, the higher proportion of initial defections are found. The detected defective items are discarded at this stage, saving energy and cost in the subsequent production steps.

Jaber et al. (2008) extended the model of Salameh and Jaber (2000) with the assumption that the proportion of defective items is lowering from cycle to cycle due to learning. Konstantaras et al. (2012) have further developed this model with the possible
occurrence of shortages, and managerial insights helping companies to choose suppliers. The ideas of both papers are applicable as possible extensions to our model.

**Model description**

A production process with two stages of screening is considered as illustrated by Figure 1. We face a deterministic, known and constant demand of rate $d$. At the beginning of each cycle, we lunch the production of a lot of size $Q$ (decision variable). The production rate is $P$ and on average, a proportion $a$ ($0 < a < 1$) of the production is defective after an initial processing step. Since this proportion is typically relatively high, a screening stage is added right after, to the process. We decide on the amount of time ($0 \leq \sigma \leq \bar{\sigma}$) is spent on the screening of each unit. Both the screening cost and the defect detection rate depend on $\sigma$. To avoid creating a bottleneck at this stage, the screening rate must be higher than the production rate and consequently the maximum time that could be devoted to the screening is $\bar{\sigma} = 1/P$ (unit of time per item). We assume that a proportion $p_1(\sigma)$ of the defects ($0 \leq p_1(\sigma) \leq 1$) can be detected at this stage, and we get rid of the defect items at the end of the processing period. Initial screening cost is $c_1(\sigma)$ per unit. It is natural to assume that if no time is spent on the screening ($\sigma = 0$) than $p_1(0) = 0$ (no defects are detected) and $c_1(0) = 0$ (no costs are incurred). We assume that $p_1(\sigma)$ and $c_1(\sigma)$ are continuous functions of $\sigma$ and at least twice differentiable.

![Figure 1. The production process with two stages of screening](image)

After having separated the defects detected during the initial screening, the production continues with more expensive but reliable operations, followed by the final screening stage. At this stage, all kinds of defects are detected so only the good output is shipped. The defective items found at this step are removed from the inventory at the end of the cycle, without rework. The time spent on final screening is fixed and its cost is $c_2$ per unit. We assume that no backlog arises, and there is no excess inventory at the end of the cycle. In order to satisfy the demand, the defect rate has to be accounted for. The defect compensated demand rate is $d/(1 - a)$ which must remain lower than the production rate (if not, the demand cannot be fully satisfied). We denote by $S = \frac{1 - a}{d} - \frac{1}{P}$ (it can be interpreted as the idle production time per unit).

Notations used in this paper are listed in Table 1, and the inventory build-up diagram of the deterministic EPQ model is shown in Figure 2. During the production period, the inventory raises at rate $(P - d)$, i.e., the production rate minus the demand rate. At the end of the production cycle $R_1 = Q/P$, the company gets rid of the initially detected defects, i.e. $Qap_1(\sigma)$ items. The defective items detected later at the final screening...
stage \((Qa(1 - p_1(\sigma)) \text{ items})\) leave the system at the end of the cycle. The total cycle length is \(R = Q(1 - a)/d\). The average inventory level is \(I_1 = \frac{1}{2}(P - d)R_1\), during the screening period and \(I_2 = \frac{1}{2}[(P - d)R_1 - 2Qap_1(\sigma) + Qa]\) during the remaining time of the cycle.

\[\begin{array}{|c|l|}

\hline
\end{array}\]

\textbf{Figure 2. Inventory diagram of an EPQ model with two stages of screening}

Processing, screening and holding costs are considered at both stages as listed in Table 2. The initial processing cost contains the cost of initial production for every item, whereas final stage processing cost does only consist of production costs of the items that passed the first screening (good and undetected defective items). Speeding up initial screening (spending less time with this process) saves some cost. However, it does also result in a lower proportion of defective items detected. The undetected defective items go through the second stage of production as well as the final screening, which results in higher processing and screening costs in the second-stage.
Table 2. Variable costs in a cycle

<table>
<thead>
<tr>
<th>Costs</th>
<th>processing</th>
<th>screening</th>
<th>holding</th>
</tr>
</thead>
<tbody>
<tr>
<td>initial stage</td>
<td>$k_1Q$</td>
<td>$c_1(\sigma)Q$</td>
<td>$hR_1I_1 = h\frac{Q^2 p - d}{2}$</td>
</tr>
<tr>
<td>final stage</td>
<td>$k_2Q(1 - ap_1(\sigma))$</td>
<td>$c_2Q(1 - ap_1(\sigma))$</td>
<td>$h(R - R_1)I_2 = \frac{Q^2}{2} s\left(\frac{p - d}{p} + a - 2ap_1(\sigma)\right)$</td>
</tr>
</tbody>
</table>

Additionally, a fixed setup cost $K$ is incurred once in every cycle. Thus, the total cycle cost writes:

$$TC(Q, \sigma) = K + k_1Q + c_1(\sigma)Q + k_2Q(1 - ap_1(\sigma)) + c_2Q(1 - ap_1(\sigma)) + hR_1I_1 + h(R - R_1)I_2$$  \hspace{1cm} (1)

Dividing the total cost in (1) by the cycle length, we obtain the average cost $C(Q, \sigma) = \frac{TC(Q, \sigma)}{R}$. After some reduction we obtain the following formula:

$$C(Q, \sigma) = \frac{d}{(1-a)}\left[\frac{K}{Q} + k_1 + c_1(\sigma) + k_2(1 - ap_1(\sigma)) + c_2(1 - ap_1(\sigma)) + \frac{1}{2} hQ\frac{p-d}{p^2} + \frac{1}{2} h QS\left(\frac{p-d}{p} + a - 2ap_1(\sigma)\right)\right]$$  \hspace{1cm} (2)

and hence, the optimization problem can be formulated as:

$$\min_{Q, \sigma} C(Q, \sigma) \quad \text{s. t.} \quad 0 \leq \sigma \leq \frac{1}{p}. \hspace{1cm} (3)$$

The average cost has to be minimized under the constraint that the initial screening should not be the bottleneck in the process, i.e., the screening rate must be higher than the production rate.

**Convexity of the cost function**

Let us suppose now that one of the two functions $p_1$ and $c_1$ is nonlinear but satisfy the assumptions A0-A1 and B0-B1:

**Assumption A0:** $c_1(0) = 0$ and $c_1'(\sigma) \geq 0$, $\forall \sigma \in \left[0, \frac{1}{p}\right]$.

**Assumption A1:** $c_1''(\sigma) \geq 0$, $\forall \sigma \in \left[0, \frac{1}{p}\right]$.

**Assumption B0:** $p_1(0) = 0$ and $p_1'(\sigma) > 0$, $\forall \sigma \in \left[0, \frac{1}{p}\right]$.

**Assumption B1:** $p_1''(\sigma) \leq 0$, $\forall \sigma \in \left[0, \frac{1}{p}\right]$.

The convexity of the cost function ensures that a stationary point is a global minimum which is also unique if the objective function is strictly convex.

Calculating the Hessian matrix:

$$H = \begin{bmatrix} \frac{\partial^2 C(Q, \sigma)}{\partial Q^2} & \frac{\partial^2 C(Q, \sigma)}{\partial Q \partial \sigma} \\ \frac{\partial^2 C(Q, \sigma)}{\partial Q \partial \sigma} & \frac{\partial^2 C(Q, \sigma)}{\partial \sigma^2} \end{bmatrix}$$
\[
H = \begin{pmatrix}
\frac{2K}{Q^3} & -hSa_p'(\sigma) \\
-hSa_p'(\sigma) & c_1''(\sigma) + (-k_2 - c_2 - hQS)ap_1''(\sigma)
\end{pmatrix}
\] (4)

The Hessian is positive definite if and only if the Hessian determinant is positive (see, e.g. Chiang, 1984), and \(\frac{2K}{Q^3}\) is positive as well. The latter condition is true. Thus, the condition (H1) must be satisfied.

\[
\frac{2K}{Q^3}[c_1''(\sigma) - (k_2 + c_2 + hQS)ap_1''(\sigma)] - [hSa_p'(\sigma)]^2 > 0.
\] (H1)

A more explicit form of Condition (H1) could be obtained for particular \(c_1\) and \(p_1\) functions under few assumptions.

**Optimal parameters**

We solve the above optimization problem under condition (H1) that guarantees the convexity of the objective function.

The Lagrangian writes

\[
L(Q, \sigma, \mu_1, \mu_2) = C(Q, \sigma) + \mu_1 \left( \sigma - \frac{1}{p} \right) - \mu_2 \sigma, \quad \mu_1, \mu_2 \geq 0.
\]

The Karush-Kuhn-Tucker points (KKT) are obtained from the following conditions:

\[
\begin{align*}
\frac{\partial L(Q, \sigma, \mu_1, \mu_2)}{\partial Q} &= \frac{\partial C(Q, \sigma)}{\partial Q} = 0 \quad \text{(L1)} \\
\frac{\partial L(Q, \sigma, \mu_1, \mu_2)}{\partial \sigma} &= \frac{\partial C(Q, \sigma)}{\partial \sigma} + \mu_1 - \mu_2 = 0 \quad \text{(L2)} \\
\mu_1 \left( \sigma - \frac{1}{p} \right) &= 0 \quad \text{(C1)} \\
\mu_2 \sigma &= 0 \quad \text{(C2)} \\
\mu_1, \mu_2 &\geq 0. \quad \text{(P1)}
\end{align*}
\]

Condition (L1) implies

\[
-\frac{K}{Q^2} + \frac{1}{2} h \frac{(P - d)}{p^2} + \frac{1}{2} hS \left( \frac{(P - d)}{p} - 2ap_1(\sigma) + a \right) = 0
\]

\[
Q^* = \sqrt{\frac{2K}{h} \left[ \frac{(P - d)}{p^2} + S \left( \frac{(P - d)}{p} - 2ap_1(\sigma^*) + a \right) \right]^{-1}}.
\] (5)

From the formula (5) we can see that higher detection rate \(p_1(\sigma^*)\) makes the optimal lot size increase.

Now, according to complementarity conditions (C1) and (C2), we have \((\sigma - \frac{1}{p} = 0 \text{ or } \mu_1 = 0)\) and \((\sigma = 0 \text{ or } \mu_2 = 0)\). These define four cases, from which \(\sigma - \frac{1}{p} = 0 \text{ and } \sigma = 0\) cannot be true at the same time. Hence, three possible solutions remain:

(a) \(\sigma - \frac{1}{p} = 0\) which gives \(\sigma^* = \frac{1}{p}\) and \(\mu_2 = 0\). In this case, condition (L2) implies
\[ \frac{d}{(1-a)} \left[ c'_1 \left( \frac{1}{p} \right) - k_2 a p'_1 \left( \frac{1}{p} \right) - c_2 a p'_1 \left( \frac{1}{p} \right) - a p'_1 \left( \frac{1}{p} \right) h Q^* S \right] + \mu_1 = 0 \]

from which

\[ \mu_1 = \frac{-d}{(1-a)} \left[ c'_1 \left( \frac{1}{p} \right) - k_2 a p'_1 \left( \frac{1}{p} \right) - c_2 a p'_1 \left( \frac{1}{p} \right) - a p'_1 \left( \frac{1}{p} \right) h Q^* S \right] \quad (6) \]

which must be positive in order for this solution to be feasible.

(b) \( \sigma^* = 0 \) therefore \( \mu_1 = 0 \). In this case, condition (L2) implies

\[ \frac{d}{(1-a)} \left[ c'_1 (0) - k_2 a p'_1 (0) - c_2 a p'_1 (0) - a p'_1 (0) h Q^* S \right] - \mu_2. \]

Hence

\[ \mu_2 = \frac{d}{(1-a)} \left[ c'_1 (0) - k_2 a p'_1 (0) - c_2 a p'_1 (0) - a p'_1 (0) h Q^* S \right] \quad (7) \]

which must be positive in order for this solution to be feasible.

(c) \( \mu_1 = 0 \) and \( \mu_2 = 0 \). In this case, condition (L2) implies

\[ \frac{d}{(1-a)} \left[ c'_1 (\sigma) - k_2 a p'_1 (\sigma) - c_2 a p'_1 (\sigma) - a p'_1 (\sigma) h Q^* S \right] = 0. \]

Hence, \( \sigma^* \) is obtained from the solution of the following equation

\[ c'_1 (\sigma) - k_2 a p'_1 (\sigma) - c_2 a p'_1 (\sigma) - a p'_1 (\sigma) h Q^* S = 0 \quad (8) \]

which must satisfy feasibility conditions.

Note that if the initial screening cost is small and increases moderately with respect to the screening time, then we have case (a), which means that the maximum possible time should be spent on the initial screening. On the other hand, sharp increase in the initial screening cost makes zero initial screening time (case b) optimal. If initial screening cost is neither very high nor very small compared to second-stage screening, processing and holding costs, then the optimal screening time comes from equation (8) in case (c) which balances all the costs.

The condition (H1) is sufficient to guarantee the optimality of any feasible KKT point among the above.

**Numerical examples and sensitivity analysis**

In this section, we provide numerical examples to illustrate the computation procedure and to derive managerial insights from various scenarios regarding the shape of the underlying functions and the values of the different parameters of the model.

Assuming 40 working hours per week, the number of working minutes per year is \( T = 125000 \). Based on the production constraint, the maximum time that can be devoted to initial screening is 1 minute per unit. All the time related parameters are converted to minutes.
Table 3. General parameters to be used in the numerical examples

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>(d)</td>
<td>demand rate</td>
<td>80,000 units/year</td>
</tr>
<tr>
<td>(P)</td>
<td>production rate ((P &gt; d/(1 - a)))</td>
<td>125,000 units/year</td>
</tr>
<tr>
<td>(a)</td>
<td>proportion of defective items in the production, (0 &lt; a &lt; 1)</td>
<td>0.04</td>
</tr>
<tr>
<td>(K)</td>
<td>setup cost (arising every cycle)</td>
<td>$1000/\text{setup}</td>

<td>$10/unit</td>
</tr>
<tr>
<td>(h)</td>
<td>holding cost, per unit of product and per unit of time</td>
<td>$30/unit/year</td>
</tr>
</tbody>
</table>

Additionally, to the parameters above (Table 3), we define multiple scenarios in which we consider various levels of the screening cost and/or detection rate. Furthermore, we vary the proportion of the defective items in the production \((a)\) and observe the effect on the optimal parameters and total cost of the system.

We consider the parameters of the nonlinear detection function to be unchanged while calculating the optimal level of initial screening for cheap, moderate, and expensive parameters of the linear screening cost function. If the proportion of defective items is 4%, then parameter values that are lower than \(\beta = 0.3\), the optimal initial screening time is 1, and for values higher than \(\beta = 2.5\), screening is not reasonable, i.e. \(\sigma^* = 0\).

Table 4. Optimal values of initial screening for various cost levels and defect rates

<table>
<thead>
<tr>
<th>Parameters, Variables</th>

<td>0.9</td>
</tr>
<tr>
<td>Level of the initial screening cost</td>
<td>low</td>
<td>medium</td>
<td>high</td>
</tr>
</tbody>
</table>

Proportion of the defective items in the production \(a = 0.04\)

| Optimal initial screening time | \(\sigma^*\) | 1 | 0.5 | 0 |
| Optimal lot size (units) | \(Q^*\) | 3982 | 3948 | 3858 |
| Optimal total cost ($/year) | \(C^* \times T\) | 3,313,716 | 3,349,839 | 3,376,538 |

Proportion of the defective items in the production \(a = 0.11\)

| Optimal initial screening time | \(\sigma^*\) | 1 | 1 | 0.49 |
| Optimal lot size (units) | \(Q^*\) | 4214 | 4214 | 3915 |
| Optimal total cost ($/year) | \(C^* \times T\) | 3,408,649 | 3,462,581 | 3,641,421 |

As to be seen in Table 4, the cheaper the screening, the more time should be spent with it. For rather low proportion of defective items in the production \((a = 0.04)\), we have shown the two extremes when initial screening is so cheap that the optimal value is the possible maximum \((\sigma^* = 1, \text{ see } #1)\), and when it is so expensive that no time should be spent with it at all \(\text{ (see } #3)\). The optimal lot size increases with the higher optimal values of \(\sigma\). The minimum of the total cost decreases as the optimal initial screening time gets higher. The minimum of the total cost is higher if the proportion of defective items increases, and the differences are also bigger.

Let us also note that an increased proportion of defections, i.e. higher value of \(a\) makes initial screening more crucial. In the example above, it is optimal to do spend time with initial screening even if the costs are high and the maximal value is the optimum for a
moderate cost level already. As illustrated by Figure 3, the minimum of the total cost is increasing with both the initial screening cost and the defection rate.

![Figure 3. The total cost function with respect to \( \sigma \), with low, medium and high initial screening costs, and higher defection rate in the second case](image)

**Conclusion**
This paper presents an inventory model with two stages of quality screening. Jointly with the production lot size, the time allocated to the initial screening is a decision variable as well. This problem is relevant for many companies that have complex operations and many defections in the first stage of the production process.

The time of initial screening determines the related costs but also the proportion of detected defections in linear or nonlinear form. With the objective of minimizing the total production cost, we proposed a procedure to calculate the optimal lot size jointly with the optimal time of initial screening.

There are several results with high relevance for managerial implications. Firstly, the decision regarding the screening time affects the total cost of the system and modifies the optimal lot size. We found out that if the cost of screening in the first stage is too high then it is more reasonable to avoid it and bear the second-stage holding, processing and screening costs. Vice versa, if first stage screening costs are small enough compared to the other types of costs, then the maximal time should be spent on initial screening to allow the detection of a maximum number of defective items. In many other cases, the optimal screening time allows us to balance the various cost components. Other parameters that can influence the decision regarding the screening time include the proportion of the defections in the production (reliability of the production process in the first stage). The findings show that doing quality control in the optimal manner and in the right time reduces the overall system cost while ensuring the desired quality level.

The model in this paper can be extended in several directions. Possible extensions include additional defections in the second production stage, backlogging or rework, random defections, errors in screening and learning effect.

Abstract

The purpose of this paper is to propose a monitoring and evaluation (M&E) framework for national logistics policy based on Banomyong et al. (2008)’s macro-logistics model. The M&E framework was populated by using data from published macro-level indicators and actual performance data of national logistics system users. An identified list of key performance indicators is provided as reference. Cambodia was used to validate the proposed framework and how the framework can support the development of national-level logistics policy. Findings show that the indicators are first used to obtain national baseline logistics performance.

Keywords: Logistics performance, Monitoring and evaluation system, Cambodia Logistics Master Plan

Introduction

Logistics is important to national competitiveness (Arvis et al., 2018). Countries have increased their interest in data related to national-level logistics performances as these will help them not only improve their competitiveness but also support the development of their national policies (Rantasila and Ojala, 2012). Considering the national-level perspective, logistics encompasses both micro and macro levels (Havenga, 2018). At the micro level, this involves firms’ own performance such as reducing logistics costs. At the macro level, the scope is on the national logistics systems (Gleissner and Femerling, 2013), the macroeconomic context (Havenga, 2018) and policy perspective (Banomyong, et al. 2008).

Based on these different scopes, the framework proposed by Banomyong et al. (2008) appears to cover a more holistic view of macro-logistics and micro-logistics issues. However, recent updates are lacking with regards to the present global business context that might impact national logistics performance.

The purpose of this paper is to provide countries with an approach for their national-level logistics policy development. Banomyong et al. (2008)’s initial framework is hereby refined with updated information gathered from both macro- and micro-level
sources. In order to validate the refined framework, Cambodia was selected as an illustrative case.

**Literature review**

Logistics development policy can be referred to as: “the policy that involves the planning, facilitating, implementing, integrating and controlling the efficient, effective flow and storage of freight, people and information within and between logistics systems, for the purpose of enhancing traders’ competitiveness in order to increase national and/or regional competitive advantage” (Banomyong, 2008, p. 45).

Havenga and Simpson (2018) suggested that policy lifecycle consists of stages related to issue identification, analysis, consultation, development and adoption, implementation, monitoring and evaluation as well as adjustment. Thus, it is evident that monitoring and evaluation (M&E) is an integral part of logistics policy deployment that provides a link between the planning and implementation stages. M&E is a stage that keeps decision-makers informed of the policies implemented as well as provides evidence of what adjustments need to be made to current policies given shifts in the country’s indicators (Havenga and Simpson, 2018).

While monitoring focuses on activities and outputs, evaluation focuses on the outcome and goals (Unicef, 1991). Considering the role of M&E in the development of national-level logistics policy, monitoring should be initiated during the conceptual phase of a country’s logistics master plan. This will link the design of the assessment with the planning phases of logistics development strategies of the country. Furthermore, monitoring will help track and evaluate the implementation of those strategies. This is a continuous process of gathering logistics and strategy deployment information to measure against pre-determined set of key performance indicators, benchmarks or previously referenced data which would keep a country in alignment with the goals and objectives of its national logistics master plan.

Logistics at the national level has gained much attention from many countries and at the global level, there already exist a number of global logistics related indicators developed by institutions such as the World Economic Forum or the World Bank to broadly measure logistics quality and performance across the board. These macro-level indicators can capture logistics performance, reflect logistics improvements and can be used as a benchmark for national competitiveness (Havenga, 2018). However, these indicators are not defined for use in a more comprehensive country specific framework. As an example, the Logistics Performance Index (LPI) can measure a country’s logistics performance perceived by external respondents but it is not a reflection of its actual logistics performance (World Bank, 2016; Havenga, 2018). Thus, indicators used in tracking and evaluating policy implementation will need to be derived not only from the existing macro level references but also collected empirically at the national level. Key performance indicators at the sector/firm level are important as these measures can reflect the actual logistics performances of a country. The logistics performance of a country will be based on the performance of national logistics system users.

To propose an M&E framework for logistics policy deployment, this paper uses the Banomyong et al. (2008)’s framework for two reasons. Firstly, this framework has already been used to assess logistics situation in ASEAN and the GMS. Secondly, the scope of the framework includes both micro-logistics and macro-logistics dimensions as suggested in the literature. Figure 1 describes that the framework is composed of four logistics system components. Infrastructure is the backbone of the logistics system while the institutional framework involves the regulatory and institutional environment.
that affects the operation of national logistics users i.e. the service providers and shippers.

![Logistics System Components](Source: Banomyong et al., 2008)

**Methodology**

Since the framework does not provide specific details within each dimensions, the purpose of the paper is to propose a more refined Banomyong et al. (2008)’s framework. The refined framework was developed based on data from two levels. At macro level, there are major internationally recognised databases which include the Global Competitiveness Report by World Economic Forum (WEF), the World Competitiveness Yearbook by International Institute for International Development Management (IMD), the Logistics Performance Index (LPI) by the World Bank and Doing Business (DB) by the World Bank. These provide some basic measurements to define macro-level indicators for the logistics M&E framework of a country. At the micro level, data need to be collected from service providers and shippers related to their actual performances.

The logistics and supply chain literature suggests many key performance indicators (KPIs) that could be used to measure a firm’s logistics performance (Gunasekaran and Kobu, 2007; Banomyong and Supatn, 2011; Banomyong and Varadejsatitwong, 2016). These KPIs derived from the literature can help in the design of questionnaires focused on observing national logistics system users’ logistics performances. The data obtained from these two levels will serve as a country’s logistics performance baseline and can be further used in the development of a national logistics policy.

To explore if such an approach could be used for national-level logistics policy development, a case study research method was used to help the authors validate their proposed framework (Voss et al., 2002; Yin, 2013). Cambodia was selected as an illustrative case. Compared to others in the region, the country faces challenges in logistics performance and needs a proper M&E system to support transport and logistics strategic planning, evidence-based policy making and the monitoring of the implementation of policies related to logistics (Banomyong, 2010).

Indicators in the M&E framework for Cambodia were separated into two groups. The first group, defined as high-level indicators, was based on existing macro-indicators available from secondary sources. Indicators already used by countries around the world
for benchmarking purposes were reviewed. These were set up in order to populate the four dimensions of the national logistics system framework (see Table 1).

</tr>
</tbody>
</table>

The second group focused on the actual logistics performance in the country. A baseline was obtained from actual empirical data i.e. logistics services users and logistics service providers capability in Cambodia. The rationale for collecting empirical data for baseline performance was based on the lack of existing data in the country.

In order to establish the baseline, a pilot survey was conducted. There were two sets of questionnaires. The first set was designed to capture an overview of manufacturing firms’ logistics performance and costs. Respondents included garments, electronics, electrical components and agro-processing. The second set was designed to capture an overview of freight forwarders and logistics service providers’ own logistics capability. KPIs in the surveys were adapted from Banomyong and Supatn (2011) and adjusted to the local context (see Table 2). The selected KPIs focused on the performance of key logistics activities based on cost, time and reliability.

Source: Banomyong and Supatn (2011)

Data collection involved manufacturing, agro-processing firms and logistics service providers in Phnom Penh, Cambodia. The majority of respondents were small and medium size enterprises (SMEs). Data was collected via a workshop format during September 2017 and December 2017. The workshops were facilitated with strong support from the Cambodian Chamber of Commerce (CCC), Cambodia Freight Forwarders Association (CAMFFA), Cambodia Trucking Association (CAMTA), Garment Manufacturers Association in Cambodia (GMAC), Rice exporters’ association etc. Respondents were approached focusing on the key strategic sectors of Cambodia. Representatives from key professional organisations including GMAC, CAMTA and CAMFFA were also involved in the validation and collection of the empirical data.

**Cambodia baseline score**

Identified indicators both at the macro and micro logistics levels in all four dimensions can reflect Cambodia’s national logistics system performance. For a rapid assessment of the logistics performance of the country, it is not necessary to compile all of the proposed indicators. The high-level indicators that need to be compiled and monitored...
are described hereunder in Table 3. These indicators are sufficient to provide a snapshot of the current logistics capability of Cambodia without being submerged by too many KPIs. Table 4 describes the baseline of Cambodia’s current logistics performance as reflected by the users of Cambodia’s logistics system.

The proposed M&E framework for Cambodia’s National Logistics Master Plan

High-level indicators and empirical KPIs need to be aligned with the developed logistics strategies. Thus, the indicators obtained from the previous section were further used to develop an assessment framework of the proposed five strategies developed in the Cambodian Logistics Master Plan. These five logistics strategies have been developed to achieve Cambodia’s SMART Logistics Vision 2025. By doing this, both quantitative and qualitative measures can be used to monitor the national logistics system performance.

The proposed improvement targets for Cambodia are based on requirements that by 2020 the country would need to achieve at least the mean score for each indicator that is under the mean. For those indicators that are over the mean, it is important that their score increases by at least one unit. The 2025 targets are based on at least another unit increase for each of the indicators. For the trading across border indicators, it is necessary to reduce the time and cost by at least 10% for the year 2020 and a further 10% by the year 2025. These targets were validated at a national level workshop in Cambodia on October 30, 2018.

**Discussions and conclusions**

This paper proposed a refined M&E framework to assess logistics performance of a country by using Cambodia logistics master plan as a validating case study. The contribution of this paper is twofold. Firstly, Banomyong et al. (2008)’s framework was updated and refined. A list of KPIs that can be used to reflect national logistics performance at the national level was provided. These indicators were employed to present the baseline score for Cambodia. However, making use of existing macro-level indicators to measure a country’s logistics performance may not be enough. Any country will need to have empirical data obtained from actual performance of its national logistics users to illustrate logistics capability on the ground. At the firm level, logistics baseline score reported by Governments can be used for benchmarking purpose in self-assessment exercises that are developed for competitiveness purposes.

Secondly, the paper provides policy-makers with a useful approach for national-level logistics policy development. It suggests how to holistically assess their national logistics systems and how to use proposed KPIs to investigate whether the developed policies satisfy the needs of its national logistics users.

As illustrated by the case of Cambodia, the refined framework and KPIs were used as an integral part of Cambodia’s Logistics Master Plan development. Identified indicators were put in place to monitor weaknesses, poor designs in implementation strategies and improper actions. This basically helped track and assess implementation of the five logistics strategies to make sure that the developed strategies are aligned to the goals and objectives of Cambodia’s Logistics Master Plan. Based on continuous monitoring, these weaknesses against targets set can then be revised to continually improve national logistics performance.

Evaluation, like monitoring, is a continuous process. The evaluation of output quality can be undertaken in such a way that shortcomings can be identified and corrected. Evaluation will feed into the planning process continuously so that the planned method of intervention can be modified to take into account realities and conditions on the ground.
Evaluation provides a tool for policy makers to ensure that focus is maintained. Therefore, performance management must align the performance metrics to the objectives and strategies of a country’s logistics master plan. The M&E framework provides the basis for national logistics performance management. Aligning performance metrics ensures that the M&E is targeted and does not disrupt the overall master plan. Without alignment, it is difficult to know what to monitor or how to evaluate it.

Abstract

Researchers seek relations between LPI scores and other statistics for developing country logistics policies. The aim of this study is to develop a framework for recommending logistics policies to improve LPI scores of competing countries, specifically the emerging economies, by examining and benchmarking the strategies of countries with high or progressive LPI scores. The study implements both qualitative and quantitative methods for developing strategic recommendations in an uncertain business environment. The developed framework is implemented to provide strategic recommendations for Turkey. This framework can be used as a strategic tool for countries to sustain and improve their worldwide trade performances.

Keywords: Logistic Performance Index, Logistics, Logistics Strategy Development

Introduction

Logistics is one of the key elements of trade (Martí et al., 2014), and logistics performance significantly affects the volume of bilateral trade. It increases the competitiveness of not only the companies but also the countries, and countries recently recognized the importance of logistics in worldwide trade (Hausman et al., 2013). This emerged the need to develop a measurement system for the logistics performance, and develop strategies to advance country performance.

LPI is a survey-based index prepared by World Bank since 2007, which is extensively accepted worldwide (160 countries involved in 2018 version). LPI is a powerful tool for
countries to benchmark and assess their logistics performance in global platform and to understand the logistics challenges as well as the areas for improvement (Gogoneata, 2008). This helps countries to understand their current position and develop country strategies and policies to improve their performance in the worldwide trade.

Political decisions and implemented policies have both direct and indirect effects on the attractiveness of a region or a country in terms of business location decisions and foreign direct investments (Ojala and Çelebi, 2015). LPI is becoming an increasingly respected tool by countries, and political authorities are increasingly using this tool to develop strategies (das Chagas et al., 2018). For example, in Indonesia, LPI is formally used to measure the performance of the Ministry of Commerce. The organization of Asia-Pacific Economic Cooperation (APEC) also uses LPI to measure the impact of an initiative to improve connectivity in the supply chain. The European Commission has used LPI in its Transport Evaluation Panel and its performance evaluation of the Customs Union (das Chagas et al., 2018).

However, knowledge is still limited to understand how LPI scores can be used to develop logistics policies to improve country trade. Literature focuses mostly to LPI or other indexes, their comparison or complementary use (e.g. Gogoneata, 2008; Hausman et al., 2013; Martí et al., 2014). To the best of our knowledge, there are not any studies in the literature examining the practices and policies of countries to improve their logistics performance and their LPI scores to provide a strategic benchmark for competing countries.

The aim of this study is to develop a framework that (i) understands the actions, policies, strategies, and investments behind LPI scores of the countries that either have risen in the ranking or have been consistently in top for the last ten years, and (ii) helps other countries, particularly, the emerging economies, to benchmark their performance and build strategies or policies to improve their worldwide logistics performance under given budget constraints.

The three research questions addressed in the study are as follows;

- **RQ1**: What are the strategies that determine and improve the countries' LPI scores?
- **RQ2**: What strategies should Turkey implement to improve LPI ranking?
- **RQ3**: How a best combination of strategies can contribute to formalize Turkish policies for improving its LPI ranking under budget constraints?

This study employs a multi-method approach. First, content analysis is applied to secondary data collected from various online sources, reports and news to code the logistics strategies implemented by the best-scored or progressive countries. Then, regression analysis is applied to calculate the effect of each coded action on each LPI criteria. This is followed by a survey implementation to estimate the costs of these actions, and a mathematical model is developed that maximizes the LPI score by picking a subset of actions for a given budget. This methodological framework is implemented to Turkey, to develop effective logistics policies for improving its competitiveness in the world trade.

This study makes a significant contribution on the logistics development of the countries and the development of the literature on the area. The methodological approach
followed in this study may lead the way for not only Turkey, but also other countries, to improve trade, and can be used to develop policy recommendations.

The outline of the study is as follows; after a literature review in Section 2, Section 3 presents the methodological framework. Section 4 discusses the implementation of the developed framework to Turkey and the last section concludes the study.

**Literature review**

The modern generation of global change is formed by complex interactions between people, firms, and organizations. Supply chains encompass nations and regions, and trade has turned out to be a 24/7 commercial enterprise. The performance in trade requires connectivity along not only roads, rail and sea, but also in telecommunications, monetary markets and information-processing (Ojala et al., 2014). A country having competitive advantage in terms of logistics performance increases its international trade, expands towards new markets and encourages businesses (Ekici et al., 2016).

Above mentioned evolution introduces LPI as a critical tool for countries to observe their performance over time, assess their relative position with respect to other countries, and outline the logistics areas to improve for achieving higher levels of performance in worldwide trade. Logistics performance needs to be understood, first, at national level to better evaluate the existing position and target exact trade and transport policy to be implemented across countries.

Studies show that, there is strong relationship between logistics and economic growth. Chu (2012) and Navickas et al. (2011) show investing in logistics is important for fostering economic growth, especially for undeveloped and developing country. As the backbone of international trade, logistics encompasses several activities such as freight transportation, warehousing, customs clearance, payment systems, which are mostly performed by private service providers for traders and owners of goods; however, it is also critical for public policies of national governments and regional and international organizations (Arvis et al., 2012). Ekici et al, (2016) mentioned that, due to the complexity of global supply chains, the efficiency of logistics depends on the efficiency of government services, investment and policies as well as other factors which influence the competitiveness of the nation as a whole.

Building infrastructure, developing regulatory regime for transport services, and designing and implementing efficient customs clearance procedures are just a few areas where government play an important role. (Ekici et al., 2016). LPI rankings serve as a benchmark for policy-makers and other interested parties for judging the relative competitive performance of their country within a global context. The logistics strategy is a set of guiding principles, driving forces and ingrained attitudes that help to coordinate goals, plans and policies, reinforced by conscious and subconscious behavior within and between partners throughout the network (Hayes and Wheelwright, 1984).

There are various studies about LPI in the literature. Hausman et al. (2013) and Martí et al. (2014) show that LPI influenced inter-country trade. Çemberci et al. (2015) and Ekici et al. (2016) discuss the relationship between global competition index and LPI. Van Gogoneata (2008) uses standard econometric techniques and LPI calculated by The
World Bank for evaluating the impact of several key macroeconomic variables on the quality of the logistics sector, whereas das Chagas et al. (2018) try to identify the most critical barriers that hinder Brazilian competitiveness with using LPI. Besides, literature focuses particularly to LPI or other indexes, their comparison or complementary use (e.g. Gogoneata, 2008; Hausman et al., 2013; Martí et al., 2014). Remedial work done in this area, showing that Global Competition Index (GCI) may increase the LPI ranking, or any increase in LPI criteria may increase competitive power (Çemberci et al., 2015; Ekici et al., 2016). However, knowledge is still limited to understand how LPI scores can be used as a benchmark to develop logistics strategies and country policies to improve trade.

A methodological framework
This study employs a multi-method approach. The steps include (i) identifying logistics policies via content analysis, (ii) determination of action impacts on LPI scores, (iii) detecting the costs and generating scenarios, (iv) detecting the optimal policies. We present each step in detail.

Identifying Logistics Policies
Content analysis is utilized in this study to analyze and interpret the textual data (Krippendorff, 2004) gathered from various online sources including logistics magazines, articles, newspapers, investments reports of the World Bank, Ministry of Transport publications and news to outline the strategies and policies implemented by countries to improve their logistics performances. Since LPI is published by 2007, data is collected for years between 2007 and 2018. The main categories and sub-coding are explored by making inferences from detailed reading of data inductively (Krippendorff, 2004).

The sample of the content analysis is identified through purposeful sampling (Flick, 2014). The countries with highest and progressive LPI scores within the last ten years are chosen. The high or increasing LPI scores are considered as an indicator of successful assessment and implementation of logistics policies. Generally, countries with steadily higher scores are among the high income countries according to the OECD report. Therefore, their actions would potentially provide important recommendations for the countries with lower or non-progressive LPI scores.

In content analysis, the logistics strategies of the sample countries are analyzed and coded by an iterative process and grouped under distinct categories. Categories with emerging data is constantly compared as the new secondary data sources are emerged and the analysis is progressed (Miles and Huberman, 1994; Krippendorff, 2004).

The reliability of the coding process was investigated by two independent researchers. In case of disagreement, the assessment of a third researcher was asked to resolve the dispute (Weber, 1990).

Determination of action impact on LPI
After the coding process is completed, we utilize regression analysis to determine the relation between the coded actions and their impact on LPI area scores. Regression analysis of data is a very powerful statistical tool (Mendenhall et al., 1996). It provides a
technique for building a statistical predictor of a response. Regression analysis is a branch of statistical methodology concerned with relating a response to a set of independent, or predictor, variables. The goal is to build a good model, a prediction equation relating response to the independent variables that will enable us to predict the response value for given independent values, with a small error of prediction.

In our notation, $T$ is set of years at which LPI scores are announced, $t \in T$, $J$ is the set of LPI areas, $j \in J$, $C$ is the set of countries analyzed, $c \in C$ and $A$ is set of actions determined by content analysis, $a \in A$. Parameters: The number of type $a$ actions taken by country $c$ at year $t$ is $N_{cat}$, and the score of country $c$ on LPI area $j$ at year $t$ is $LPI_{cjt}$. We estimate the impact of action $a$ on LPI area $j$, $\alpha_{aj}$ via regression analysis.

Note that, actions in $A$ set and the number of actions taken by a country in a year ($N_{cat}$ values) are the outputs of the content analysis. An action taken by a country may improve the score on one LPI area but the same action may deteriorate the score of another area. To capture such effects of the actions, we conduct the regression analysis on each LPI area separately.

As one may expect, not all actions have significant impacts on each area. In order to find the most suitable regression model for each area, we employ backward elimination method with the threshold value of $\alpha=0.1$ and obtain the $\alpha_{aj}$ values.

**Cost detection and scenario analysis**

After determining the set of actions and their impacts on each LPI area, we need to estimate the relative costs of these actions. For this purpose, we prepare a questionnaire to be answered by a target group of logistics experts.

We deploy an online questionnaire to increase the interactivity and provide flexibility to participants. Each participant could respond the questionnaire only once. We ask participants to estimate the relative costs of actions by assigning a score between 1 and 100 for each action. Recall that $\alpha_{aj}$ value represents the contribution of action $a$ on the score of LPI area $j$. In the survey, we include all actions that has at least one LPI area $j$ with a positive $\alpha_{aj}$ value.

Let $E$ be the set of experts, $e \in E$, and $rea$ be the response of expert $e$ for action $a$. We normalize the response of each expert so that the total budget of all actions add-up to 100. We consider each action separately and treat the normalized survey results as samples from random distributions of action costs. For each action, we fit a random distribution to the normalized expert responses using Arena Input Analyzer.

Let $D(a)$ be the suggested distribution for the cost of action $a$. Using these random distributions, we generate the action costs of an instance $k$. Let $c_{ka}$ be the cost of action $a$ in instance $k$. We use $K$ as the set of all instances.

**Optimal policy determination**

In the final stage of the framework, we develop a mathematical programming model that aims to maximize the LPI score by selecting a subset of actions under a given budget constraint. We define the actions based on content analysis, estimate the impacts of these
actions on each LPI criteria by regression analysis and generate the costs of taking these actions based on survey results.

We define additional parameters. Let $w_j$ be the weight of LPI area $j$, $LPI_{0j}$ be the current LPI area $j$ score of country under consideration, $b$ be the available budget and $B_k$ be total cost of actions in instance $k$, $B_k = \sum_{a \in A} c_{ka}$.

The decision variables are $x_a$, $LPI_{0j}^*$ and $LPI_0^*$. The decision variable $x_a$ gets the value of 1 if action $a$ is selected and 0 otherwise, $LPI_{0j}^*$ and $LPI_0^*$ are the modified LPI area $j$ score and LPI score of country under consideration, respectively.

$$\text{Maximize } LPI_0^* = \sum_{j \in J} w_j LPI_{0j}^*$$  \hspace{1cm} (1)

s.t. 

$$LPI_{0j}^* \leq LPI_{0j} + \sum_{a \in A} \alpha_{aj} x_a \quad j \in J$$ \hspace{1cm} (2)

$$LPI_{0j}^* \leq 5 \quad j \in J$$ \hspace{1cm} (3)

$$\sum_{a \in A} c_{ka} x_a \leq b \quad j \in J$$ \hspace{1cm} (4)

$$LPI_{0j}^* \geq 0 \quad \forall a \in A$$ \hspace{1cm} (5)

$$x_a \in \{0,1\} \quad \forall a \in A$$ \hspace{1cm} (6)

The objective function (1) aims to maximize the final LPI score, defined as the weighted sum of the modified LPI scores of each LPI area. Constraint sets (2) and (3) define upper bounds on the modified area scores. Constraint set (2) imposes that for each LPI area, the modified area score cannot exceed the sum of current LPI score and the total impact of taken actions. Constraint set (3) defines the upper bound for each LPI area. Constraint (4) ensures that the total cost of taken actions do not exceed the budget. Constraint sets (5) and (6) define the decision variables.

We analyze the trade-offs between the available budget and the final LPI score. For a given instance $k$, we solve the above mathematical model for different budget values such that $b=5\%, 10\%, 15\%, \ldots, 95\%, 100\%$ of $B_k$ value. For each budget value $b$, we analyze the final LPI score and the selected actions for the given budget.

**Implementation of the methodological framework: A Case of Turkey**

The methodological approach explained in the previous section is implemented in Turkey, an emerging country, ranked $18^{th}$ in the world economic size with $718B$ Gross Domestic Product (GDP), and has $198.6B$ imports, $157.9B$ exports, over 10 million Twenty-foot Equivalent Unit (TEU) logistics capacity and connects east and west.

As a result of the content analyses, the logistics actions of high-scored and progressive countries are identified under 234 codes, which are then grouped under 158 sub-groups and categorized to 16 distinct actions.
In order to outline the actions having significant impact on six LPI areas, separate regression analysis is conducted to these 16 actions, one for each LPI area. Each analysis is implemented via backward elimination method, and the actions with $p$ values less than 0.005 are considered as having significant effects. Actions having positive effect on at least one LPI area are discussed in detail. Other actions are omitted in the rest of the study, since there is no motivation to spend budget on an action that has either zero or negative effect on all LPI areas.

According to the results of the regression analysis, there are six actions (out of 16) that have positive affect in at least one of the LPI areas. Table 1 presents the two actions affecting multiple LPI areas. The remaining action impacts are as follows: Efficiency studies on infrastructure 0.823; Marketing on ease of arranging shipments 0.504; use different modes of port on customs 0.384; and use different modes of transportation on infrastructure 0.42.

<table>
<thead>

<td>0.509</td>
<td>0.389</td>
<td>0.513</td>
<td>0.454</td>
<td>0.495</td>
</tr>
</tbody>
</table>

Based on regression analysis, there are actions with negative effects on LPI. We believe that, these actions are implemented successfully by the developed countries. However, the negative impact of these actions on LPI scores would be caused by the emerging or less developed countries, which could not adopt these implementations effectively to their existing system.

We discuss the six actions with at least one positive affect in detail:

*Cooperation:* This action addresses the cooperation between two or more countries, or, between policy makers and private sector on customs operations, economic or logistics activities. Since the first introduction of LPI scores, more countries’ public agencies and private stakeholders are implementing well-grounded programs to address the weakest links and stimulate cooperation along the macro supply chain (Ojala et al., 2010), rather than taking separate or individual actions. For example, countries including Kenya, Uganda and Burundi perform well in regional integration (establishing a trade corridor). A closer look on LPI scores of these countries shows the impact of the action (Arvis et al., 2016).

*Environmentalist Mindset:* Sustainable environmental thinking is an emerging field as a market driver (Rao and Holt, 2005; Ojala et al., 2010). This action addresses the countries, which are involved in environmental business activities; such as waste management, emission reduction, environmental protection. Reduction and control of the CO2 emission rates in the world comes first in terms of environmental activities. Encouraging the use of environmentally friendly vehicles and equipments by the government, and the development and strict supervision of waste disposal facilities are some actions that can be implemented as an indicator of environmental thinking. Policies can be implemented to provide incentives to motivate stakeholders towards environmental activities.
Marketing: This action is associated with strategies such as customer-orientation, advertising, and promotion of private sector. Marketing is also one of the most important elements in trade (Brooks et al., 2017). If the country wants to increase the volume of their ports, they should attract the interest of foreign shippers by implementing marketing strategies. For example, improving the customer orientation in the port management would increase the competitiveness of the port in worldwide trade (De Langen and van der Lugt, 2006).

Use Different Modes of Port: Actions developed to improve the port business models are found to be important to improve the LPI scores of the countries, such as forming a transfer center (a combination and distribution point in a transport network) or the use of the host model (e.g. Landlord: Port land owned by the state, but all operations carried out by private companies). This action can facilitate operational management and eliminate unnecessary complexities in ports.

Use Different Modes of Transportation: The actions of combining different types of transport (multi-modal transportation) and establishing a corridor model are evaluated under this action. Countries that take this action usually transport by connecting transport networks. One of the objectives of this strategy is to reduce the traffic in the preferred transportation mode, and to shorten the delivery time. Also establishment a regional corridor would support this action, due to the landlocked countries.

Efficiency Studies: The countries activities on efficiency studies, such as removing unnecessary administrative barriers, investing to remove bottlenecks, maximizing container efficiency, are evaluated under this category. The most remarkable action is making investments to remove bottlenecks. For example, Canada uses performance indicators to measure efficiency in ports and supply chains (Ojala et al., 2010), as measurements can help to detect opportunities to remove inefficient activities.

We next conduct the survey to a group of 27 logistics experts, with an average of 12 years of industrial experience, to estimate the costs of the selected six actions. We normalize the expert responses as described in Section 3 and fit random distributions for the cost of each action using Arena Input Analyzer. The fitted distributions are as follows: Cooperation, Normal (14.8, 5.35); Efficiency Studies, Normal (15.7, 4.68); Environmentalist Mindset, Normal (18.1, 4.49); Use Different Modes of Transportation, Normal (14.1, 5.06); Marketing, Triangular (10, 15.2, 30); and Use Different Modes of Port, Triangular (12, 16.8, 28).

Using the suggested random distributions, we generate 100 different instances. Note that, in each instance, the set of actions and impacts of these actions on each LPI are common. However, the costs of the actions are randomly generated. For each instance we compute the budget required to implement all actions (the total cost of all actions), and then solve the developed mathematical model for 20 different budgets levels, from 5% to 100% of the total budget. We develop the mathematical model and conduct the experiment on GAMS. Totally, we solve 2000 mathematical models and the total run time of all models is less than 5 minutes.
Figure 1 reports the mean, minimum and maximum LPI scores for different budget levels. The LPI score starts at 3.15, current LPI score of Turkey, and increases to 3.99, best possible LPI score when all actions are taken. By using 20% of the budget required, the mean LPI score reaches to 3.53, roughly half of the possible range.

We also count the number of instances each action is selected for different budget levels. Even for small budget levels, environmentalist mindset has the highest selection rate. This is due to the combination of its high impact on several LPI areas and reasonable cost requirements. The mathematical model prefers to take the environmental mindset action even if the budget is 15% of the total action costs. Moreover, efficiency studies and cooperation actions are frequently selected actions even at lower budgets. Use of different modes of port action also contributes the LPI score, but mathematical model avoids taking this action nearly in all instances unless the budget level is 100%. Based on the experiments, the order of actions to be taken are as follows: (1) Environmentalist Mindset, (2) Efficiency Studies, (3) Cooperation, (4) Marketing, (5) Use Different Modes of Port (6) Use Different Modes of Transportation.

Conclusion
In this study, we propose a framework for developing logistics policies based on the LPI scores. We implement the proposed framework to Turkey and suggest strategies for improving Turkey's LPI score.

The frameworks start with analyzing the actions taken by selected countries and groups these actions via content analysis. Next step is to determine the impacts of the actions on the LPI scores of the selected countries using the regression analysis. Afterwards, the costs of the actions are determined via surveys and several instances are generated based on survey responses. The penultimate step is to determine the best actions for different budget levels via a mathematical programming model. Finally, the results are analyzed to suggest strategies. We implement the proposed approach to Turkey, the suggested actions are ranked as environmentalist mindset, efficiency studies, cooperation, marketing, use different modes of port and use different modes of transportation. Especially the first three actions are highly recommended in case of limited budget.

We develop a framework that utilizes quantitative and qualitative methods. A further research direction is to improve the framework by suggesting methods for making better decision within the framework such as, country selection, impact and cost estimation.
Also it is possible to conduct a retrospective analysis to assess the power of the framework and calibrate the necessary components.

Abstract

As construction projects advance more complicated, practitioners and researchers always deliberate on performance improvement. However, it is even ambiguous about what is performance and how to measure it. Through critically reviewing literature from 1987 to 2019, the need for an integrated measurement system is a considerable gap because contemporary frameworks just research one of the multi-facets of performance from a particular angle. For comprehensively measuring performance from the contractor perspective at the project level, a hierarchical performance measurement model (HPMMCP) will be developed using the quantitative method through Structural Equation Modeling with Amos.

Keywords: Structural Equation Modeling with Amos; Construction Projects; Performance Measurement;
Introduction

Research Background
Over the past few decades, the gradually complicated global business environment and rising competitiveness have emphasised the significance of performance measurement and further improvement (Neely, 2005). However, before structuring model to promote performance, it is even vague about what is the performance and how to measure it. According to Micheli and Mari (2014), if you cannot measure the performance, you just cannot improve it. Similarly, Kaplan (2009) indicates measurement is as fundamental to managers as it was to scientists. Therefore, performance measurement with high research and practical value is the imperative foundation of all the research and management of performance improvement.

Specific to the construction industry, which usually acts as an impetus to trigger the economic growth, plenty of government documentation mention that construction performance is difficult to accurately measure and meet the requirements of environmental change and progressing alteration. (Harris and McCaffer, 2013). Comparing with companies, to some extent, the project usually could be seen as a contemporary organization. However, the construction project is a little bit different than other projects owing to the typical feature of the construction sector. The average length of UK construction projects is more than 6 years, which may exist longer than some companies. If taking continuous maintenance into consideration, the extended project duration will be far more lengthened. Considering the specificity and significance, it is necessary to develop a performance measurement model for construction projects.

Owing to the lack of comprehensive performance measurement model of construction projects from the contractor perspective, firstly, it is a quite sincere obstacle for how to choose the qualified contractor by the client and how to certify they are qualified by the contractor (Aboelmagd, 2018). Secondly, misutilization of measurement models from one dimension of technical field (accounting, marketing, operation, or supply chain management) does impede performance comparison among different construction projects. Thirdly, project managers are burdensome and problematic to make development strategies, implement decision making, design performance-related pay for the employees, and even gain more investment because of unclear priority weights of different performance aspects. Therefore, a generalized construction project performance measurement model has great research value and practical value to develop.

Purpose
As construction projects advance more complicated, practitioners and researchers always deliberate on performance improvement. However, it is even ambiguous about what is performance and how to measure it (Bourne et al., 2003). Integrated performance measurement system and unified project performance index need to be developed and expanded (Nassar and AbouRizk, 2014). The purpose of this research is to develop a hierarchical performance measurement model (HPMMCP) for construction projects from the contractor perspective.
Literature Review

Concept of Performance Measurement
On the basis of different priorities, some researchers more focus on the association between project objectives and performance measurement. Sinclair and Zairi (1995) define that performance measurement as a process for assessing how successful organisation or individuals have been realised their objectives. Differently, some authors define project performance measurement from the perspective of application value. Performance measurement could be defined as a systematic method as a tool to evaluate the inputs and outputs in the process of project execution for constant enhancement (Chan, 2001).

As for construction projects, performance measurement has been defined as the formal and typical collecting and assessing of inputs, efficiency and effectiveness of construction projects (Chan et al., 2001).

Significance of Performance Measurement
Beatham et al. (2004) mention performance measurement is being included as a portion of strategic process control planning owing to four justifications including position checking, position communicating, priorities confirmation, and progress compulsion. Firstly, performance measurement could constantly keep track of the procedure in every phase and evaluate the ongoing situation as position checking. Secondly, position communicating as another reason could notify clients and working staff the specific working performance evaluation results with an aim to improve the transparency and promote employee involvement. Thirdly, priorities confirmation means that performance measurement is beneficial to confirm the unified priorities and sequence of every activity and during the project life-cycle. Fourthly, progress compulsion demonstrates that explicit performance measurement contributes to identify potential enhancement spaces and further promote performance advancement.

Performance measurement is recognized as a vital method of identifying the in promoting sustainable and feasible competitiveness for the UK construction projects and sector (Ahmad-Latif fi, 2012). The significance and necessity for an integrated and well-structured model to flexibly, effectively and accurately measure construction project performance are highlighted through analysing the importance of performance measurement.

Similarities and Distinctiveness between Construction Project and Company
The project is defined as a consociation with a temporary institution for delivering the particular service or production, which is regards as a lower-expense and speedy solution for a complicated consequence (Canonico et al., 2013). Comparing with other interim projects, the duration of the construction project is quite long. According to APM body of knowledge, the project life cycle covers the whole project duration until successful project delivery (Management, 2012). However, the extended life cycle may never be terminated owing to constant use of construction output (buildings, civil engineering, and specialized construction production) and continuous maintenance. In practice, considering the construction company insolvencies, to some extent, construction projects even have longer existence time than corporations. Therefore, the performance measurement of construction projects needs to holistically balance temporary and permanent objectives.
Performance Measurement Framework

Balanced Scorecard
Balanced Scorecard as one of contemporary performance measurement is structured by Kaplan and Norton (1992) to prevent researcher or practitioners for unduly focusing on the financial measures rather than operational measures. Scorecard (BCS) is the model to widely measure the performance in organisation level from four perspectives including financial, internal processes, customers, and learning and innovation (Kaplan and Norton, 1995).

Bassioni et al. (2004) note that BSC as one of the most vital performance management tool was utilised and cited during the last 75 years. The four BSC perspectives associate long-term enterprises’ strategic objectives with explicit short-term activities (Pienaar and Penzhorn, 2000). The strategies for unit, division, department or even whole organisation should be learned by overall companies to guide their working activities, assess individual behaviours, adapt to the environmental changes. (Morris et al., 2006)

Although Balanced Scorecard is the most prominent model in research and practice, it still exists some disadvantages (Neely et al., 2000). BSC only generally identify the four dimensions without measurable and fixed sub-indicators. In application, the firms using BSC still spend a high proportion to go into liquidation (Bourne et al., 2000). Furthermore, actual perspectives related to construction suppliers and contractors are supposed to cover. Hence, there is a gap for exploring and developing a more comprehensive model for measuring project performance.

The European Foundation for Quality Management
EFQM is a non-profit institution build up in 1988 originally with an aim to motivate business excellence in European. Based on concise practical experiences of private or public companies across the whole Europe, the EFQM assessment format as the huge breakthrough in performance and quality management has been applied effectively (Van Marrewijk et al., 2004). According to Hellsten and Klefsjö (2000), EFQM excellence model as the management way is concentrated on quality, which is in allusion to long-term organisation success by way of customer satisfaction, acquired advantages of all members, and business improvement (Lee and Quazi, 2001).

The limitation of the shortcoming of EFQM cannot be ignored. There is no evidence to support the assumption for the same weights (50%) between enablers (formative factors) and results (reflective factors) in EFQM. The coefficients of every factor need to be calculated using a holistic model. Furthermore, the measurement model ought to identify reflective factors for accurately, efficiently assessing performance rather than classify formative factors for how to influence performance.

The Performance Prime
Neely et al. (2001) proposed a performance measurement model, which is focused on stakeholders and integrates the demand of stakeholders based on five related facets (strategies, processes, capacity, stakeholder satisfaction, and stakeholder contribution). This model gives performance measurement research a brand-new perspective to explicitly separate stakeholders satisfaction and their contribution (Powell, 2004). On the other side, The Performance Prism also receives some critique. Medori and Steeple (2000) mention that the lack of measures selection causes low feasibility and application of the framework without guidance. It is time-consuming and cost-
consuming to utilize the model in practice because companies need to identify all measures by themselves.

**Discussion**

Through critically reviewing the contemporary frameworks including Balanced Scorecard (BSC), European Foundation Quality Management (EFQM), and Performance Prime, these frameworks could coexist simultaneously on the grounds that every framework merely research one of the multi-facets of performance from a peculiar perspective and utilize obscure classification principle (Jin et al., 2013). According to Neely et al. (2002) and Bassioni et al. (2004), the need for a comprehensive model to cover all aspects of performance measurement and realize performance benchmarking generalization is a considerable gap.

**Model Establishment**

**Factor Identification**

An appropriate performance measurement framework provides a ‘balanced’ picture of the concrete business. That is the reason why different types of projects and business may need a diverse framework to more accurately align well with the specific project. After critically reviewing and discussing the project performance methods, frameworks, systems, measurement indicators adopted in the literature from 1987 to 2019, HPMMCP as a formal and unified construction performance evaluation system is structured for accurately and comprehensively measure performance covering financial and non-financial, internal and external, current and developmental potential aspects.

In HPMMCP, the first level is the integrated project performance, which should be further quantified and calculated to realise comparison among projects using project performance index (PI). Matching with the hierarchical structure and top-down method, for developing a more comprehensive and dynamic model, six unobservable factors (Financial performance, operational performance, client satisfaction performance, developmental potential performance, quality performance, and safety performance as can be seen in table 1) are used at the project level as a second layer.

<table>
<thead>
<tr>
<th>Table1 – Performance Measurement Factors</th>

<tr>
<td>Operational Performance</td>
</tr>
<tr>
<td>Client Satisfaction Performance</td>
</tr>
<tr>
<td>Developmental Potential Performance</td>
</tr>
<tr>
<td>Quality Performance</td>
</tr>
<tr>
<td>Safety Performance</td>
</tr>
</tbody>
</table>

Furthermore, every unobservable factor in the second level needs to be measured using some observable factors in the third layer in accordance with structural equation modelling.

**Financial, Operational, and Client Satisfaction Performance**

Financial Performance could be evaluated by three factors including profitability, cost variation, and billing. The operational performance will be assessed by six indicators, such as schedule variation, team satisfaction, equipment resource utilization, material
resource utilization, workforce capacity utilization, and sufficient communication. Furthermore, client satisfaction performance is measured through client demand fulfilment degree, client service, intention to the subsequent project.

**Developmental Potential (New Factor)**

In psychology, Dabrowski (1966) developed the Theory of Postive Disintegration (TPD), which research personality development. Developmental Potential as the cornerstone of the TPD is the in the first time proposed to describe the constitutional endorsement which measures the possibility of character and mental growth of a given person. Dabrowski (1966) indicates that there are many features contained in the concept of developmental potential.

Based on sociology and psychology, where there is a person, there is a character. One person has own personality so social collectives could equivalently exist. Through analogy with personality, a team of individuals has its own ‘Teammality’. In organizations, it should be could ‘Organizationality’. As for the construction project, it could be named ‘Projectnality’. Personality as one of the concepts in sociology, psychology, and healthcare research area already is transferred to utilize at the organization level. According to Blagoev et al. (2019), orgnalizationality could be seen as a more gradual differentiation to measure either organizations or non-organizations.

In this research, DP as a reflective indicator is switched from TPD to measure the growth possibility of project performance. If it shows not promising for the performance development that means current performance is not good enough, even if the situation of current financial statements, client satisfaction, and operation are qualified. The hypnosis is if there is a strong developmental potential which means the current project performance is actually good. Present status of projects does cause the result in the future. If the DP is weak, it not only just indicates that the financial performance has a high possibility to fall in the future but also do shows the current comprehensive performance is not good.

Developmental Potential represents a constellation of performance reflective factors. To more specifically, DP could be divided into Contract DP and Construction Project DP. It is nearly impossible to only measure construction project DP and ignore contractor DP. Thesis two DPs could integrate diverse measurement perspectives to more accurately reflect performance. Project DP could be further measured by innovation behaviour, organizational level satisfaction, consistency with corporate strategies, environment sustainability, and life-cycle maintenance as seen in Table 2.

### Table 2—Project Developmental Potential Performance

<table>
<thead>
<tr>

<td>Innovation Behaviors (Product and Process)</td>
</tr>
<tr>
<td>Organizational Level Satisfaction</td>
</tr>
<tr>
<td>Consistency with corporate strategies</td>
</tr>
<tr>
<td>Environmental Sustainability</td>
</tr>
<tr>
<td>Life-cycle Maintenance</td>
</tr>
</tbody>
</table>

In Table 3, Contractor Team DP will be measured by five indicators including Dependability, Competiveness, Risk Resistance Capacity, Innovation Motivation and Ability, and Flexibility.
Table 3—Contractor Team Developmental Potential Performance

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>Innovation Motivation and Ability (Product, Process, Marketing)</td>
<td></td>
</tr>
<tr>
<td>Flexibility (meet unplanned challenges; problem-solving ability)</td>
<td></td>
</tr>
</tbody>
</table>

There is no developmental potential in the future is because the present project is no doing well. Therefore, DPP is a crucial indicator to measure immediate mode performance model.

Quality and Safety
Quality and safety as two prerequisites screen out the qualified construction project, which meets the initial standards by laws and regulations, industry requirements, and contract agreements. If one of quality and safety is not qualified, there is no need to keep calculating PI number.

In Table 4, Quality contains three fundamental requirement indicators including Technical Specification of Deliverables required by Laws and Regulations, by the UK Construction Industry, by Project Contract. Furthermore, the higher requirement of quality also is covered including Functionality, Construction Field Rework, Compliance degree with flexible requirements, Life-cycle Maintenance.

Hierarchical Model for Construction Project Performance Measurement

After critically reviewing papers related to performance measurement factors, models, structures, and theories, the HPMMCP is built as can be seen in Figure 1.

Figure 1: Hierarchical Performance Measurement Model for Construction Projects (HPMMCP)

This HPMMCP model earns high research and practical value. Firstly, it rationalizes the linkages between reflective performance indicators and project objectives. Secondly, HPMMCP comprehensively measures construction performance covering different aspects and maintain the generalization utilizing a large sample size, which effectively realizes the performance comparison among diverse construction projects. Managers could assess their project with other competitors to improve management and show stronger successful performance evidence in bidding conference. Thirdly, it is approached in setting up two prerequisites (quality and safety) that model not only assesses the project process but also guarantees project product. On the basis of implementing project delivery and providing qualified final outputs, project performance status and developmental potential will be measured by a hierarchical composition of reflective measurement indicators. Fourthly, HPMMCP thoroughly measures financial and non-financial performance, internal and external performance, prompt reflective performance and developmental potential performance in the subsequent project duration. Fifthly, HPMMCP propose a brand-new factor (DP) switched from sociology, which evaluates whether consequent circumstance is promising to reflect current performance. If the developmental potential of the project is weak, the present performance cannot be described as successful performance even
current financial numbers all show well. HPPMMCP provides an ingenious and comprehensive tool that directs management attention to what is vital for not only current performance status but also long-term performance. It assists for contractor teams to design, operate, validate their current performance measurement system.

Research Design and Methodology

Research method is required in conjunction with purpose, therefore, a quantitative method is used to test a theory and assign the weights in HPMMCP. After cross-sectional data collection from questionnaires, Structural Equation Modeling (SEM) as statistical analysis tool will be further relied on calculating weights, maintaining highly data adaptability, reliability, and validity, and reducing measurement error (Kline, 2015).

![Steps of Research Design](image_url)

Figure 2: Steps of Research Design

In Figure 2, the research is designed in three steps: (1) structuring a performance measurement framework at project level from contractor perspective, (2) utilizing SEM to calculate weights among different factors and completing model establishment, (3) testing model by the questionnaires data from UK construction projects.

Conclusion

This paper has succinctly argued that construction project performance measurement has a huge significance and value. However, there is a lack of an integrated performance measurement model from the contractor perspective at the project level. The HPMMCP will be established to fill the gap and optimize construction project performance evaluation. First-hand data collected for UK contractors would be collected by questionnaires and analysed by Structural Equation Modeling with Amos to calculate all the weights and errors. After model modification, HPMMCP could effectively improve UK construction project performance measurement.

Abstract

High wastage rates and unsatisfactory performance gains affect on-site working for industrialised housebuilding (IHB) production. Rarely used performance management systems (PMS) are often quoted as one obstacle to support systematic productivity and efficiency improvements. To prepare the field for the development of an informative PMS a multiple case study is carried out, in order to show the potential on applied performance management systems. The three cases show diversified application of performance management (PM), ranging from various performance indicators used for management decisions to almost ignoring generated measures. Different approaches in developing PMS for the identified corporate strategies are analysed.

Keywords: performance management, industrialised housebuilding, on-site assembly

Introduction

The construction industry, including industrialised housebuilding (IHB), suffers under high wastage rates, poor use of resources (Josephson et al., 2002; Josephson and Saukkoriipi, 2007), and limited productivity increases (Bornett et al., 2016) compared to other industrial sectors. Even though not clearly specified in literature, the improvement potential for IHB is considered to be immense and IHB companies should be able to better quantify and assess this potential.

The production processes of IHB companies have a unique position within construction industry, as story-high wall, ceiling and roof elements or modules are prefabricated within a factory and assembled on-site. The prefabrication of elements or modules is in the advantageous position of being able to implement clear structured processes, similarly to manufacturing industries. Increasing the productivity and
efficiency of these off-site processes is far easier as for on-site activities, as clear responsibilities can be defined and a measure and control of performance criteria is simple. It is obvious that off-site activities contributed the most to performance improvement in the IHB sector (Lessing et al., 2015).

In contrast, the performance improvement of on-site activities lags far behind. This may be explained in part by the inability to satisfactorily assess the performance of on-site production. The current methods do not provide accurate assessments of the effects of interventions, they are not reliable enough, are too cost- or time consuming for regular management of performance (Raffoni et al., 2018). Very many factors impact on the accurate measurement of performance falsifying or distorting the resulting data. Additionally the complexity of an IHB order-fulfilment process must be considered (Sardén, 2005). Further difficulties occur due to the on-site operations and to the segmented order fulfilment processes, as well as the variety of in-house and suppliers’ employees involved (Knauseder et al., 2007).

IHB companies commonly implement performance management system (PMS) only for the assessment of core processes within the prefabrication processes or for analysing simple indicators such as on-site assembly duration in past-project evaluation (Lessing et al., 2015). This problem was noticed by Barker and Naim (2008) as they revealed that more than 60% of housebuilding companies do not collate data for performance management (PM) of on-site assembly. Neither do they use it for PI.

To ensure a sustainable improvement based on a companies’ strategies, suitable PMS and performance indicators are an indispensable tool for control and the achievement of management objectives (Raffoni et al., 2018). To better cover the performance measurement and management of the IHB order fulfilment process, there is a need to improve PM of on-site construction processes.

Studies analysing the current PM within the IHB sector are rare, which makes defining the current situation and identification of improvements difficult. This paper aims to overcome this and reveal the state of art in on-site performance measuring, thereby identify the potential areas for improvement and prepare the field for the further development of significant PM systems. The multiple case study investigates the following research questions: (1) What is the state-of-the-art of performance measurement and assessment within an IHB on-site context? (2) What are the needs for improving performance management for various IHB production strategies?

**Literature Review**

The production processes of IHB companies divide in off-site and on-site activities. Off-site activities have a clearly structured process similar to those of manufacturing industries. The activities reoccurring and repeated many several times a day (Lessing et al., 2015). This contrasts with on-site production which is most commonly project-based, the predominant organisational form in construction industry. Activities performed during order fulfilment often recur in follow-up projects, although they may take place once as a specific feature within a construction project. The organisational form of the order fulfilment process may be classified as an intermediate position between process and project orientation (Höök, 2008). Beyond the effects on operational management this type of organisational form influences the whole PMS, from representing a companies’ strategy, in performance criteria for on-site assembly, to data collection and analysis and finally, to the output of suitable performance indicators (PI).

Compared to other building sectors, prefab construction clearly benefits from its building systems as well as its design and production processes, when implementing PMS. The building system ensures that frequently used components, elements and their
intersections are standardised (Gibb, 2001; Lessing et al., 2015). This higher degree of standardisation within the building system became necessary due to the introduction of production machinery within prefab facilities, logistical issues and a rapid on-site assembly to name just a few. Compared to other construction systems, processes frequently reoccur and therefore lend themselves to better controlling, so the systematic improvement of processes and building system is possible (Höök and Stehn, 2008).

**Production strategies in IHB**

IHB companies’ unique production strategies’ differentiates themselves in the construction sector by:

- specialisation by building type, such as detached single-houses or residential buildings,
- the positioning of a company as cost leader or differentiator (Schreyögg and Koch, 2015) and
- the flexibility and productivity of the applied building system (Gibb, 2001).

Based on the work built of the flexibility and productivity of a building system, Barlow et al. (2003) highlighted various ways in which customers influence the design of buildings as well as the effects of this on the supply chain, the building system itself and the processes of housebuilding companies. The alignment of the customer order decoupling point (CODP) within a companies’ order fulfilment process defines, as a consequence, its abilities to customise a product to the customers’ satisfaction. This interconnection between the abilities of a production system and its ability to customise a building for a clients’ needs was investigated by Jonsson and Rudberg (2015). The production classification matrix in figure 1 shows an ideal range between the degree of prefabrication and the degree product standardisation.

**Performance measurement and management**

PM facilitates better control the development of IHB organisations’ economic performance and its ability systematically learn from experiences (Abu El-Ella et al., 2013; Bessant and Caffyn, 1997) The tools of PM should be embedded within an organisations system of regularly performance reviews. The output should promote decisions making revising the way of business operations (Kaplan and Norton, 1996; Womack and Jones, 2010). In this context a PMS should contain a balanced set of PI, developed for the specifics of a companies’ strategy (Davenport and Harris, 2007).
Obviously, there are differences between the applicability of various PI, which may serve to report on past performance, help to control ongoing processes or both (Beatham et al., 2004). Measurements for helping to control ongoing processes are indispensable for identifying latent problems, assess the effect of intended actions and to provide feedback on target setting for further managerial decisions (Raffoni et al., 2018).

Previous work on PMS within construction industry focused on developing PI. Beginning in the 1990’s various authors suggested PI enabling a control of performance criteria as safety, quality, rework, time or cost predictability, and environmental issues to name just a few. Most of them aimed to permit benchmarking between different organisations and construction supply chains. Less attention was paid to the relevant measures required for decision making processes to better attain the companies’ management objectives. A further shortcoming was the neglect of data acquisition issues for these indicators (Raffoni et al., 2018). Furthermore, these studies did not focus on the specifics of IHB production, hence, they are not well suitable to this industry.

A few publications focused on the specifics of performance measurement in IHB and provide a very limited insight into the measurement of on-site production performance. A case study by Lessing (2006) found that performance measurement and re-use of experience is implemented in IHB companies variously from no use measurement up to total measurement of tasks within some parts of the order fulfilment processes. This includes at a maximum, the measurement of few key activities within prefabrication, the debriefing of design and an observation of the complete on-site assembly duration.

Most developed key performance indicators (KPI) as proposed in Jonsson and Rudberg (2017) aim to measure performance of production systems on a strategic level. They are useful when assessing the abilities of production systems to meet market demands, but are not intended for applications where the focus is on continually improving an existing production system at an operational level. Raffoni et al. (2018) revealed the necessity to break down a companies’ strategic objectives into performance criteria and onto the creation of PI to impose a control and management function at the operational level which follow the corporate strategy.

Höök (2008) argued that in the few cases where IHB companies analyse on-site performance, they build their analysis is based on inappropriate PI such as construction lead time. It is also claimed that using financial metrics from cost unit accounting have limited benefits as they do not provide a suitable assessment of operational management objectives. Despite this it is a common measure in IHB companies. Current financial metrics do not reveal for the effects of interventions (Halman and Voordijk, 2012).

Newer approaches to assess the performance of improvement inventions are based on feedback from site visits or rely on a comparison between an estimated and a measured lead time for a specific process. These are mostly more resource intensive and not widespread. Many of them also have underlying biases or are not able to handle the complexity of the building process (Söderholm, 2010). Moreover, most known performance measurement approaches lead to difficulties caused by information overload, missing analysis of causes and effects and a failure to provide a comprehensive view on the building process (Raffoni et al., 2018). Consequently, construction site assembly is currently considered to be poor from an indicator perspective (Lessing et al., 2015).

**Research design**

A multiple case study approach is developed and involving IHB companies from Germany, Austria and Switzerland producing and assembling detached and multi-story houses. In order to collect insights from various corporate strategies specific cases are
selected, based on a systematic qualitative analysis of published company data on production principles. The sample includes 76 companies from the selected countries. From these, three cases are selected in order to covering various characteristics of product standardisation and alignment of the building systems. A description of the cases is given in the end of this section. How these cases are classified within the production system classification matrix from Jonsson and Rudberg (2015) is shown in figure 1.

Based on Yin (2018) various sources of evidence were considered in order to gain data. Documents and archival records were excluded for the reason due to unavailability and factual redundancy. Direct and participant observations were unsuitable for this scientific problem as they may have exceeded the time and cost budget for the study. Companies might also be cautious about directly involve researchers in such a high sensitive area. The finally best option seemed to collect data from the cases through interviews, whilst being aware of the weakness of this data collection method.

The face-to-face interviews were conducted by two researchers with representatives from the selected companies. The interviewees were mainly general managers or production managers, which in some cases involved experts from other departments. To focus the interview guidelines were developed grounded in theory of performance measurement and business performance analytics in construction industry. It was structured in five thematic fields and included 11 main questions. The interviews involved questions on a companies’ corporate strategy and how it was broken down into performance criteria and PI, how decisions are built on these measures, how data are collected in an on-site context, the needs for improving weaknesses of current PM and a check for cases classification. To avoid biases within the interview guide, it was developed iterative by two authors following the procedure from Helfferich (2011) and was pretested by other researchers.

The interviews took between one and a half and three hours. As the interview partners were not allowed to audio record the interviews the scientists separately documented proceedings, which were subsequently combined. Interviews are analysed with a thematic coding and content analysis approach according to Hopf and Schmidt (1993). In a first step each interview is analysed separately, followed by a cross-case analysis to detect similarities and differences.

Case A

Case A is a larger industrialised housebuilder, which successfully has built detached and multi-story buildings for centuries. Their customers are private as well as commercial and institutional clients from Central Europe. To serve various customer segments they have established different brands through the customization opportunities. The IHB company has an established production system with the prefabrication of elements, including preassembly of components off-site and on-site assembly of these elements. The prefabrication degree is higher for the main brand with a more standardised product. Previously, the strategic focus was on cost leadership for the main brand. Currently they are shifting their strategic focus to deliver an affordable quality product.

Case B

The prefabricated housebuilder in Case B is a mid-size company providing mainly detached houses to private clients. The prefabrication degree of case B is at the level of prefabrication and preassembly of elements, which means that components as windows or similar installations are assembled off-site. The company provide a high degree of individualisation frequently working with a clients’ architect, to provide a unique
structure. Their output is the least constrained by the building system. They are further differentiated by the scope of services they provide to clients, the guarantee for high quality standards as well as specific material and components featured. They calculate the features and services to build a home for each single project for sales and cost unit accounting.

Case C
The company representing Case C is a larger construction company, with a prefab housebuilding division. The housebuilding division serves detached and multi-story buildings to mainly private clients in Central Europe. The off-site prefabrication level of this case is very similar to those of Case B. The restrictions defined from their building system is located between Case A and B. To meet the requirements, this housebuilder is working together with contracted architects, which enables to serve architectural planned homes adapted to the requirements of their building system. This company differentiates from competitors through a high material and product quality as well as a short realisation period compared to other companies with prefabrication and preassembly of elements.

Case study findings
The findings of the analysed cases are presented in tables 1 and 2. The three cases show a diverse application of PM, ranging from a variety of PI used for management decisions as in case A & B to almost ignoring all the generated measures from case C. Despite the importance of PM for case A and B, they follow different approach to the generation of their data. For case A, indicators analysing the productivity are their preferred basis for controlling processes, whereas the indicators used from case B are predominantly financial metrics. The preference to these types of indicators was selected due to the individuality of the built projects, which only enable useful assessment on target/actual comparison.

The analysis of PI reveals that almost all company have their own perceptions of parameters such as productivity or quality of on-site work. Companies are interested in models they can adapt for their specific needs, as each of them pursues its own strategic goals. In addition, qualitative feedback was highlighted of major significance for the topic of quality control and management, as it documents the causes of problems or defects.

As presented in table 2 simple digital technologies to collect data now exist for on-site data collection. A app was implemented in case A which supported mobile time recording and site documentation. Additionally, it supports quality management by reporting rework time with photos and descriptions of the points of failure. Case B implemented a consistent ERP system which facilitates the direct work time recording. Rework is recorded by time and task description. This case really highlighted the importance of reporting on-site data quickly, which ensures accurate analysis and processing of deviations in on-site production. This was also emphasised by the guideline to immediately analyse target attainment after completing a construction service. Additionally, this case also uses paper based checklists for quality and process control issues. Case C works exclusively with paper based documents for data collection.

The reliability of self-generated data was high in case A & B. Case C argued that they need to verify outcomes of indicators, due to the lack of an option to split up measures outcomes and interconnect them with reported data on failure.

The application of performance measures in management tasks is various widely. Case A showed an incorporation of indicators in various planning, management and
controlling tasks. One interesting feature was, for example, the use of measures on failure data to specify the training needs of on-site teams. Case A seems to be the highest level of PMS of all three examples. Analytics used for these management activities are descriptive, diagnostic and predictive. Case B uses performances measures for controlling activities, which are at least as important for their process improvement. Case C focuses also on using performance measures for controlling activities, though the measures generated by case A & B have a predominantly descriptive function.

The companies highlighted the need to improve their PM in the area of quality management and capacity planning. Automatic data generation as one option to gain data from on-site assembly was excluded from case B based on the argument that it maybe not applicable due to the individuality of their products.

**Discussion**

The case study shows that PMS concerning on-site assembly have become state of the art. All three cases collect and analyse indicators of on-site production. Especially, case A and B have implemented a sophisticated set of PI’s which are used as the basis of management decisions. This finding contradicts the arguments found in the literatures, that only few companies apply performance measures for this part of the production process. In addition, the argument that inappropriate measures are applied to assess the on-site performance can be rejected. Two cases incorporate their measures in various management decisions and trust in their data and analysed measures. The
argument, that on-site production is currently considered poor from an indicator perspective can clearly be rejected.

To adapt a company’s own PMS to its corporate strategy as suggested by the literature is definitely necessary. Case B, which has a very flexible building system, is forced to do target/actual comparisons based on its cost unit accounting. The customisation of the buildings offered require this kind of comparison for financial metrics. Deviations from the target trigger management activities. On the contrary, case A is able to use PI on a more general basis. Their building system has a higher degree of product standardisation. They do not have the need to control each building individually to generate information on the on-site production activities. However, they also use actual/current comparisons for parts of the production process, where the individuality of the buildings produced requires it.

Case B indicate that finance metrics from cost unit accounting are an appropriate measure for IHB companies with a higher degree of product customisation. For the application for this type of metrics it seems important to ensure a rapid assessment after completion of a construction service. Additionally, data to rework or other process deviations should be processed in a way which enables an assessment of failure causes and effects. Again this contradicts the literature which argues, that metrics out of cost unit accounting do not provide a suitable assessment of management objectives. When looking at case C it is easy to understand this argument, since their collection of data did not provide them with the ability to connect data of failure causes with the effects visible at the time of reporting. To overcome the current approach of using financial metrics for performance assessment in IHB there is a need to be a rethink about the way data is collected on-site and analysed.

A pivotal role is also given to digitalisation concepts which enable faster feedback on on-site processes, by the use of digital tools for reporting of working time as shown in cases A & B. These tools provide the opportunity to identify and react much more accurate on weaknesses in current processes.

The requirement to improve the current state of on-site PM was emphasised in areas of quality management and capacity planning. When comparing the cases, it is clear that IHB industry is very inhomogeneous in its application of PMS and the use of information generated for management decisions. The need to improve use of PMS within the industry is clear. It seems important that companies with a lower developed PMS are able to learn from the management practices of those companies which take a lead within PM and find and deploy suitable data collection and analysis tools themselves.

**Conclusion**

The assessment of various performance variables from construction site processes is essential for a systematic identification of performance weaknesses and to ensure their elimination. In this manner, PM provides a targeted improvement of building systems and on-site processes, to raise IHB companies’ competitiveness.

The systematic selection of companies from Germany, Austria and Switzerland guarantees a good overview of the IHB segment with the research illustrating the development of PMS in assessing on-site performance by these companies. It further shows the assessment outcomes which are used in controlling activities and for management decision making. Despite an increase of applying PMS the findings indicate, that the implementation of PMS and the management practices applied are very diverse within the industry.

There are companies with a more and some with a less sophisticated PMS, which provides potential for improvement. Identified improvement potential is a starting point
for further research, to develop concepts which allow a better inclusion of indicators of construction site processes within PMS. Additionally, there is a need to include more cases to gain data from companies with different characteristic values, concerning their specialisation by building type, the positioning of a company as cost leader or differentiator and the flexibility and productivity of the applied building system. A limitation of the current paper is that it is founded on three cases. Due to the limited number of cases, a careful use of the current studies’ findings is suggested.

Abstract

This research proposes a dual analysis pattern oriented to the operational aspects of the company, which, on the one hand, investigates efficiency in the use of resources and in obtaining results, and on the other hand, analyzes the innovation routines. The results confirm empirical evidence that capabilities emerge from several interrelated routines and that there is a strong conceptual link between features, routines, and performance, expanding comprehension related to the specific ways in which capabilities can be built and developed.

Keywords: Innovation, Performance, Capabilities.

Introduction

Critics of the Resource Based View (RBV) consider analyzes of operational capabilities’ performance, in general, very aggregated, which hinders the examination of composition and interaction of the operational resources used (Bromiley, Rau, 2015, 2016). Management research also recognizes the importance of capabilities to achieve competitive advantage, but rarely investigates capabilities at the operational level where they actually occur (Peng et al., 2008). These gaps guide the development of this research, which, from a more operational perspective, aims to understand how companies organize their structures to induce innovations and create competitive advantages that become superior operational performance.

This way, based on Economics, with support of the theoretical model related to the Production Possibilities Frontier, which establishes limits for productive capacity of a company, the efficiency of each one of the sample companies was measured, with the support of the DEA methodology (Data Envelopment Analysis). On the other hand, Evolutionary Economics and Dynamic Capabilities, both theories that position routines as the capabilities foundation, support the orientation of this research in studying capabilities through their underlying routines. Therefore, capabilities were modeled as a second-order latent construct, and each set of routines was measured, supported by CFA-SEM (Confirmatory Factor Analysis and Structural Equation Modeling), as a latent first-order construct from measurement items developed according to the theory. In addition,
this way of conceptualizing and measuring capabilities, from a set or bundle of routines, is supported by requirements such as inimitability, value and rarity that are characteristics of the capabilities, in correspondence with the RBV (Helfat; Peteraf, 2003, Peng, 2008).

Therefore, this research proposes a dual analysis standard oriented to the operational aspects of the company that, on the one hand, investigates, compares and thoroughly evaluates the efficiency in the use of resources and in obtaining results (DEA), and on the other hand, it maps, analyzes and measures operational procedures or routines (CFA-SEM). In order to make feasible the proposed analysis, we used primary data from 212 Brazilian hotels (response rate 43%), randomly selected, in 2016.

**Methodology**

The diffusion of innovation among hotel companies reflects a high degree of heterogeneity, mainly characterized by the low propensity to develop new products and processes, especially in independent establishments or in smaller companies. Therefore, the hotel sector, in particular, has become a fertile field for research that intends to investigate significant levels of structural heterogeneity and variance in the routines of operational processes. (Howell et al., 2004). Consequently, this research has found a convenient environment for the development of an investigation that seeks to unravel the phenomenon underlying organizational operational interactions that produce synergies - in creating, integrating and recombining resources - in order to obtain new forms of value and thus the production of new sources of competitive advantage (Helfat; Peteraf, 2003, Peng et al., 2008).

Considering (a), on the one hand, the need to understand the operational means or routines that create essential competitive advantage to achieve superior operational performance (Peng et al., 2008). (b) Taking into account, on the other hand, criticisms of the RBV for ignoring the performance variations that occur within most companies, from a more operational perspective (Bromiley, Rau, 2015, 2016). (c) Based on the Resource-Based View (RBV), according to which internal organizational mechanisms - as previous factors of absorptive capacity - can be considered as sources of innovation (Cohen; Levinthal, 1990) and competitive advantage (Zahra; George, 2002), capable of providing superior performance. Considering the above, this paper investigates the superior operational performance of organizations through the internal organizational mechanisms related to the development of integrated routines (Tidd et al., 2008) and structured according to the specificities of each company and the context in which they act (Birkinshaw et al., 2011).

A new dual analysis environment was proposed for the evaluation and analysis of the relationship between innovation and operational performance. Thus, based on two tools frequently used in the research – (a) Data Envelopment Analysis (DEA), which became a of the most applied analysis tools to measure efficiency in several service activities, especially in the hotel sector; and (b) Factorial Confirmatory Analysis and Structural Equations Modeling (CFA-SEM), the degree of relationship of this efficiency (DEA) with the capabilities of improvement and innovation was measured.

From the measurement of the efficiency of each company, using DEA, it becomes possible to analyze and evaluate the routines, of improvement and innovation, according to the model of Peng et al. (2008) of each one of these companies, and, in this way, observe and seek to understand the elements underlying the relationship between these routines and efficiency, from a more operational perspective. In this sense, the unit of analysis of this work is the hotel, where the routines are effectively implemented, and the processes are performed. Data envelopment analysis is a technique used to measure allocative efficiency that seeks to minimize inputs or maximize outputs in production
processes. It aims to measure the allocative efficiency of productive units that present multiple inputs or multiple outputs. DEA refers to a technique based on linear programming that allows a) to identify a possible efficiency frontier for a given sample of organizations that have similar or homogeneous operational characteristics and belong to the same segment of activity; and b) to make comparisons on the efficiency achieved between the use of resources and the respective results obtained by each of the organizations in their operational processes, and it is possible to identify best practices in the use of resources by efficient production units.

In relation to the innovation analysis, the research by Peng et al. (2008) operationalizes the concepts of improvement and innovation capabilities as packages of higher-level routines, proposed from a model with second order factors. The measurement items were also developed for each set of routines they identified. And, from a large sample, they used a rigorous empirical method to examine the structure of latent variables related to their capabilities. Thus, according to the conclusions obtained by the research published by these authors, the understanding that capabilities are represented by interrelated bundles of routines was empirically demonstrated from the theoretical foundations of the field of Operations Management and Management literature (Peng et al., 2008). Considering the identification of routines relevant to the improvement or innovation capabilities, as well as the measurement scales selected based on previous studies, the Confirmatory Factor Analysis was adequate for the analysis (Shah; Goldstein, 2006).

In order to facilitate the proposed analysis, we used primary data from 212 hotels that answered an electronic questionnaire made available via the web to 493 randomly selected hotels - 43% response rate - from a register of 2,173 hotel companies and potential suppliers of Petrobras, in the Brazilian territory, for the year 2016. To be accepted in this register, the hotel that intends to provide services to Petrobras must fulfill a set of pre-contractual operational requirements which, in the case of this research, guarantees the degree of homogeneity (similarity) necessary for the nature of the applied methodology. The operational data used for the empirical analysis were collected from the hotels in three successive waves, between 08/09/2016 and 03/22/2017. To evaluate the potential late response bias, the initial and final responses were compared with t-test (Armstrong; Overton, 1977), whose results did not present significant differences between the samples. As there was a single informant per hotel, the potential bias common method was not evaluated. The amount of sample elements was slightly below the rule that determines the ratio between subjects and variables, in the proportion of 10:1 (Hair Jr et al., 2012), for CFA-SEM. In relation to DEA, the literature recommends at least a number of DMUs (Decision Making Units) equivalent to twice the product between the number of input and output variables (Dyson et al., 2001), that is, 28 DMUs for the case of this research. For all respondents it was guaranteed confidentiality regarding the identifications of the respective companies. The profile of the respondents corresponds mainly to employees who occupy managerial positions or higher (79%) and with more than 4 years in the current position (83%), which indicates that most of the respondents are able to provide the information requested in the questionnaire.

For each hotel, data were obtained from 33 different variables, which are divided into two groups, according to the analyzes performed: a) seven input variables and two output variables, used in the DEA, to measure the efficiency of hotels; and b) twenty-four variables used to measure the impact of the underlying routines on improvement and innovation capabilities, according to the model developed by Peng et al. (2008). The variables for the DEA evaluated structural, qualitative, performance and adherence aspects to technological changes, while the variables for the modeling of innovation and improvement constructs used the same items of the questionnaire of Peng et al. (2008),
with the necessary adaptations for the hotel sector. The standardization adopted in the previous research was maintained through the application of the questionnaire with a seven-point Likert scale. The aforementioned adaptation was criticized and validated by a group of eight senior executives working in the hotel sector, while the results analysis was evaluated with the support of these senior executives and researchers from the University of Algarve.

Based on a large literature review, we selected the input variables used to measure efficiency (DEA) a) classification of the hotel by Petrobras; b) number of monthly hours worked by employees; c) number of rooms; d) percentage of employees using peripherals, such as tablets, smartphones, point of sale, order terminals, scanners, printers and others connected to the network or hotel systems in their activities; e) occurrence of the last event related to the introduction of new technologies or the development of processes or services; f) impact caused by the introduction of the latest technology or by the last development of processes or services; and g) occurrence of the last training regarding new technologies or the development of processes or services. And the output variables considered were: a) customer evaluation and b) annual percentage occupancy rate (Hu; Cai, 2004; Sigala 2004; Wagner, Shimshak, 2007; Hsieh; Lin, 2010). The variables to measure improvement and innovation (CFA-SEM), used as basis the theoretical construction of Peng et. al. (2008), adapted for 24 items used in the measurement questionnaire, divided in relation to the respective innovation and improvement capacities, and subdivided in relation to the respective sets of routines.

The correlation, asymmetry and kurtosis levels of the variables meet the needs of the analyzes performed. The bivariate analyzes reinforce the understanding observed in the analysis of correlations and clusters, whose variables that characterize certain groups present a higher degree of correlation with each other. In the case of the CFA-SEM variables, the data were collected using a proposed likert scale and analyzed in accordance with the three structural equation modeling (SEM) requirements: independent observations, random sampling and non-linearity (Hair Jr et al., 2012). The analysis of the absent and discrepant data was performed and no impact was observed for the quality of the sample. Univariate analyzes showed a normality pattern. The combined distribution of the pairs of variables presented bivariate normality, with linear and homoscedastic bivariate graphs and the patterns of asymmetry and kurtosis were within acceptable limits (Hair Jr et al., 2012). The multicollinearity tests were performed with the SPSS and no dimension had two or more indicators with variance greater than 0.50. However, the degree of multicollinearity of the items included in the CFA-SEM suggest the need to treat the data, because the condition index was 32. This action was not performed so that the model did not lose adherence to the original model. In any case, the condition index was very close to the limit (30), which allowed the analysis to continue.

In order to meet the main objective of this research, five structural models were proposed, as follows: Model 1 - Apply the model of Peng et al. (2008) for a group of hotel companies considered to be efficient according to measurement by the DEA; Model 2 - Apply the model of Peng et al. (2008) for a group of hotel companies considered to be inefficient according to DEA measurement; Model 3 - Replicate the model of Peng et al. (2008) for all the hotel companies in the sample; Model 4 - Include in the model of Peng et al. (2008) a categorical efficiency variable according to DEA and factor composition according to CFA; and Model 5 - Replicate the model of Peng et al. (2008), with a second-order factor, in order to verify the hypothesis that, in the service area, especially in the hotel sector, there is a greater concern of managers with the improvement to the detriment of innovation (Aranda, 2002; Assink, 2006). In this case, the two second order factors of
the model of Peng et al. (2008) could be replaced by only one second factor, that is, improvement.

**Results**

To measure efficiency, the DEA technique was applied, considering variable returns of scale and orientation to outputs, through the software Frontier, and it was observed that 41 hotels operate with total efficiency (100%), 65 with high efficiency (91% to 99.99%) and the remaining 106 have different degrees of inefficiency (51% to 90%). Sensitivity tests were also performed for the results found (Ramanathan, 2003).

Innovation and improvement are two-dimensional constructs and, according to Peng et al. (2008), the indicators used to measure different aspects of these constructs "have already been submitted to factorial analysis by several authors who have found the aforementioned structure." For researchers who have developed this model, improvement and innovation capabilities are shaped as a second-order latent construct, consistent with the concept of a bundle of routines. In this sense, each set of measurement items is used to measure a latent construct of the first order, that is, a specific set of routines. This way of conceptualizing the capabilities is supported by the RBV (Barney, 1991).

Confirmatory factorial analysis (CFA) was used to evaluate the overall fit of the model, the reliability and validity of each first order factor. CFA involves the estimation of an a priori measurement model, in which the observed variables are mapped to the latent constructs according to the theory (Peng et al., 2008). Since it identified routines relevant to the capabilities of improvement or innovation and measurement scales selected from previous studies, CFA has become a suitable technique for this research (Shah; Goldstein, 2006). Since improvement and innovation capabilities, although different, are related (Cole, 2001), were also evaluated - global fit model, reliability and validity of the measuring instrument - through the CFA. Together, the structural equation modeling (SEM) was used to simultaneously evaluate the relationships between the different constructs of each proposed model:

In relation to the structure test, the models 1 and 2, although approaching a similar solution to previous research in the CFA, were not processed by AMOS because they did not meet the sample size requirements for structural equation models (Wolf et al., 2013). The models 3, 4 and 5 were processed in the SPSS (CFA) and AMOS (SEM) and, for each of the three proposals, therefore, a second order factor model was specified. Thus, in each of the three proposed models, each measurement item loaded its first-order routine and, simultaneously, each first-order routine loaded the second-order construct. With 3 models available, the tests were then started to evaluate the adjustments of each model.

Regarding the adjustment of the models, the chi-square was used to evaluate the theoretical model. The value of the chi-square can vary between zero, when considering the saturated model, and a maximum value, when no relation between the independent model variables is considered. A statistically non-significant result for the chi-square indicates that the sample covariance matrix and the covariance matrix estimated by the model are similar (Amorim, 2012). If the difference is significant, it cannot be said that the model fits the data, so that the chi-square test should not be statistically significant (Mueller, 1999). This test, however, is sensitive to sample size and number of variables in the model (Hair Jr et al, 2012) and may sometimes induce inappropriate rejection. The root mean square error (RMSEA) is a relevant overall adjustment index. It should be less than 0.08 and preferably less than 0.05 (Kline, 2005; Loehlin, 2016). The Tucker-Lewis index (TLI) evaluates the incremental adjustment, as well as the comparative adjustment index (CFI) and the incremental fit index (IFI). For these three indices, values above 0.90 indicate a good fit (Hair Jr et al., 2012).
The model 3, whose objective was to replicate the model of Peng et al. (2008) for all the hotel companies of the sample, presented better adjustment than the other models, according to table 1: normalized chi-square was 1.144 (p < 0.001), RMSEA was 0.026, below the limit, and CFI, TLI and IFI were, respectively, 0.985, 0.983 and 0.985.

Since the models can be considered nested, it is possible to compare them with the chi-squared difference test to indicate that the two constructs can be considered effectively different from each other (Carneiro, 2007). Thus, between models 3 and 4, the chi-square difference was 727.7 and the difference of degrees of freedom was 27, so the observed difference is greater than the statistical limit of significant 55.5 (p < 0.001). In the case of models 3 and 5, the chi-squares difference was 36.9 and the degrees of freedom of 7, therefore, greater than the limit of 24.3 (p < 0.001). And for models 4 and 5, the chi-squares difference was 691.8 and the degrees of freedom of 20, therefore, greater than the limit of 45.3 (p < 0.001).

We also examined the standardized residues of the three models, because when the residuals are small, the model is considered a good representation of the data. Generally, it is recommended that no more than 10% is greater than 2.5 (Hu; Bentler, 1995). None of the standard residues has an absolute value greater than 2.5.

In relation to the validity and reliability, in the model 3 all the adjustment measures are above the recommended cut-off points and, therefore, suggestive that the specified model can capture the relations between the variables adequately. A priori, the specification of the factorial structure that presents a good overall fit through the CFA provides a more rigorous test of convergent and discriminant validity (Campbell; Fiske, 1959). Once the model 3 presented the best fit, analyzes of the validity and reliability of this model and its factors were performed.

Convergent validity aims to verify the similarity or convergence between individual items that measure the same underlying latent variable. In this research, the loads were verified in the aspects of signal, magnitude and importance in the context of the model. It was found that all loads of the first-order factors were above 0.50, with the exception of item 4 (we believe that the improvement of a process is never complete, there are always conditions for further improvements), which presented result close of limit, ie 0.48. The second-order factor presented loads greater than 0.60, all loads with positive and statistically significant signs (p < 0.01) (Chin, 1998).

Discriminant validity refers to the degree to which the measures of different latent variables are unique and distinct from each other. It needs to be demonstrated both among first order factors and second order factors. In this study, the average variance extracted (AVE) method was used (Shook et al., 2004). In this method, the AVE of each pair of factors must be greater than the square of the correlation between this construct and any other construct (inter-construct correlation), which indicates the discriminant validity (Fornell; Larkin, 1981). The variance extracted from the four constructs was above 50%. This indicates that the measurement error was smaller than the explained variance and suggests convergent validity (Shook et al., 2004).

Regarding the composite reliability aggregate measure of the degree of intercorrelation or internal consistency between the measurement items of the same construct, a reliability value greater than 0.70 is recommended (Peng et al., 2008). All factors presented composite reliability above the cut-off point of 0.70, ie, all constructs presented adequate levels (Hair Jr et al., 2012).

The models 3, 4 and 5 were processed in SPSS-CFA and AMOS-SEM, with model 3 presenting results similar to the previous research for construct improvement (continuous improvement, process management and leadership involvement) while the innovation construct presented differences from the original model. Thus, instead of three first-order factors (the search for new technologies, the multifunctional development of products and the development of processes and equipment) and a second-order factor - innovation - there was only one factor of the first order, which was called “research and development management” with support in the literature (Coombs, Miles, 2000; Djellal et al., 2003; Krasnikov, Jayachandran, 2008).

As performed by Peng et al. (2008), we also tried to evaluate other forms of analysis of different models, i.e.: a) to evaluate a model in which each first-order factor is loaded into a single second order factor, as in this work, b) evaluate other possible models with two second order factors, as shown in the work of Peng et al. (2008). However, in this study, possible models with two second order factors did not manifest themselves with the sample data.

About the impact of performance improvement, the main objective of this research is to analyze how hotel companies guide their internal resources, according to the proposed conceptual framework, in order to induce innovations, create competitive advantage and achieve superior operational performance. In Figure 1, it was demonstrated the routines and how they are organized in order to contribute to the improvement capability, supported by confirmatory factorial analysis (CFA) and structural equation modeling (SEM). It was also possible to measure and evaluate the efficiency of each hotel unit, comparing which inputs, and in what volumes, are able to produce certain results, that is, to achieve relative efficiency levels within the sample, supported by the Data Envelopment Analysis (DEA). However, since the capability improvement is related to the productive activity, permeating its processes and manifesting itself in the different forms of organization of its elements - inputs, routines and products -, then this capability must be significantly related to operational performance of each hotel (He; Wong, 2004).

To evaluate the relationship between improvement and performance, the effects of the improvement capability on performance were estimated by regressing their factor scores.

\[ Figure 1: \text{Model 3 presented the best overall adjustment in relation to the other proposed models. Source: prepared by the author.} \]
on an index of three measures of operational performance (Chen et al., 2004): (a) Customer satisfaction (Kandampully; Suhartanto, 2000; Bowen; Chen, 2001); (b) Occupancy rate (Banker et al., 2000; Morey, Dittman, 2003; Abdullah, Haan, 2012); (c) Efficiency (Anderson et al., 2000; Hwang, Chang, 2003; Barros, 2005; Paço, 2014). The performance measures used in this work are objective, and the customer evaluation was obtained from the TripAdvisor site (O’Connor, 2010; Li et al., 2013; Filieri et al., 2015), the occupation rate was informed through the questionnaire used and the efficiency rate of each hotel was measured with the DEA, based on data on inputs and products reported by the hotels in the questionnaire. A standardized regression equation was estimated for the three mentioned operational performance variables (Flynn et al., 1990). Before estimating the regression model, the assumptions for regression analysis were verified and no violation of regression assumptions was found.

The improvement capability is significantly related to the three performance measures as can be observed in table 2. The observed regression result meets the objective of this research because it indicates that the improvement capability is significantly related to the operational performance and its impact varies according to the type of operational performance involved. This result, like that of Peng et al. (2008), contributes to establish the validity related to the capability measures criterion.

Conclusions
One of the main results achieved by this research is the understanding that the routines associated with the improvement capability form separate and internally consistent bundles of routines, i.e., the bundles of routines are significantly related to operational performance. Thus, this research was able to confirm the notion of capabilities as a bundle of routines, also for the service area, especially for the hotel sector, and to establish an "objective" conceptual link between routines, capability and operational performances for this sector of the economy. A second finding of this research refers to the fact that, for the hotel sector, instead of three first-order factors (search for new technologies, multifunctional product development and development of processes and equipment) - and a second order factor - innovation - only one first-order factor was found, which was called “research and development management”, with support in the literature (Coombs, Miles 2000, Djellal et al., 2003, Krasnikov; Jayachandran, 2008). Thus, another important aspect of the research results refers to the fact that the routines related to the innovation process are present in the model and significantly impact the improvement capability. The literature supports this hypothesis in several empirical researches (Aranda; Molina-Fernández, 2002; Assink, 2006; Hertog et al., 2011). A third finding of this research refers to the identification of the improvement capability impact on indicators that reflect the performance of a hotel. The results of the research bring important academic and managerial contributions. From the academic point of view, it advances in the understanding that the capabilities represent bundles of routines for the services area, confirming a more operational perspective for the Research in Operations Management, under a RBV conception. For managers, it contributes to the development of effective behavioral patterns, that is, the development of routines integrated to the broader skills, considering the specifics of each company, as well as the context in which they operate.

Factors enhancing productivity in industrial environments

Michael Güldenpfennig (mgu.om@cbs.dk)

Kim Sundtoft Hald
Copenhagen Business School, Department of Operations Management

Abstract
Although productivity has been explored for centuries as part of operations management, a comprehensive theory of the factors that lead to productivity improvement is still missing. The objective of the present study is to identify from literature these factors and their interrelationship. A structured literature review and a contingency theoretical perspective is applied. In relation to findings, nine factors categories and 57 factors are identified as having been portrayed in the extant literature as having effect on productivity. Moreover, a factor-productivity conceptual model is developed, highlighting the elements of productivity improvement as opportunities for productivity management within industrial organizations.

Keywords: Productivity, Contingency theory, Literature review

Introduction
Productivity is a key factor for sustainable survival and growth. The World Bank Group (WBG) and the International Monetary Fund (IMF) named productivity improvement as one of their three major objectives for nations and countries (Kim, 2018). The progressing globalization with trends such as offshoring of manufacturing or consolidation of industrial sectors increases the pressure to stay competitive in the market (e.g. Wacker et al., 2006; Walker et al., 2014; Naoum, 2016). That makes it important for firms to focus on improvement of the input-output ratio that might result in a competitive advantage in their industry (e.g. Bernolak, 1997; Tangen, 2005). In the past, innovations led to major productivity gains such as the moving assembly line or labour specialization (Schmenner, 2015). However, today’s emerging technologies, such as digitalization or Industry 4.0, can only contribute partly to the enhancement of productivity. Instead and because resources within organizations are limited, productivity improvement initiatives requires prioritisation and an understanding of the entire bouquet of opportunities, their interrelationship and the context in which they operate. Therefore, a systematic and effective productivity management that takes into account the manifold productivity enhancement facets is essential for organizations existence and continued growth.

Productivity has been explored in operations management literature and related disciplines in the last four decades and different kinds of productivity have been in focus (Tangen, 2005). Multiple factors influencing productivity have been identified in their particular context and analysed in surveys (e.g. Noble, 1997; Mapes, 2000) and case studies (e.g. Gunasekaran et al., 2000; Krishnan and Srinivasan, 2007). Thus, research on productivity is comprehensive but also fragmented and an advanced theory of the factors leading to productivity improvement is still missing (e.g. MacHuca et al., 2011; Zhang et al., 2012). Hence, there is no study that summarizes factors effect on productivity across studies and unfolds consolidated findings into managerial practices.
Drawing on a contingency approach, this study aims to extend theory on the interrelationship between productivity enhancing factors and its implications to productivity management: Based on the contingency theory, what are the antecedent factors to productivity and how do they relate to productivity management?

The contingency theory provides a structure to the different variables that are involved in the productivity enhancing mechanisms: On the one hand, the environmental variables that are beyond manager’s control, and on the other hand, the resource factors that are within manager’s sphere to influence (Luthans and Stewart, 1977; Sousa and Voss, 2008). Based on prior research of 841 selected articles of the last 40 years within peer-reviewed operations management journals, nine factor categories and 57 factors are identified as having effect on productivity. In relation to findings, a factor-productivity framework is developed with theoretical substance of the identified productivity improvement factors and their interrelations.

Reviews on productivity

Although productivity is a major concern to operations management, the portion of articles having productivity as a central theme, is still very low (Walker et al., 2014). In order to exemplify this, we were only able to identify three previous comprehensive reviews of productivity related research within the field of OM.

Almost 40 years ago, Aggarwal (1980) identified 99 factors influencing productivity out of 27 case studies across industries in the US. He did some effort to classify these factors into ten factor groups. Aggarwal (1980) elaborated six “uncontrollable situations”, nowadays called contingencies, that hurt productivity, such as old traditions or rigid organizational structures. His review can be understood as a comprehensive summary of productivity improvement strategies at that time.

Schmenner (2015) reviewed the innovations that took place to improve productivity between the year 1776 and 1950. This emergence of innovations resulted in a major efficiency or effectiveness step at the time, when the joint effects of multiple innovative factor came together. Examples of such innovations are the moving assembly line (years 1913/1914) or lean manufacturing (from 1940s on). According to Schmenner (2015), these innovations are underlying concepts that further improvements can ground on and which are successful across industries. He elaborated “the theory of swift even flow” which according to Walker et al. (2014) is one of the few unique OM theories.

With the objective to discover the major trends and issues of productivity, Jin et al. (2016) analysed 213 core studies in the period between the 1970s and the year 2013. They identified nine productivity issues and grouped them into four categories: fundamental (labour, technology, IT systems), additional (process, tool and method), environment (trade, regulations), and performance (business performance, operational performance). From the nine productivity issues, they derived from focus group interviews six megatrends. For the period from the 2000 on, they discovered “information” and “innovation” as the megatrends and cutting edge within productivity literature.

Towards a contingency approach to productivity management

The objective of this study is to apply contingency theory (CT) to productivity because of our ambition to identify the mechanism of productivity management. Thereby, we follow the recommendation of Sousa and Voss (2008) that see CT as a useful theoretical lens for OM issues, especially for areas where theory is not advanced. The CT assumes that when organizational structure fits to environmental forces organization efficiency and thus productivity increases (Burns and Stalker, 1961; Lawrence and Lorsch, 1967).

Sousa and Voss (2008) distinguish between three types of variables involved in the
interplay between the environmental forces and the organization structure aiming for a fit: The contextual variables that represent the environmental forces, the response variables characterizing all organizational and managerial action taken, and the performance variables measuring the results of the fit. Luthans and Stewart (1977) elaborates the response variables and distinguished between the resources and the management of an organization that characterize the response on environmental forces.

Venkatraman (1989) identified six types of organizational fit and one of them, mediation, has been investigated in multiple applications of the CT (e.g. Shah and Ward, 2003; Demeter et al. 2011; Peng et al., 2011; Chavez et al., 2015). Hence, there are five kinds of variables that are elements in our initial framework of productivity management.

**Contextual variables** - Multiple factors and their antecedents characterizing the context of industrial organizations have been discovered in OM literature (e.g. Aggarwal, 1980; Schmenner and Cook, 1985). The ability to manage environmental variables is very limited and only, if at all, possible to change long term with substantial effort (e.g. Luthans and Stewart, 1977; Sousa and Voss, 2008). Scholars distinguish between the external and internal environmental variables (e.g. Siggelkow, 2001; Pedersen and Sudzina, 2012; Zhang et al., 2012). The external variables represent forces that are not in range of control of the organization (e.g. governmental laws, economical character, etc.) while internal factors are within the responsibility of the organization but are dependent on the managers’ level in hierarchy (Luthans and Stewart, 1977).

In contrast, resource variables (e.g. Luthans and Stewart, 1977; Mohanty, 1988; Franco and Bourne, 2003), represent all tangible and intangible resources management has direct control of and on which they can operate to receive desired change (Luthans and Stewart, 1977; Dangayach and Deshmukh, 2001). Human, financial, informational, and technological resources, grouped in different categories, representing the wide spectrum of influence, for instance from the skills of an operator to the reputation of the organization within the industry or region (Dangayach and Deshmukh, 2001).

**Management variables** - The intervening variable, the management, includes all individuals in the organization with authority to make decisions. According to Luthans and Stewart (1977), managers need to consider environmental and resource variables as well as their relationship to initiate changes in strategy with the objective to establish fit resulting in productivity improvement. Recent studies emphasize goals as essential and important drivers for performance (Zhang et al., 2012). The most important targets concerning performance are termed competitive priorities, which are cost, quality, delivery, dependability, flexibility and innovations (Noble, 1997; Peng et al. 2011).

**Mediator variables** - According to Drazin and van den Ven (1985), mediation follows an interaction approach, where either the fit between a single contingency variable and a single response (resource or management) variable generates performance or a feasible set of those variables. Management introduces management practices as mediators, that help to channel certain resource variables (Youndt, 1996; Shah and Ward, 2003; Sousa and Voss, 2008; Baird et al. 2011; Garcia et al., 2014; Tortorella et al. 2018).

**Productivity variables** – Productivity can only be analysed in two ways, either by comparing a variation within the industry on a certain point of time or within the same organization over a period (Bernolak, 1997; Noble, 1997). The productivity variables are represented by financial and non-financial measures (e.g. Bourne et al, 2005; Pederson and Sudzina, 2012). Most organization measure labour productivity as a ratio between labour costs/hours and turnover (e.g. Noble 1997). Others include equipment or capital productivity. Total Factor Productivity represent a measurement system including all input resources and analytical methods are applied such as Malmquist or Tornqvist productivity index (Jin et al., 2016).
**Research methodology**

This structured literature review (e.g. Tranfield et al., 2013) grounds on the initial framework of productivity management derived from CT applications in OM. For clarity reasons, we explain some wording that results from the theoretical implications of the previous section: Factors have a relationship on productivity. The factors are characterized by antecedents that operationalize the factor. Factors are consolidated in factor categories. Our review is organized in the following way (Figure 1):

1. **Selection of relevant literature**
   - Literature on theoretical implications

2. **Coding for factor categories**
   - Button-up approach from sample

3. **Consolidation of factors, antecedents and effects**
   - Top-down approach from core studies

4. **Managerial implications**
   - Interrelations of factors

5. **Comprehensive factor-productivity framework**
   - Specialties of productivity management

*Figure 1 – Research methodology*

**Phase 1** - For data collection, the Scopus electronic search engine has been utilized to identify relevant articles (e.g. Walker et al., 2015; Jin et al., 2016). For the identification of the most relevant peer-reviewed journals we applied the quality assessments of OM journals of Petersen et al. (2011), Fry and Donohue (2013) and Harzing’s Quality Journal List (63rd edition, 29 July 2018). As a result, 841 relevant English language articles were identified from the top nine OM peer-reviewed journals of the period from 1980 until 2018. In order to identify the most relevant information, the 841 articles were classified in three categories using pre-defined inclusion criteria (e.g. Tranfield et al., 2013).

**Phase 2** - In our review, the purpose of the coding was to prepare the multiple identified antecedents, factors, and their effects for consolidation and comparison. The coding, was according to grounded analysis performed as a button-up approach and was applied to antecedents and factors categories (Easterby-Smith, 2015). The coding structure and the assignment of factors to the coding structure was discussed among the authors for validation reasons. For every factor identified having a relationship to productivity, a factor code was assigned. In addition, a factor category was assigned to every identified factor having influence on productivity found in the articles.

**Phase 3** - Once codes were assigned, the effects of each factor-productivity-relation was summarized resulting in a consolidated finding about that particular factor. For quantitative research, mostly surveys, the significance level has been relevant, while for quantitative research, the recommendations or experiences have been evaluated concerning their effects (Gunasekaran et al., 2000; Krishnan and Srinivasan, 2007).

**Phase 4** - After factors and their effects were analysed, managerial implications were formulated. We expected, that especially in situations of interaction of factors, important information for management could be deduced from the relationships between factors. Finally, the managerial implications identified in the article where summarized.

**Phase 5** - The initial framework of productivity management has been updated and the identified factor categories were assigned to one of the four variable types.

**Findings on managerial implications for productivity improvement**

Based on the literature analysis, 327 single factor-productivity relationships and their effects on productivity where identified. The 327 single relationships, presented in Table 2, are related to 57 factors that were grouped into nine factors categories. Those nine categories represent the four variables type identified in the theoretical sections,
which are: Contingency variables; Resource variables; Management variables and Mediator variables. For each of those four types of variables, OM literature mirrors how they can affect productivity and contribute to productivity improvement.

**The productivity enabling variables and their interrelations**

The analysis found support for the existence of all the different types of variables defined in section 3 and provided insights into their interrelationship. For the contingency
variables, it can be concluded that the external environment (47 relationships) and organizational context (44 relationships) influences productivity quite evenly by the number of identified effects. Compared to the other variables, however, the contingency variables seems to have less positive effect (17 of 91 relationships) and therefore might not contribute as strongly as the others to productivity improvement.

The moderating effect of contingency variables on the relation between resource variables and productivity measures has been found to be relevant in two ways. Firstly, we identified a contingency factor “resource availability for the firm”, that received unison strong support for affecting productivity (Mohanty, 1992; Mapes, 2000; Rantanen, 2001; Bhattacharya and Narayan, 2015). Secondly, we discovered from literature, that contingency variables having their “counterpart” among resource variables. Especially the contingencies connected to resource factors categories Labour and Workplace (e.g., Schmennner, 1991; Demeter 2011; Sartor et al., 2016; Spring et al. 2017; Orzes et al., 2017) and Product (Mukherjee et al., 2000; Eckstein et al., 2015; Abolhassani et al., 2018) need to be considered for productivity management in accordance to the analyzed literature.

Compared to the contingency variables, resource variables were found to affect productivity more intensive (75% vs 92% of single relationships). Among resource variables, the categories ”Labour & Workplace” and ”Process” were the most relevant (101 of 147 relationships) while the resource factor category “Product” according to the analysis plays for productivity improvement only a minor role in OM (3 of 147 relationships). From the literature, we identified two dominating factors among resource variables. The factor “Knowledge & Skills of workforce” is considered very relevant as a contributor to productivity improvement (Mohanty, 1992; Gunasekaran et al. 1994; Bernolak, 1994; Rantanen, 2001; Mapes, 2002; Demeter et al., 2011). That implies from the reviewed literature, that focusing on the training of people or hiring higher-skilled people as well as the involvement of human resource department could be understood as a key element for productivity management. Also strong agreement and support for the productivity improving effect of the factor “Material flow character” can be found in the literature (Schmenner and Cook, 1985; Schmenner and Swink, 1998; Mapes, 2000; Gunasekaran et al., 2000; Neumann et al., 2006; Demeter et al., 2011). Hence, this is a support for one of the few original OM theories, the “Theory of swift even flow” (Schmenner and Swink, 1998).

Also in relation to management practices, strong support was found on its positive impact on productivity improvement (32 of 45 relationships). Especially there were a general agreement around the enabling nature of two management practices: First, “Just-In-Time”, is understood as a concept to reduce stock and inventory at all stages of the supply chain and to increase the material flow, and was found to have improving effects on productivity (Gunasekaran et al., 1994; Shah and Ward, 2003; Fisher, 2007 about Hayes 1981). Second, “Lean and 5S”, was found to have a positive effect on productivity improvement across multiple publications (Bernolak, 1997; Gunasekaran et al., 2000; Shah and Ward, 2003; Chavez et al. 2013 and 2015).

Managerial implications
By evaluating the interrelations between the different variables, it is further possible to extract and summarize a set of managerial recommendations in relations to the five resource factor categories.

The resource Labour & Workplace is connected to responsibilities of the human resource (HR) manager. In order to enhance productivity in the organization, the literature indicates that the HR manager consider labour regulation as relevant for the case of site
location selection (Bhattacharya and Narayan 2015). In addition, organization should accept their social responsibility and aim for social certification standard SA8000 (Sartor et al., 2016). In addition, HR manager could improve the implementation of motivational and incentive systems, which should be aligned with layout/flow and the work organization (Neumann et al., 2006). Competitive salaries and promotion of physical and mental health of employees will further improve the productivity of the organization (Mohanty, 1992). Also, dedicated positions for productivity improvement, process engineering should be created for productivity reason (Mapes, 2000). Literature also indicates that the HR manager should promote a careful assignment of mandatory work to line and shift leaders to ensure spare time for productivity improvement, for example to support line operators (Krishnan and Srinivasan, 2007).

The resource Material & Supply Chain belongs to the responsibilities of the supply chain (SC) manager. The SC manager should implement a supplier strategy that is appointed by certified suppliers, daily deliveries and pull supply system (Garcia et al., 2014). Furthermore, only a few different suppliers should be in the portfolio and supplier management should be a combination of pressure and training. (Fisher, 2007; Garcia et al., 2014). The SC manager should initiate inventory reduction program and implement JIT and Kanban to avoid shortage of material (Gunasekaran et al., 2000). The new program implementation should be accompanied by enough training of operators and show strong management commitment (Gunasekaran et al., 2000). When the SC manager is to select a successor or a manager for supplier management, a manager with high-perceived management strength should be selected (Schmenner, 1991).

The production manager and manufacturing engineering manager take the responsibility for the resources of Process and Technology. In order to enhance productivity in their organization they should rely upon cooperation in many directions to save resources. Thus, they should promote cross-industry cooperation for fusion of technologies, which implies a strong corporation within the industry (Jin et al., 2016). In addition, production planning should be done at corporate level rather than only at single sites (Schmenner and Cook, 1985). Further, managers should urge for alignment of technology and management to avoid technical improvements that do not fit the strategy or the budget (Kao et al., 1995). Production and manufacturing engineering manager should careful prove the introduction of new technology. It should be only considered after re-assessment and optimization of old technology (Bernolak, 1997). A final managerial recommendation is to keep the age of equipment low and exchange old equipment as soon as possible (Schmenner, 1991).

Finally the research & development (R&D) manager is responsible for the Product. Since R&D is not that present in OM research, only few implications can be derived from our analysis. Nevertheless, in focus for OM stands the manufacturable designs for new products that the R&D manager needs to ensure (Fisher, 2007). In order to promote and facilitate such a manufacturable design, R&D manager are urged to install extensive cross-functional discussions involving manufacturing, design, and sales (Fisher, 2007).

The framework of productivity management

Based on the theoretical derivation and findings from our analysis the following framework describing the mechanism of productivity management can be derived (Figure 2).

The analysis identified four relationships that were all found to be relevant for productivity change: First, the existing resources of the organization can have effect on productivity directly or via a mediator. Second, the directions and intensity of these effects are influenced by contingency forces. Third, management can assign and change
existing resources of the organization. Fourth, management can implement mediators, which in turn alter the original effect of contingency variables. In addition, we identified two new relationships, which have not been considered in the theoretical section and are an additional contribution of the detailed analysis: Within the group of resource variables, there are relations of the factors among each other (1). Contingency variables affect management variables and with them managerial decisions (2).

**Figure 2 – Updated factor-productivity framework**

**Discussion and conclusion**
The present review shows that the literature is rather diverse in relation to which factors affect productivity as well as to the size and direction of the identified effects. Only for a few of the factors, existing research do agree on their relevance for productivity.

By comparing the different types of variables concerning their ability to influence productivity, the analysis also showed some diversity. For the mediator variables, represented by management practices, current literature always report an effect on productivity. In contrast, for the contingency variables, multiple contributions report no effect on productivity.

As the result of our analysis of the managerial implications, we also identified diversity in the applied managerial mechanisms. Table 3 exemplifies three different mechanism of general management all used as productivity management mechanisms: Cooperation, delegation and reduction (Table 3).

This paper contributes to research and practice in several ways. For researchers, it provides a current, comprehensive and structured overview of the variables and factors of productivity improvement. Nine factor groups and 57 factors enhancing productivity was identified from operations management literature. This factor structure could become a foundation for comparing and positioning future research concerning productivity-related factors. Secondly, this review provides a theoretical framework for productivity enhancing mechanisms by describing the different roles and relationships of contingency, response, mediator and management variables.

For practitioners it is a catalogue to identified contingency factors that need be considered in certain situations and for planned management actions. Furthermore, the derived managerial implications provide a bouquet to operationalize productivity improvement initiatives. Thus, this review presents a comprehensive overview of the opportunities to manage productivity for certain function within an organization (i.e., Labour & Workplace, Material & Supply Chain, Product, Process, and Technology).

However, like any other study this study has some limitations. One limitation is related to the fact that we mirrored in our review the operations management literature on contingency theory applications, however the identified relationships of the variables and factors where not empirically verified. The developed factor categories are only one way to cluster the multiple factors and their antecedents and other congregations could be possible. Another limitation is related to the fact that the consolidated effects of each factor considered each finding equally, regardless of the type of research (i.e. survey, case study, etc.), the sample size and significance level.

In relation to future research, the identified relationships in the developed productivity-enhancing framework should be verified empirically. Thus, developing a database to record the relationships of factors discovered contingency combinations would make findings more comparable and help educe new theory. Further, more research is needed on how productivity and performance more generally might hold a different set of implications for their management: What is unique in relation to productivity management compared to the management of other performance dimensions? Does productivity management lead to a more sustainable organization?

Abstract

Performance Management and Measurement (PMM) practices is a key consideration for management and companies. Presently, research on PMM is scarce and often carried out from a headquarter level. In addition, focus is often on Performance Management Systems (PMS) and their ability to achieve objectives, but misses out on the people function and how, and if, a PMM system is contextually and institutionally fitting. Hence this research focus on PMM practices and their fit in South-East Asia. The findings provide avenues for research and suggestions on working with PMM from a people function perspective.

Keywords: Performance Management, People and performance, South-East Asia

Introduction

As organisations continue to expand globally, the need to evaluate and redefine their strategies, structures and processes as to achieve and maintain competitive advantages (Busco et al., 2008; Biron et al., 2011). In this context, the introduction and adoption of PMM practices as a means to increasing employee performance across global MNEs have become a focus area for management within organisations (Biron et al, 2011; Dossi & Patelli, 2010; Azofra et al., 2002; Xi, 2011; Nankervis & Compton, 2006). The need for both scholars and practitioners to conceptualise a more refined PMM that will facilitate the process of performance measurement (PM) was highlighted by Eccles (1991), and since then, specific PM models have been developed and are currently widely used among organisations as means to track and measure performance. These include, but are not limited to, Performance Pyramids, Tableau de Board, Economic Value Added, Balanced Score Card and Business Navigator (Xi, 2011; Mahlendorf et al., 2012; Chen & Dodd, 1997; Chen & Dodd, 2011; Kaplan & Norton, 1992; Ax & Björnenak, 2005). Through these models, both financial and non-financial aspects of performance are considered,
defined, measured, managed and the outcomes are used to inform organisations’ performance.

However, as MNEs globalise, the role of PMM faces new challenges as global organisations aspire for the entire MNE, both HQ level, regional HQs and subsidiaries to utilise a standardised PMM system (Buchelt, 2015; Xi, 2011; Shih et al., 2005; Mellahi et al., 2016). Standardisation is thought to allow the MNE to achieve desired outcomes across all of the organisation (Busco et al., 2008; Biron et al., 2011; Bourne et al., 2018). The scope of PMM in MNEs is broad, it encompasses dynamics of people and teams, interaction among sub-units, relationship between parent and subsidiary organisations, as well as PMM in the supply chain (Bourne et al., 2018). With global workforces, the need to adapt to the challenges of measuring, administering and controlling operations within diverse geographical and cultural contexts has become critical to MNEs success (Welch & Welch, 2006; Busco et al, 2008; Barrett et al., 2005; Vo & Stanton, 2011). There are suggestions that for today’s MNEs, people are a competitive advantage and hence being able to measure their performance is of particular interest (Buchelt, 2015). Hence, the need to ensure standardised practices and processes between the subsidiaries and headquarter (HQ) to ensure there is congruence is seen as a key organisational challenge.

Current PMM research has seen a focus on the functions of PMM practices and processes in relations to organisations’ performance, however there is paucity in literature surrounding the use of these practices and processes within MNEs operating in the international markets (Xi, 2011; Vo & Stanton, 2011; Mellahi et al., 2016, Claus, 2008; Claus & Hand, 2009). This paucity is surprising considering the significant role PMM practices and processes play in the organisation’s strategic priorities in relation to subsidiaries, managers and employees, and the different types of behaviours that are expected and rewarded by MNEs (Biron et al., 2011; Fletcher & Williams, 1996). PMM practices and processes have also been shown to influence non-operational aspects of the organisation; the people function as it deals with the assessment and development of employee competence, enhancement of employee performance and distribution of rewards (Cascio, 2006; Fletcher, 2001; Schuler et al., 1991). This gap in literature have prompted this study to explore the perceptions of subsidiary professionals and provide their understanding of PMM practices and processes and their deployments. This is the first step of a study where first the perceptions are investigated, then both HQ and subsidiary are investigated and finally measured. The aim of this paper is two-fold. Firstly, it seeks to discover how does the PMM practices and processes facilitate the people function within subsidiaries of MNEs operating in SE Asia? Secondly, it seeks to discover the perceptions of subsidiary managers on the contextual and institutional fit of the PMM practices and processes. The paper is structured as follows. Firstly, a theoretical foundation providing an overview of PMM processes and practices within MNEs and subsidiaries. Secondly, an outline of the research methodology. Thirdly, findings from this study are described and discussed. Finally, conclusion and implications for future research and practice are briefly discussed.

**Background and Theoretical Foundation**

**Principles and Definition of Performance Management**

PMM practices and processes have been widely utilised by Human Resource (HR) practitioners within organisations to achieve and improve individual and organisational performance (Nankervis & Compton, 2006; Vo & Stanton, 2011; Aguinis & Pierce, 2008; DeNisi & Murphy, 2017). While a range of models and techniques which measure both
financial and non-financial measurements have been identified, and PMM practices and processes in organisations are not new, scholars have not agreed on an acceptable model of employee PM (Gibbs, 2008; Vo & Stanton, 2011; Buchelt, 2015). Despite the lack of consensus on employee PM model, a review of literature has shown that there is some consensus on three PM features: (1) Establishing employee objectives, (2) Monitoring and measuring employee performance, (3) Providing feedback and rewards systems, and planning to improve future individual and organisational performance (Milliman et al., 2002; Murphy et al., 2004; Mabey & Salama 1995). With the three agreed PM functions in mind, this study hence adopts DeNisi and Murphy (2017, p.421) definition of PM where PM is defined as “wide variety of activities, policies, procedures and interventions designed to help employees to improve their performance”. We believe this definition provides a broader scope than other proposed competing definitions, and also encapsulates the basic principles of PM identified and adopted by this paper. We also believe that this definition fits within a dominant HR paradigm which investigates the relationship between HR Management (HRM) and organisational performance (Wright & McMahon, 1992). In this paradigm, the relationship between HRM and organisational performance is defined as the “planned HR deployments, with activities intended to enable an organisation to achieve its goals and objectives (Wright & McMahon, 1992, p.298). This definition moves away from traditional HRM, whereby it attempts to link HRM practices with the strategic management processes of an organisation, as well as it emphasizes on the co-ordination among different HRM practices through a pattern of planned action. By adopting this lens, it provides us with a clear delineation of the role of PM in facilitating the people function within organisations.

The use of Performance Management and Measurement within MNEs

With globalisation, there has been a trend to standardise processes so that Central HQ (CHQ) can compare and contrast performance across the entireness of the MNE (Chung et al, 2014; Luo & Tung, 2007; Ramamurti, 2012). One area where this have been of particular interest is in the area of PMM (Mellahi et al., 2016). While PMM practices and processes have been recognised to have profound impact on enhancing organisational effectiveness, as well as maintaining competitive advantage, there is significant paucity on existing body of literature on how MNEs utilise PMM practices and processes with their overseas subsidiaries (Mellahi et al., 2016; Thite et al., 2012). Previous studies have suggested that effective PMM policies and practices needs to consider culture and local practices within the contexts of the subsidiaries (Amba-Rao, 2000; Srinivasa Rao, 2007). However, such suggestions lead to a lack of ability to compare and contrast and significant between and within the MNEs depending on both host and home country specific factors (Coates et al., 1992; Rosenzweig, 2006). Early studies on PM in international settings saw two competing tensions, namely convergence theory and divergence theory, which sought to explain the degree to which PM practices and processes can be transferred from one country to another (Lindholm, 1999, Vo & Stanton, 2011). Convergence theorists argued that convergence, driven by the advancement of technology, has facilitated MNEs to employ identical practices across countries (Sparrow et al., 1994). That subsidiary is able to mimic similar practices and processes across the entire MNEs to ensure there is convergence. Alternatively, divergence theorists argued the importance of the uniqueness of each context made convergence impractical and suggested that practices and processes should be adapted to suit local contexts (Brewster & Larsen, 1992). This thought suggests that there is acceptable variation between host and parent country. Since then, PM practices have received attentions from scholars within the comparative HRM, and a number of studies suggested that cultural differences
can influence elements of PM practices and processes, and that the transferability of PM between host and national countries cannot be assumed (Vance et al., 1992; Paik et al., 1996; Snape et al., 1998; Milliman et al., 1995; McEvoy & Cascio, 1990; Bernthal, 1996; Pucik, 1988; Mendonca & Kanungo, 1997). However, there is a paucity of recent such studies that look at PMM practices within MNEs, this is an empirical weakness since given the expansion of MNEs in foreign markets there is a need to see more recent evidence discussing how subsidiaries work with PMM and this prompted this study to explore the perception of subsidiary professionals and provide their understanding of PMM processes.

**Theoretical Framework**

Our study uses Comparative Institutionalism (CI) as a starting point to investigate the phenomena of interest. Comparative Institutionalism theory (CIT) is a framework widely used to study the spread of organisations practices across countries (Vo & Stanton, 2011), as well as providing insights into the sources of organisational heterogeneity across societies (Edman, 2016). CI draws from several perspectives; organisation studies, sociology and political economy (Hotho & Saka-Helmhout, 2017). Since it is concerned with how the forms, outcomes and dynamics of economics organisations can be influenced and shaped by societal institutions, and their consequences (Morgan et al., 2010), we believe CI will provide an interesting insight into the current phenomena and add to current literature surrounding PMM practices and processes. In addition, CI is deemed to be more cognizant to the notion that institutional orders and their associated logics can be diverse across different societies, due to historically embedded institutional processes and arrangements that are dictated by its society (Hotho & Saka-Helmhout, 2017). CI sees three distinct features, firstly an institutional perspective that pays explicit attention to the institutional arrangements at the societal levels, which takes into account the political, financial and education systems, which have been shown to have an effect on the level of the organisational field (Hotho & Saka-Helmhout, 2017). Secondly, a configurational perspective that focus on the interdependence between societal institutions, which means, rather than analysing societal institutions in isolation, CI calls for the consideration of distinct societal institutional configurations when conceptualising the notion of institutions (Crouch, 2010). Thirdly, CI also pays explicit attention to the link between societal institutions and firm- and society- level outcomes (Hotho & Saka-Helmhount, 2017). At the firm level, CI shows that societal background institutions can impact on resources that are available to organisations, and the capabilities they develop (Estevez-Abe et al, 2001; Casper & Matraves, 2003; Hall & Soskice, 2001). With this understanding, we propose that the variations across societies in which the subsidiaries of MNEs operate in, can influence the state, the market, the profession as well as the organising principles required to operate the organisations.

**Research Methodologies**

A total of 28 participants were interviewed using semi-structured interviews. The sample was defined as: a person who is formally responsible for PM practices and processes within the Singaporean-subsidiary of a MNE. Our point of departure was that it was primarily important to research the participants’ experiences and opinions. In the mapping of the perceptions of PM programmes, it was stressed in the beginning of the interview that we did not want the official corporate statements. Rather we would like to hear how things were in the local reality, favourable and unfavourable aspects, successes and failures, earlier experiences and future scenarios in respect of PM. Among the sampled participants, 36% were female and 64% male, and the firm tenure ranged from four to 30
years; hence the majority of participants were tenured and experienced practitioners. No local HR-practitioners or employees were interviewed (this is taking place in the follow-up study, carried out currently). All participating interviewees were expatriates and had a previous history with the company before relocating to Singapore. There was enough experience amongst the participants to be deemed topic experts. In addition, these participants were active within HR generally had a more strategic HR function; overseeing several countries and not working with daily compliance tasks. All interviewees were employed in the subsidiaries of Scandinavian MNEs. All CHQ were in Scandinavia, but a common trait among the MNEs was that a substantial part of their business was outside Scandinavia (currently all the MNEs have more than 50% of their turnover outside Scandinavia). The interviews took place in a broad variety of companies from major sectors (all Industry Standard Coding Identification main codes represented).

Even though the study is based on the perceptions of 28 interviews, our experience was that the attitudes and perceptions held by the interviewees tended to converge over time. It is a rather homogeneous group of actors we have interviewed, within a very limited geographical area. Many of the interviewees knew each other from different professional forums, and it cannot be ignored that this has influenced the responses. Saturation therefore emerged rather quickly, matching theoretical evaluations within the qualitative methodology literature. Francis et al. (2010) and Constantinou et al. (2017) have in their investigation found that saturation level in interview studies is achieved very fast, when carrying out thematic analysis. Francis et al. (2010, p. 1231) mention 15 interviews whereas Constantinou et al. (2017, p. 583) claim that the threshold can already happen at the seventh interview. This does however depend on the breadthness of the selected themes and sub-themes, as well as the level of homogeneity within the population. Finally, it is the gatekeeper’s reasoning we are investigating adhering to the understandings presented by Falconbridge et al. (2009). We hence assumed that the interviewees are the ones making the decisions and, in that respect, it is more a study of their “translations” of CHQ policies and programmes, and how and from which criteria they define and select. We have selected illustrative interview quotes from the 28 transcribed interviews. It is obviously based on our personal selection among hundreds of pages but in many respects, the quotes are very good proxies for the attitudes held in general by the participants. The research team read through the transcripts, adding notes, trying to seek out the “true meaning” of the participants’ experiences. Reading and reflecting on the material allowed us to get a holistic view of the general themes and perceptions held by the interviewed participants (Cresswell, 2009). Our findings support the notion that institutional orders and their associated logics can be diverse across different societies, and in this case, due to financial embedded institutional processes and arrangements that are dictated by the employees.

**Findings and Discussions**

Participants have shared their experience on how the role of PMM practices and processes facilitate the people function within the organisation through the means of developing competence and talent among employees. This notion has been previously suggested by scholars (Biron et al, 2011; Dossi & Patelli, 2010; Xi, 2011; Nankervis & Compton, 2006). Participants have also agreed that the role of PMM practices and processes in today’s business environment can transcend beyond the operational scope, and the process can be used to facilitate growth of employee in identifying their current performance and ways to enhance performance (Milliman et al., 2002; Murphy et al., 2004; Mabey & Salama 1995). Through the data gathered from our participants, it was
identified that, a small number of employees have in fact accepted PM as an opportunity for individual career development and such notion has also been previously reported by Maley and Moeller (2014).

“PM, we measure not just competences but also values and results. The employees are looking at what they get out of PM, what competences they can see developed.”

“Ah it’s a matter of setting a goal, an aspirational goal, then the manager is expected to set a pathway for the employee.”

What was also evident through this study is the notion that the contexts, in which the subsidiaries operate in, have influenced elements of PM practices and processes, and the transferability of PM between parent and host countries cannot be assumed (Paik et al., 1996; Snape et al., 1998; Milliman et al., 1995; Bernthal, 1996; Mendonca & Kanungo, 1997). For example, a large number of the participants have highlighted the employees’ perception of the role of PMM as a tool in bargaining for a higher salary and additional financial rewards or benefits. These findings have provided further support to earlier findings that PM practices and processes is not only used for the assessment and development of competence, but it can also be used to facilitate the distribution of rewards (Cascio, 2006; Fletcher, 2001).

“PMS, I try to talk about values and they talk about money. Good luck talking values with people that are trying to make ends meet. That works in Scandinavia but not out here.”

“The issue with PMS is that since it’s here linked solely to additional financial rewards or promotion……our system is bound not to work.”

The challenge faced is that the institutional context of SE Asia is not receptive for PM as being a tool to develop a competitive strategic advantage, instead it is focused on rewards, and in this particular context, extra remuneration. In SE Asia, almost all companies offer a so called 13th month of remuneration, and this is what PM has been contextualised as by employees. In this context, the measurements are hence linked to monetary rewards, making any discussions about competence development rather moot. It might be suggested that PM needs to be de-coupled from the 13th month reward appraisal process that most of the participants believed hindered any focus on competence or value development.

“PM, while we attempt to link them to overall goals, at firm, unit and individual level, down here such reasoning is to abstract. If a person has performed their way good, the idea that they aren’t rewarded accordingly leads to frustration.”

“The locals see the appraisal as a time when the manager decides whether they get a full 13th month salary or not”

Despite this tension, responses from the participants have highlighted a somewhat positive perception regarding the contextual and institutional fit of PMM practices and processes within their respective subsidiaries. These perceptions align with the notion proposed by the CIT framework; in which there can be variability in organisation practices across parents and host countries due to the heterogeneity across the societies.
“The local context is more regional to be honest, the region here sees similarities that we need to work with. There is a vast difference in what is expected by our employees versus what HQ assumes. For example, we expect the employees to suggest their own goals, that’s not doable in SE Asia.”

Furthermore, participants have reported a PM system that adheres to a top-down alignment. The PM model used, such as MBO, was perceived among employees to be a ‘fair’ method in obtaining robust feedback pertaining to the performance and used as an opportunity for further development of competence.

“We use MBO, goals are initiated by the employee and agreed upon by the line manager…that is great on paper.”

“PM is hierarchal down here, we must accept that, the employees demand it. The manager sets the path and if they point out a path then the employee feel taken care of and feel that this employer will look after them.”

The findings derived from this study have provided support for our proposal earlier, in which, the variations across societies in which the subsidiaries of MNEs operate in, can influence the state, the market, the profession as well as the organising principles required to operate the organisations. Whilst there is the recognition for the need of standardised practices and processes with the subsidiaries and HQs to ensure competitive advantage is maintained and achieved, the importance of contextual and institutional fit cannot be overlooked to ensure there is acceptance from employees. By drawing on CIT framework, we propose that the view, forms, outcomes and dynamics of PMM practice and processes in this case have been influenced and shaped by societal institutions due to the heterogeneity of MNEs and their subsidiaries.

Within this context, the institutional arrangement at the societal level, namely the role of the financial system appears to be a driving force among employees who have perceived PMM practices and processes as a means to bargain for more reward. As relayed by participants in our study, this tension has an effect on the organisation when it comes to managers attempting to instil values and align these values to achieve competitive advantage as required by HQ. From a configurational perspective, the responses from our participants have prompted us to analyse all aspects of the societal context when trying to make sense of the experience and perception of our participants. It was unreasonable to analyse these responses without considering the contexts in which the subsidiaries operate in, which have been influence by a range of systems (financial, political and economy). Finally, the societal context in which the subsidiaries operate in have impacted on the view of PMM practices and processes, and in turn, impact also on the resources associated with the role of PMM. Instead of using PMM as an opportunity to develop competence and values, employees are seeking extra remuneration and detracting away from the role of PMM as perceived by HQ.

**Limitations and Future Research**
While this study has provided some recent and empirical findings and insights into PMM practices and processes among subsidiaries in SE Asia, it is imperative to keep in mind that these findings and insights are only applicable to the participants that were involved in this study, as well as the subsidiaries in which they were employed within. Despite these limitations, the findings and insights have provided empirical support for the field
of PMM, and also add on to the current paucity in literature. In the interest of progressing understanding of PMM practices and processes within subsidiaries, we offer the following considerations for future research. Firstly, that a larger sample is used to add breadth to the findings we have presented and secondly, to measure the impact that these findings may have on the effect and results that are expected from a globalised PM program.

Conclusion
Through this study, there is evidence to suggest that PMM practices and processes within subsidiaries can facilitate the people function by identifying areas for improvement. Interestingly, there is also the perception that PMM practices and processes are used as a tool in bargaining for pay increase, promotion and additional rewards, which is contrary to the perception of MNEs. Despite this tension between the view of PMM between MNEs and their subsidiaries, participants in this study have expressed a somewhat positive view of PMM practices and processes. In addition, there is also evidence to suggest that the transferability of PMM practices and processes from MNEs to subsidiaries cannot be assumed, as participants have indicated having to adapt some of these practices and processes to ensure there is a better alignment to the requirements of the context in which the subsidiaries operate within. The CIT framework adopted by this study delineated how the processes and practices within organisations can be influenced and shaped by its own societal context.

Abstract

The motor vehicle manufacturing sector is regarded as the engine of Europe. There is more to a healthy motor vehicle manufacturer than the financial statistics. However, current efforts in the field of performance measurement and management haven’t provided sufficient quantitative trend analysis with environmental concerns for motor vehicle manufacturers. This research aims to design an integrated framework which can serve as an approach to the missing trend analysis. This framework exclusively involves quantitative analysis based on secondary data. This framework can form the basis for a statistic which can assist users to better understand their decisions with environmental concerns.

Keywords: Trend analysis, Autoregressive models, Motor vehicle manufacturer

Introduction

The motor vehicle manufacturing sector is regarded as the engine of Europe. On the other hand, this sector has a negative impact on the environment directly and indirectly. Its manufacturing activities involve consuming a large volume of resources and generating products as well as various pollutants. For example, the volumes of carbon dioxide emitted in the year 2017 contributed around 72% to global greenhouse gas (source: PBL Netherlands Environmental Assessment Agency). Therefore, there is more to a healthy motor vehicle manufacturer than the financial statistics.

So far, much concentration is on the historical performance and on the things that have already happened (Unahabhokha et al., 2007). Manufacturers forecast their performance mainly relying on experts’ judgment and some financial data for decision making. In other words, current efforts in the field of performance measurement and management haven’t provided sufficient quantitative trend analysis with environmental concerns for motor vehicle manufacturers. To narrow this gap, this research aims to
design an integrated framework which can serve as an approach to the missing trend analysis.

To measure multi-dimensional company performance, performance analysts use composite indicators (CIs). A CI may be defined as a single index “which is formed when individual indicators are compiled on the basis of an underlying model of the multidimensional concept” (Glossary of Statistical Terms from the Organisation for Economic Co-operation and Development). Historical data of a variable collected at regular intervals in time sequence is called a time series. Time series analysis can assist decision makers to better understand variables’ trend and more accurately forecast its future value. There are several conventional methods for trend analysis such as the deductive method, the joint opinion method and regression models. Besides, there are several advanced tools that have been applied to quantitative trend analysis such as adaptive neuro-fuzzy inference system (ANFIS).

The rest of the paper is organized as follows. Section 2 presents a literature review on company performance measurement indices for manufacturers and on trend analysis methods. Section 3 presents the method in this paper, namely, an integrated framework which can serve as an approach to the missing trend analysis. Section 4 provides concluding remarks, limitations in this research and two recommendations for further research.

**Literature**

*Company performance indices of manufacturers*

Constructing CIs involves five phases, including selecting variables, weighting variables, aggregating variables into a single index and post analysis of the index. This research does a literature review on CIs at the company level for manufacturers.

To discriminate stable car companies from unstable ones, the average value leverage factor was proposed. Its value is based upon the average R-value by a linear least squares correlation analysis between three variables, namely, turnover per employee, profit per employee and research and development expenditure per employee. Companies can be ranked according to the scores from this stability factor (Beelaerts van Blokland et al., 2018).

A global performance measurement model for decision making was developed based on the performance measurement questionnaire and analytic hierarchy process (AHP) (Chahid et al., 2014). With a case study in an automotive supplier, the authors said their work presented a complete view of performance measurement in the Moroccan automotive manufacturing sector.

To develop a composite sustainable supply chain performance index for measuring organizations’ contribution towards supply chain sustainability, an integrated method of literature review for selecting 42 indicators, Liberatore score and fuzzy AHP for weighting qualitative indicators and the signal to noise ratio approach for weighting quantitative indicators (Gopal and Thakkar, 2015).

Evaluation of organizations’ sustainability performance was performed by a sustainability index with the technique of AHP for indicators’ weights, min-max for the normalization, and simple additive weighting (SAW) for aggregating. A case study in a Portuguese automotive company was presented, but due to the sufficient data and responses to the questionnaire, only a partial conclusion was drawn (Salvado et al., 2015). Afterwards, a similar research was done by assessing the level of sustainability performance of the UK automotive supply chain from 1999 to 2014. The main difference between the two researches is that this one used the Delphi technique for
weighting and with ambiguity associated to indicators selection (Azevedo and Barros, 2017).

A quantitative measurement model was proposed with a new conceptual framework. Methods involved techniques of fuzzy logic and analytic network process. A case study in nine truck manufacturers was presented with data during the fiscal year 2004 to 2015. The result out of the Technique for Order of Preference by Similarity to Ideal Solution was used as a validation which indicated the higher accuracy of the model (Zeng and Beelaerts Van Blokland, 2018).

Trend analysis methods
ANFIS (Jang, 1993) was developed which is endowed with neural learning capabilities of ANNs (Mavi et al., 2017). ANFIS is able to solve tough realistic problem due to it: 1) presents a better learning ability; 2) achieves highly nonlinear mapping; 3) requires smaller size of training data set (Mavi et al., 2017).

For testing the model performance, root mean square error (RMSE) and mean absolute error (MAE) are commonly used. RMSE is a frequently used performance criterion which measures the difference between values predicted by a model or forecaster and the target or desired values. It is suggested that the RMSE is not a good indicator of average model performance and might be a misleading indicator of average error and therefore the MAE would be a better metric for that purpose (Willmott and Matsuura, 2005). However, the RMSE appears to be more appropriate to represent model performance than the MAE 1) when the error distribution is expected to be Gaussian, and 2) considering the RMSE satisfies the triangle inequality requirement for a distance metric (Chai and Draxler, 2014).

In terms of the application of trend analysis at the company level, some studies focus on forecasting financial trends, such as the sales of the printed circuit board with a weighted fuzzy neural network (Chang et al., 2007), the sales of medical products with a comparison study on feed forward neural networks, radial basis networks and ANFIS for their accuracy and convergence (Koulouriots and Mantas, 2012), the supplier evaluation and selection with ANFIS, using mean square error and linear regression analysis for evaluation (Özkan and İnal, 2014), the online market research with a warning system based on neuro networks and fuzzy logic (Kaiser et al., 2011) and a customer satisfaction model based on neuro-fuzzy technique (Chan et al., 2012).

Method
This research designs an integrated framework of quantitative trend analysis for motor vehicles manufacturers. This approach consists of six phases. In phase I, a conceptual framework of company performance for motor vehicle manufacturers is developed. To identify the variables, a literature review is conducted. Besides, this research refers to released documents 1) from motor vehicle manufacturers, 2) from the International Organization of Motor Vehicle Manufacturers and 3) from the Global Reporting Initiative.

Construct a composite indicator of company performance
During phase II to phase IV, a company performance index for motor vehicle manufacturers (IMVM) is constructed. The adoption of methods should be suitable in specific applications. Otherwise, the methods as well as the results derived might be controversial. For instance, there is one crucial assumption in real cases that there is
some degree of non-compensability between variables. Therefore it is improper for researchers directly adopt several techniques such as the SAW method.

The method in Phase II is the Shannon entropy equation for weighting variables. Phase III is a normalization method based on the min-max method. In Equation (1), $x^*_ij^t$ is the normalized value of variable $j$ on manufacturers $i$ at the fiscal year $t$. “+” denotes the variable which satisfies “the larger its value is, the better the result gets” and “-” denotes the variable which satisfies “the smaller its value is, the better the result gets”.

$$
x^*_ij^t = \begin{cases} 
\frac{x'ij}{\max_i x'ij} + 1, & \text{for } (+) \\
\frac{x'ij}{\min_i x'ij} + 1, & \text{for } (-) 
\end{cases}$$

The method in Phase VI is a geometric mean for aggregating individual variables into the single index $I_{MVM}$. Construct an multiplicative function in Equation (2), where $I^t_i$ is the overall performance index for manufacturer $i$ at fiscal year $t$, $w_j$ stands for the final weights of indicator $j$.

$$I^t_i = f\left[ x^*_ij^t, w_j \right] = \prod_{j=1}^{n} x^*_ij^t^{w_j}$$

**Trend analysis of company performance**

There are several conventional methods for trend analysis such as the deductive method, the joint opinion method and regression models. Besides, there are several advanced tools such as ANFIS that have been successfully applied to quantitative trend analysis. Based on a literature review, this research adopts two commonly used methods, namely autoregressive models and ANFIS for trend analysis. In phase V i), the $I_{MVM}$ trend is analyzed based on autoregressive models. Different autoregressive models can be developed for different manufacturers. Calculate the mean square error (MSE) between the real value and the estimated value during the fiscal year (FY) 2008 to FY 2017. In phase V ii), the $I_{MVM}$ trend is analyzed based on ANFIS. The implementation of ANFIS in this research can follow five steps.

1) Build a dataset of input variable and the output variable, split it into two sets, and input the data sets. Around 70%-90% of all data (Azadeh et al., 2011) works as the training data set for finding the optimal ANFIS structure, while the rest data works as the testing dataset for validating the model.

2) Decide the membership function (MF) type and the number of the MFs for each variable. The Trimf and the Tramf are often used MFs due to their computational simplicity for decision makers. In order to choose the appropriate MF(s), a comparison study on some error criteria from different MFs can be conducted in this step. The lower value of the error, the suitable the MF is.

3) Give other parameters for learning, and apply a hybrid learning algorithm to the model. Important parameters include the number of iterations (epochs) and the value of Error tolerance. Error tolerance is best left set to 0 considering the trend of the training error remains unclear.

4) Start learning process using command anfis. The training will stop after the training data error remains within the Error Tolerance.
5) Test forecasting capability of the developed model. Conduct the comparison of independent values and the corresponding output values by training and testing data respectively. RMSE is widely used as the termination error criterion considering it is the most commonly used measure to reflect the goodness of model fit (GüNeri et al., 2011). The lesser the RMSE value is expected.

In phase VI, the results from the two methods are compared. The method with less errors can be identified. Use the identified method to calculate the $I_{MVM}$ value from the FY2018 to FY2020. All the phases within the integrated framework of company performance trend analysis for motor vehicle manufacturers are shown in figure 1.

![Figure 1 – An integrated framework of company performance trend analysis for motor vehicle manufacturers](image)

**Conclusion**

This paper contributes to current literature in the field of performance measurement and management with an integrated framework to analyze company performance trend for motor vehicle companies. Two trend analysis methods are involved, namely autoregressive analysis and ANFIS. Environmental variables can be identified and included into the conceptual framework of company performance measurement for motor vehicle companies. Besides, the index $I_{MVM}$ is transparent about the methods which are used. This quantitative trend analysis as well as the $I_{MVM}$ is based on secondary data. By the comparison study on the errors from autoregressive models and from ANFIS, the better trend analysis method can be identified. This trend analysis can serve as a statistical tool. This tool can assist users to better understand the consequence of their decisions in the complex business management.

There are two limitations and accordingly two recommendations for further research as follows. 1) The construction of the composite indicator missed the post analysis phase. This indicates that the effectiveness of the index hasn’t been validated. Therefore,
a post analysis phase is suggested. 2) A computational demonstration of the method is was missing. Therefore, data analysis with a case study in motor vehicle manufacturers is suggested.

When deviating from standard processes leads to higher performance - How companies can improve complexity management by understanding deviations of process standards

Melanie Zahner (melanie.zahner@rwth-aachen.de)

Prof. Dr. Julia C. Bendul (bendul@scm.rwth-aachen.de)  
RWTH Aachen University

Abstract

Deviations from predefined process standards often occur in order to reach higher performance levels. Based on a structured literature review and a data analysis of over 1,000,000 data lines, we developed a theoretical framework to understand the characteristics of desired and undesired process complexity. To validate the positive performance impacts of process deviations we present a case study of two production companies and demonstrate the findings of their analyzed end-to-end processes of actual process paths, as opposed to their predefined processes. We conclude with actionable alternatives on how management can use complexity to enhance logistic performance.

Keywords: Process complexity management, business process reengineering, process mining

Introduction

With expanding interlinking activities between business partners and the increasing demand of customers for individual products, complexity management became an integral part of the management agenda. Fulfilling this new market need and simultaneously enhancing logistic and financial performance has become one of the major challenges for top management (Bode, Wagner, 2015).

Complexity can influence performance in both positive and negative ways. For example a larger product variety can help the company to open up new markets and increase revenue (Aitken et al., 2016).

(Marley et al., 2014), (Bode, Wagner, 2015), (Fisher, Ittner, 1999) investigated the negative impacts of complexity on increasing supply chain disruptions, a higher failure rate and increasing need for supervision and control. Aitken et al. (2016) raised the position that there is a difference between necessary and unnecessary complexity: Necessary complexity can be helpful to reach strategic company goals, for instance by accepting a larger product variety to offer customers a wider product range. Unnecessary
complexity can hinder reaching the strategic company goals and thus, must be avoided. However, complexity can also have positive performance impacts when deviating from predefined process standards.

Latest technology developments gave rise to software programs called process mining tools, which help to analyze large data volumes and identify actual taken process paths within a company’s business wherever electronic data is available.

In this research we aim to understand the positive aspects of additional process complexity through deviation from standard processes by using the term “desired” and “undesired” complexity. We aim to investigate the characteristics and emergence of desired and undesired complexity and to develop a heuristic framework to illustrate the cause-and-effect-relationships between impact factors and performance effects of desired and undesired process complexity. Further, we show how latest process mining tools can be used to identify process deviations in order to apply this approach to multiple processes by introducing a case study of two companies.

The remainder of the article is structured as follows: First, we illustrate a review of the current state of literature. Second, we present the theoretical background. Third, we expose our heuristic framework and highlight the research gap. Fourth, we present and discuss the main findings of our case study. The paper concludes with some theoretical and managerial implications and gives advice for further research.

Structured Literature Review
In order to investigate the current state of literature and highlight the research gap we did a structured literature review on articles between 1998 and 2017. For the literature review we identified 18 keywords, which were supplemented during the search process, documented in Table 1.

Table 1: Keywords for literature research

</table>

These keywords were combined to research strings resulting in 248 papers. For the subsequently followed forward and backward search relevant criteria were defined. This search resulted in 314 papers. To reduce the number of papers we choose criteria such as focus on process complexity, measurement techniques of complexity and business process improvement methods, resulting in 38 papers. All remaining papers were investigated by using a structured analysis approach. The focus of the article analysis was investigating (1) the used theory, (2) characteristic of complexity, (3) complexity drivers and (4) the impact of complexity on performance to develop a general understanding of complexity and to develop a framework to explain the cause-effect relationship between the different complexity types.

Theoretical Background
We give a brief definition of process complexity. In order to show how process complexity can be analyzed we present several graph theoretical measurements and
highlight the influence of process complexity on performance. Then, we present reasons for deviating from process standards and show how business process reengineering can be solved with the help of process mining tools. Based on this analysis we highlight the research gap.

**Process Complexity**

A high task variety, a variety of different inputs and uncertainty are characteristics of complex processes (Mani et al., 2010). (Karimi et al., 2014) added to that definition the uncertainty and interdependence between the individual activities of a business process. (Größler et al., 2006) state process complexity also named internal complexity is an answer to the complexity resulting from the outside business environment. (Schäfermeyer et al., 2012) indicates that business processes even need a certain level of complexity to be able to respond to the environment.

Process complexity therefore can be defined as a process characteristic describing the effort which is needed to fulfill the process goal. Task variety, involved parties and subject areas determine the level of process complexity.

As business processes are the core element of a company’s operations, it is absolutely important to understand the characteristics and influences on process complexity to be able to respond with the correct management action.

**Measurement of complexity**

In order to define the level of complexity and therefore respond with the correct action alternative it is necessary to measure the degree of complexity.

In the field of network research there exist several indicators to measure complexity (Boccaletti et al., 2006). For this paper we used the relevant indicators which are necessary to define the level of process complexity. The shortest path length is one of the basic indicators which defines the shortest connection between two nodes within a network. Another quite commonly used indicator is the so called betweenness centrality. This measurement is based on the shortest path length and characterizes a node as important if it belongs to a high value of shortest path lengths. (Boccaletti et al., 2006).

**Performance vs. Complexity**

The majority of business literature focuses on the negative impacts of complexity.

According to (Bode, Wagner, 2015), (Marley et al., 2014) (Allesina et al., 2009) complexity should be reduced or avoided wherever possible. They argue with the negative impact of complexity on logistical performance, a more complicated decision-making process and increasing supply chain disruptions.

Following the argumentation of the normal accident theory, the likeliness of failures increases with an increasing complexity and tight coupling of processes (Perrow, 1999). This theory was applied in several research field of supply chain management, manufacturing and transportation to explain why failure and process disruptions occur. According to this theory due to the high number of interactions errors will occur in unexpected ways. In combination with the tight coupling, therefore failures can spread easily within the network and it’s “normal” that failures and therefore disruptions will occur (Marley et al., 2014).

(Aitken et al., 2016) questioned whether the only possible impact of complexity is negative and therefore distinguish in their paper between “strategic or necessary” and “dysfunctional or unnecessary” complexity.

According to the authors (Aitken et al., 2016), (Bozarth et al., 2009) strategic
complexity empowers the company to reach their strategic goals like a higher product variety increases the complexity but also enables the company to gain market share. In contrast, dysfunctional complexity in a process impedes its performance. Thus, a healthy level of complexity can have positive performance impacts and even deviations from standard processes can lead to an increase in performance.

**Deviation from Process Standards**
People often take alternatives to reach their goals despite of predefined standard process steps. They do so actively but sometimes also unconscious.

Deviating from standard processes could mean on the one hand, doing process steps in a different sequence than the standard process pretends. On the other hand deviation could also result in a completely new set of process activities which are not intended in the standard process.

Especially the external factors time pressure and multitude of information encourage the phenomenon of cognitive bias and lead people to deviate from predefined standard processes (Arnott, 2006). The employee has to react fast and there is not enough time to comply with all necessary process steps, therefore the employee seeks possibilities for reaching the process goal as fast as possible in spite of known, standard process requirements (Bendul, 2016).

Additionally, missing knowledge and lack of transparency are reasons influencing why people deviate from process standards. They are just not aware of how the process should be exactly executed and therefore decide on their own what they think is the best way to reach the process goal. Lastly, another reason might also be that employees sometimes get the instruction from their supervisors to do a task in an unique way, which is not in line with companywide defined process standards.

While these are more of an unconscious action, some people also actively deviate from standard process. They are convinced that their process path is better than then defined one to reach the process goal. Moreover, after a process change this is a quite common phenomenon. According, people also tend to do their task the same way they have carried out in the past, even if new process standards have been implemented by the company’s management. (Marjanovic, 2000).

**Business Process Reengineering and Process Mining**
As presented in the previous section on normal accident theory, depending on their complexity level, systems contain an inevitable failure potential and the only way to abandon this is to redesign the system. This is also true for the system of business processes. Beside other business process improvement techniques such as Six Sigma, continual business process improvement and core process redesign, Business Process Reengineering (BPR) is one approach to improve business processes (Grant 2016).

BPR is a method used for achieving higher performance through a radical change of current business processes (Hammer, Champy, 1993). Therefore, BPR entails a total rethinking of how processes are currently carried out and how process goals can be achieved. (Murray, et al., 2000).

When selecting which processes should be reengineered, a company should focus on strategic processes. Strategic processes are defined as core processes which are directly related to the company’s business purpose and contribute to reach the strategic goals (Hanafizadeh, Osouli, 2011).

Other than the need to select the right processes to re-engineer, choosing the right
method for their alteration is a key factor for successful BPR. Cheung (1998) suggest two types of appropriate approaches for BPR projects, one is non-digital and the other is software-supported or software enabled.

Process Mining is a young software technology which could be used as a support tool for BPR. Based on the analysis of event-logs within the system of a company this technology enables analyzing really taken process steps. It supports process analysis, process policy conformance and the understanding of process models and is therefore a useful tool to support business process improvements (Polpinij et al., 2015).

**Theoretical Framework of Process Complexity and Research Gap**

*Process Complexity Framework*

Based on our structured literature review, we developed a heuristic framework for explaining the emergence of process complexity, taking into account its characteristics and interdependency to other complexity types within a production company.

![Fig. 1 Process Complexity Framework](image)

In general, there are three categories of complexity within a production company; which are product, process and organizational complexity (Größler et al., 2006).

Different developments such as technical development, market and customer demands are global trends which have either directly or indirectly influenced product or process complexity (Bode, Wagner, 2015). The different product variations and relevant number of components determine the product complexity.

Process complexity in general is determined by the number of possible process path alternatives and process steps actually taken (Mani et al., 2010). Organizational complexity can be characterized as the structure of hierarchy and delegation levels in an organization. Product complexity as itself also influences process complexity and organizational complexity (Größler et al., 2006). Organizational complexity can be characterized as the structure of hierarchy and delegation levels in an organization (Größler et al., 2006).
Their interdependencies can be exemplified through the following sample; a larger number of product variants and components require a larger number of suppliers which in turn often require different sourcing processes. Thus, an increase in product variants and therefore complexity, often directly leads to correspondingly higher process complexity. Increasing the number of product components also leads to the need for more employees (for example for product design, construction etc.) and therefore, also to an increasing organizational complexity (Bode, Wagner 2015).

These interdependencies go both ways, product complexity impacts organizational complexity, but organizational complexity can also effect products. Organizational complexity is often characterized by many levels of hierarchy and unclear responsibilities, which can lead on the one hand to higher product complexity due to unclear construction standards for example and on the other hand to a higher process complexity (Aitken et al., 2016).

Human factors are also reasons for deviating from predefined standard processes which influence process complexity (Arnott 2006), (Marjanovic, 2000). It is undisputable that process complexity impacts the performance of processes in terms of their lead times, inventory, delivery reliability and working capital (Bode, Wagner, 2015), (Aitken et al., 2016) as well as on network indicators like robustness, shortest path length and betweenness centrality (Boccaletti et al., 2006), (Meyer et al., 2015).

**Research Gap**

Aitken et al. (2016) argue that the desirability of different complexity levels should be distinguished, such that an acceptable level is identified depending on the strategic relevance. As only negative impact of complexity on corporate performance has been addressed in literature, there is a need for further research of the positive impact of process complexity on specific key performance indicators like process throughput times.

Furthermore, the reasons for deviation from predefined process standards must be further investigated. To further discussion on this gap, this paper aims to contribute to the research goal; how process deviation increase corporate performance in terms of process throughput times and how people behavior affect deviation from process standards.

**Case Study**

In order to explore above-mentioned question we present a case study of two German production companies (see table 2) and demonstrate the findings of two analyzed end-to-end processes, with a combined total of 1.794.000 data records of process paths truly taken, as inputted by employees in each respective companies SAP system. The characteristics of the two chosen companies are presented in the table below:

<table>
<thead>
<tr>
<th>branch</th>
<th>company I</th>
<th>company II</th>
</tr>
</thead>
<tbody>
<tr>
<td>metalworking plant engineering</td>
<td></td>
<td>aviation</td>
</tr>
<tr>
<td>annual turnover</td>
<td>&gt; 900 Mio. €</td>
<td>&gt; 400 Mio. €</td>
</tr>
<tr>
<td>employee</td>
<td>2.000</td>
<td>1.500</td>
</tr>
</tbody>
</table>

The two chosen production companies dispose about all relevant key business processes with a relevant spectrum of attributes and complexity aspects like number of suppliers and customers, invoices in different currencies and delivery routes. The two chosen companies are large corporations. Therefore, also the company size, involved
departments and employees as well as the data and process volume represent the situation of a multitude companies. As both companies are production companies they often deal with all three presented complexity types; of product, process and organizational complexity. Moreover, there are many involved parties which contribute to the complexity, such as various departments, and employee hierarchies within a single process, which allows for an assessment of the underlying human factors on process complexity can be investigated.

For the analysis we used extracted data of one accounting period from the company’s Enterprise Resource Planning (ERP) system of the purchase-to-pay and the order-to-cash process. In total 1.794.000 single data records were analyzed by using a process mining tool, named Celonis.

Table 3: Analyzed data records

<table>
<thead>
<tr>
<th>process</th>
<th>data record</th>
</tr>
</thead>
<tbody>
<tr>
<td>purchase to pay</td>
<td>1.593.000</td>
</tr>
<tr>
<td>order to cash</td>
<td>201.000</td>
</tr>
</tbody>
</table>

Based on event logs within the ERP system and the time stamps of the several process step activities the process mining tool is able to mirror the actually taken process paths. Based on the analysis of the time stamps Celonis is also able to determine the used throughput time. It is possible to define a target process and doing a conformity check if the process path and the specific steps are the same as they were defined in the target process or if there occurred some process violations.

The central measured values from the tool are the throughput time based on the analysis of the time stamps and the cases per step, based on the analysis of the IT-documents per process activity. In the following section we show the process deviations taken, as well as their identified influence on performance indicators.

Findings

Comparison of Planned vs. Actual Process Paths

The standard process predefined by management are first shown for purchase-to-pay (Figure 2) and order-to-cash (Figure 3).

Fig. 2 Standard purchase-to-pay process
To validate our framework about desired and undesired complexity we present the following example from our analysis of the invoicing part of the order to cash process. We investigated in the order to cash process a normal throughput time of 23 days. For this sub process part a normal throughput time of 8 days is defined as a standard. The activity “send overdue notice” for sent invoices where there is no cash income yet, is defined by the company as a desired activity. Even the throughput time of the whole process increased by 17 days and also the process complexity increased due to the extra loops, it is a necessary complexity increase and certainly also by management a desired process step, from a company strategic point of view.

Figure 4 shows the comparison to Figure 2 of the network topology between the purchase-to-pay standard process with its accepted path alternatives and the process path actually within the company.

As also the figure illustrates, we investigated a higher static complexity due to the increase of possible path alternatives. Also, a higher dynamic complexity occurred due to the taken process paths and the deviation from the standard process.

We investigated the shortest path length of the taken process path. \( D_{ij} \) defines the length between one node \( i \) to another node \( j \).

\[
L = \frac{1}{N(N-1)} \sum_{i,j \in \mathcal{N}, j \neq i} d_{ij}
\]
The shortest path length increased by 7-9%. This means there is a higher effort necessary to reach the process goal and confirms the increase in complexity.

By using a process mining tool process throughput times can be easily investigated. We analyzed the throughput times of the two end-to-end processes in the several taken process path variants. Apart from the standard process there were 655 alternative actions in the purchase-to-pay process of Company I and 11,421 variants in Company II, taken by the employees involved in the process. In the order-to-cash process 636 variants exist in Company I and 76 variants in Company II.

Regularly the throughput times increased when deviating from predefined standard processes. But we also identified between 10% and 20% process variants where the deviation from the standard process has led to a decrease of throughput time by 10-12%.

Further, we found that even when people deviate from predefined standard process within the process activity sequence, the start point and the process end for each taken variant was always identical. This indicates that the employees which are involved in the respective processes, actively or unconscious, take alternatives but always to reach the identical process purpose. For example in the purchase to pay process we investigated cases where the process starts directly with the order and afterwards the purchase request was placed in and approved in the system. This indicates that the employee was under time pressure to quickly receive the goods and there was no time to wait for the approval of the request.

**Performance increase due to process deviation**

Further, we investigated, deviations from standard processes resulting in a shorter throughput time for example due to different starting activities as predefined in the standard process or due to different process activities within the process or due to a different sequence of process steps. These were undesired process steps, but contributed to a better corporate performance.

Therefore, this is already a first indication for a necessary Business process reengineering. This implies that the really taken process path leads to a better performance result than the defined standard process. Are there undesired process alternatives which lead also to a performance decrease management should choose action alternatives to abolish this situation. In case there is a performance increase and also the process steps are desired management should proceed and maintain the current situation. Whereas a performance decrease in combination with desired process steps also indicates a necessary business process reengineering. This implies also that the predefined standard processes lead to a lower performance than the really taken process paths.

**Conclusion**

This paper investigated the characteristics and emergence of desired and undesired process complexity.

The presented heuristic framework illustrates the cause-and-effect-relationships between impact factors and performance effects of desired and undesired process complexity. It has been shown that an increase of process complexity and the deviation from standard process can increase performance.

First approaches have been developed to explain reasons and influencing factors of process deviations.

From a practical perspective the used data analytics methodology of the process mining tool shows how current data analytics tool can be used in practice and help to analyze big volumes of process data and identify really taken process paths within a
company’s business. Further we gave advice for management to choose the correct action alternative based on the level of desired complexity and the performance impact.

Abstract

The literature covering the design of performance measurement systems (PMS) is extensive. Empirically based cases showing how to identify and present the information to support decision-making in the best way is however not as commonly described. The purpose of this article is therefore to close this gap and to propose a novel methodology, the Pull approach, for designing performance measurements. It will provide a description of the Pull approach, position it into context in the literature and exemplify how the methodology could be used by presenting industrial case studies.

Keywords: Operations strategy, performance management, KPI

Introduction

The upbringing of this paper was an industrial need to design more effective performance measures. Measures that really measure the right things, resulting in information that is needed for decision making on all organizational levels. The literature covering the design of performance measurement systems is extensive. However, how to identify and present the information to support decision-making in the best way is not as commonly described. The purpose of this article is therefore to close this gap and to propose a novel methodology for designing performance measurement or indicators.

This article will provide a description of the Pull approach, compare it to similar or alternative approaches in the literature, and illustrate how the methodology is used through a number of industrial cases. Finally, reflections and conclusions will be done as well as a description of planned future research.
Methodology
There are several performance measurement system (PMS) design methods presented in the literature. A literature review of methods for PMS design was carried out, with the purpose to position the Pull approach in comparison to alternative methods.

Further was case study methodology used to structure and carry out the industrial case studies. Three different cases from the same industrial company are presented in this article. The cases illustrate and evaluate the use of the same methodology for different kind of performance measures and at different hierarchical levels. Case A was the first case, conducted during a welding line installation. In Case B the methodology was used in a project implementing an equipment scanning weld quality. In Case C the methodology was instead used to identify cost of poor quality measures.

The Pull approach workshop has elements of action research. However, the social context is limited to one company and the democratic aspects that, while being important to create a good work environment, are limited by the organization of the company.

Literature review
The literature covering performance measurement systems and their design are extensive. Yadar and Sagar (2013) describe the historical development of performance measurement and management (PMM) frameworks, focusing on the years 1991-2011. In the first half integrated and balanced PMM systems were developed, such as balanced score card (Kaplan and Norton, 1992). In the second half more dynamic multi-stakeholders perspective have been more in focus e.g. the Performance Prism (Neely et al, 2001). Yadar and Sagar (2013) emphasize the need of validating frameworks empirically and to apply it in a practical context. They further state that there is a limited mechanism available to help transform information into value-adding activities. Ravelomanantsoa et al (2018) present a state of the art of different approaches for performance measurement systems design. The approaches are compared based on their characteristics of being recommendations, structural architectures, procedural architectures, generic performance indicators, methodological support tools or reference models. They state that a complete methodology cannot stop at the PMS design but must be implemented in the company information system. They identify a gap in this area since only a few approaches take this step into account.

Ravelomanantsoa et al (2018) also point out that none of the approaches take the form of the performance indicator into account. They thereby identify another gap regarding data visualization and the influence the cognitive impact might have on the decision-making.

When it comes to the design of a PMS it is important to not start by asking “What should we measure?” (Neely and Bourne, 2000). Before the PMS can be designed, the levers that different stakeholders can pull in order to achieve the organizational goals must be identified as well as the cause and effect relations between these levers. Then the right performance measures (PMs) can be designed based on the understanding of the priorities of the organization and the actions needed to achieve the goals. For the design of individual PMs several authors recommend using the performance measurement record sheet developed by Neely et al. (1997) which consists of 10 elements that needs to be addressed for each PM. However, the gap regarding data visualization identified by Ravelomanantsoa et al (2018) can also be found in this framework since none of the elements are addressing the presentation of data.

Boyer and McDermott (1999) define strategic consensus as the level of agreement within an organization regarding the relative importance of cost, quality, delivery and flexibility to the organization’s operational goals, as well as the relationships between
these competitive priorities and operational policies. Their case studies revealed that operators and managers in the same firms exhibited significant inconsistencies in their manufacturing priorities, indicating a lack of strategic consensus. That is also in line with Marinho and Cagnin (2014) who show that in practice the notion of stakeholder involvement, mutual experimentation and learning, and of a common vision is still neglected. Further Goh (2012) identifies stakeholder involvement and engagement in the process of an effective public sector performance measurement system as one of the key factors. A Pull approach can be one way to facilitate the discussions necessary to enable this stakeholder involvement and strategic consensus.

**Pull approach description**

Given the theoretical arguments previously described, regarding the need of empirical studies as well as strategic consensus, visualization and stakeholder involvement, the remainder of this paper will be devoted to the Pull approach. The background of the methodology is an industrial need to design more effective PMs. The Pull approach is summarized in Figure 1. The Pull approach emphasizes a collaborative attitude and is preferable done as a workshop. When deciding on participants in the workshop, the aim should be cross functionality since it will bring knowledge both from push and pull perspectives.

![Figure 1- Illustration of the Pull approach used in the case studies.](image)

The Pull approach was originally designed as an alternative to the technology push that the industrial researcher saw in her organization. The performance measures were designed based on the available measurement technology, not based on an actual need for certain information to make important decisions. The Pull approach turned around that logic and instead promoted the organization to start with identification of the stakeholders, the internal customer of information (Ericson Öberg, 2016). That can be compared with the explanation by Martin (1994) where technology push is mainly driven by internal research and development activities and market pull is driven by external market forces (that in this case would represent the stakeholders).
The first step is to identify who needs to make a decision, since the performance indicators or information should assist in the decision-making. The next step is to decide what information is necessary for that decision-maker and how it should be presented to convey the information in the best way. When this is clear it is time to define in detail what properties to measure and their definition. Finally, the requirements on data gathering and analysis method can be defined, e.g. level of automation. When those steps have been conducted for all internal customers it is easy to see what is in place and where there are any gaps. The gaps can be compiled into an action list with responsible persons and dates.

The first applications concerned measures for assessing welding quality in a heavy machinery industry. The industry-employed researcher that developed the methodology realized that the same way of working can be applied for different kind of performance indicators and at different organizational levels. This idea was developed as part of the researcher’s PhD thesis (Ericson Öberg, 2016) and it was included in a handbook for designing, implementing, using and revising performance measurement systems (Almström et al, 2017). However, the methodology, the “Pull approach” was not detailed nor put in a perspective of similar approaches to design performance measures, in the handbook or in the PhD thesis. That omission became apparent when the same constellation of researchers that wrote the handbook, wanted to use the methodology in a new research project “SMART PM”. There was no comprehensive method description that any of the researchers could use to help the participating industrial companies to focus on the right performance indicators.

Initially the Pull approach was inspired by SIPOC, which is a tool commonly used in Total Quality Management (TQM) and Six Sigma projects to create a high level process map. The elements are suppliers, inputs, process, outputs and customers (Brook, 2010 and Parkash and Kaushik, 2011). The mapping is often done following the material or information flow starting with supplier, but it can also be more lean influenced with a pull approach with the reversed order (Guerorguiev, 2018) or starting with the output (Silverstein et al, 2017). In the Pull approach, the reverse order is used, starting with the information customer, the stakeholder.

**Empirical findings**

**Case A – welding line installation**

Case A was the first time the methodology was used. During the workshop conducted by four people, 10 internal customers were identified with more than 60 information need items, see Figure 2 below. The four people attending were industrial the Phd student, the welding specialist, and two manufacturing project managers. Several improvements of the methodology were identified e.g. to limit the scope and include more participants in the workshop.
Case B – scanning of welds
In this case, scanning of welds showed in Figure 3, six internal customers of information were identified. It resulted in several defined information needs, ranging from preferred parameter settings to improvement project comparisons. One learning was to involve the managers with the budget responsibility for the area, in order to enable the implementation of identified gaps.

Figure 3 - Scanning of welds to assess quality.

Case C – cost of poor quality
This workshop regarding cost of poor quality, see Figure 4, was not done face to face but online with participants in different countries. It required more preparations in terms of describing the inputs as well as compiling the results. Six internal customers were identified. A conclusion from the workshop was that the same definition and data gathering could be used for several different information needs.
How to carry out a Pull workshop

Based on the experiences from the cases a standard procedure has been formulated to be used primarily for our need in the research project SMART PM that involves manufacturing companies of different sizes. However, the workshop is designed to be of use in different contexts and the procedure and the following instructions can easily be adapted as needed.

Preparation for the workshop

Before the actual workshop is carried out, the company needs to identify an area or section in the workshop that will be focused. Next step is to, for the chosen area, define which problem that needs to be solved. Which strategic or operational decision-making needs improvement? What are the current and desired modes? The next preparation step is to decide which stakeholders that should participate. The recommendation is that at least one person from the following functions is to be included:

- Supervisor
- Operator
- Production engineer
- Maintenance

Depending on the problem that needs to be solved or which improvement needs to be implemented, for example representatives from planning, logistics, finance, quality and environment could also participate.

In the SMART PM project, the workshop is led by one or more of the participating researchers and is conducted for at least two hours. If the company wants to use the methodology, the workshop can be led by the problem owner. The time spent depends on how many stakeholders’ information need are discussed.

Implementation of the workshop

During the actual workshop, the following steps are carried out:
1. Start by briefly discussing the topic, so that all stakeholders have a common picture of what the problem is or what should be achieved. (about 5 min)
2. Identify who needs to make a decision related to the identified topic, because the information that is needed is developed to support the decision. This step provides a list of internal stakeholders. (about 5 min)
3. Identify the information needed to make the decision. Review all stakeholders' information needs to provide a complete picture of the needs. (about 5 min per stakeholder)
4. Decide on how, how often and when the information should be presented to different stakeholders. Do this for each identified information. (about 5 min per information)
5. When this is clear, it is time to define in detail which parameters / PMs are to be measured and how to define them. (about 5 min per information)
6. Finally, the measurement and analysis method can be defined. How should the information be collected? What equipment is needed to collect the information? Can the information collection be automatic? Make an analysis for each measurement. (about 5 min per information)
7. Compile which actions need to be performed, by whom and at what time, to accomplish the identified change to move from current to desired mode. (about 1 hour)

The time required to complete the workshop depends on how many stakeholders participate and how complex the problem or improvement is (how much information needs to be collected and visualized). A guiding estimation is that it takes 3 hours to complete the workshop.

**Expected results**

After the workshop we expect to have:
- A clear picture of what is to be achieved
- A case study description with a relatively detailed plan for implementation
- A method that can be used for structured work with information management for decision-making.

**Discussion**

A lot of the performance measurement system design models described in theory are conceptual and on a high level. As pointed out in literature there is a need for methods supporting the implementation of getting the measurement a part of the company’s information system. The Pull approach is a hands-on method that is ready to be used by people involved in performance measurement design in industry. It suits best as a methodological support tool, where also e.g. Six Sigma belongs according to Ravelomanantsoa (2018).

This article contributes to the operations management theory by providing examples and illustrations of established performance measurement theory through the industrial case studies. It further contributes to the industry through the success stories that these cases illustrate. That is also in line with the desire for strategic consensus through collaborative design which cannot be achieved if functions address issues separately. The result in itself is not always the important part but the process to achieve it. The involvement of the stakeholders in the process not only make them reflect upon their own information need, but also give an increased understanding of other stakeholders’ situations.

The initial case studies demonstrated that the Pull approach has the potential to be
suitable for different types of problems and PMs. That flexibility is necessary since organizations will face increased speed of change in information needs for different stakeholders. Further studies and analyses of cases from different companies and contexts are however necessary, which is already planned in the SMART PM project.

Conclusion

Even though the area of performance measurement systems design is well covered in the literature, some important gaps still exist to explore. This paper proposes a novel methodology, the Pull approach, for designing performance measurements to identify and present the information to support decision-making in the best way.

The Pull approach will be further used in the research project SMART PM where the focus is on digitalization of the use phase (measure, analyze, report, and make decisions). Several companies of varying sizes and industry areas will participate to make it possible to analyze the Pull approach’s suitability in different contexts.

Abstract

Prior research has not adequately examined performance measurement and management practices driving supplier satisfaction and performance. By using survey data (482 supplier responses), this study finds that supplier evaluations do not directly improve supplier satisfaction nor performance but their effect is mediated by collaborative performance management. This study contributes to the literature by examining the outcomes of performance measurement in an inter-organizational setting; highlighting the perspective of a supplier and non-financial performance information; and by presenting performance measurement and management practices in a supplier-buyer relationship as new antecedents for supplier satisfaction. Future research avenues are proposed.

Keywords: Performance management, Purchasing and supply management, Supplier satisfaction

Introduction

Buyer-supplier relationships have been a widespread theme for both researchers and practitioners in the past decades. Information sharing in supply chains and business relationships has likewise gained a lot of attention and its benefits are widely acknowledged (Cheng et al., 2011). However, the outcomes of information sharing depend on “what information is shared, how and with whom” (Li and Lin, 2006). Existing studies on buyer-supplier relationships often highlight the benefits of close supplier collaboration (Lambert et al., 2004) but more focused studies are needed providing an understanding of the actual practices applied in these relationships. The aim of this study is to analyze the role of performance measurement and management practices of a buyer-supplier relationship in improving supplier performance and supplier satisfaction.

Until very recently, most studies on performance measurement and its outcomes have concentrated on intra-organizational performance instead of inter-organizational relationships. Earlier studies indicate that inter-organizational setting affects performance measurement and its outcomes (e.g., Cousins et al., 2008; Jääskeläinen, 2018) but there are only limited empirical evidence until now. Moreover, there has been a call for studies that address the phenomenon of collaborative performance measurement from the
viewpoint of actual performance outcomes of interfirm relationships (Dekker et al., 2016). In this study, the interest is in collaborative performance management, which is studied as a mediator for the benefits supplier evaluation and performance information sharing.

Trust is typically seen as an enabler of communication and interaction between actors (e.g., Ireland and Webb, 2007). In any case, the role of trust cannot be ignored when close relationships between companies are studied. While there are not many studies explicitly studying trust and performance management, several studies have been carried out on the relationship between trust and management control mechanisms (Caglio and Ditillo, 2008; Velez et al, 2008). The results are unclear and conflicting (Velez et al., 2008). Some studies find trust as complementary to formal control mechanisms (such as performance measurement) while others indicate substitutive relationship between formal controls and trust (e.g., Caglio and Ditillo, 2008).

Supplier satisfaction is important for buyers since satisfied customers more probably invest in their customer relationships. More studies on the antecedents of supplier satisfaction in cross-industrial settings have been called for (Pulles et al., 2016). Altogether, there seems to be a gap of studies investigating trust, and performance measurement and management practices driving supplier satisfaction. This study intends to fill this gap.

**Hypotheses formulation**

With the performance of a wider supply chain rather than a single firm in mind (Maestrini et al., 2017), trust plays a significant role in open information sharing (e.g., Ireland and Webb, 2007; Narasimhan and Nair, 2005). Mutual trust has been identified as crucial in inter-organizational use of accounting information (e.g., Kajüter and Kulmala, 2005) and performance information sharing (Mouritsen et al., 2001). Trust reduces the fear of exposing confidential information and loss of power when sharing information (e.g., Li and Lin, 2006). Indeed, in this study, a supplier’s trust is linked to the supplier’s willingness to share performance information with a buyer. The following hypotheses is formulated:

**H1** The presence of a supplier’s trust in a buyer-supplier relationship is positively related to the sharing of performance information in the relationship.

Trust supports long-term collaborative relationships between supply chain partners (Spekman et al., 1998). Collaboration in performance management benefits from trust (Velez et al., 2008). Trust is supportive to mutual goal setting (e.g., Spekman et al., 1998) and a predictor of collaborative behavior between business partners (Ring and Van de Ven, 1994). Based on the indications of earlier studies, this study suggests that supplier's trust is supportive to collaborative performance management in business relationships. Consequently, the following hypothesis is posed:

**H2** The presence of a supplier’s trust in a buyer-supplier relationship is positively related to the existence of collaborative performance management.

Supplier performance measurement can align goals and priorities in the supplier-buyer relationship (e.g., Danese and Romano, 2012). A link between the use of supplier performance measurement and collaboration (e.g. joint problem solving) between buyer and supplier has been identified (Mahama, 2006). Collaborative relationships can specifically benefit from effective supplier evaluation (Cousins et al., 2008). In turn, the deficiencies in the performance measures and accounting practices may inhibit their use in inter-organizational collaboration (e.g., Busi and Bititci, 2006; Caglio and Ditillo, 2008). Transparency of supplier evaluation criteria and results reflecting mature practices
is an antecedent of the benefits, since these support the supplier in understanding customer expectations (Prahinski and Fan, 2007). The following hypothesis is presented:

**H3a Mature supplier evaluation practices are positively related to collaborative performance management.**

Supplier evaluation may improve the performance of suppliers (Hald and Ellegaard, 2011; Prahinski and Benton, 2004). Lack of supplier evaluation may lead to opportunistic behavior and deviation from collaboration (Danese and Romano, 2011). The benefits are dependent on the communication of supplier evaluation results (Sundtoft and Ellegaard, 2011). Consequently we hypothesize:

**H3b Mature supplier evaluation practices are positively related to supplier performance.**

Supplier evaluations can have a positive impact on the quality of the supplier-buyer relationship (e.g., Cousins et al., 2008; Mahama, 2006). Supplier evaluations can be seen as an example of mature supplier relationship management practices of a buyer. Earlier research suggests that the maturity of a buyer’s supplier relationship management practices can have a positive impact on how a supplier perceives the status of its customer (Bemelmans et al., 2015). We hypothesize:

**H3c Mature supplier evaluation practices are positively related to supplier satisfaction.**

Collaborative performance management requires that supply chain members have common and agreed targets for performance (Marchand and Raymond 2008) and share performance information (Busi and Bititci, 2006). Prior research posits that with firms engaged in collaborative performance management, collaborative goals between these firms cause a demand for information sharing between them (Dekker et al., 2016). Disclosing cost information between organizations may relieve the tension in negotiations and increase trust and commitment to a long-term relationship (e.g., Bastl et al., 2010). We hypothesize:

**H4a Performance information sharing in a business relationship is positively related to collaborative performance management.**

As supplier development aims to increase supplier performance, firms successful in supplier development share information with their suppliers (Carr and Kaynak, 2007). In addition to sharing information from a customer to a supplier, also information sharing from a supplier to a customer may be important in influencing supplier performance (Zhou and Benton, 2007) and eventually supplier performance as well (e.g., Prajogo and Olhager, 2012). Inter-organizational accounting information can reduce the costs of inter-organizational processes (Bastl et al., 2010). In turn, isolation of demand and supply processes may result in mismatches (Esper et al., 2010). Hence, we hypothesize:

**H4b Performance information sharing in a business relationship is positively related to supplier performance.**

Even though prior research seems a bit inconclusive about whether information sharing between supply chain members leads to higher supplier performance (Pooe et al., 2015), some studies conclude more widely that information sharing leads to higher satisfaction in the supply relationships (e.g., Nyaga et al., 2010; Kembro and Näslund, 2014). Supplier satisfaction is driven by the operative practices of a business relationship, such as a communication (Hüttinger et al., 2014). We hypothesize:

**H4c Performance information sharing in a business relationship is positively related to supplier satisfaction.**

Collaboration (e.g. joint problem solving) between companies has a positive impact on performance in supply chains (e.g., Mahama, 2006). Earlier literature shows that supplier’s commitment is needed for supplier development to increase supplier
performance (Prahinski and Benton, 2004). Mutual commitment is a key embodiment of collaborative performance management (cf., Ferreira et al., 2012). Therefore, we hypothesize:

*H5a* Collaborative performance management is positively related to supplier performance.

While earlier research has indicated that collaborative relationships and activities increase buyer’s satisfaction (Nyaga et al., 2010; Whipple et al., 2010), research has also found that collaborative relationships (Forker and Stannack, 2000), relational behavior (Hüttinger et al., 2014) and intensity of collaboration (Essig and Amann, 2009) positively affect supplier satisfaction (Hüttinger et al., 2014). Thus, we hypothesize:

*H5b* Collaborative performance management is positively related to supplier satisfaction.

Figure 1 presents the research framework and hypotheses. The main antecedents of the model are buyers’ supplier evaluation practices, performance information sharing in the relationship and supplier’s trust. Collaborative performance management (joint approach for setting targets and reviewing performance in a business relationship) is used as a mediator in the model explaining both supplier performance and supplier satisfaction. This study also utilizes control variables: key supplier status (defined by buyer), company size, service-orientation of a supplier and relationship length.

**Methodology**

**Empirical data**

The survey was sent to the suppliers of four buyer companies. The unit of analysis is the supplier-buyer relationship between the respondent’s company and one of the buyer companies. The buyer companies are large Finnish companies operating in business-to-business markets. Two companies are manufacturing (machinery industry and equipment) and the two others are service industries (information and communications technology, ICT). The industries were selected to achieve variation in several contextual settings, including both service and manufacturing companies.

The questionnaire comprised 30 items measured with a 7-point Likert scale ranging from ‘strongly disagree’ to ‘strongly agree’. The measurement scales of studied variables were designed based on existing literature. The survey was tested with the intended population and fellow researchers, which led to minor changes in the phrasing of the questions to avoid confusions and to assure that the intended respondent understand the statements correctly. Some changes were also made to the order of the questions used in the survey. The items of the survey can be requested from the authors.
The respondents had access to the web-based questionnaire for three weeks, and two reminder messages were emailed to the respondents. Non-response bias was tested by dividing the responses into the following three groups: initial invitation, first reminder, and second reminder. T-test between the groups for the main constructs of this study revealed no statistically significant differences, indicating that non-response bias is not a problem in the study.

The survey was sent to a total of 1,840 suppliers in the autumn 2018. A total of 482 usable responses were received, meaning a response rate of 26.5%. The respondents were the suppliers’ contact persons (key account managers, CEOs and senior managers) for their relationship with the specific customer and thereby well-informed regarding the particular customer relationships.

The size of the supplier companies was rather evenly distributed varying from companies with annual revenue of around 2M€ to companies with more than 500M€ revenue, and the companies had typically long relationships with their customers (more than 10 years). Slightly less than one third of the suppliers had obtained key supplier status according to their customer. Majority of the suppliers (70%) were direct suppliers.

Analysis methods
The survey data was analyzed by using IBM SPSS Statistics 24 and SmartPLS 3.0. PLS-SEM is a component-based estimation method that maximizes the amount of variance explained and does not assume data distributions. PLS-SEM is particularly useful when the research focuses on prediction and explaining the variance of key target constructs (Reinartz et al., 2009). We applied PLS-SEM for the following reasons. First, it is useful for testing predictive models with latent variables when the theory is less developed, and the purpose is in theory development instead of theory testing, such as in the case of our study (Hair et al., 2014). Second, PLS-SEM is a suitable choice when the investigated model is complex. Third, PLS-SEM can be used when the variables are non-normally distributed. A bootstrapping procedure with 5,000 rounds was used in the analysis.

The number of missing values varied between 0-5%. Casewise (listwise) deletion was applied by reducing the sample size to 359. Harman’s single factor test revealed that no single factor was accountable for the majority of variance in the data indicating that common method bias is not likely a problem in our study.

This study utilized reflective constructs whose internal consistency and reliability were examined by using composite reliability (CR) (Fornell and Larcker, 1981), average variance extracted (AVE) and factor loadings (e.g., Hair et al., 2014). The Composite Reliability (CR) varied between 0.885 and 0.954, exceeding Nunnally’s (1978) threshold of 0.7. The values for AVE varied between 0.53 and 0.919, exceeding the 0.50 cut-off (Fornell and Larcker, 1981). All the Cronbach alphas were higher than 0.7, as suggested by Hair et al. (2014). Most of the survey items had outer loadings higher than the 0.7 threshold (Henseler et al., 2009). Two items with a loading higher than 0.6 was utilized in the study. When using the threshold of 0.2 was used for investigating cross-loadings between the items, no cross-loadings were found. The squared correlations between the pairs of constructs is always lower than the AVE for each individual construct indicating satisfactory discriminant validity (Fornell and Larcker, 1981).

Multicollinearity was tested by using the variance inflation factor (VIF). The outer VIF values varied between 1.6 and 6.8, which is well below the cut-off level of 10, often considered as an indicator of serious multicollinearity (Duzann and Shariff, 2015). The effect size ($F^2$) of the relative impact of a specific exogenous latent variable on an endogenous latent variable was examined with Cohen’s test. The test for the predictive
relevance of the model was carried out by applying $Q^2$ statistics through the cross-validated redundancy approach (Hair et al., 2014).

**Results**

Tables 1-4 present the results for the hypotheses of this study. Table 1 shows that supplier’s trust has a strong positive effect ($\beta=0.475$, $p < 0.001$) on the supplier’s perception of performance information sharing in the relationship. $F^2$ for the effect size is medium. None of the control variables seems to have an effect on performance information sharing in the relationship.

As hypothesized, supplier’s trust has a positive relationship with collaborative performance management ($\beta=0.259$, $p < 0.001$) (Table 2). The effect size for this path is small. Also supplier evaluation practices are positively related to the collaborative performance management ($\beta=0.350$, $p < 0.001$) with medium effect size. In addition, performance information sharing is positively associated with collaborative performance management ($\beta=0.243$, $p < 0.001$). Effect size for this path is small. None of the control variables has a significant effect on collaborative performance management.

Table 3 presents the results on the drivers of supplier performance. It can be seen that the levels of performance information sharing ($\beta=0.246$, $p < 0.001$) and collaborative performance management ($\beta=0.274$, $p < 0.001$) are positively related to a supplier’s performance. The effect sizes for both of these paths are small. The hypothesis suggesting
A direct link between supplier evaluation practices and supplier performance is not supported. Large company size seems to be slightly associated with higher supplier performance ($\beta=0.078$, $p < 0.05$) but the other control variables have no statistically significant effect on the results.

Table 4 presents that hypotheses regarding the links between mature supplier evaluation practices and supplier satisfaction, and performance information sharing and supplier satisfaction are not supported. In turn, collaborative performance management has a strong positive relationship ($\beta=0.456$, $p < 0.001$) with supplier satisfaction. The effect size for this path is medium. Large companies seem to be slightly less satisfied ($\beta=-0.086$, $p < 0.05$) with their customers. Other control variables do not have a significant effect.

Overall, it can be seen that the structural model explains 23% of the variation in performance information sharing, 50% of the variation in collaborative performance management, 19% of the variation in supplier performance and 41% of the variation in supplier satisfaction. Although all these numbers can be seen as satisfactory, it can be perceived that there are clearly also other explanatory factors for performance.
information sharing and supplier performance, which were not included in our structural model. The tests for predictive variances suggests that the model has predictive variance varying from large (collaborative performance management) to medium (supplier satisfaction) and small (performance information sharing and supplier performance).

**Discussion and conclusions**

Despite the increasing amount of research on performance measurement in supply chains, empirical studies demonstrating the outcomes of performance measurement in supply chains or collaborative dyads are rare (e.g., Maestrini et al. 2017). This study presented how supplier evaluation practices and performance information sharing link to supplier satisfaction and supplier performance and how collaborative performance management mediates these outcomes. It contributes to the literature by demonstrating the importance of trust in facilitating performance management in a buyer-supplier relationship. It is known that trust affects positively the sharing of information in business relationships (e.g., Ireland and Webb, 2007; Sahay, 2003) and this study extends the same observation to the supplier’s sharing of performance information. It is also known that trust supports mutual goal setting (Sahay, 2003) and collaborative behavior between business partners (Ring and Van de Ven, 1994). This study extends these findings to collaborative performance management in buyer-supplier relationships.

This study adds to the studies on the outcomes of information sharing in supply chains (e.g., Kembro and Näslund, 2014) by specifying the information shared as performance information (Kehoe and Boughton, 2001). While earlier studies has investigated the benefits inter-organizational accounting (e.g., Caglio and Ditillo, 2008), this study extends these studies by highlighting the perspective of a supplier and non-financial performance information. This study also explains some of the mixed results regarding the benefits of information sharing in supply chains (Pooe et al., 2015). It is suggested that performance information sharing may directly improve supplier performance but its effect on supplier satisfaction is mediated by collaborative performance management.

Supplier evaluations are an embodiment of mature purchasing and supply management practices and they have evidently several positive effects on buyer-supplier relationships, e.g. in the form of goal alignment (Danese and Romano, 2012) and improved communication (Sundtoft and Ellegaard, 2011). While earlier studies have identified a link between supplier evaluations and supplier performance (Hald and Ellegaard, 2011; Prahinski and Benton, 2004), this study finds that this link is indirect. Collaborative performance management practices are required in order to obtain the benefits in the form of supplier satisfaction and supplier performance. Hence, against some earlier observations, it is not yet enough to have transparent criteria for supplier evaluation (Prahinski and Fan, 2007) nor good communication practices for the results (Sundtoft and Ellegaard, 2011).

More studies on the factors affecting supplier satisfaction status have been encouraged (Hüttinger et al., 2014). This study contributes to the literature of supplier satisfaction by providing empirical evidence with a large data set in a cross-industrial setting (Pulles et al., 2016) and by presenting performance measurement and management practices in a supplier-buyer relationship as new antecedents for supplier satisfaction.

This study utilizes the responses of suppliers; a future study could increase the understanding of the impacts of performance information sharing and collaborative performance management on the buyer performance. Further studies could differentiate supplier groups, e.g. service/manufacturing suppliers, suppliers with customized/standard solutions, direct/indirect suppliers or key/non-key suppliers. Further studies could also use objective measures for supplier performance.

Abstract

Big data analytics discloses new opportunities for supply chain performance measurement systems (SCPMS). However, the potential of big data analytics in SCPMS is dispersed in the literature, and it has not been thoroughly investigated yet. This paper addresses this issue via a literature review that provides a clear understanding of the big data analytics applications in SCPMS. The obtained findings are categorized according to the dimensions of big data analytics capabilities, which affords a structured perspective of the area and provides insights for future research directions. In this sense, the achieved results are promising for both practitioners and researchers.

Keywords: Performance Measurement Systems, Supply Chain, Big Data Analytics

Introduction

Supply chains are generating a vast amount of data, used for planning and controlling purposes. The growth in the data generation is known as big data, which can be defined as “a holistic approach to manage, process and analyze 5 V’s (i.e., volume, velocity, variety, veracity, and value) in order to create actionable insights for sustained value delivery, measuring performance and establishing competitive advantages” (Wamba et al., 2015). Despite its vagueness, this definition describes important characteristics, processes and potential impacts of data-driven scenarios. The use of analytics techniques in big data is called big data analytics.

Performance measurement is a process of quantifying the efficiency and effectiveness of a past or an ongoing activity (Neely et al., 1995). Performance measurement systems consist of a set of multidimensional performance measures (Bourne et al., 2003) which can support the decision-making of business activities such as planning and controlling.

With the help of big data analytics, managers can collect and analyze a large amount of heterogeneous data; consequently, they can measure and gain more insights into their businesses, which can bring improved decision-making and performance (McAfee and Brynjolfsson, 2012). Accordingly, big data analytics has the capability of improving decision-making processes by allowing better performance measurement mechanisms (Nudurupati et al., 2016).
Big data analytics enables more robust data analysis and performance calculation (Maestrini et al., 2017) which can affect the supply chain performance measurement systems (SCPMS). Data collected in real-time enables to measure performance quickly (Dweekat et al., 2017), enhancing the speed and flexibility of the data-driven decision-making (Addo-Tenkorang and Helo, 2016). As an example, Waller and Fawcett (2013) state that big data analytics enables to gather weather, traffic congestion, and driver characteristics data, allowing to calculate optimal routing which brings benefits to transportation management.

Therefore, big data analytics can give new opportunities for SCPMS. However, to the best of our knowledge, the potential of big data analytics application in SCPMS is dispersed in the literature and has not been thoroughly investigated yet. To address this gap, this paper aims to identify big data analytics applications in SCPMS. Within this context, the following research question is put forward: What are the big data analytics applications in SCPMS?

A literature review was conducted to gather scientific works dealing with big data analytics application in SCPMS. Then, the papers selected in the literature review are investigated according to the dimensions of big data analytics capabilities identified by Arunachalam et al. (2018).

This paper is organized as follows. First, the section “Research Method” presents the literature review process, including the searched database, inclusion and exclusion criteria; and the dimensions of big data analytics capabilities. Next, a theoretical background on SCPMS and big data analytics is provided. Then, the big data analytics applications in SCPMS are presented and categorized according to the dimensions of big data analytics capabilities. Finally, the paper ends presenting research limitations, outcomes of this work, and possibilities for future research.

**Research Method**
The authors conducted a structured literature review on the application of big data analytics in SCPMS. The adopted approach was based on the guidelines presented by vom Brocke et al. (2009). The literature review aims to support the mapping of the current understanding of big data analytics applications in the field of SCPMS and to develop the existing knowledge of the studied topics further.

The search in the database Scopus, realized in October 2018, selected papers which have the combination of search terms big data, supply chain, measure and its derivations such as measurement and measuring in the field of title, abstract and keywords. We selected the Scopus database because it is “the largest abstract and citation database of over 20,000 peer-reviewed journals”, covering other databases such as Elsevier, Emerald, Taylor and Francis, and Springer (Mishra et al., 2016). Only journals, conference papers, and book chapters written in English were selected. Since big data analytics is a recent topic, no time boundary was stated for the publications. In total, the initial search resulted in 38 papers.

The authors analyzed all titles and abstracts and included papers which potentially describe the application of big data analytics in SCPMS, or the relationship between these two topics. The papers, which do not mention applications of big data analytics, or do not mention measures or measurement systems in the supply chain domain were excluded according to the exclusion criteria. Beyond the selected papers, a reference tracking called snowball (i.e., checking the references of the selected papers in a backward and forward search) resulted in the inclusion of additional papers. In the end, the total amount was 20 papers.

The findings obtained by the conducted literature review were categorized according
to the dimensions of big data analytics capabilities identified by Arunachalam et al. (2018). As a result of their study, a comprehensive systematic literature review of peer-reviewed journal papers published between 2008 and 2016, Arunachalam et al. (2018) identified five key dimensions of big data analytics capabilities, i.e., Data Generation, Data Integration and Management, Advanced Analytics, Data Visualization, and Data-Driven Culture.

Among these dimensions, Data-Driven Culture was not considered in our work. Although data-driven culture is of seminal relevance to the topic of big data analytics, particularly in the context of SCPMS, the work of Arunachalam et al. (2018) directs the focus of this dimension towards more elements such as organizational culture, political issues, people skills, and culture capability. Such a focus is, however, outside the scope of our work.

**Theoretical Background**

This section is divided into two parts. In the first part, we give an overview of SCPMS. In the second part, we discuss the definition of big data and big data analytics.

**Supply Chain Performance Measurement Systems**

A supply chain is defined as a network of organizations connected by the flow of materials, information and financial resources that are involved in the different processes and activities that produce value in the form of products and services delivered to the final customer (Christopher, 1992; Stadtler and Kilger, 2015). The relationship between companies in a supply chain contributes to the improvement of the operational performance in areas such as quality, cost, and flexibility. Supply chain management targets onto the integration of business processes ranging from the acquisition of raw material to delivery of the final product to the customer (Mentzer et al., 2001).

Performance measurement systems (PMS) consist of a set of multidimensional performance measures which can be created and used to identify whether customer needs are met where problems exist; assist companies to understand its processes; ensure decisions are based on facts, not on supposition; and show if improvements planned actually happened (Bourne et al., 2003; Gunasekaran and Kobu, 2007; Parker, 2000).

Measuring the performance of the supply chain has a broader scope of a traditional PMS, whereas SCPMS can control and monitor the performance of multiple supply chain members and not only a single company’s boundaries. Thus, SCPMS becomes more challenging, since it involves the collection of data from many sources (Maestrini et al., 2017).

Therefore, the definition for SCPMS is mostly equal to the PMS definition, while adding the aspect of the supply chain environment. SCPMS can be defined as a set of carefully chosen measures related to the supply chain goals, which can be used for a stable quantification of the efficiency and effectiveness of supply chain processes and relationships that adequately reflect the current performance while revealing improvement potential towards the defined goals (Maestrini et al., 2017).

The SCPMS lifecycle usually consists of 4 phases: design, implementation, use, and review. The goal of dismantling the SCPMS into different phases is to ensure the successful adoption of such a system (Maestrini et al., 2018). According to these authors, the design phase defines the unit of analysis (e.g., supply chain processes), the extent of involvement of external members (i.e., active, passive or no involvement), and the performance measures. In the implementation phase, data collection, performance measures calculation, and reporting management occur. The use phase involves
communication and feedbacks upon performance. Finally, updating existing targets, and developing new measures are included in the review phase.

**Big Data Analytics**

In today’s digital era, big data has become a significant topic across several organizations (Addo-Tenkorang and Helo, 2016). Many authors have defined big data in different ways, but most of them agree on similar aspects. Big data comprises characteristics like high dimensionality, numerous possible data sources, significant amounts of data that require new forms of processing which can enhance decision-making, insight discovery and process optimization (Chen and Zhang, 2014).

Five main V dimensions are mentioned in the literature, i.e., volume, variety, velocity, veracity, and value. Volume refers to the enormous amount of generated data. Variety is described as the different types of data (i.e., structured, semi-unstructured or unstructured) that could be collected from heterogeneous sources. Velocity relates to the speed with which data should be collected and analyzed in order to make accurate decisions. Veracity means which extend data can be trusted. Finally, value should be the outcome of the data analysis and which should also lead to achieve business advantages (Demchenko et al., 2013; Hu et al., 2014).

The combination of big data and analytics - big data analytics - allows to get meaningful insights, turn data into valuable information, and make the decision-making process more efficient (Demirkan and Delen, 2013; Sanders, 2016). Big data analytics is a research area which can provide numerous opportunities for academic and management practitioners (Wamba et al., 2018).

Three types of analytics can be distinguished: descriptive, predictive and prescriptive. Descriptive analytics involves the description of current and past situations, aiming to identify problems or opportunities and verify what happened in the business. Predictive analytics uses data to predict what will happen in the future or to advance future hypotheses. Prescriptive analytics informs what to do, and uses models to specify optimal behaviors and actions. It can also propose strategic solutions based on analyses (Davenport, 2013; Gravili et al., 2018; Wang et al., 2016).

In the supply chain context, big data analytics can provide valuable insights for decision makers, leading to a multitude of benefits that can bring competitive advantage (Wamba et al., 2015). Some benefits are related to enhancing the speed and flexibility of making decisions, which can be more data-oriented. The real-time data streams can improve the decision response time (Addo-Tenkorang and Helo, 2016; Brinch, 2016; Tiwari et al., 2018). Additionally, big data analytics can be used to optimize transportation, identify optimal distribution center locations and delivery routes, therefore, minimize costs, improve productivity and inventory management, and optimize of stock levels (Sanders, 2016).

**Findings: Big data analytics in SCPMS**

This section presents a detailed summary of the finding obtained by the conducted literature review. As described in the section Research Method, the dimensions of big data analytics capabilities identified by Arunachalam et al. (2018) were employed here to categorize the findings.

**Data Generation**

In the implementation phase of SCPMS, performance-relevant data need to be effectively collected (Dweekat et al., 2017). Big data analytics advances opportunities for external data collection which can be collected across different supply chain members.
and at different levels stemming from heterogeneous sources and different types of data (i.e., structured, semi-unstructured or unstructured) (Ramakrishnan and Ma, 2018; Vassakis et al., 2018). Mobile devices are an example of a data source, which can enable companies to measure more accurately (Vassakis et al., 2018).

Nudurupati et al. (2016) conducted a case study and found that big data analytics can make it possible to have new measures. As an example of new measures determined using a big data source, Bertolini et al. (2017) presented and validated several Radio Frequency Identification (RFID)-based measures, which can only be calculated via RFID, i.e., it was not possible to have these measures without RFID.

As another example of the big data analytics benefit to SCPMS, it can help track and analyze employee performance measures allowing the identification of top performers and unsatisfied workers. With the use of big data analytics for this measure, companies can see real-time data rather than annual reviews which are sometimes based on human memory (Tiwari et al., 2018). Additionally, the use of real-time data to measure the managerial activities performance can bring benefits to companies by permitting them to respond quickly to competitors (Vera-Baquero et al., 2015).

It is worth nothing, in the SCPMS design phase, before collecting the data used for the performance measures, it is necessary to define the objective of the measurement process, and what should be measured (Bourne et al., 2000). Companies need to concentrate on measuring what brings benefits to competitive priorities, customer service, and firm profitability (Sanders, 2014). Besides that, measuring supply chain performance should be context specific; thus, performance measures differ in different circumstances (Mishra et al., 2018).

**Data Integration and Management**

The Data Integration and Management dimension includes elements such as data governance; data integration; and data quality, characterizing the ability of companies to use techniques to integrate, transform, and store data from heterogeneous data sources (Arunachalam et al., 2018).

As already mentioned, data can come from various supply chain members containing different types of data with different structures; for this reason, the integration of all gathered data is very relevant to the performance measurement. However, data integration from multiple companies is a challenge in SCPMS (Maestrini et al., 2017). Besides the difficulty of integrating data from different sources, the challenge arises as a result of companies which abstain from sharing data among the members of the chain since data usually represents a valuable asset that could give a competitive advantage (Arunachalam et al., 2018).

One critical element big data analytics application in SCPMS is data quality. Poor data quality can negatively affect the decision-making in the supply chain and its performance (Arunachalam et al., 2018; Hazen et al., 2014). Therefore, it is suggested to use methods like statistical process control to monitor, control, and improve the data quality (Hazen et al., 2014).

Before the introduction of the next dimension, it is relevant to understand that big data analytics is performed through two kinds of processing approaches, real-time processing and batch processing (Arunachalam et al., 2018; Hu et al., 2014). The main difference between them is that in the batch model the data is first stored and then analyzed, whereas, in the real-time approach, the data is analyzed as soon it arrives. As it could be inferred, these two approaches also lead to architectural differences. For instance, batch processing architectures require large and complex storage systems, and stream processing architectures demand high-performance processing systems (Hu et al., 2014).
**Advanced Analytics**

Advanced Analytics dimension encompasses elements to process data and extract value. Analytics include applications that support decision-making allowing managers to make better decisions (Gravili et al., 2018).

In order to conduct different types of analytics (i.e., descriptive, predictive, and prescriptive), companies need advanced analytic techniques which can turn the large volume of heterogeneous data into significant insights (Gravili et al., 2018).

Analytic techniques comprise several techniques like time series analysis and forecasting used to extract meaningful patterns and predicts the future based on historical data (Wang et al., 2016), cluster analysis, Bayesian classification, decision tree, artificial neural networks, support vector machine (Kitchin, 2014), logistic regression, and random forests (Rozados and Tjahjono, 2014). Those techniques can be used to calculate the supply chain performance measures.

**Data Visualization**

Data Visualization dimension is related to the visualization of performance measures utilizing dashboards and reports. Chen and Zhang (2014) explain that this category entails a huge significance for big data analytics since it should represent the results clearly enough to extract the hidden knowledge of the data. In this dimension, organizations use different tools to set and visualize the results easily and deliver them adequately and timely to make decisions (Arunachalam et al., 2018). In the context of SCPMS, the results are the performance measures, which can be related to different supply chain activities (e.g., strategic, tactical, operational) and processes (e.g., plan, source, make, and deliver) (Gunasekaran et al., 2004).

The reports and dashboards should be produced according to the needs of each company or each area in terms of content, frequency, and transparency (Maestrini et al., 2018). Therefore, big data analytics can provide support regarding data reliability, timeliness, and task automation. Arunachalam et al. (2018) mention some benefits included in the Data Visualization dimension such as monitoring future demand, visualizing delivery routes, and tracking material. This dimension, as well as Data Integration and Management, and Advanced Analytics are part of the SCPMS implementation phase.

As part of the SCPMS phases use and review, there are benefits which can be obtained using SCPMS. The SCPMS support continuous improvement, decision-making, and behavior change, control supply chain strategy, facilitate a transparent communication between people, and improve organizational performance (Gunasekaran et al., 2004; Maestrini et al., 2017; Sanders, 2016).

Franco-Santos et al. (2007) identify different roles for performance measurement systems like strategy management and learning. Just like any other performance measurement systems, these roles are the same in the supply chain context. The big data analytics application likely enhances those outcomes. However, the benefits of SCPMS can only be obtained if the performance measures are correctly interpreted and analyzed and if the necessary actions take place in the companies. Additionally, review the performance measures is an important process for companies which want to keep their measures aligned with the strategy (Bourne et al., 2000).

**Final Remarks**

This paper addresses the gap in the SCPMS literature by moving a step forward towards identifying big data analytics applications in SCPMS, and categorizing them according
to the four dimensions of big data analytics capabilities introduced by Arunachalam et al. (2018) (i.e., Data Generation, Data Integration and Management, Advanced Analytics, and Data Visualization). The identified big data analytics applications in SCPMS include, for example, the use of different data sources to create new measures or bring more information to the existing ones; the importance of integrating external and internal data; chances of real-time measurement; different analytic techniques which can be used; and the dashboards and reports created with the support of big data analytics.

The findings presented in this paper are limited to the literature review conducted in one database. A new literature review could be conducted considering more databases and white papers. In this way, the results could be broader. As the second limitation, this work does not focus on challenges and restrictions that the use of big data analytics in SCPMS can bring, for example, high volume accumulates data noise and creates high computational costs (Wang et al., 2016). In this manner, further research could usefully explore these challenges and present possible countermeasures to them.

The results of this study are promising for both practitioners and researchers. Practitioners could use the results of this research to understand which big data analytics applications in SCPMS could fit in their supply chain. Researchers, on the other hand, might use the findings of this research to have a structured understanding of big data analytics applications in SCPMS. Besides, this work can be used as a theoretical foundation for future studies. Thus, this work serves as a preliminary study leading its way to other researchers to improve it. The next step will be to analyze the outcomes of this research empirically in order to check how practitioners react to the use of big data analytics in SCPMS.

Abstract
With the aim of improving the understanding of the influencing roles of social- and technical matters in Shop Floor Management (SFM) this paper addresses how companies can facilitate a digital transition of SFM visualisation boards. By combining a pragmatic understanding with Science-Technology-Society studies that social- and technical matters form sociotechnical practices, this paper studies SFM in three companies. Findings are; the social- and technical matters are interrelated and influence SFM. In all three companies the main challenges are technical matters – inappropriate information architecture and data collection. In one company, the challenge is a habitual approach for doing SFM meetings.

Keywords: Shop Floor Management, Pragmatic, Sociotechnical practice

Introduction
Doing SFM is, by its nature, a social activity, in which visualisation boards (Parry and Turner, 2006) are the glue for the social interplay among the practitioners (Galsworth, 2017). Yet, in the era of industry 4.0 the practitioners witness new digital features embedded in the technical equipment (Rajan and Safiotti, 2017; Tao and Zhang, 2017; Zhuang et al., 2018). These new technologies influence both the performance management and continues improvement actions as well as the working practice at the SFM level (Kagermann et al., 2013; Tezel, 2016; Winby and Mohrman, 2018).

Despite new technologies pave the way for using digitised visualisation boards to accomplish performance management and continues improvement actions, the application of this kind of digitised equipment at SFM level is still incipient (Meissner et al., 2018). Rather than using the digitised visualisation board, the practitioners are applying analogue visualisation boards originating from the principles of conducting short and effective SFM meetings (Iuga, 2017) and the power by hand mindset (Galsworth, 2017). As a result, this paper argues, that the prevailing managerial approach at SFM level is characterised by the industry 2.0 era (like Eaidgah et al., 2016), which paralyses our understanding of how to digitise the SFM level.

With the aim of improving our understanding of how to digitise SFM visualisation boards, we focus our study on the actions and the consequences of actions. To do so, this
study draws on pragmatism (Dewey, 1938) and combines this understanding with the idea from Science-Technology-Society studies (Henderson, 1999), that social and technical matters form a sociotechnical practice (STP). Thus, actions are influenced by the composition of the STP and, simultaneously, actions influence the composition of the STP. An empirical study of performance management and continues improvement actions in three different companies form the basis of exploring two research questions: 1) **What are the characteristics of the STP?**, and 2) **How can a company facilitate a gradual transition towards a digitised era?**

The paper’s contributions are an illustration of applying a pragmatic approach to study performance management and continues improvement activities at the SFM level with the aim of revealing different characteristics of STPs when doing SFM meetings. The proposed framework consists of two dimensions: a social dimension and a technical dimension. By combining these dimensions, the model suggests four characteristics of STPs.

**Theory**

The section starts with elaborating the notion of actions within a STP from the viewpoint of pragmatism after which a framework to study the unfolding STP is presented.

**Theoretical positioning**

Joan Woodward’s empirical study of 100 manufacturing organisations in the 1950s (Woodward, 1958) sow the seeds of lengthy academic discussions of whether the **social- or technical** matters determines actions. At the threshold of the current industrial revolution, the huge focus on the benefits of embedding digitised technologies in the manufacturing equipment seems to favour the **technical** matters at the expense of the **social** matters (Winby and Mohrman, 2018). As an example, Yin et al. (2018) account for how Industry 4.0 has reshaped the SFM level and thus brought smart manufacturing on the forefront. A group of researchers (e.g. Kagermann et al., 2013) argues that the exponential development of digitised technologies, big data and artificial intelligence pave the way for the application of digitised manufacturing equipment that are autonomous, capable of controlling themselves in response to different situations and that the equipment is self-configuring. It indicates that the ongoing development of artificial intelligence (Zhuang et al., 2018) and machine learning algorithms (Rajan and Safiotti 2017) combined with interoperability and interconnection among technical equipment (Tao, et al., 2017) will result in a situation where the majority of actions at SFM level is performed by **technical** matters.

However, the **technical** enabled actions have some limitations compared to the **social** enabled actions. In all likelihood artificial intelligence and machine learning algorithms embedded in the technical equipment will not exceed practitioners’ reflective capabilities in the near future. In contrast to computer-controlled equipment, practitioners are capable of drawing on their common sense, reflective experience, and creative- and social intelligence as well as perception and manipulation capabilities to accomplish actions in unstructured and changing contexts (Frey and Osborne, 2013). Thus, actions are in some situations enabled by **social- or technical** matters or by a mixture of **social- and technical** matters.

Subscribing to pragmatism (e.g. Dewey, 1933; 1938) the enabling **social- and technical** matters for actions depend on the problematic situation being handled (Dewey, 1938). With his concept of imbrication Leonardi (2013) demonstrates these unfolding roles of matters and also that both **social- and material matters** (here **technical**) have the capacity to act; these **socio-technical** actions result in the two distinct group of influencing
matters become interlocked in a particular sequence. However, given that humans have intentionality (Leonardi, 2013), they decide how the socio-technical matters become imbricated and forms a STP (Leonardi, 2013). The STP influences and is simultaneously influenced by actions in a trajectory manner (Mathiasen, 2015). Despite appreciating the notion of imbrication, the following section spells out the understanding of actions within a STP; i.e., action and thinking, action and meaning-making, and habitual and reflective actions.

*Action and thinking* is inseparable and situation-dependent. Pragmatism (e.g. Dewey, 1938) rejects any kind of dualism including the viewpoint, that human behaviour can be divided into a triggering stimulus, subsequent a thinking process, and finally, an action.

*Action and meaning-making* go hand in hand. In other words, when a practitioner acts, his/her observations of and reflection about influencing socio-technical matters enter into a process of inquiring (Dewey, 1933; 1938). In this process of inquiring, the socio-technical matters acquire meaning when each of the involved practitioners strives to understand what is going on and gradually handles the problematic situation. This understanding implies that each practitioner uses socio-technical matters to create their individual understanding, but the creation of both individual and common understanding also involves other practitioners’ understanding.

*Habitual and reflective action* should be understood as two extremes on a continuum. Dewey (1933) advocates for this dual nature of thinking-in-action and highlights that a human conducts both habitual- and reflective actions. While the latter is a prerequisite for accomplishing the meaning-making process and thus gain new experience, the former habitual attitude of mind has two different roles, which are being a stabilising factor for living in present-day society and being a standard way of drawing inferences (Dewey, 1938, p. 21). In the following the framework to study the influencing roles of sociotechnical matters are presented.

**Conceptualisation the framework for studying the sociotechnical practice**

This section starts with explaining four stages of STPs within a framework studying the STPs, next the social- and technical matters in the framework are described, and finally figure 1 summaries the framework. Zhuang et al. (2018) propose the following four stages of working practices (here STP).

The *Single Point STP* is characterised by a low influence of social- and technical matters presented in the framework. In this STP, the organization and management do not meet the optimal requirements to accomplish successful SFM. The STP is stuck in old habitual procedures without any support from technologies to aid in decision-making. Most data are gathered manually, and as a result, the data gathering and analytical processes is not fully reliable. This practice release passive (reactive) management and control methods (Zhuang et al., 2018).

The *Integrated STP* is characterised by a low-medium influence of the social- and technical matters presented in the framework. In this STP, most data are gathered automatically and is real-time, but the organisation show a passive strategy of processing and analysing the data. The decision-making at the SFM level at this stage is believed to increase as the real-time data provide a more reliable data foundation. This practice release real-time management and control methods (Zhuang et al., 2018).

The *Collaborative STP* is characterised by a medium influence of the social- and technical matters presented in the framework. In this STP, the appliance of wide applications as machine learning and big-data related technologies makes it possible to enhance the decision-making and thereby the performance level as these technologies support a stronger analytical foundation for assessing the data. As these new features
seems has a huge impact on the practice, the human behaviour at shop floor have not been adjusted to this transition stage, and therefore this might course several organisational and management challenges. This practice release predictive management and control methods (Zhuang et al., 2018).

The Smart/Intelligent STP is characterised by a high influence of the social- and technical matters presented in the framework. In this STP, the manufacturing system can predict behaviour of the equipment status, human resources and make decisions autonomously based on a solid and reliable data foundation. This practice demands a proactive management strategy, where the technical equipment and human are in balance to assess and analyse the data. (Zhuang et al., 2018).

The Social Matters
Clear objectives - The origin of SFM management is not consistently defined and nor are the objectives but most companies associate the pursued objectives by the use of lean principles (Hertle et al., 2015). Therefore, SFM objectives are typically structured from quantitative figures such as operational figures as KPIs (Hertle et al., 2015, Steenkamp et al., 2017). The SFM objectives are necessary for the accomplishment of the SFM activities, as they base the foundation to secure a common goal for the practitioners to work towards (Eaidgah et al., 2016). Without clear common objectives, it is impossible to accomplish SFM as a social activity (Ahrens and Mollona, 2007).

Structure and procedures - At present there is identified an increasing practical and theoretical interest in how organisations can organise and integrate knowledge to support their management activities (Beckhy, 2003, Zhuang et al., 2018). Academia suggest that organizations should use structures and processes, such as clear guidelines and routines to codify and transfer knowledge in their social-collaborative environment e.g. SFM board meetings, so the knowledge is transferred to have the same meaning for everyone involved in the activity (Beckhy, 2003; Kumari and Kulkarni; 2016, Holm, 2018). Holm (2018) among others state that it is important to acknowledge the social interaction at the SFM level to ensure commitment from the practitioners, meaning, the practitioners should be involved more actively in the procedures.

Managerial Approach - Manufacturing enterprises are currently facing extensive challenges with regard to adapt new technological features referred to the concept of smart manufacturing (Schumacher et al., 2016). Subsequently, the increasing complexity on all organisational levels create uncertain environments for the companies to act within, as their organizational and technological capabilities not has adjusted in synergy along with the new technological features (Hertle et al., 2015; Schumacher et al., 2016; Holm, 2018). Academia state that the competency development of the practitioners are the most important aspect within this transition, because the current competency levels are low and do not possess a high degree of flexibility, adaptability and initiative (Hertle et al., 2015; Syberfeldt et al., 2016; Buer et al., 2018). Holm (2018) and Zhuang et al. (2018) agrees upon that the development of the capabilities at the SFM level is a prerequisite for changing the current management controlled by old reactive habitual procedures.

The Technical Matters
Visualisation boards - The prevalent academia suggest that enhanced transparency by obtaining real-time data to enhance better decision-making at the SFM level offers the advantage of being more agile e.g. respond quickly to volatile demands (Friedemann et al., 2016; Steenkamp et al., 2017; Buer et al., 2018). However, the problem at the SFM level is that the practitioners constantly receives torrents of data from their environments, which not are easy or relevant to understand (Eaidgah et al., 2016). Academia and
practitioners at the SFM level using visual management boards have addressed this problem. No common and clear definition defines visual management boards, but drawing on academia this paper define these as dashboards, which have digital representation capacities that support the practitioners’ understanding of accomplishing SFM activities (Eaidgah et al., 2016; Steenkamp et al., 2017; Galsworth, 2017).

Information architecture - The information architecture at the SFM level is a blueprint and navigational aid to the content of information-sharing (Toms, 2002) at the board meetings. How the interaction among the practitioners is conducted, is strongly influenced by the environments information architecture. As the manufacturing currently is a battlefield of competition, companies have started to adapt advanced technologies to aid in decision-making to achieve better planning and control (Zhang et al., 2011). Hence, the management and control facilities at the SFM level are required to adopt technologies that enhance real-time data and interoperability to secure enhanced performance if the companies wants to stay competitive (Zhang et al., 2011).

Data foundation – A valid data foundation is a prerequisite for harvesting the beneficial outcomes of applying digital technologies to support decision-making at the SFM level (Meissner et al. 2018). Many processes discussed at the SFM level today is managed through manual “pen-and-paper” processes, where the data is not stored digitally (Buer et al., 2018) and as a result, this hinder the company to reapply information, hence, data is often lost if it is not stored digitally in an easy assessable way. By automating the data gathering, the data will more likely be gathered under the right conditions and the data foundation will be strengthen and the probability of errors are reduced (Buer et al. 2018).

Figure 1 summarises the framework for studying the STP.

The conceptualised framework consists of two dimensions: a social- and a technical dimension. By combining these two dimensions, the frame suggests a scale evaluating the social- and technical matters from a low to a high degree, wherefrom four characteristics of STPs are identified. The four STPs, which are; Single Point STP, Integrated STP, Collaborative STP and Smart/intelligent STP are inspired by Zhuang et al. (2018) and these reveal different approaches in term of using analogue and digitised boards when accomplishing SFM activities.
Methodological considerations
The research draws on pragmatism (Dewey, 1938) and combines this understanding with Science-Technology-Society studies (Henderson, 1999), that social and technical matters fuse into a STP. The empirical data is collected by one of the authors and it consists of observations of SFM board meetings followed by semi-structured interviews in three large international companies. One of the authors took the role as a complete observer and did all interviews. To structure the interviews, we draw on the observations of the SFM board meetings and the conceptualisation of the framework presented in the theoretical section. The observations was discussed during the semi-structured interviews with practitioners to enhance the trustworthiness of the observational findings. Each observation lasted in average two hours, while the interviews in average lasted 30 minutes. Notes were taken simultaneously during the observations and interviews.

Drawing on Stake’s (2000) case study, the three companies are considered as particular cases, which provide us insight into the STPs in which performance management and continues improvement actions are conducted. The three companies are designated; Company 1, Company 2 and Company 3, see table 1 for further information.

Table 1- Overview of the three case companies regarding company size, industry as well as the number of SFM board meeting observations and interviews conducted in each company

Analysing and discussion

With the aim of improving our understanding of how to digitise SFM visualisation boards, this section commences with an analysis of “what are current characteristics of the STP in the three case companies”. Next, this understanding is used to elaborate how can a company facilitates a gradual transition towards a digitised era.

The empirical study of performance management and continues improvement actions in the three different companies shows rather different characteristics of the STP across the three case companies.

**Company 1** had clear objectives for issues being discussed during the SFM meetings. This combined with well-structured SFM meetings and huge focus on complying with the overall procedures for accomplishing the meeting resulted in proactive actions. The practitioners reflected on both the information depicted on the visualisation boards and comments from the manager and colleagues. This collaborative approach formed a practice in which the practitioners achieve a common understanding of the problematic issues being discussed. In order words, actions at the SFM meetings were aligned. As for the technical matters, the company had not yet implemented digitised visualisation board all around the factory. Likewise, the information architecture and in particular the data foundation in company 1 is insufficient for generating reliable data and real-time data to utilise the real-time nature and predictive power of data. Based on the interviews with the company, the top management is aware of the information architecture and thus data foundation is the bottleneck for developing the SFM level into a STP enabling smart and intelligent application of data and information.

**Company 2** had likewise clear objectives for issues being discussed during the SFM meetings. The SFM meetings followed standardised procedures, which combined with rigid structures resulted in a habitual mindset and thus reactive actions. The practitioners did not reflect on the information depicted at the visualisation boards and appeared as silent participants. As for the technical matters, the company had only implemented digitised visualisation board in a very limited part of the factory. Likewise, the information architecture and in particular the data foundation in company 2 is insufficient for generating reliable- and real-time data to utilise the real-time nature and predictive
power of data. Based on the interviews with the company, the top management has realised an urgent need for improving the meetings and they think that the low commitment among the practitioners is caused by using too unstructured data having a debatable reliability. Top management thinks that a reliable data foundation and real-time data will enhance the SFM performance level into a STP enabling strong analytical data assessment and data transparency, thus using real-time data to predictive decision-making.

Company 3 had likewise clear objectives for doing the SFM meetings. The SFM meetings are well-structured and the procedures ensured close collaboration among the practitioners. The managerial approach drew on appropriate procedures, but these were too rigid. Due to the rigid procedures, the practitioners actions were routinized, despite they apparently reflected on both the information depicted on the visualisation boards and comments from the manager and colleagues. Indeed the discussions were one-dimensional and it was difficult to see a problem from different angles. As for the technical matters, the company did not use digitised visualisation boards. Likewise, the information architecture and in particular the data foundation in company 3 is insufficient for generating reliable data and real-time data to utilise the real-time nature and predictive power of data. Based on the interviews with the company, the top management has realised an urgent need for improving the managerial approach to achieve a common culture and improve the competency level at shop floor. The company desires to enhance the data foundation and the data assessment in an attempt to transform the STP enabling real-time data analyses.

Based on the above analyses including a ranking of the social- and technical matters into low, medium and high, the influencing roles each of the companies’ current STP and intended STP is placed in figure 2.

![Figure 2. The current and intended STP of the three companies.](image)

To achieve sufficient benefits it is important to balancing the social- and technical matters (e.g. Kagermann et al., 2013) for which reason the intended STP of the three companies are placed on the diagonal line suggested by Zhuang et al. (2018). The proposed transition route for each of the three companies are illustrated as the dotted arrow from current to intended STP to show how the companies must develop their strategy to reach the intended STP. Academia suggests that the transition must happen gradually and that the companies need to achieve a sufficient balance between the influencing roles of social- and technical matters respectively, before moving forward to a more digitised STP (Tao et al., 2017; Zhuang et al., 2018). As it appears from figure 2, the current STP for all three
companies are not in balance. In general, for the three companies, the technical matters constrain the transition to the intended STP. The analysis indicates that it is mainly an insufficient data foundation and problematic information architectures, which hinder the companies in transforming the SFM into the digitised era. The prerequisites for entering the digital era at SFM meetings in company 1 and 3 are that the management should facilitate a technical development of the information architecture. The current information architecture in both companies do not facilitate proper data collection, data coding and data storage. In other words, the interoperability among the technical equipment, from sensors to application levels (e.g. Tao et al., 2017), is too weak. As for company 1 the main problem in terms of insufficient data foundation is actually that none of the practitioners in the manufacturing are allowed to gain access to data stored in the SAP systems (Enterprise Planning systems). Retrieving core data and information from SAP is restricted to few key employees working in the IT-department. In company 3, the management should digitise the current manual coding of the automatically collected data; as it is not, the automatically collected data are useless due to the underlying causes are not stored in the SAP systems. The challenges in company 2 are dual. The technical issues are identical with company 1 and 3; i.e., the focal point for the management should be to enhance the information architecture and data foundation. Despite the company has clear objectives to be discussed during the SFM meetings, the social dimension needs to be improved. Currently, the SFM meetings seem to be a “coffee meeting” in which the practitioners wail about unusual data to make proper decisions. The manager should challenge the habitual attitude of mind, which permeates both the practitioners and management. This could be facilitated if the standard procedures are rephrased in way that forms a more open, flexible and reflective collaboration during the SFM meetings.

Conclusion
The purpose of the paper is to improve the understanding of how to digitise SFM visualisation boards. Based on the analyses of three high automated companies, the paper shows that the unfolding STP during the SFM meetings are characterised by a huge focus on the social matters at the expense of the technical matters.

The STP at SFM level when practitioners are operating with highly digitised manufacturing equipment is completely different compared with the STP when applying non-digitised SFM visualisation management board. By digitising the SFM visualisation board, companies benefits from access to real-time and reliable data to enhance data transparency, which will pave the way for more effective decision-making at the SFM level. Likewise, the “socio” part will not be catch in two rather different “technical systems”. As the application of digitised visualisation boards will reduce the gap between the two different “technical systems” to a level, in which practitioners will be more capable in developing new capabilities and thereby gain maximal benefits from both the digitised manufacturing equipment and digitised visualisation management boards.

Abstract

This paper explores the narratives around productivity in UK manufacturing firms. Whilst we hear a lot about the UK’s poor productivity from politicians and economists, this paper explores the conversations within manufacturing firms. Initial evidence from a project funded by the ESRC through the Productivity Insights Network is presented. It appears that there are many different narratives around productivity and often the conversations in the manufacturing firms bear little resemblance to the productivity statistics being presented by politicians and economists. The work is innovative in that it moves the conversation from the economists, politicians and statisticians to the manufacturing workplace.

Keywords: manufacturing, productivity

Introduction

Productivity growth, or the lack of it, has become a global concern (OECD, 2015; WEF, 2017). As Krugman (1994) suggests: “productivity isn't everything, but, in the long run, it is almost everything”. The most recent data from the Office for National Statistics
(ONS) suggests that many of the biggest EU nations are also facing negative labour productivity growth (Romei, 2019). Governments all over the world are concerned about productivity growth (OECD, 2015; WEF 2017). The most recent data from the Office for National Statistics (ONS) suggests that many of the biggest EU nations are facing negative labour productivity growth (Financial Times, 13 Jan 2019).

The UK based authors have been hearing regular reports in the media about the UK’s poor performance in terms of productivity growth, which since the global financial crisis of 2008 has been falling behind its European neighbours and G8 member nations. But as operations researchers, who spend significant time out in industry, the authors started to question whether the media headlines aligned with what they were seeing and hearing in manufacturing firms. So the authors wanted to explore productivity from the perspective of manufacturing firms.

There has been very little academic work that looks at the narratives around productivity within firms. Recently there have been a few studies by professional bodies who have started to look at productivity from the perspective of the firm. The CBI (2017) report “Unlocking Regional Growth” is one of the few studies that has taken the conversation down to the level of the firm, although the analysis was still very much at a macro level. Similarly, the EEF 2016 and 2018 reports also pull out key factors that are influencing productivity in the manufacturing sector. But none of these studies actually take the conversation to the workers on the shop-floor.

Fast forward 10 months and the work reported in this paper is an early stage output of an exploratory study funded by the UK’s Economic and Social Research Council (ESRC) through the Productivity Insights Network. The project discussed in this paper takes the productivity discussion down to the operational level of the workers in manufacturing organisations. It seeks to investigate the narratives around productivity in manufacturing firms. It seeks to understand how productivity is understood at different levels of the firm and asks the question whether productivity is being discussed and measured at different levels. The project engages in conversations with employees at different levels within manufacturing firms and is innovative in that it moves forward the conversation around productivity in a meaningful way, engaging the employees.

This conference paper is an early output from the project and is structured as follows. Firstly the authors investigate the dialogues taking place around productivity in the literature (and particularly considering this in the context of manufacturing). This involves interrogating the literature from a number of academic domains, as well as looking at industry reports. The research approach of the project is then discussed before the authors present findings from initial interviews with people working in manufacturing firms. The paper concludes with a discussion on these preliminary findings and explores future avenues for research.

What does the literature tell us about productivity?

In the UK, our poor productivity performance, particularly compared to other economies, has become a popular subject for politicians, economists and commentators. The lack of improved productivity growth is perceived as problematic (CBI, 2017; EEF, 2016; IoD, 2018; McCann, 2018). So what is the big concern? And what are these productivity statistics actually telling us? To answer these questions we have to first look at how productivity is being defined and measured by these commentators. And herein lies one of the first problems – there are multiple definitions of productivity (eg. this is highlighted by CMA July 2015). According to the ONS Productivity Handbook (2017) “productivity represents the relationships between inputs and outputs in the production process”. The European Association for National Productivity Centres (EANPC 2005:12) defined...
productivity as “an expression of how efficiently and effectively goods and services are being produced”. These definitions highlight how productivity essentially measures the efficiency in production by relating the output obtained from some given inputs. Productivity measurements typically adopt physical or economic units and relate them as an output–input ratio. So it follows that to improve productivity the key levers are increasing output (addressing the numerator) or decreasing the input (addressing the denominator) or ideally working on both simultaneously.

When we hear productivity figures discussed in the media, we need to look closer at what is actually being discussed. Economists look at both the levels and at the growth rates of productivity. When we hear about comparisons between countries it is important to understand what is being compared. It could be a snapshot of productivity at a point in time or productivity growth over time.

Then we have the main measures of productivity – labour productivity and total factor productivity. This is another thing to check when examining reports about productivity. Labour productivity as the name suggests focuses on output per unit of labour input. And within this approach some studies look at output per worker or output per hour worked. This could be important in looking at national figures as it is known that in some countries people work longer hours than others. Italy and France are said to work significantly less hours a year than say the USA largely due to different holidays, while workers countries such as the Netherlands typically work a 4 day week, with many companies experimenting with it in different locations. The Mexican’s, Korean’s and Costa Rican’s are currently averaging the longest working hours annually. However these are average contracted hours – and some might argue bear little resemblance to the actual hours worked by people (the Independent, 19 July 2018). The other approach, total factor productivity (TFP) takes into consideration other input resources (not just the labour), including expenditure on capital and resources. It could be argued that it is more difficult to get a real handle on TFP, especially at a macro, aggregated level. TFP growth looks at the difference between output growth and the growth of inputs (labour and capital).

CMA (2015:p42) observe that the measurement of productivity presents a series of challenges, “for example for measurement purposes the value of output rather than the volume is sometimes used. With this measure, high levels of prices, for example due to market power, can erroneously give the impression of high productivity”. One of the problems is often when productivity is discussed in the media reporters are not clear on what type of productivity is being discussed or the units being measured. Next time you hear a report on productivity the authors challenge you to stop and see if it is clear what is being discussed. Productivity measurements can also focus on different levels of analysis for example the overall economy, a sector of the economy, the enterprise, the plants, the machineries or the individuals. In terms of academic discourse on productivity, until recently much of the work has been within the economics and policy domains. But more recently we are seeing a wider discourse on productivity. Researchers from a range of social science disciplines are now talking about productivity, linking productivity levels to technological, organizational, demand, and market related factors. Examples include organisational structures (e.g. Syverson, 2011; Garicano and Heaton, 2007), human capital (Fox and Smeets, 2011), incentives and rewards (Lazear, 2000), human resources practices (Ichniowski and Shaw, 2003) and managerial talent and practices (Bloom and Van Reenen, 2007).

Given the current interest in productivity in the UK, the Productivity Insights Network (https://productivityinsightsnetwork.co.uk/) was established in January 2018. Funded by the Economic and Social Research Council (ESRC) they are a network of multi-disciplinary social science researchers, whose aim is to change the tone of the productivity

26th EurOMA Conference Operations Adding Value to Society
debate. To date the network has undertaken a number of reviews. Possibly the most comprehensive cross-disciplinary look at productivity to date is Philip McCann’s (2018) “Productivity Perspectives Synthesis”. In this McCann explains how the way we think about productivity has changed over the years.

**What do we know about the productivity narrative in manufacturing organisations?**

The authors are specifically interested in the narratives around productivity in manufacturing firms. There have been very few academic papers looking at productivity in manufacturing in the academic literature. Whilst they did not set out to look at productivity in manufacturing, Smart et al (2017) identified “productivity and innovation” as a theme in the industrial sustainability literature. Smart et al (2017) conducted a systematic review, reviewing 574 articles on industrial sustainability and suggest that industrial sustainability is yet to achieve a paradigmatic consensus. Instead three distinct and unifying dialogues emerge from their review: “productivity and innovation”, “corporate citizenship” and “economic resilience” were identified. The authors note a “preoccupation with efficiency strategies” (p1427). They note that much of the productivity and innovation literature (relating to industrial sustainability) comes from the operations/production management literature with significant focus on material and resource use and efficiency. Within the operations management literature, we do see much more focus both in the literature and in firms around efficiency rather than productivity. Mankins (2017) suggests that narratives within firms often focus on efficiency and are often conflated with productivity. CMA (2015) also observe the confusion over efficiency and productivity in everyday language.

Whilst there is little work on manufacturing productivity in the academic literature, in the past few years there have been a number of reports from professional bodies such as the CBI, IoD and EEF (now renamed Make UK). The CBI (2017) explored influences on the UK’s productivity success in their report “Unlocking Regional Growth” and the EEF (2016, 2018a, 2018b) has produced a number of reports highlighting key issues for UK manufacturing including the factors influencing productivity success. EEF contributed one of the most relevant studies for this project, “Productivity: the state of the manufacturing nation” (EEF, Spring 2016). They noted that the productivity growth of manufacturing outperformed that of services and the whole economy in the two decades to 2014, suggesting that manufacturing may not be the source of the UK’s weak performance” (p3). Whilst being positive about the actions of manufacturers the EEF suggest that manufacturers need to focus more on improving productivity of the company as a whole rather than just the factory, and on adopting major advances in technology (p3). Relevant to this paper, EEF (2016:p3) put forward the view that “manufacturing has the potential to be a major driving force behind improving the productivity performance of the UK economy” and go further to suggest “the sector will get further if government and businesses are talking the same language about productivity”. The EEF report concludes that by focusing too much on a macro-economic view of productivity we “could be missing a trick”, suggesting it is important to “dig deeper” and look at different sectors and indeed the businesses themselves. Echoing this view, one of the most recent calls comes from CIPD in their Labour Market Outlook (winter 2018-19:p15). CIPD point out that often these headline media productivity figures are derived from “official statistics” that aggregate data “from the whole economy, representing outputs as disparate as cars, haircuts, and public services. And observe that “it is no wonder that this abstract macroeconomic concept may feel distant from the everyday practice of employers”.

CIPD asked their members if productivity is a term often used when discussing performance. And half agreed they do – but there were big differences by sector. The
CIPD survey suggests that 71% of manufacturing firms are using the term – but the term is used by only 18% of education employers and just 16% in the voluntary sector. CIPD (2019:p16) suggest that this discrepancy might come from the fact that “measurement is much easier in some industries than others. It is much easier to measure the value of a car that is openly traded in the market than a teacher’s lesson.”

In a similar investigation the Institute of Directors, IoD (2018: p9) report that “60% of IoD SME members do not formally monitor productivity in their organisation”. IoD suggest that many small business leaders prefer to frame productivity as “working smarter” but opt to focus their measurement on other measures such as profit and revenue. IoD call for “supporting businesses to understand and monitor their productivity”. The IoD calls for a better understanding of what productivity is, what it means for performance, and how it can be monitored, in order to promote a “productivity mindset” in SMEs.” (p9). A similar call for better understanding and common language comes from Be the Business (May 2018). So there is a clear gap in understanding around the narratives of productivity at the level of the firm. And there is a call to arms that says only by speaking common language can we really drive real improvements in productivity that the UK wants to see.

**Research design of the “Manufacturing Productivity Narratives” project**

The authors of this paper wanted to address this gap, at least in the context of manufacturing firms, and to engage with people in manufacturing firms to really understand the narrative around productivity. The researchers also seek to engage in conversation about the drivers and constraints – from the perspectives of people working in manufacturing firms. Indeed the project will also go on to analyse whether there are different views at different levels of the firms and in different sectors. But this will be reported in later papers.

The project is a short, 9 month, pioneer project funded by the UK’s Economic and Social Research Council (ESRC) through the Productivity Insights Programme (Reference ES/R007810/1). Further information on this and related projects can be found at [https://productivityinsightsnetwork.co.uk/](https://productivityinsightsnetwork.co.uk/). It is an empirical study incorporating an exploratory, inductive systems thinking approach with a multiple case study design. The project focuses on firms within four key sectors in the UK: food & drink, automotive, aerospace, pharmaceuticals, as well as looking at high value manufacturing (HVM) organisations across the sectors. The aim is to move the productivity conversation forward, away from the economists, politicians and statisticians to the workplace by engaging with employees in manufacturing firms. Qualitative data are collected from 20 purposefully selected firms via 60 semi-structured interviews with three levels of personnel (Director, Manager and Supervisor), observations during site visits, firm-related archival data, and a review of secondary information about the firm and sectors. Engaging directly with employees working in manufacturing companies, provides a much-needed perspective from inside the firm and across the firm hierarchy, a perspective highlighted as crucial by Boys (2019) who advocates the need to “continue research into firms’ attitudes and awareness of the issue.” Interim findings will be shared via two workshops in regional locations with key manufacturing stakeholders from industry and Government, before final reporting in July 2019.

**Initial findings**

Whilst presenting early stage findings (a fuller analysis will be presented at the conference in June) this section of the paper delivers initial insights into how productivity is understood and measured at different levels in manufacturing firms. The data presented
in this paper is based on 20 interviews transcribed to date. By June our analysis will include a significantly higher number of interviews and will be stratified by sector and by level in the firm.

Usage of the term “productivity” is common but not universal
So far in our investigations more interviewees have confirmed that productivity is discussed in their organisation than those saying it is not a term used. The following quotes demonstrate this,

“You’ve got a target and productivity is something that at the very start of the shift I tell my team the target at the end of the shift is that we should reach a certain point.” (C2)

“Yes, we look at this on a rolling basis” (E1)

“We use the word productivity” (F2)

But it is certainly not used by all firms interviewed to date,

“Not as such. We use various terms for how effective we are at... how efficient we are. I guess... not really productivity.” (B1)

“We don’t refer to productivity by its name” (D2)

The terminology is variable
A significant number of interviewees recognise that the language is confusing and the terminology used differently by different people. This is evidenced in the following quotes from interviews:

“Yes but variations across sites. Not a standard.” (F2)

“It is nothing to do with the way government looks at productivity in GDP terms” (E1)

“Externally one of the real bugbears that I have is that everybody means something different by it [productivity], so it is a completely meaningless word to use externally. Internally we’re absolutely specific. Externally, the first question we ask is what are you actually measuring. What is the basis of comparison between what you’re telling me and what you’re asking me and my company”? (E1)

“Productivity is quite an old-fashioned terminology [...] productivity can often be constrained into only the manufacturing side. (D1)

Productivity is linked to other narratives
Throughout our interviews to date we are finding that productivity definitions can sometimes get entwined with narratives about efficiency, effectiveness, measurement and company and site specific terminology. Conversation often turns to measures to try to show what they mean by productivity. When talking about measuring productivity interviewees have talked about many things including; machine utilisation, OEE, on-time delivery, standard work, and output per unit of time. The following quotes show a range of things people conflate with productivity.

“Efficiency well that sort of overlaps with productivity” (E1)

“We don’t refer to productivity by its name. [...] We’re trying to drive efficiency through effectively greater output with a similar size headcount over the period. That’s
how we would I suppose at the broadest sense measure productivity. Are we winning the orders that we generate in the sales, are we increasing the margins? As a business are we getting more efficient in terms of the outcome financially of the business?” (D2)

“How efficient you are, not effective but efficient… this is my interpretation. How efficient you are at turning the raw material into the finished good… well, as a business how efficient you are at satisfying the customer. Fulfilling that customer desire, the whole way through, so selling... you know, the cost of sale, that’s important, I didn’t even mention that. I don’t think we ever measure any cost of sale type efficiency of productivity. Cost of sale, cost of design, the whole value chain piece, the cost of making it, delivering it, supporting it. That whole efficiency piece.” (B1)

“The measure of productivity is quite simply we break down all of our task into an hour’s content through industrialisation studies and work studies. We do that as part of the NPI, the product introduction process, and then we use that to set a standard for all the jobs in the facility. We then do a working out of how many people we need to run the facility. In doing that and taking into account all our costs as well, we work out effectively what’s called our cost rate. That is a cost per hour that we run the business by. So, that’s important. (A2)

“We use the word productivity. We record... we look at efficiency in utilisation but more utilisation.” (F2)

“Productivity can often be constrained into only the manufacturing side. So, we tend to follow more business-oriented KPIs that give you a measure of growth. […] I think we talk more about growth, improving our competitiveness than we do, than being fixated on something like productivity. […] So, when I hear productivity, my first go-to metric would be our five-year plan.” (D1)

This is consistent with what some of the reports from the professional bodies were saying, as well as evidence from the academic literature (eg. Smart et al 2017 and Mankins 2017)

Internal communication
In our interviews we are picking up on different language at different levels of the firm (this will be further analysed and presented in June). But the quotes below give some suggestions of the issues:

“It’s sort of translated ... as it goes through the organisation it’s translated into an appropriate language for the audience, if that makes sense, rather than having a standard headline” (F2)

“They might not know the productivity off the cuff, the charge hand would, by the way, but [...] they’d be able to show you where it’s measured there, and also how it’s tracked day by day at that level. (E1)

“Inside the company whilst as employees we’re using productivity all the time to talk about in our measure and standard hours” (E1)

If politicians and policy makers want to be utilising the correct levers to improve productivity then they need to be able to speak the same language as those within firms, including manufacturing. So it is important that we understand the language used.

Conclusions and further work
Consistent with our expectations from the limited literature, our initial primary research is suggesting that productivity means different things to different people within manufacturing and is measured in many different ways. Some manufactures will track aggregated measures at a high level, such as turnover per employee but often the conversation is more about the manufacturing shop floor and will be measured using multiple metrics eg. OEE, output per line, downtime etc. There is no single measure being used in the firms we have spoken to but rather multiple measures are used. This is in line with what we found by interrogating the existing but limited existing literature (eg EEF 2016, CIPD 2019). Often productivity is measured against some kind of target, standard or benchmark. For some this might be standard units of work and for others it might be against a target.

Speaking to people within manufacturing organisations is exposing a greater richness of the challenges and complexities. Some economic and policy studies have talked about certain sectors as being more productive than others in the UK. ONS for example suggests that chemicals and pharmaceuticals alongside automotive being the most productive sectors in terms of output per hour (£). EEF also talks about manufacturing productivity being higher than services and higher than the overall national picture. But statistics only tell you so much. Engaging in conversation with people within the manufacturing firms themselves reveals a much more complex picture. If we take a sector such a pharmaceuticals then we see some firms with big manufacturing sites with almost continuous manufacturing. Unsurprisingly such operations will look highly productive – with high volumes, low variety, high levels of automation, low staffing levels etc. But the other side of the pharmaceutical sector we can also see companies who are engaged in a lot more of the development work – needing significant investment, with high levels of regulation that see little or no return in the short term. So it’s not as simple as talking about sectors being productive.

Obviously manufacturers who have low variety, high volume and who are highly automated products will have economies of scale and might look productive (eg. pharma and automotive come out well in ONS figures) – particularly if you are talking about labour productivity and if you are measuring units of output. But at the same time companies operating in high vale areas where there is significant design and customisation – may also be productive as long as they are charging premium prices for their products and the market can bear it. And if you are measuring output in value, rather than units. Which brings us to whether firms who are operating as high value manufacturers - in terms of competing on things other than price (design, innovation, quality etc.) will be more productive. Well that depends on how you are measuring it. As we saw from our review of the literature there are many different ways of measuring productivity. You could argue that a firm who is HVM has more opportunity to manipulate the numerator (the output in terms of value £). Whereas a firm who is operating more at the commodity side of things has less scope to manipulate the output in £ through innovation – and will naturally focus more on the efficiency angle and reducing the inputs. If we are using value (revenue) as our output measure then we can see how much such a company’s productivity is at the mercy of market forces – no matter how hard they work at reducing inputs. If the demand and hence the price of the good was to shoot up then obviously the company’s productivity would shoot up, without the company actually doing anything different. But the slip side if the price goes down then productivity, if measured using value will go down.

Conversations in our study so far are dominated by talk about reducing inputs and efficiency, with very little about increasing business outputs. Whilst EEF in 2016 did hear some talk of step change investment and investment in R&D, as yet we are not
hearing this. More commonly the focus is on waste reduction, utilisation, lean, supply chain etc. If this continues to be the case then this perhaps opens up interesting avenues for further research and potential targets for improving productivity.

Relevance/Contribution

By engaging with workers at all levels and exploring the current pressures and metrics at different levels of the firm this paper starts to identify some of the opportunities for improving productivity, moving the conversation forward and addressing some of the challenges of measurement. This really moves the focus from a macro level to a micro level. Whilst presenting only early stage findings (a fuller analysis will be presented at the conference in June) this paper delivers insights into how productivity is understood and measured at different levels in manufacturing firms. The research uncovers different clusters of definitions used within manufacturing organisations and contrasts these with the economic definitions used by economists and politicians. The research also uncovers the use of productivity definitions that show a real disconnect between the levers of government and the levers of the firm as well as show where they can align. The paper contributes to the operations management literature relating to productivity measurement, and providing empirical evidence from the manufacturers themselves rather than just data from their manufacturing sectors. The paper may also be of interest to managers in industry and to policymakers by improving the evidence base.

Plant Location, Design and Layout
Abstract

The presented paper describes a method for the continuous migration planning for the design of global production networks. Based on the input of the strategic- and tactical planning the paper focuses on setting up a migration plan by defining certain migration projects, which describe structural changes in the form of different migration steps. Moreover, restrictions concerning the financial budget and time frame as well as potential dependencies during the implementation are considered. In order to guarantee a continuous tracking of the implementation and to provide an efficient overview of the migration status the idea of a migration cockpit is presented.

Keywords: Production network; Continuous network design; Migration planning
Introduction
The environment of global production networks becomes increasingly fast changing, due to globalization, technology changes accompanied by digitalization and demographic changes (BCG and Fraunhofer IPA, 2015; strategy&, 2017).

Access to new sales markets does not only offer advantages to companies, but also demands a high degree of adaptability. In a volatile environment, producing companies must be able to react as quickly to changes in order to save costs. Consequently, the network design becomes more challenging because of increased dynamics and complexity.

Most production networks are historically grown and motivated from evolutionary and opportunistic decisions (Christodoulou et al., 2007; Friedli et al., 2014), each individually decided for itself by corresponding argumentations and detailed cost analysis (Ferdows, 2009). Consequently, an integration of network decisions into existing organizational structures is only considered in rare cases.

There is no generic solution for the design of global production networks. Many approaches deal with the strategic design of global production networks by using mathematical optimization models (Cheng et al., 2015). Thereby, a detailed view on the implementation and the migration planning is not considered (Neuner, 2009).

That this procedure is not sufficient for today’s dynamic environment is reinforced by the fact that many network decisions are reversed (Sayem et al., 2018). In order to avoid mistakes and to enable a fast respond to changes, a process for the continuous design of production networks is required (Reuter et al., 2016).

Migration planning in research
Many existing approaches only slightly touch on aspects of a continuous migration planning. Some use detailed mathematical optimization models to find the best network configuration. However, they see the migration as a deterministic procedure without continuous evaluation (Jacob, 2005; Stoffel, 2016).

Many approaches focus only on the economic efficiency. The technological feasibility and possible dependencies are not considered. Therefore a continuous evaluation of the migration progress is not ensured (Moser, 2018; Schuh et al., 2014).

Some approaches determine a migration plan to achieve the optimal production network. Though, it is only on a high aggregation level. A detailed view on migration projects and dependencies is not discussed. As a result it is not easily possible to identify interactions in the network and to initiate measures (Lanza and Ude, 2009).

Summarizing, many approaches focus on time and costs, however, technological feasibility still plays a subordinate role. Despite detailed modelling, the creation of a detailed migration plan is usually disregarded. Migration planning often serves to select and evaluate appropriate network alternatives. Further, the implementation of the migration is mostly seen as a deterministic approach. A continuous evaluation by monitoring the migration progress as well as making adjustments during the migration are not provided. Moreover, a suitable visualisation of the migration status is not intended.

Approach for setting up a migration plan
This paper aims to define a method for the continuous migration planning for the design of global production networks in accordance to the reference process for the continuous design of production networks (Schuh et al., 2017). The migration planning focuses on the implementation of the target network. Therefore, all relevant decisions regarding the network strategy, -design and product allocation were already made on the strategic and
tactical planning level and can be regarded as predefined (Schuhe et al., 2018). This information represents the input for the migration planning (cf. figure 1).

Based on the input, the gap to achieve the target network configuration can be derived. The gap describes the differences between the current- and target network configuration regarding the design of the sites and the product allocation in the network. The migration planning has the task to close this gap through the conduction of different structural changes. Structural changes are divided in the categories construction, deconstruction, technology shift and changes in product allocation (Sälzer, 1985). Thus, the migration presents an amount of different structural changes.

To conduct the closing certain migration steps have to be defined, which describe the transition in detail. Due to the individuality of each company and the associated production network, it is not possible to provide a general instruction for defining the necessary migration steps. Rather, the determination of respective migration steps must be examined separately for each individual case, situation- and purpose-specifically. Still, an attempt is made to describe generically a procedure for determining relevant migration steps for the respective structural changes. Approximately three migration phases have to be formed, into which the steps can be divided:

- **Planning and preparation**: This phase includes all organizational tasks which have to performed in the beginning of the actual structural change.
- **Technical implementation**: In this phase, the actual network change takes place, thus the technical implementation of the structural changes.
- **Integration into existing organizational structure**: Once the structural changes have been completed the changes must be integrated into the existing organizational structure. Corresponding tasks of the respective sites or processes are to be carried out to the desired extent. Thus, it includes the start-up phase towards a stable production.

Thus, different migration steps can be categorized concerning their migration phase and their structural change. Besides the logical relationship between individual migration phases, strong dependencies can occur between individual migration steps. The dependency exist primary in the form of a sequential relationship. A dependence on several migration steps is therefore also conceivable.
A coordination of all necessary migration steps under consideration of existing dependencies would make the creation of a suitable migration plan extremely complicated. As a result, individual migration steps are be summed up into separate migration projects, between which dependencies can exist. The migration projects form the planning basis for the subsequent creation of the migration plan.

In general, it must be ensured that migration projects only contain migration steps that are in a factual context to each other. Accordingly, migration steps can be combined into vertical migration projects overlapping different migration phases of a concrete structural change.

The scope of summarized steps varies from project to project. While the migration steps of a project are already dependent on each other due to the factual context, different migration projects or different migration steps can be dependent on each other beyond project boundaries. The dependencies do not have to refer to a structural change, but can lie in the form of horizontal dependencies between different structural changes. For example, it can simultaneously involve the dismantling of an existing site and the expansion of other sites.

The context of vertical migration projects and horizontal dependencies is shown in figure 2.

In addition to the characteristics of the design of the sites, products and processes, restrictions must be defined in which have to be taken into account for the migration. On the one hand, a time horizon has to be set for the implementation of the migration. On the other hand, a migration budget limits the available financial resources. In order to increase the flexibility for planning, an acceptable overrun should be defined for the budget and time horizon. Further, the overrun supports the continuous tracking of the current migration status during the implementation.

Beyond the restrictions, possible dependencies should be identified, which can occur during the migration because of certain structural changes. Structural changes do not affect only the directly involved sites but can also have an extensive impact on the whole production network. The resulting influence can have either a positive or a negative effect on the overall network. Negative interactions along the migration can have a negative impact on the success of the migration project and thus on the targeted outcome. In order to prevent this and make appropriate adjustments, it is important to identify interactions...
at an early stage. In the context of the design of global production networks, the relevant interactions that occur mainly consist of the violation of existing capacity conditions and requirements, e.g. process capacity and resource availability.

After defining the migration restriction and relevant dependencies, the migration plan can be set up. To find the best migration plan a net present value approach is chosen. The associated objective function is shown in equation (1).

\[
MAX \sum_{t=0}^{T} \left( E_t - \sum_{i=1}^{I} I_{ij} \cdot x_{ijt} \right) 
\cdot p^{-t}
\]  

(1)

\(E_t\)  Describes the incoming payments received during period \(t\). Since migration can have a far-reaching impact on the entire production network, it is important to ensure that the proceeds from the direct and indirect involvement of sites are taken into account. For example, it could be that an important process has to be restarted by a technology shift. Other locations that are dependent on this process are therefore also not able to call up their full performance potential during the ramp-up phase, which also indirectly influences their revenues from the migration. In order to find out which locations are indirectly influenced by the migration, a detailed analysis of the network process structure is required.

\(I_{ij}\)  A migration project can involve several time-independent investments. In this case, the variable describes the amount of investment associated with the migration step \(j\) of the migration project \(i\). It is important to note that in this case, the investments are only cash-effective investments. Consequently, only external investments should be taken into account with regard to migration costs. While the repayment phase of any debt financing was not taken into account when estimating the duration of the respective migration projects, repayment and interest payments to be made must be considered over the entire period, as they have a significant influence on the net present value. The amount of the investments to be made is based on the cost estimation of the migration projects.

\(p^{-t}\)  Presents the discount factor for period \(t\) with \(p = \text{discount rate} + 1\)

\(x_{ijt}\)  As a decision variable it can only take the values \(\{0,1\}\). It specifies the period in which a concrete migration step is performed, taking into account existing dependencies. If the migration step is conducted in the period \(t\), its value is \(1\), otherwise \(0\).

After the migration plan with all relevant information about the individual migration projects has been created, the actual implementation can take place. Due to the high dynamics and complexity in which the company and thus also the production network are, a deterministic implementation of the migration plan is not recommended. A continuous evaluation of the migration must be consulted.

Each individual migration project is evaluated with regard to its implementation and compliance with the restrictions. The evaluation of the migration results from the evaluations of the respective migration projects. The cost and time frame can be
reviewed by a performance value analysis, it provides information on the current cost and time situation with additional consideration of the degree of completion.

Further, existing dependencies should be analyzed to identify prematurely any issues. Occurring changes concerning the restriction or dependencies can lead to delays or require an adaptation of the migration plan. Therefore, a continuous evaluation of the migration has to be carried out.

Depending on the scope of the migration project, a large number of migration projects is required to achieve the desired target network configuration. As a result, it is difficult to track the current migration status. For the upper decision-making level it is important to know to which extent their specifications are integrated into the reality in order to plan further network strategies. Consequently, in a simple visualization, the migration status of the entire migration project should be displayed (figure 3).

![Migration Cockpit](image)

*Figure 3: Migration cockpit to track the current migration status*

The migration cockpit provides visualized information concerning the current migration status for the technology-, finance- and time perspective. A three stage scaling evaluates each perspective. If the perspective is in the given frame feasible, the migration occurs as planed without any issues. Under acceptable deviations realizable means, that certain restriction are not met, but the migration can still be realized in the aspired way (e.g. the expenses have exceeded the budget, but the overrun compensates the deficit). While the first two stages lead to successful implementation of the migration plan, the third stage underlines serious deviations, which require the need for action.

Thus, a suitable visualization in form of a migration cockpit gives a brief overview of the current migration status and points out directly, in which perspective adjustments or a closer look are required.

**Conclusion**

In order to conduct a successful production network design, this paper presents a method for continuous migration planning. By setting up detailed migration projects and pointing out existing dependencies, a continuous tracking of the migration progress and interactions in the network is possible.

Furthermore, the paper provides an outlook, how the migration status can be displayed in a migration cockpit. As part of a global control center, it supports decision makers by giving an overview of the current migration progress at any time.

Abstract

Logistics costs represent a large portion of overall costs. This research is focussed on a plant belonging to an aerospace component supplier, and its purpose is to reduce the layout costs in one of its warehouses. Both qualitative and quantitative approaches are used. 44 scenarios based on layout decisions, storage assignment policies and alternative picking routes fitting the company were compared. Findings showed that travelling distance could be reduced when the allocation of items in shelves follow their picking frequency and when class-based storage with return routing policies is used; using these guidelines does not impact process time and picking quality.

Keywords: Case study; Layout efficiency; Warehousing

Introduction

The ability to compete is paramount and efficiency, regardless of the organisations’ overall approach, is an issue companies continuously strive for. Companies in peripheral geographies face additional challenges to compete in primary markets, as they have to overcome additional costs derived from their location. Geography cannot be overcome without relocation costs, but costs can be explored to compensate for this factor.

Although storage of products by itself does not add value to the customer (Tompkins and Smith, 1998; Carvalho, 2018), it has an immediate impact on the warehouse operation costs (Tompkins and Smith, 1998; Rushton et al., 2017).

Warehousing costs are an essential key in the overall costs a company has to support and can be streamed to compensate for the geography ones. Excluding inventory costs, the picking activity alone represents about 55% of the warehousing costs (Drury, 1998). Additionally, travelling during the picking activity is estimated to require about 50% of the time of the resources (Tompkins et al., 2010). Even small savings in this travelling time can have a generous impact on the operation costs.
This research focuses on a plant, Lauak Portugal, located in a peripheral European country. This plant is a partner factory of an aerospace metallurgical company, Groupe Lauak, that has plants in many different countries. These plants compete among themselves for company contracts. Service quality and fulfilment of due dates to customers are relevant in this industry. Although most products are developed jointly with the customers, the cost issue is a pertinent aspect for maintaining the competitiveness of the plant within the group. It is thus essential to continuously monitor costs while looking for strategies that allow reducing them, with warehousing costs, and particularly picking-related costs, playing a vital role in this search. The purpose of this research is thus to improve the warehousing costs in one problematic warehouse for the plant, contributing to its competitiveness inside the company.

This research is grounded on a systematic literature review on warehousing procedures and layout alternatives (Tompkins and Smith, 1998; Tompkins et al., 2010; Stock and Lambert, 2001; Rushton et al., 2017), which support the development of theoretical scenarios. The analysis of these scenarios is based on data collected from interviews, observation, documentation and archival records. A case study approach is conducted following literature recommendations (Yin, 2018; Voss et al., 2002).

**Literature background**

Logistics management aims to offer the highest possible level of customer service while decreasing response time and logistics costs. To achieve the most suitable solution for each company case, a trade-off between these dimensions (service quality, time and cost) must be reached. It is based on how the several logistics activities are conducted.

Warehousing is one of the many logistics activities identified in the literature (see for instance Stock and Lambert (2001), Rushton et al. (2017), Carvalho et al. (2018)). Despite being essential to the whole chain, in most cases, this logistic activity by itself does not add any value to the final customer (Tompkins and Smith, 1998; Christopher, 2016; Carvalho et al., 2018). As Ballou mentions (2004: 470), “storage become an economic convenience rather than a necessity”. Warehousing activities help companies managing their gap between supply and demand, decreasing supply chain vulnerability and decoupling demand from production capabilities (Ballou, 2004; Rushton et al., 2017; Bartholdi and Hackman, 2017; Carvalho et al., 2018).

When holding materials at a warehouse, the layout decision has a strategic impact as it will impact the trade-offs within the logistics attributes. Minimising travel distance and facilitating internal flows are the aims of the layout decisions (Carvalho et al., 2018). Its typology is usually classified based on how products are moved inside the facility and the location of the doors. Typically they are: Directional or Flow-through; Broken flow or U-shaped flow (Carvalho, 1996; Tompkins et al., 2010); L-shaped flow when the receiving and shipping areas are neither located side by side nor in opposite sides of the facility; a mixture between the three main typologies (Rushton et al., 2017).

In many situations, facility constraints lead the layout configuration; nonetheless, if it is possible to decide, there are guidelines to be considered. Flow-through layouts reduces travelling time inside the warehouse and decreases the traffic and internal congestion because the receiving and shipping areas are on opposite sides (Carvalho et al., 2018), but this typology is more suited for factory warehouses, cross-docking platforms, or facilities that deal with materials with more or less similar rotation (Rushton et al., 2017). U-shaped layouts lead to reduced average travel distance, as the start and end points of its flows are close, and reduced space allocated to the reception and shipping areas; it is more suited for the storage of products with different rotations and/or shapes and weights, which
might difficult their movement (Carvalho et al., 2018; Rushton et al., 2017). Regardless of flow typology, all warehouses have the same main internal movements.

Each warehouse has its internal activities. However, all of them have the same 4 main functions (Tompkins and Smith, 1998; Rushton et al., 2017; Bartholdi and Hackman, 2017; Carvalho et al., 2018): Reception of products; Storage until they are needed; Picking to satisfy an order; and Shipping to the user that requested them.

When assigning locations to storage of products, three main ways can be identified: 1) define a fixed/dedicated location to each product; 2) randomly store products in whatever empty places are available during the reception period (which leads to a higher average travel time (Glock and Grosse, 2012)); 3) define areas for each product, but not a specific location (each product has a single associated area, yet is randomly stored inside it – class-based storage) (Hausman et al., 1976).

The fixed location alternative, although simple in terms of locating products in the facility, requires that the company keeps space available for the maximum level of inventory for every stock keeping unit (de Koster et al., 2007). Random storage, although simple to conduct and leading to better space utilization (Stock and Lambert, 2001; Carvalho et al., 2018), requires computerized central registration as product location is continuously changing (Carvalho et al., 2018) and leads to greater travel distance to complete the same picking list (Stock and Lambert, 2001; Carvalho et al., 2018) if products do not have similar rotation. Class-based location tries to combine the advantages of the two previous methods (Chan and Chan, 2011; Carvalho et al., 2018). It increases the warehouse performance up to 40% when compared to the random storage (Rao and Adil, 2013) and reduces travel distances as products are located in the facility based on their rotation (Chan and Chan, 2011).

Hall (1993: 76) defined picking as “the process by which items are retrieved from stocking locations in a warehouse”. The picking activity has a direct impact on the trade-off of the logistics attributes as it has to balance the efficiency of the use of resources (which impact time and cost) and effectiveness (measured usually in terms of the number of errors) produced (Carvalho et al., 2018). Depending on the defined goal, there are four main ways to pick products (Van den Berg and Zijm, 1999; Tompkins and Smith, 1998; Ballou, 2004; Rushton et al., 2017; Carvalho et al., 2018): 1) Pick by Order (the picker has the responsibility to collect every item from one order and only one at a time); 2) Pick by Line (the picker collects the quantity required to satisfy at once several different orders from each location); 3) Zone Picking (requires dividing the warehouse into areas, and the picker collects all the items stored per zone, changing to another after collecting all the products from that zone); 4) Batch Picking (a few numbers of orders are assigned to a single picker, who is responsible for collecting all the products from those orders at the same time).

Choosing between the different picking techniques should be aligned with the warehouse policy. A company should pick by order when orders have many lines to pick (Carvalho et al., 2018). Although it is simpler when the picking is paper-based, the productivity level is the lowest due to the time the picker needs to complete an order (Tompkins and Smith, 1998; Carvalho et al., 2018; Rushton et al., 2017).

Using picking by line leads to a higher number of errors but also to a faster conclusion of activities (Carvalho et al., 2018). Due to the number of errors it can lead to, it is more suited for companies with a few lines to pick per order (Carvalho et al., 2018).

Resembling picking by order is zone picking. It is most suited for companies operating different systems and equipment inside the same warehouse (Tompkins and Smith, 1998; Carvalho et al., 2018), when orders are usually too big for a single picker, or if there is any justification for physical storage segregation (Rushton et al., 2017). It leads to more
errors but at the same time shows higher productivity (Carvalho et al., 2018). The same way zone picking is for picking by order, batch picking is more suited for picking by line (Carvalho et al., 2018).

Selecting the best picking method depends, among other issues, on product range, order size, and the equipment used to collect the products (Rushton et al., 2017).

Companies can foster their efficiency using picking routes policies (de Koster et al., 2007; Roodbergen et al., 2008; Çelk and Süral, 2014). Several routing strategies are possible inside a warehouse, among which: i) Transversal Strategy, in which the picker enters at one side of the aisle, crosses it, and exits on the opposite side (Goetschalckx and Ratliff, 1988; Hall, 1993); ii) Return Strategy, in which the picker enters on an aisle and picks all the products from one side and then returns collecting products from the other side of the aisle, exiting on the entry point (Goetschalckx and Ratliff, 1988) (also called Largest Gap Return Strategy, according to Hall (1993)); iii) Mid-Point strategy, which is the same as the return strategy, but the return point is the middle point of the aisle (Hall, 1993); iv) S-shape curves, which is basically a traversal strategy where the picker does not need to cross an aisle if there is no picking to do (De Koster and Van Der Poort, 1998; Roodbergen & De Koster, 2001a).

Manzini et al. (2007) studied the impact of several variables on picking cycle time and concluded that return is the best strategy when it comes to a quadratic warehouse, and transversal when a company operates a rectangular one. Due to its simplicity, the S-shaped strategy can be used by some companies, but the real savings arise when companies select an optimal algorithm as a picking method. Particularly, Ratliff and Rosenthal (1983) propose an algorithm that allows determining the optimal picking route that minimises the travelling distances inside the warehouse. According to these authors, the procedure starts by selecting the closest shelf to the entry point. After picking that product, the shelf closer to the initially selected product should be the next chosen one. The picker should follow this procedure until the order list is completed.

Whatever warehouse policy a company adopts, it must consider the type of products, their size, shape, weight and rotation, the location of the products in the facility, the picking policies and the service policies. It is only from the aggregation of these different aspects that time and cost can be reduced while maintaining service quality.

The company: Lauak Portugal

Lauak Portugal is a partner factory of Groupe Lauak, a French group that owns a set of industrial companies supplying the aeronautical market. This research is focused on one specific plant based in Setúbal, Portugal, that transforms metal sheet into a wide range of aircraft components.

This plant has four warehouses: two for raw material (thin and thick material), one for work-in-process, and one for the final product. The company considers that the picking process in the final product’s warehouse is consuming an excessive amount of time and, for this reason, this research is focused in this specific warehouse.

The warehouse for final products has three horizontal aisles (hereafter referred to as A1 [bottom aisle], A2 [middle aisle] and A3 [top aisle]), organised with 44 shelves. It follows a U-flow configuration. Shelves are organised according to 3 product families:

- FAI: prototypes waiting for quality approval to be shipped to the customer;
- ESKU: products of a partner factory of the group;
- PFBE: final products owned by Lauak Portugal; it is considered the most relevant family inside this warehouse.

Independently on the product family, products are randomly stored on the shelves that are dedicated to its particular family. There are different boxes on the shelves to
accommodate small and medium size products. Large items are freely placed on the shelves. Regarding the picking process, it follows a picking list organised according to the delivery date, with products that have the closest delivery date being the ones that should be picked first. This organisation clearly shows that the picking process is far from being optimal. This research thus explores alternative picking routes along with alternative allocations of products on the shelves, and the impact of these alternatives in the total travelling distance in the picking process. The savings achieved in terms of travelling distance will have an impact on the warehousing costs, thus resulting in savings in the total cost supported by the company.

**Methodology**

This research is based on case study approach (Voss et al., 2002; Yin, 2018), and involves several consecutive research steps:

- **Step I:** Characterizing the current operation in the warehouse, with emphasis on the organisation of the warehouse, on the allocation of products and on the picking activity;
- **Step II:** Defining a set of alternative theoretical scenarios for storage assignment of products and picking routes;
- **Step III:** Assessing and comparing alternative theoretical scenarios;
- **Step IV:** Presenting recommendations for the company.

Different tools are used in each of these steps, either to collect or to treat data.

**Step I: Characterizing the current operation in the warehouse**

The detailed and accurate characterisation of the current operation in the warehouse requires the collection of a wide variety of data. Following both qualitative and quantitative approaches, several information sources are used, following Yin (2018): documentation, archival records, informal interviews, and direct and participant observations.

A qualitative approach is based on unstructured informal interviews with employees with different hierarchical roles to understand in detail the warehouse organisation and internal operations. Particularly, the head of logistics, the picker and the warehouse manager are interviewed. Direct observation and official documents are also used, allowing to assure data triangulation (Eisenhardt, 1989; Voss et al., 2002; Yin, 2018).

Quantitative data is also measured using direct and participant observations, namely: i) distances travelled between and across aisles and shelves inside the warehouse; ii) data related with the picking activity in one specific period; iii) the volume of each product and shelf location in the warehouse. Additionally, the daily stock is extracted from the company's ERP (archival records), and the average stock is calculated based on this information.

**Step II: Defining a set of alternative theoretical scenarios**

A set of alternative theoretical scenarios for the storage assignment of products and picking routes are defined based on literature recommendations. Particularly, 66 scenarios are considered based on 22 picking routes and 3 storage assignment strategies.

- Picking routes: the Traversal, Return, and Mid-Point strategies are used (Goetschalckx and Ratliff, 1988; Hall, 1993; de Koster and Van Der Port, 1998; Roodbergen and de Koster, 2001a). The S-Shape Curves strategy is not specified because it is equivalent to the Transversal strategy in this specific warehouse. Also, the algorithm proposed by Ratliff and Rosenthal’s (1983) is also considered as an
alternative picking route. By examining these four different strategies, 22 picking routes are obtained, according to Table 1;

- Storage assignment: Random (SA-1), Class-Based (SA-2) and Fixed/Dedicated (SA-3) strategies are considered, following the recommendations of Hausman et al. (1976), De Koster et al. (2007), Chan and Chan (2011), Glock and Grosse (2012) and Carvalho et al. (2018). ABC analysis is used to classify products for Fixed/Dedicated and Class-Based strategies, using the picking frequency as criterion (Chan and Chan, 2011).

Table 1. Picking Routes

<table>

</tbody>
</table>

These 66 scenarios should be compared with the current situation in the warehouse, i.e., with a reference scenario (hereafter called *Current Scenario*) representing the picker’s real movements inside the warehouse in one specific period.

Step III: Assessing and comparing alternative theoretical scenarios

The efficiency of the theoretical scenarios defined under Step II is assessed in terms of the total distance travelled inside the warehouse, according to Equation (1):

\[ \sum_{i=1}^{n} \sum_{j=1}^{n} D_{ij} \times T_{ij} \]  

in which \( i \) and \( j \) represents a location point inside the warehouse (it can be the entrance or a shelf), \( n \) represents the number of shelves plus one (to include the entrance), \( D_{ij} \) represents the distance between a location point \( i \) and \( j \) (with \( i \neq j \)), and \( T_{ij} \) represents the frequency in which the distance between location point \( i \) and \( j \) is travelled.

These scenarios are then compared with the current scenario in the warehouse (hereafter called Scenario 0), in which a specific warehouse layout, storage assignment and picking route are used in the daily operation (as described in the following section). To allow this comparison, all scenarios should be simulated with the same data used to characterise Scenario 0 (i.e., data related to the number of products received and delivered during a specific period).

Step IV: Presenting recommendations for the company

Based on the results obtained by comparing all the scenarios, managerial recommendations are presented to the company.

Case study

This section first presents the scenarios selected for analysis and then follows for the key results obtained based on the simulation of these scenarios.
Selected theoretical scenarios
Within the set of 66 scenarios defined above, only 44 are further analysed in this research – the Fixed/Dedicated storage is not used in the analysis as it is not considered a doable policy by the company. Within this setting, only Random Storage (SA-1) and Class-based Storage (SA-2) are considered, together with the 22 picking routes (PR1 to PR22) – Table 2 presents a summary on the scenarios considered for analysis.

Class-based Storage requires classifying the different products. The following steps were conducted:

- First: Products are first classified according to the families already in use to organise the warehouse: FAI, ESKU and PFBE (classification imposed by the company). There are specific areas in the warehouse for each family, and it is not possible to mix families;
- Second: Within each family, ABC analysis is used to classify products in A, B and C items, according to the picking frequency;
- Third: Within each family and class, items are further divided into small, medium and large items. This classification is also required because the size of the products will also affect the selection of the shelf where it should be stored.

Based on such classification, 9 classes are defined. PFBE products should be first allocated to the shelves closer to the warehouse entrance, followed by ESKU products, and then by FAI products (according to company recommendations). Within each of these product families, items with a higher turnover (A items) should be stored closer to the warehouse entrance. Afterwards, within each family and class (A, B and C), products should be allocated randomly, although respecting the organisation in terms of volumes (it is not possible to mix small, medium and large items in the same shelf).

Key results
The 44 scenarios are simulated using data related to the picking activity recorded for one specific period of activity, and the current scenario was also analysed for this period. Table 3 summarises the key results of this simulation.

The results obtained for the first 22 scenarios – scenarios related to the 22 picking routes and random storage (PR-1/SA-1 to PR-22/SA-1) – are summarised in the left half of Table 3. According to these results, the proposed scenarios allowed reducing the travelling distance between 38.45% and 46.25%, when compared to the currently travelled one per month in the picking activity. Within these 22 scenarios, the ones that allow obtaining the highest saving in terms of travelling distance are the ones identified in bold in the table and that are characterised by picking routes mixing transversal and return strategies (PR-2/SA-1, PR-3/SA-1 and PR-15/SA-1).

</table>

The right half of Table 3 summarises the results obtained for the four scenarios that resulted in the shortest travelling distance when random storage is considered, but now with class-based storage being imposed. These three scenarios were simulated with the same data used for the other 22 scenarios, but while imposing the new allocation of products in the warehouse according to the products’ classification proposed above. Implementing these scenarios would allow reducing the travelling distance in the picking process at an even larger extent, when compared to the current scenario, with reductions of around 64%.

**Discussion**

Random storage theoretical scenarios showed to be able to reduce the distance travelled (and consequently warehousing costs) in every picking policy considered when compared to the current company policy. Nonetheless, it has to be taken into account that random storage may lead to a more time-consuming picking process if investments in information systems are not conducted as additional time might be required to find the items. This way, the reduction of at least 38,45% in distance travelled may not represent a similar reduction in the required picking time.

As the company has 3 different product families, each with items showing different picking frequencies, Class-based Storage was also analysed as a more organised random storage alternative. Findings showed that this storage assignment policy leads to even
more reduced travelled distance. Although items are also randomly stored in a specific area and within that area they are organised on the shelves based on their size, they are nonetheless easier/quicker to find than in the Random storage alternative – this is because there is a quite limited number of alternative locations where they can be found. This alternative showed a reduction in the distance above 64%, which is likely to accommodate an eventual increase of time in finding the specific item in the shelves.

Picking quality should not be affected by any of the storage assignment policies or by any of the picking routes considered as no changes in terms of a more picking by line or picking by order orientation were considered.

It is possible to state that the company is currently using a suboptimal solution and that, without any investment, can reduce warehousing costs.

Conclusions

This research aimed at assessing picking policies to reduce warehousing costs, therefore contributing to Lauak Portugal competitive position within Groupe Lauak. Diverse different storage assignment (SA) policies and various picking routes (PR) were considered. From 66 possible initial scenarios (3 SA; 22 PR), 44 were considered (2 SA; 22 PR) as the remaining did not suit the specific case.

The 3 different product families were considered in defining zones in the warehouse. Families were divided into classes based on picking frequency; each class was further classified based on the size of the product as they require different shelving conditions.

Results show that significant savings in terms of the travelling distance in the picking activity can be achieved when alternative picking routes are considered, with even higher savings being obtained when the allocation of products in the shelves follow the picking frequency of products. Nevertheless, when comparing the results obtained when different picking routes are simulated (with the same storage assignment of products), no significant differences arise. Additionally, Class-based Storage showed to be a more organised solution than Random storage when product families exist.

This research contributes to practice, specifically to the analysed company. Additionally, this approach, with necessary adjustments, can be adopted by other companies to assess their policies and to find more efficient warehousing solutions.

A period of less than a year was considered, which might limit the usability of these findings. Analysing a full year would allow including seasonal uses of items, which might influence the frequency of use of the different locations. Nevertheless, the period considered was considered by the company as representative of its overall operation.

As further research, several topics may worth pursuing. Particularly, although not considered as feasible by the company, alternative layouts could be evaluated since it may result in further improvements in the picking activity. Also, a more in-depth analysis in the nature of products may lead to the organisation of products into different families, with an expected impact in the classification and allocation of products. Finally, exploring optimisation methods to identify the optimal scenario could also be pursued.

Abstract

Logistics costs represent a large portion of overall costs. This research is focussed on a plant belonging to an aerospace component supplier, and its purpose is to reduce the layout costs in one of its warehouses. Both qualitative and quantitative approaches are used. 44 scenarios based on layout decisions, storage assignment policies and alternative picking routes fitting the company were compared. Findings showed that travelling distance could be reduced when the allocation of items in shelves follow their picking frequency and when class-based storage with return routing policies is used; using these guidelines does not impact process time and picking quality.

Keywords: Case study; Layout efficiency; Warehousing

Introduction

The ability to compete is paramount and efficiency, regardless of the organisations’ overall approach, is an issue companies continuously strive for. Companies in peripheral geographies face additional challenges to compete in primary markets, as they have to overcome additional costs derived from their location. Geography cannot be overcome without relocation costs, but costs can be explored to compensate for this factor.

Although storage of products by itself does not add value to the customer (Tompkins and Smith, 1998; Carvalho, 2018), it has an immediate impact on the warehouse operation costs (Tompkins and Smith, 1998; Rushton et al., 2017).

Warehousing costs are an essential key in the overall costs a company has to support and can be streamed to compensate for the geography ones. Excluding inventory costs, the picking activity alone represents about 55% of the warehousing costs (Drury, 1998). Additionally, travelling during the picking activity is estimated to require about 50% of the time of the resources (Tompkins et al., 2010). Even small savings in this travelling time can have a generous impact on the operation costs.
This research focuses on a plant, Lauak Portugal, located in a peripheral European country. This plant is a partner factory of an aerospace metallurgic company, Groupe Lauak, that has plants in many different countries. These plants compete among themselves for company contracts. Service quality and fulfilment of due dates to customers are relevant in this industry. Although most products are developed jointly with the customers, the cost issue is a pertinent aspect for maintaining the competitiveness of the plant within the group. It is thus essential to continuously monitor costs while looking for strategies that allow reducing them, with warehousing costs, and particularly picking-related costs, playing a vital role in this search. The purpose of this research is thus to improve the warehousing costs in one problematic warehouse for the plant, contributing to its competitiveness inside the company.

This research is grounded on a systematic literature review on warehousing procedures and layout alternatives (Tompkins and Smith, 1998; Tompkins et al., 2010; Stock and Lambert, 2001; Rushton et al., 2017), which support the development of theoretical scenarios. The analysis of these scenarios is based on data collected from interviews, observation, documentation and archival records. A case study approach is conducted following literature recommendations (Yin, 2018; Voss et al., 2002).

**Literature background**

Logistics management aims to offer the highest possible level of customer service while decreasing response time and logistics costs. To achieve the most suitable solution for each company case, a trade-off between these dimensions (service quality, time and cost) must be reached. It is based on how the several logistics activities are conducted.

Warehousing is one of the many logistics activities identified in the literature (see for instance Stock and Lambert (2001), Rushton et al. (2017), Carvalho et al. (2018)). Despite being essential to the whole chain, in most cases, this logistic activity by itself does not add any value to the final customer (Tompkins and Smith, 1998; Christopher, 2016; Carvalho et al., 2018). As Ballou mentions (2004: 470), “storage become an economic convenience rather than a necessity”. Warehousing activities help companies managing their gap between supply and demand, decreasing supply chain vulnerability and decoupling demand from production capabilities (Ballou, 2004; Rushton et al., 2017; Bartholdi and Hackman, 2017; Carvalho et al., 2018).

When holding materials at a warehouse, the layout decision has a strategic impact as it will impact the trade-offs within the logistics attributes. Minimising travel distance and facilitating internal flows are the aims of the layout decisions (Carvalho et al., 2018). Its typology is usually classified based on how products are moved inside the facility and the location of the doors. Typically they are: Directional or Flow-through; Broken flow or U-shaped flow (Carvalho, 1996; Tompkins et al., 2010); L-shaped flow when the receiving and shipping areas are neither located side by side nor in opposite sides of the facility; a mixture between the three main typologies (Rushton et al., 2017).

In many situations, facility constraints lead the layout configuration; nonetheless, if it is possible to decide, there are guidelines to be considered. Flow-through layouts reduces travelling time inside the warehouse and decreases the traffic and internal congestion because the receiving and shipping areas are on opposite sides (Carvalho et al., 2018), but this typology is more suited for factory warehouses, cross-docking platforms, or facilities that deal with materials with more or less similar rotation (Rushton et al., 2017). U-shaped layouts lead to reduced average travel distance, as the start and end points of its flows are close, and reduced space allocated to the reception and shipping areas; it is more suited for the storage of products with different rotations and/or shapes and weights, which
might difficult their movement (Carvalho et al., 2018; Rushton et al., 2017). Regardless of flow typology, all warehouses have the same main internal movements.

Each warehouse has its internal activities. However, all of them have the same 4 main functions (Tompkins and Smith, 1998; Rushton et al., 2017; Bartholdi and Hackman, 2017; Carvalho et al., 2018): Reception of products; Storage until they are needed; Picking to satisfy an order; and Shipping to the user that requested them.

When assigning locations to storage of products, three main ways can be identified: 1) define a fixed/dedicated location to each product; 2) randomly store products in whatever empty places are available during the reception period (which leads to a higher average travel time (Glock and Grosse, 2012)); 3) define areas for each product, but not a specific location (each product has a single associated area, yet is randomly stored inside it – class-based storage) (Hausman et al., 1976).

The fixed location alternative, although simple in terms of locating products in the facility, requires that the company keeps space available for the maximum level of inventory for every stock keeping unit (de Koster et al., 2007). Random storage, although simple to conduct and leading to better space utilization (Stock and Lambert, 2001; Carvalho et al., 2018), requires computerized central registration as product location is continuously changing (Carvalho et al., 2018) and leads to greater travel distance to complete the same picking list (Stock and Lambert, 2001; Carvalho et al., 2018) if products do not have similar rotation. Class-based location tries to combine the advantages of the two previous methods (Chan and Chan, 2011; Carvalho et al., 2018). It increases the warehouse performance up to 40% when compared to the random storage (Rao and Adil, 2013) and reduces travel distances as products are located in the facility based on their rotation (Chan and Chan, 2011).

Hall (1993: 76) defined picking as “the process by which items are retrieved from stocking locations in a warehouse”. The picking activity has a direct impact on the trade-off of the logistics attributes as it has to balance the efficiency of the use of resources (which impact time and cost) and effectiveness (measured usually in terms of the number of errors) produced (Carvalho et al., 2018). Depending on the defined goal, there are four main ways to pick products (Van den Berg and Zijm, 1999; Tompkins and Smith, 1998; Ballou, 2004; Rushton et al., 2017; Carvalho et al., 2018): 1) Pick by Order (the picker has the responsibility to collect every item from one order and only one at a time); 2) Pick by Line (the picker collects the quantity required to satisfy at once several different orders from each location); 3) Zone Picking (requires dividing the warehouse into areas, and the picker collects all the items stored per zone, changing to another after collecting all the products from that zone); 4) Batch Picking (a few numbers of orders are assigned to a single picker, who is responsible for collecting all the products from those orders at the same time).

Choosing between the different picking techniques should be aligned with the warehouse policy. A company should pick by order when orders have many lines to pick (Carvalho et al., 2018). Although it is simpler when the picking is paper-based, the productivity level is the lowest due to the time the picker needs to complete an order (Tompkins and Smith, 1998; Carvalho et al., 2018; Rushton et al., 2017).

Using picking by line leads to a higher number of errors but also to a faster conclusion of activities (Carvalho et al., 2018). Due to the number of errors it can lead to, it is more suited for companies with a few lines to pick per order (Carvalho et al., 2018).

Resembling picking by order is zone picking. It is most suited for companies operating different systems and equipment inside the same warehouse (Tompkins and Smith, 1998; Carvalho et al., 2018), when orders are usually too big for a single picker, or if there is any justification for physical storage segregation (Rushton et al., 2017). It leads to more
errors but at the same time shows higher productivity (Carvalho et al., 2018). The same way zone picking is for picking by order, batch picking is more suited for picking by line (Carvalho et al., 2018).

Selecting the best picking method depends, among other issues, on product range, order size, and the equipment used to collect the products (Rushton et al., 2017).

Companies can foster their efficiency using picking routes policies (de Koster et al., 2007; Roodbergen et al., 2008; Çelik and Süral, 2014). Several routing strategies are possible inside a warehouse, among which: i) Transversal Strategy, in which the picker enters at one side of the aisle, crosses it, and exits on the opposite side (Goetschalckx and Ratliff, 1988; Hall, 1993); ii) Return Strategy, in which the picker enters on an aisle and picks all the products from one side and then returns collecting products from the other side of the aisle, exiting on the entry point (Goetschalckx and Ratliff, 1988) (also called Largest Gap Return Strategy, according to Hall (1993)); iii) Mid-Point strategy, which is the same as the return strategy, but the return point is the middle point of the aisle (Hall, 1993); iv) S-shape curves, which is basically a traversal strategy where the picker does not need to cross an aisle if there is no picking to do (De Koster and Van Der Poort, 1998; Roodbergen & De Koster, 2001a).

Manzini et al. (2007) studied the impact of several variables on picking cycle time and concluded that return is the best strategy when it comes to a quadratic warehouse, and transversal when a company operates a rectangular one. Due to its simplicity, the S-shaped strategy can be used by some companies, but the real savings arise when companies select an optimal algorithm as a picking method. Particularly, Ratliff and Rosenthal (1983) propose an algorithm that allows determining the optimal picking route that minimises the travelling distances inside the warehouse. According to these authors, the procedure starts by selecting the closest shelf to the entry point. After picking that product, the shelf closer to the initially selected product should be the next chosen one. The picker should follow this procedure until the order list is completed.

Whatever warehouse policy a company adopts, it must consider the type of products, their size, shape, weight and rotation, the location of the products in the facility, the picking policies and the service policies. It is only from the aggregation of these different aspects that time and cost can be reduced while maintaining service quality.

**The company: Lauak Portugal**

Lauak Portugal is a partner factory of Groupe Lauak, a French group that owns a set of industrial companies supplying the aeronautical market. This research is focused on one specific plant based in Setúbal, Portugal, that transforms metal sheet into a wide range of aircraft components.

This plant has four warehouses: two for raw material (thin and thick material), one for work-in-process, and one for the final product. The company considers that the picking process in the final product’s warehouse is consuming an excessive amount of time and, for this reason, this research is focused in this specific warehouse.

The warehouse for final products has three horizontal aisles (hereafter referred to as A1 [bottom aisle], A2 [middle aisle] and A3 [top aisle]), organised with 44 shelves. It follows a U-flow configuration. Shelves are organised according to 3 product families:

- **FAI**: prototypes waiting for quality approval to be shipped to the customer;
- **ESKU**: products of a partner factory of the group;
- **PFBE**: final products owned by Lauak Portugal; it is considered the most relevant family inside this warehouse.

Independently on the product family, products are randomly stored on the shelves that are dedicated to its particular family. There are different boxes on the shelves to
accommodate small and medium size products. Large items are freely placed on the shelves. Regarding the picking process, it follows a picking list organised according to the delivery date, with products that have the closest delivery date being the ones that should be picked first. This organisation clearly shows that the picking process is far from being optimal. This research thus explores alternative picking routes along with alternative allocations of products on the shelves, and the impact of these alternatives in the total travelling distance in the picking process. The savings achieved in terms of travelling distance will have an impact on the warehousing costs, thus resulting in savings in the total cost supported by the company.

Methodology
This research is based on case study approach (Voss et al., 2002; Yin, 2018), and involves several consecutive research steps:

- **Step I:** Characterizing the current operation in the warehouse, with emphasis on the organisation of the warehouse, on the allocation of products and on the picking activity;
- **Step II:** Defining a set of alternative theoretical scenarios for storage assignment of products and picking routes;
- **Step III:** Assessing and comparing alternative theoretical scenarios;
- **Step IV:** Presenting recommendations for the company.

Different tools are used in each of these steps, either to collect or to treat data.

**Step I: Characterizing the current operation in the warehouse**
The detailed and accurate characterisation of the current operation in the warehouse requires the collection of a wide variety of data. Following both qualitative and quantitative approaches, several information sources are used, following Yin (2018): documentation, archival records, informal interviews, and direct and participant observations.

A qualitative approach is based on unstructured informal interviews with employees with different hierarchical roles to understand in detail the warehouse organisation and internal operations. Particularly, the head of logistics, the picker and the warehouse manager are interviewed. Direct observation and official documents are also used, allowing to assure data triangulation (Eisenhardt, 1989; Voss et al., 2002; Yin, 2018).

Quantitative data is also measured using direct and participant observations, namely: i) distances travelled between and across aisles and shelves inside the warehouse; ii) data related with the picking activity in one specific period; iii) the volume of each product and shelf location in the warehouse. Additionally, the daily stock is extracted from the company’s ERP (archival records), and the average stock is calculated based on this information.

**Step II: Defining a set of alternative theoretical scenarios**
A set of alternative theoretical scenarios for the storage assignment of products and picking routes are defined based on literature recommendations. Particularly, 66 scenarios are considered based on 22 picking routes and 3 storage assignment strategies.

- Picking routes: the Traversal, Return, and Mid-Point strategies are used (Goetschalckx and Ratliff, 1988; Hall, 1993; de Koster and Van Der Port, 1998; Roodbergen and de Koster, 2001a). The S-Shape Curves strategy is not specified because it is equivalent to the Transversal strategy in this specific warehouse. Also, the algorithm proposed by Ratliff and Rosenthal’s (1983) is also considered as an
alternative picking route. By examining these four different strategies, 22 picking routes are obtained, according to Table 1;

- Storage assignment: Random (SA-1), Class-Based (SA-2) and Fixed/Dedicated (SA-3) strategies are considered, following the recommendations of Hausman et al. (1976), De Koster et al. (2007), Chan and Chan (2011), Glock and Grosse (2012) and Carvalho et al. (2018). ABC analysis is used to classify products for Fixed/Dedicated and Class-Based strategies, using the picking frequency as criterion (Chan and Chan, 2011).

</tr>
</tbody>
</table>

These 66 scenarios should be compared with the current situation in the warehouse, i.e., with a reference scenario (hereafter called Current Scenario) representing the picker’s real movements inside the warehouse in one specific period.

**Step III: Assessing and comparing alternative theoretical scenarios**

The efficiency of the theoretical scenarios defined under Step II is assessed in terms of the total distance travelled inside the warehouse, according to Equation (1):

$$\sum_{i=1}^{n} \sum_{j=1}^{n} D_{ij} \times T_{ij}$$

in which $i$ and $j$ represents a location point inside the warehouse (it can be the entrance or a shelf), $n$ represents the number of shelves plus one (to include the entrance), $D_{ij}$ represents the distance between a location point $i$ and $j$ (with $i \neq j$), and $T_{ij}$ represents the frequency in which the distance between location point $i$ and $j$ is travelled.

These scenarios are then compared with the current scenario in the warehouse (hereafter called Scenario 0), in which a specific warehouse layout, storage assignment and picking route are used in the daily operation (as described in the following section). To allow this comparison, all scenarios should be simulated with the same data used to characterise Scenario 0 (i.e., data related to the number of products received and delivered during a specific period).

**Step IV: Presenting recommendations for the company**

Based on the results obtained by comparing all the scenarios, managerial recommendations are presented to the company.

**Case study**

This section first presents the scenarios selected for analysis and then follows for the key results obtained based on the simulation of these scenarios.
Selected theoretical scenarios

Within the set of 66 scenarios defined above, only 44 are further analysed in this research – the Fixed/Dedicated storage is not used in the analysis as it is not considered a doable policy by the company. Within this setting, only Random Storage (SA-1) and Class-based Storage (SA-2) are considered, together with the 22 picking routes (PR1 to PR22) – Table 2 presents a summary on the scenarios considered for analysis.

Class-based Storage requires classifying the different products. The following steps were conducted:

- First: Products are first classified according to the families already in use to organise the warehouse: FAI, ESKU and PFBE (classification imposed by the company). There are specific areas in the warehouse for each family, and it is not possible to mix families;
- Second: Within each family, ABC analysis is used to classify products in A, B and C items, according to the picking frequency;
- Third: Within each family and class, items are further divided into small, medium and large items. This classification is also required because the size of the products will also affect the selection of the shelf where it should be stored.

Based on such classification, 9 classes are defined. PFBE products should be first allocated to the shelves closer to the warehouse entrance, followed by ESKU products, and then by FAI products (according to company recommendations). Within each of these product families, items with a higher turnover (A items) should be stored closer to the warehouse entrance. Afterwards, within each family and class (A, B and C), products should be allocated randomly, although respecting the organisation in terms of volumes (it is not possible to mix small, medium and large items in the same shelf).

Key results

The 44 scenarios are simulated using data related to the picking activity recorded for one specific period of activity, and the current scenario was also analysed for this period. Table 3 summarises the key results of this simulation.

The results obtained for the first 22 scenarios – scenarios related to the 22 picking routes and random storage (PR-1/SA-1 to PR-22/SA-1) – are summarised in the left half of Table 3. According to these results, the proposed scenarios allowed reducing the travelling distance between 38.45% and 46.25%, when compared to the currently travelled one per month in the picking activity. Within these 22 scenarios, the ones that allow obtaining the highest saving in terms of travelling distance are the ones identified in bold in the table and that are characterised by picking routes mixing transversal and return strategies (PR-2/SA-1, PR-3/SA-1 and PR-15/SA-1).

</table>

The right half of Table 3 summarises the results obtained for the four scenarios that resulted in the shortest travelling distance when random storage is considered, but now with class-based storage being imposed. These three scenarios were simulated with the same data used for the other 22 scenarios, but while imposing the new allocation of products in the warehouse according to the products’ classification proposed above. Implementing these scenarios would allow reducing the travelling distance in the picking process at an even larger extent, when compared to the current scenario, with reductions of around 64%.

**Discussion**

Random storage theoretical scenarios showed to be able to reduce the distance travelled (and consequently warehousing costs) in every picking policy considered when compared to the current company policy. Nonetheless, it has to be taken into account that random storage may lead to a more time-consuming picking process if investments in information systems are not conducted as additional time might be required to find the items. This way, the reduction of at least 38.45% in distance travelled may not represent a similar reduction in the required picking time.

As the company has 3 different product families, each with items showing different picking frequencies, Class-based Storage was also analysed as a more organised random storage alternative. Findings showed that this storage assignment policy leads to even
more reduced travelled distance. Although items are also randomly stored in a specific area and within that area they are organised on the shelves based on their size, they are nonetheless easier/quicker to find than in the Random storage alternative – this is because there is a quite limited number of alternative locations where they can be found. This alternative showed a reduction in the distance above 64%, which is likely to accommodate an eventual increase of time in finding the specific item in the shelves.

Picking quality should not be affected by any of the storage assignment policies or by any of the picking routes considered as no changes in terms of a more picking by line or picking by order orientation were considered.

It is possible to state that the company is currently using a suboptimal solution and that, without any investment, can reduce warehousing costs.

**Conclusions**

This research aimed at assessing picking policies to reduce warehousing costs, therefore contributing to Lauak Portugal competitive position within Groupe Lauak. Diverse different storage assignment (SA) policies and various picking routes (PR) were considered. From 66 possible initial scenarios (3 SA; 22 PR), 44 were considered (2 SA; 22 PR) as the remaining did not suit the specific case.

The 3 different product families were considered in defining zones in the warehouse. Families were divided into classes based on picking frequency; each class was further classified based on the size of the product as they require different shelving conditions.

Results show that significant savings in terms of the travelling distance in the picking activity can be achieved when alternative picking routes are considered, with even higher savings being obtained when the allocation of products in the shelves follow the picking frequency of products. Nevertheless, when comparing the results obtained when different picking routes are simulated (with the same storage assignment of products), no significant differences arise. Additionally, Class-based Storage showed to be a more organised solution than Random storage when product families exist.

This research contributes to practice, specifically to the analysed company. Additionally, this approach, with necessary adjustments, can be adopted by other companies to assess their policies and to find more efficient warehousing solutions.

A period of less than a year was considered, which might limit the usability of these findings. Analysing a full year would allow including seasonal uses of items, which might influence the frequency of use of the different locations. Nevertheless, the period considered was considered by the company as representative of its overall operation.

As further research, several topics may worth pursuing. Particularly, although not considered as feasible by the company, alternative layouts could be evaluated since it may result in further improvements in the picking activity. Also, a more in-depth analysis in the nature of products may lead to the organisation of products into different families, with an expected impact in the classification and allocation of products. Finally, exploring optimisation methods to identify the optimal scenario could also be pursued.

Abstract

This paper examines differences and similarities between motivations of manufacturing offshoring and backshoring. By analysing two unique databases of manufacturing offshoring (113 cases) and backshoring (468 cases) from China, we find that flows from China to high-cost countries (whether offshoring or backshoring) share some common drivers, such as allowing proximity to customers, exploiting the “made in” effect, and seeking specialised resources. Our findings highlight reasons why manufacturing may expand its presence in Western countries as a result of both repatriations and of foreign direct investments from large economies such as China, and therefore point to potential areas of policy intervention.

Keywords: Reshoring, Offshoring, Location

Introduction

Ever since the nineties, the rise of manufacturing offshoring from high-cost to low-cost locations has received considerable attention from both business and academia (Schoenherr et al., 2008; Fredriksson and Jonsson, 2009). However, more recently some of the former low cost countries have seen a drastic increase in various costs (Kumar, 2009), including labour. Weakened location advantages have led many Western firms to relocate some manufacturing activities back to their home countries. In academia, this notion of manufacturing backshoring – namely a company decision to bring production or sourcing back to the home country, has attracted great interest (Foerstl et al., 2016; Fratocchi et al., 2016; Kinkel and Maloca, 2009; Gray et al., 2017; Ketokivi et al., 2017). Research though, has not paid equal attention to
“raisons d’être” of offshoring of manufacturing to high-cost countries by companies headquartered in China (Deng, 2012), other than market expansion and critical assets acquisition (Li et al., 2016).

Additionally, previous research suggests that there is a disconnection between motivations for backshoring and offshoring. Backshoring typically concerns flows from low-cost to high cost countries and its motivation is predominantly value-driven (Johansson et al., 2018; Fratocchi et al., 2016), while offshoring involves flows from high-cost to low-cost countries, and is predominantly cost-driven (Da Silveira, 2014; Fratocchi et al., 2016). What remains unknown is whether this difference still holds when the geographical directions of reshoring and offshoring are aligned.

This paper aims to offer a new perspective on the differences and similarities between the motivations of manufacturing offshoring and backshoring, by comparing manufacturing location moves by Chinese companies to North America and Europe (offshoring) and relocations of North American and European companies from China to the headquarter countries (backshoring). Findings may be of special interest for understanding the distinctive advantages of locating manufacturing in the West and for the design of policies aimed at attracting manufacturing and FDI to high-cost countries.

**Literature background**

**Theory**

The eclectic paradigm of international production (Dunning, 1980, 2000) proposes a unifying frame whereby location advantages are just one of three broad factors affecting international production. In particular, the attractiveness of the Location-specific endowments of alternative countries interacts with the firm's Ownership of a set of income- generating assets (Barney, 1991), and the firm's interest to Internalize activities (Buckley and Casson, 1976; Williamson, 1985) for the generation and/or exploitation of competences (OLI model). Further, Dunning (2000) subsumes the location drivers into four categories of contextual factors that affect the international configuration of production: (1) “the economic and political features of the country or region of the investing firms, and of the country or region in which they are seeking to invest”; (2) “the industry and the nature of the value added activity in which the firms are engaged”; (3) “the characteristics of the individual investing firms”; (4) “the raison d’être for the FDI,” i.e., whether the direct investment or alliance is market-seeking, resource-seeking, efficiency-seeking (motivated by rationalization), or strategic assets seeking (i.e., intended to protect or improve ownership advantages of the firm). Dunning's paradigm has been applied to explain several types of location decisions, and reshoring (Ellram et al., 2013). As our study focuses on manufacturing location decisions at the country level and we do not consider the make-or-buy aspect, the eclectic paradigm’s location advantages is a suitable tool for our analysis.

**Offshoring and backshoring: Empirical evidence**

Since academia started to focus on the concept of offshoring in the early 2000s, numerous empirical studies have investigated the factors motivating companies to offshore manufacturing. Among these motivations, cost reduction, has emerged as one of the most important motivations for offshoring (Aron and Singh, 2005; Canham and Hamilton, 2013; Da Silveira, 2014). Firms have offshored production activities to low-wage countries to seek lower costs of labour and other productive inputs (Doh, 2005; Jensen and Pedersen, 2011). Other
motivations include opening up new markets, access to foreign distribution channels, access to materials and goods, producing in the proximity of the customer, securing knowledge, and following the investor (cf. Dunning, 1980, 1988; Hollenstein, 2005; Kinkel et al., 2007; Kinkel and Maloca, 2009; MacCarthy and Atthirawong, 2003). Of all low-cost offshoring destinations, China, in particular, has attracted significant scholarly interest due to its position as the world factory (Zhang, 2006). Economic factors such as cost reduction, cost saving, and capital investment reduction have been the major drivers for companies to offshore manufacturing to China (Fang et al., 2004; Salmi, 2006). More recent studies note that motivational factors such as improved product quality, increased efficiency, and availability of major logistic platforms, (Nassimbeni and Sartor, 2007; Towers and Song, 2010; Sinha et al., 2011) have also played key roles in foreign firms’ decisions to offshore manufacturing to China.

On the other hand, since the notion of reshoring emerged as a hot topic in recent years, many studies have also examined the motivations for reshoring (cf. Ellram et al., 2013; Fratocchi et al., 2014; Gray et al., 2013). For instance, Kinkel and Maloca (2009) found that factors such as lack of flexibility, delivery ability, and quality problems at the foreign locations were the root cause of reshoring. In the case of the UK automotive sector UK, Bailey and De Propris (2014) found that rising costs overseas, high quality production in the UK, simpler transport and logistics, the availability of a skilled workforce, a strong supply chain, and better quality R&D and innovation were the most prominent motivations for reshoring. Fratocchi et al. (2016) identify as many as 31 prominent motivations for reshoring by reviewing both scholarly and practitioner studies. Two motivations, namely the reduction of labour costs between the host and home countries and poor quality of production abroad were found to be the most frequently acknowledged motivations for reshoring. However, based on the literature review and evidence collected from secondary sources, the authors conclude that value-driven motivations tend to characterise reshoring more frequently than offshoring.

**Chinese outward FDI to developed economies**

The recent phenomenon of Chinese outward foreign direct investment (OFDI) to advanced economies is reshaping the global business landscape in many ways (Deng et al., 2017). However, the motivations behind such operations remain unclear. While mainstream theory tends to assume that firms internationalise to exploit competitive advantages, it has been found that Chinese firms, on the contrary, generally internationalise in order to address competitive disadvantages (Child and Rodrigues, 2005). Extant literature suggests that Chinese OFDI to developed economies is mainly driven by the search for strategic resources, such as superior skills, marketing expertise, and proprietary technologies (Deng, 2007; 2012). In particular, when investing in developed economies, Chinese firms tend to seek sophisticated technology or advanced manufacturing know-how by acquiring foreign companies or their subunits that possess such proprietary technology (Luo et al., 2010). Additionally, Buckley et al. (2008) point out that while knowledge acquisition has become increasingly important to Chinese MNEs, much of Chinese investment in some developed economies is also resource seeking, in addition to the appeal of developed countries’ markets (Child and Rodrigues, 2005). In terms of firm characteristics, it is revealed that Chinese firms with high state ownership are likely to focus on developing markets, whereas firms affiliated to a higher government level increase OFDI in developed countries (Wang et al., 2012). Specifically, large State-owned Asset Supervision and Administration Commission (SASAC) controlled firms are especially attracted to richer developed markets (Ramasamy et al., 2012).
Methodology

Two independent databases were used, while adopting homogeneous procedures for gathering and classifying data. Regarding manufacturing backshoring from China to North America and Europe, the database built from secondary sources of Ancarani and Di Mauro (2018) was used, and backshoring cases originating from China and directed to Europe and North America were extracted (468). Regarding manufacturing offshoring from China to North America and Europe, an analogous database was built using secondary data extracted from Chinese press sources (113 cases). The use of secondary data is granted by the fact that the phenomena of Western companies’ reshoring from low-cost countries and Chinese offshoring to high-cost environment is unfolding and ongoing. Therefore, newspaper articles, as a type of secondary data, can provide timely and pertinent research source (Yeung et al., 2016) to assist in capturing the essence of these contemporary events in a longitudinal context.

For the backshoring database, a data set on backshoring from 2011 to the end of 2017 was developed by gathering information from several sources. First, the historical archives of relevant international business newspapers, national-level newspapers and business magazines were considered. Then, articles adopting selected keywords (reshoring, back-shoring, backshoring, nearshoring, back-reshoring, insourcing, on-shoring, in-shoring, reverse globalization, relocation, repatriation in combination with manufacturing) were searched for. Additionally, white papers by major consulting companies (e.g. Boston Consulting Group, McKinsey, Accenture and Grand Thornton) were also reviewed. Finally, internet search engines with the above-mentioned keywords were used to further check that no relevant news concerning reshoring was missing. With respect to US companies, data collected by the Reshoring Initiative (www.reshorenow.org) was also gathered.

For the offshoring database, the following steps were taken in collecting the data. First, we searched for newspaper articles that used offshoring-related keywords (namely, moving production to, start production in, and establishing a factory in) together with the names of developed economies as listed in the UN’s most recent country classification (https://www.un.org/development/desa/dpad/wp-content/uploads/sites/45/WESP2019_BOOK-web.pdf) in the CNKI (China National Knowledge Infrastructure) database. The CNKI is China’s largest and most comprehensive academic online library, covering more than 600 core full-text Chinese newspapers (CNKI, 2019).

Two of the authors are native Chinese speakers and the working language of the research team is English. The authors held meticulous discussions and reached a consensus on the translation of each keyword and motivational factor extracted. A keyword table in both the Chinese and English languages was created to ensure transparency and traceability. The researchers then used internet search engines, namely Google and Baidu, to search for magazine articles and company news releases, using the above-mentioned keywords to further check that no relevant information concerning the moving of manufacturing from China to high-cost environments was missing. The entire data mining process was conducted manually by the researchers.

For both of the databases, we carried out pre-testing with twenty sources, to ensure that the researchers used aligned inclusion and exclusion criteria for all cases. For the backshoring database, the unit of analysis was the single decision/project to move back offshore activities. For the offshoring database, the unit of analysis was the single decision/project to move manufacturing from China to high-cost environments. We counted two cases if a company has reshored production from two different host countries/moved production from China to two
different high-cost host countries. Chinese firms’ overseas production activities involving joint ventures with local firms, mergers and acquisitions of local firms, and natural resource exploitations were excluded. The agreed criteria were then applied to the entire sample.

For data analysis, we applied a content-analysis method inspired by Krippendorff (2004). The purpose was to identify the various motivational factors influencing firms’ manufacturing backshoring/offshoring decisions. The motivational factors were inferred from company interviews reported in the articles, or from reporters’ descriptions of each case. As the process of extracting motivational factors from large blocks of text and categorising them is interpretative, to avoid misinterpretation, the researchers reviewed each case and categorised their observed motivations independently. Then the results were cross-validated. In the case of different results, the researchers reviewed the source article together, discussed meticulously, and reached an agreed decision.

Next, a principal components exploratory factor analysis (EFA) was performed to discover the structure of the identified motivational factors and build aggregated motivations. Varimax rotation was employed to generate interpretable scores and factor loadings. The results from the two independent databases are presented and compared in the below section.

Results

The backshoring sample is entirely made up of private firms, 60% of which are SMEs. In terms of reshoring country, 58% of firms return to the US and the remaining proportion to EU countries. Most prominent industries are textile and clothing (19%), electronics (18%) and machinery (16%).

In the Chinese sample, the EU countries and North America are the two most significant areas represented. Developed Asia and the Pacific is the other area featured. The sample includes cases of offshoring by Chinese firms from a variety of manufacturing industries. A few industries – clean energy, food processing, automotive and household appliances – stand out due to the higher number of cases. In terms of firm ownership, the vast majority of firms that have engaged in offshore manufacturing are private firms, with only a minority of firms being state-owned. In addition, almost all of the firms are large firms, with only a small handful being SMEs. A breakdown by host country region, firm size, and firm ownership type reveals that Chinese SMEs only offshore manufacturing to the EU countries, while large Chinese firms mainly offshore manufacturing to North America. The vast majority of private Chinese firms offshore manufacturing to North America and the EU countries, whereas North America is the destination for half of the SOEs.

The EFA procedure allowed identifying ten higher-ordered factors with eigenvalues higher than one that drive Western firms’ backshoring behaviour (see Table 1). These factors account for 64.03 percent of variance. Western firms’ backshoring activities are motivated by responsiveness, quality, direct costs, total cost of sourcing, hidden costs, innovation, brand recognition, lack of skills, and loyalty. For the Chinese sample, two highly frequent motivations (market expansion and changes in tariffs and taxation) were excluded from EFA because of their very low correlation with remaining motivations. EFA led to identify four higher order factors that drive Chinese firms’ offshoring activities (see Table 2), explaining 72.72 percent of the total variance. Chinese firms’ offshoring factors include responsiveness, quality, cost, and customer proximity.

Discussion
We start by comparing offshoring factors identified for Chinese firms with offshoring motivations in previous literature. As already discussed, cost has been widely considered as a factor for manufacturing offshoring towards low-cost countries (Roza et al., 2011; Ellram et al., 2013; Linares-Navarro et al., 2014; Tate et al., 2014; Di Mauro et al., 2018), while market expansion and strategic asset seeking have been used to explain Chinese firms’ outward FDI toward advanced economies (Deng et al., 2017; Li et al., 2016). However, same for the case of
Chinese firms’ offshore manufacturing to high-cost countries, and thus deserve further research attention.

By comparing the EFA results of the two samples, our study shows that there is overlap as well as differences in motivational factors between the phenomena of Chinese manufacturing offshoring and Western manufacturing reshoring. Although previous studies suggest there are disconnections between the motivational factors for reshoring and offshoring, as offshoring is driven by cost-related considerations whereas reshoring is motivated by value-related factors (Fratocchi et al., 2016), our research finds that offshoring can also be motivated by value-related considerations (Fratocchi et al., 2016) and by strategic seeking motivations other than innovation.

Overall, our results suggest that Chinese offshoring to advanced economies and Western backshoring are both motivated by the need to lower total manufacturing costs, increase responsiveness, and achieve higher perceived quality. The motivation to lower total manufacturing costs is especially apparent in the case of Chinese textile firms’ offshoring to the USA, where the labour costs are higher, but other costs such as international logistics, utilities and raw materials are lower. Quality-related factors such as the “made in” effect, commonly known as the country-of-origin (COO) effect, also represent an important motivation for Chinese firms’ offshoring activities. In terms of differences between the two samples, market expansion and changes in taxation are the two most prominent and unique factors for Chinese offshoring, while innovation, lack of skills, brand recognition, and loyalty to home country are motivational factors unique to Western’ firms’ backshoring activities.

**Conclusion**

In this research, we set out to understand the similarities and differences between manufacturing backshoring and offshoring from China to high-cost countries. By analysing two unique databases, we compare backshoring and offshoring motivations. Since manufacturing location/relocation from low-cost to high-cost countries is a novel research topic and empirical evidence is rather limited, we thus provide a better understanding of these current phenomena and enrich the extant body of knowledge. Interesting findings have emerged from the preliminary comparative analysis of motivations. First, our research finds that flows from China to high cost countries (whether offshoring or backshoring) share some common drivers such as allowing proximity to customers, exploiting the “made in” effect, and seeking specialised resources. These results highlight reasons why manufacturing may expand its presence in Western countries as a result of both repatriations and of foreign direct investments from large economies such as China, and therefore point to potential areas of policy intervention.

Abstract

The adoption of best practices in project management depends on the existence of an infrastructure for supporting project managers and teams. Companies have created Project Management Offices (PMO) for this purpose. This research presents an investigation carried out in final phases of an action research for implementing a PMO to support new product development (NPD) process in a high-tech company. Results suggest that in NPD projects, activities of “logistic support” as prototype-parts planning and control can help PMOs to reduce tensions in the project’s work climate, because they bring PMO personnel to the value-added chain of the project.

Keywords: High-technology industries, Product development, Project Management Office.

Introduction

The adoption of best practices in project management (PM) depends on the existence of a minimum of infrastructure supporting project managers and teams. Companies have created Project Management Offices (PMO) for this purpose. According Crawford (2002), a PMO is an organizational structure established to facilitate PM activities and bring improvements to the organization's management by managing the portfolio and aligning projects with corporate strategy.

The implementation of PMO is an issue that deserves attention, due to: the difficulty in properly dimensioning it in terms of size, standards, procedures and training of qualified people (Aubry and Brunet, 2016); the cultural barriers involved (Crawford, 2002); and even external issues such as the decision structure, strategy and project portfolio management of the company (Bredillet et al., 2018). In spite of researches carried-out in the last ten years, the literature often reject predictive manners of PMO implementation, because of its intrinsic strategy-structuring process.
High-tech companies have complex projects running and often coexist with several of them in parallel. Therefore, the obstacles to the adoption of PMOs are especially important. In these companies, support resources are often seen as a waste and PM techniques as "bureaucratic" methods that decrease creativity and speed (Jugend, 2015).

This research presents an investigation carried out in final phases of an action research in which a research group helps a high technology company to implement a PMO for support their new product development process. In the research, the group implemented a set of activities, and at the end, they submit a questionnaire to the company people for gathering data from satisfaction with PMO functions. This paper discusses the results of this questionnaire.

Theoretical background

Authors as Kerzner (2006) and Heldman (2003) named PMOs differently: strategic Project offices; Project support office; program support office; Project management office; project management’s support office; and program office. According the authors, the first PMOs happened in military, aerospace and civil construction projects in the middle sixties.

At the end of seventies to the middle eighties, as Project management software started to be common, these offices were expanded to other areas. Technical people started to be located on PMO for supporting Project activities. At the end of eighties and middle of nineties, those PM software increased their capacity for monitoring and controlling Project efforts enabling PMOs for working in multi-project contexts, and alignment among projects and business strategies.

According Crawford (2002), a Project office can be as simple as few people working in scheduling, or many people working on planning, monitoring and reporting. PMO models must be in accordance to company demands. Some authors classify them in function of their report functions in the company hierarchy (Crawford, 2002) or according to its main functions (Hobbs and Aubry, 2008), or even according to its control over project machine (Project Management Institute, 2017).

Dai and Wells (2004) compare PM practices and performance in companies with and without PMO. These authors identify more effective PM practices in PMO-supported companies, especially in terms of better PM methodology implementation and high-level of lesson learning processes. Mullaly (2006) analyses PM practices in Canadian and North-American companies. He observes that more maturity levels imply on better Project performance, and relates these results with the presence of a Champion for implementing PM practices. On the other hand, Crawford (2006) suggests that a PMO dedicated to support or to direct projects drives more maturity in PM practices.

Hobbs and Aubry (2007) studied functions and typologies of PMOS. They identified groups of functions that generally comes together in PMO operations. Some functions relates to monitoring and control Project performance, others focus in PM competencies and methodologies. A third group base their activities on multi-project management. A fourth group is oriented to strategy management, and the last one is directed to organizational learning. From the 27 researched functions, three could not be statistically grouped: perform specialized tasks, manage client interfaces, and recruit, select and define salaries for Project managers.

Aubry, Hobbs e Thuiller (2007) point a tendency in research PMOs under a positivist background resulting in difficulties to understand and manage them. Hobbs and Aubry
(2007) identify in a large variety of forms and functions, the difficulty for define PMOs in general. These authors found that monitoring and controlling functions are more common in PMOs, and conclude that PMOs reinforce PM maturity and vice-versa in a virtuous cycle.

Julian (2008) studied the role of PMO leaders on knowledge transfer among projects. He identifies an approach focused on poor performer projects, which generates a defensive posture from Project personnel. Hobbs, Aubry and Thuillier (2008) thought PMOs as organizational innovation elements. They found for the first time that PMOs transitions in terms of functions they perform along the time. They also mapped the main tensions that PMOs face in companies. According the authors, the myriad of PMOS found are direct consequences of mentioned tensions:

- economic relating PMO costs and Project performance;
- political meaning disputes over Project mandates and reports about success or failure;
- client relationship, internal or external ones;
- the trade-off among standardization or flexibility of PM procedures; and
- control over the Project resources between PMO, Project managers and functional managers.

Project Management Body or Knowledge (Project Management Institute, 2017), the most popular PM framework states that there are several types of PMOs in organizations according “... the degree of control and influence it has on projects within the organization”. They identify the following types of Project offices: (1) supportive, with low control on projects, mainly providing consultancy and serving as Project repository; (2) controlling PMOs that provide support and require compliance to frameworks, methodologies and governance issues; and (3) directive, with high power over the projects taking control of them and demanding reports from Project managers.

This summary of PMO research shows they are subject to a large set of tensions and issues related to the fact that projects are temporary, and organization must to evolve continuously. Directive PMOs provide success in short time, but can strive organizational climate in the medium and long-term horizons. In spite of monitoring and control functions be necessary for company governance, they do not create value on project chains (Barbalho and Martins, 2019). The PMO researched in this study must to control project progresses, but other functions were necessary for creating a positive climate for PM practices and also for helping teammates in delivering project results.

**Methodology**

This research project as a whole was conducted under an action research approach (Coughlan and Coghlan, 2002), but the final phases here presented were planned and executed only by researchers for analysing the entire effort, and correct guidelines. A questionnaire was built and the personnel of the company involved in projects under influence of PMO implementation were asked to answer it.

The set of activities supported by the PMO were listed, but not classified according their dimensions of supportiveness, control or directive approach. Our goal was to understand the profile of satisfaction with PMO activities for suggesting guidelines for PMO implementation in this kind of company. The literature suggest that engineers are contrary to bureaucracy and their technical background commonly blind them to managerial demands of companies (Mintzberg et al., 2002).
Researchers submitted the listed activities to project teams. Instead of only listing activities, researchers converted them on affirmative and positive statements. For example, for progress reporting, one positive sentence evaluated its function for project status communication, and another evaluated the background it generates for improving project performance.

Nine developers from 21 involved on the projects researched answered the questions summing up 43% of people from projects impacted. This sample allow mixing personnel from different engineering backgrounds as mechanical, electrical and thermal technologies. They answered about their agreement to the affirmative statement in a likert scale written as “total agreement”, “agreement”, “indifference”, “disagreement” and “total disagreement”. All nine developers were interviewed for this research in form to explain about the PMO practice questioned, the statements and scale. PMO personnel were not involved in these meetings for interviewees.

Results

The researched company is a medium sized Brazilian company specialized on optomechatronic products. It develops and manufacture high precision surgical equipment for ophthalmology, satellite cameras for environmental monitoring, and defence products. In the time of this research, the company employed 350 workers, from which almost 60 engineers and highly specialized technicians. Only more impacted personnel were included on this research, mainly those senior engineers who are working on new project’s execution.

The context of this research is a situation in which a large new project started. Before it, the company develop mainly medical equipment, and had few projects from defence industry. The new project double company revenues and demanded more attention on project management issues. It was full of milestones and predicted fines for delays. A department unit previously in charge of quality audits was assigned to implement project management practices. This group started the PMO here researched. For doing this, it personnel ask for a research group in a large Brazilian University for help them on implementation, especially because of cultural resistance internal to the project teams.

Along of the action research, and as demanding by new contracts, the research group jointly to the PMO personnel, implemented some monitoring and control activities in form to prevent the company of fines by delays. These activities stay on traditional PMO functions according Hobbs and Aubry’s classification. A previous survey with project teams and managers had showed a degradation in work climate, because of pressures for project management compliance.

These results were interpreted as a necessity to add activities to comply with requests of a supportive and less mandatory profile of PMO actuation. These new set of activities were not contractual, but necessary for help project teams to organize and increase productivity without directly perform new tasks; and because of internal politics affecting work climate. They were implemented also for non-contractual projects; because the company senior managers would like that medical equipment projects had the same treatment of aerospace and defence efforts.

Table 1 presents the whole list of activities implemented by the PMO for PM process improvement, even before of adding tasks for avoiding PMO-teams conflicts, and the questions submitted for project teams as affirmative statements.
Table 1 – List of PMO activities and questions to evaluate them

</tbody>
</table>

After submitting these questions for project personnel, the research group classified them following the groups of functions identified by Hobbs and Aubry (2007). The type identified as "A" presents activities with a profile related to the monitoring and control of the project activities, that contractual agreed demands. They are performed under a controlled approach, according Project Management Institute (2017) classification. Activities of type "C" are those that can be considered as organization and control of documents and results of the project, denominated by the authors of "organizational learning". Activities of type "B" were related to the logistic activities added to the PMO to reduce the barriers imposed by the tension established between PMO and project teams and managers, as already discussed. They are thought as services provided by PMO to teams in form to reduce time pressures over project deliveries, a kind of partnering role as stated by Müller, Glückler and Aubry (2013). Activities “B” run through a traditional supportive framework (Project Management Institute, 2017).

Table 2 presents the results of interviews for evaluating the questions.
Table 2 – Agreement and disagreement with PMO activities

</tbody>
</table>

The results presented in Table 2 merge profiles of disagreement and agreement in form to facilitate the discussion of results. In general, the designers interviewed considered PMO activities effective for helping them. We observed that the activities within the typologies "B" and "C" have a high percentage of satisfaction of the company's engineers, while the "A" type activities have almost the same level of "disagreement" and "agreement" in terms of satisfaction.

The results indicate that the activities with greater character of control over the work of the engineers were considered unsatisfactory according to their perception about the services offered by the PMO. PMO practices that support the daily activities of project personnel, such as monitoring the manufacturing status of parts, procurement of components, etc., were more satisfactory. The organization and control of the documentation generated in the engineering sector were almost as satisfactory as those of logistical support were, but the degree of responses that consider the service "indifferent" is greater, and its level of dissatisfaction in lower. As logistic support demands some inputs from designers for enabling the management of parts, materials and processes, this kind of activity has a major level of control than working with project documents. It means the lower the level of control, the higher the team satisfaction with PMO activities.

During the time of this research, the PMO develop and maintained schedules from 12 different new product projects, built and release progress reports from two large projects for 15 months, requested more than 2900 production orders, manage them and deliver their parts, materials and processes for helping project teams in design-build-test cycles. In this time, the PMO coordinate twenty-five week meetings for time monitoring and manage more than 200 documents from medical equipment and more than 500 from aerospace. These practices started to be monitored by performance indices. Summarily, in the beginning 3,5 days by a manufacture order are spent, and this indicator decrease to less than 2 hours lead time in average. Acquisitions for imported items decrease from 140 days to 50 in average, and projects cycle-time reduced from 1800 days to 260 days.

In general, the data allow us to infer that, although the PMO practices were considered very positive by the project personnel, this degree of satisfaction is strongly determined by the support activities for manufacturing the prototypes while the effective project management activities present a degree of satisfaction considerably lower than the others. Actually, if each type “A” activity would be analysed separately, some of them, as progress reporting issues or develop project schedules, are almost totally dissatisfied by respondents.

**Conclusion**

This article summarizes an effort to implement a Project management office in a company that historically developed medical equipment and was working on large
development contracts of aerospace industry. A pre-existent group of quality audits were assigned to implement Project management functions. The pressures over Project personnel to comply to PM functions and also deliver product results bring conflicts among them and PMO personnel. A new set of functions were implemented in form to increase partnering work among these groups as a way for decreasing tensions.

This way of working corroborate to previous literature in terms of conflicts in PMO structuration (Aubry, Hobbs and Thuillier, 2008) and PMO roles (Müller, Glückler and Aubry, 2013).

In this research, all new activities performed by researched PMO were submitted to project personnel for an analysis of satisfaction. Supportive functions are more satisfied for project personnel, such as monitoring parts, materials and processes necessary for manufacture product parts to enable assembling and tests. More control-based activities, traditionally implemented in project management efforts are less satisfactory as understood as project teams, which corroborate to previous literature on PMO tensions.

These results suggest that in new product development projects, activities of “logistic support” as prototype planning, prototype-parts purchase, prototype-parts production planning and control, can help PMOs to reduce tensions in the project’s work climate, because they bring PMO personnel to the value-added chain of the project. In other words, this kind of activity brings PMO to the project schedule. Consequently, teammates stop to see PMO works as only mandatory-based actions and start to see them as partners for project results.

Main limitations of this work stay on the unique case approach. More research must be done for confirm if and in which conditions the kind of activity of logistic support really help project teams and PMO personnel for improve project results and reduce tensions in new product projects.

Abstract
Recognising that sustainability in project management is a nascent field. For the need to build integrated models to support the development of an accepted school of thought, this paper uses the Deception Impact Model to explore the impacts from the current Boeing 737 MAX case to explore the impact of deception in the context of different phases of sustainable project management: product design, certification, and training. We highlight the importance of tracking deception in sustainable projects considering the severity of deception as the project moves through different stages and its impact on stakeholders and broader society.

Keywords: Sustainable project management, Ethical Practice, Deception,

Introduction
Sustainability in project management is a nascent field. Currently accepted schools of thought in project management include the optimization school, the governance school, the success school, the decision school and the process school. When analysing the components of a school of thought, three criteria defining a school are commonly acknowledged. These incorporate a shared vision or perspective and common methods and tools, a community in relation to an established publication base, and finally impact in terms of integration into practice and standards (Silvius, 2017). Recognising the global community acceptance of sustainability per se, evidence of increasing research and publication in this area (Silvius and Schipper, 2014; Silvius, 2017), and viewing the emerging discussion in terms of impact and integration of practice and standards (Hammadi et al., 2018; Silvius, 2017), it could be claimed that sustainability in project management is an emerging school. To further elaborate on the characteristics that
define the sustainability school of thought, Silvius (2017, p. 1491) presented four commonly shared characteristics relating to the criterion content: considering projects in a societal perspective, having a management for stakeholders approach, applying triple bottom line (TBL) criteria, and taking a values based approach to projects and project management. Thus having established the existence of the sustainability school of thought in project management, it is incumbent on researchers to explore the relevant criteria to develop and build the school of thought.

Hammadi et al. (2018) demonstrated the outcome of activities within business as being increasingly far-reaching and impacting at societal levels, they questioned the upstream and downstream impacts of activities on stakeholders and customers in the context of supply chain activities, investigated how this related to the triple bottom line of an organisation and queried organisation’s taking a values-based approach to decisions at the strategic and operational levels. An outcome of this approach was the establishment of the use of deception often resulting from a gap between strategic CSR or sustainability goals and implementation of standards and practice. Indeed, one of the dangers highlighted by Prasad and Holzinger (2013) is the false implementation of CSR in companies and their projects as this runs the risk of turning this sustainable strategy into a simple marketing strategy that helps the company to make money without really inserting it in their processes and projects.” (Marcelino-Sádaba et al., 2015).

The result of the integration of these dimensions when applied to ethical decision making in operations provided the foundation for the development of the Deception Impact Model (DIM). Drawing of this model and the principles of sustainability - economic, social and environmental - the aim of the current study is to explore sustainable project management by examining the current case of the Boeing 737 MAX, a project increasingly exhibiting the antecedents in terms of deception at a range of product design phases and project life cycle stages that clearly demonstrate that this project is not sustainable due to the use of deception.

The latest events of the Boeing 737 MAX demonstrate the disadvantage of the project (with 346 death on two flights/crashes - 157 Ethiopia/189 Indonesia) direct outcomes and the delayed impacts these might have on the triple bottom line. Project looks good, one event shows that the planning and execution might have involved deception to “cut curves”. The aftermatch investigations reveal a lack of control, external independent inspection, stakeholder satisfaction, market competition, and downgrading risks.
New product development projects from a supply chain point of view include upstream and downstream stakeholders. New product development projects for sustainable products are complex, mainly due to the challenges of integration of sustainability dimensions into the processes of project management. These challenges include engaging stakeholders, project procurement, project risks, project communication, and the determination of the project team (Silvius, 2017). Not integrating sustainability dimensions may result in the end product that achieves project outcomes for one dimension of sustainability but at the cost of other dimensions. The gap between stated sustainable objectives and actual outcome of the project (not integrating all sustainability dimensions) is termed as Color-washing which is a form of deception. Figure 1 depicts that projects are difficult to manage if we include sustainability requirements and involve stakeholders globally. We notice that with small group of stakeholders or in a close group in a project the severity of deception is not high. But as we involve many stakeholders globally, severity of deception may increase because of the fact that aims of these stakeholders may be conflicting, so it is difficult to obtain sustainability outcomes from sustainable project management. In sustainable project management, stakeholders role is important in determining the sustainability objectives of the project. It is not an easy job, since the interests and aims of the stakeholders in a project may be conflicting and give rise to deception. The role of the focal firm is to balance/integrate these objectives by focusing on operations or by changing operations.

The purpose of this paper is to highlight the importance of tracking deception in sustainable projects by considering change in severity of deception as project moves a focal firm from one state to another state and to determine the impact it has on consumer.

**Background on Project Management**
Projects in operations management are characterised by their unique and generally resource-constraint objectives to implement organisational change. Projects are driven by exogenous factors to initiate a response to a changing situation or environment, with the expectation to exert positive impact for the executing organisation. Project,
Operations and supply chain management are closely related, projects are often considered as the start of operations and have similar functions, if not identical, to those performed in operations management (Waller, 2003).

Projects, or their proposals, can be the response for an external future opportunity (e.g. bidding on large construction projects), changing market situation (e.g. changed competition on primary markets), or organisational change (new manufacturing process, change of strategy or management). Projects and their objectives must contribute to the corporate strategy, and it is successful when these objectives are accomplished within the given constraints. Projects are unique and temporary, involve many non-routine and complex tasks for specific deliverables or work products, and therefore face heightened levels of risks and uncertainty when contrasted with day-to-day operations (Slack and Brandon-Jones, 2018).

Managing a project often requires trade-offs and compromises, to ensure successful completion of the project. It also requires the ability to solve problems, set goals, and compromise. It is these goals that determine the process of planning, testing, evaluating and monitoring the improvement progress. A complex project requires a more detailed and comprehensive scope. Strong commitment in the definition phase of the project life cycle can result in less room for later changes during project execution and cause a team “lock-in” status, encouraging the team to find short-cuts if milestones cannot be achieved.

Climate change and therefore focus on sustainability has brought sustainable business practices to the forefront. Corporations today are under pressure to maximise returns for investors and need to conduct activities that are less detrimental to the environment and society. Project managers have to commit to the concept of Triple Bottom Line and implement sustainable practices to fulfil this. Multiple stakeholders, both public and private, are often acting with conflicting interest and different levels of influence are involved in the decision making and planning process (Aaltonen and Kujala, 2010). Furthermore, different user stakeholders have different internal opinions and are likely to have different interpretations and expectations of what will be produced (Atkinson et al., 2006).

![Figure 2: Criteria for sustainable project management (Source: Wang et al., 2014, p. 248)](image)

Silvius and Schipper (2014, p. 79) define sustainable project management as “the planning, monitoring and controlling of project delivery and support processes, with consideration of the environmental, economic, and social aspects of the life cycle of the project resources, processes, deliverables and effects, aimed at realising benefits for stakeholders and performed in a transparent, fair and ethical way that includes proactive...
stakeholder participation.” Wang et al. (2014) summarises this clearly in Figure 2. Many definitions of sustainability encapsulate the intergenerational aspect to meet the present needs without harming future generations to meet their own needs (Bruntland, 1987). Sustainability ensures that the project contributes to the sustainable business of delivering goods and services for the project duration and to the future generations (Tufinio et al., 2013), thus ensuring the project lifecycle is integrated in sustainable project management. The United Nations also recognises the global importance of sustainability in the UN 17 Sustainability Development Goals (United Nations, 2015). SDG 12 of the 2030 Agenda for Sustainable Development aims to ensure sustainable consumption and production patterns along the entire supply chain “needs to be significant focus on operating on the supply chain, involving everyone from producer to final consumer” (United Nations, 2015).

Contrasts in characteristics between project management and sustainable project management relate to time orientation (short vs. long), intergenerational interests (stakeholders vs. future generations), objectives (deliverables vs. life-cycle), scope (time/budget vs. people/planet/profit), and complexity (reduced vs. increased) (Silvius et al., 2012, p. 167). This establishes the need to investigate the integration of sustainability and project management in an ethical approach, addressing the economic, social and environmental goals of the project whilst acknowledging the project stakeholders. Such a challenge requires exploration of customer impacts, deception, and implementation of TBL whilst acknowledging the characteristics of project management.

Emerging competitive markets and government regulations can compel organisations to meet certain standards. State agencies are responsible for the enforcement of public regulation have had very limited influence over corporate practices (Santos et al., 2017). On the other hand, the government agencies lack the capacity to enforce increasingly complex policies of environmental and sustainable development legislation (Labonne, 2016). Often the practice of industries engaging in self-monitoring with their measurement leading to the industry cutting corners to deal with growing economic pressures.

Figure 3: Deception Impact Model (left) and example for project trajectory (right)
Deception Impact Model for Project Management

The Deception Impact Model (Hammadi et al., 2018) is to set the severity of deception in the context of how organisations recognise the TBL as a strategic value and how consumers perceive the organisation. Figure 3 shows on the left the distinguished cubes describing the states we consider for an organisation; see Hammadi et al. (2018) for more details. The dimensions (deception, TBL, impact on the consumer) can be seen as a driver (progressive transition) or risk (regressive transition) organisations face and require consideration when defining strategies or values. Project management defines trajectories from initial positions (current states) to anticipated positions (objectives) for a (positive) change along all dimensions. Figure 3 shows the trajectory $t_i$ from $s_i$ to $s_{2i}$, improving the TBL as well as the impact on consumers. The dotted vectors ($r_j$ to $r_s$) exemplify risk implications the project can experience. Here, each risk implication represents a TBL dimension; e.g. change on financial markets (economic), blocked approval due to protect animals (environmental), or causing long-lasting health impacts (society).

Even though the intention of the project is not deceptive, external causes can shift the mind toward the compensation trajectory $c_j$ of the occurred risk. To fulfil the objectives, it might be necessary to apply deception despite original intentions for the project; i.e., if the project might fail otherwise. As shown in Figure 1, the outcome is matching the objectives. The following section demonstrates the application of DIM using the latest Boeing scandal as an example.

Case Study Boeing 737 MAX

The current unfolding of the Boeing 737 MAX project after the crashes in Indonesia and Ethiopia with 346 deaths show how predominantly sustainability objectives caused in a chain of strategic and operational decisions the negative impact for all stakeholders including society. This section depicts the events and potential cases of deception. Information was gathered from manifold news articles, reports website; a complete list cannot be provided due to page restrictions. A starting page with references to sources can be found on Wikipedia (page “Boeing 737 MAX”).

Case Description

The market is dominated by two key competitors offering medium and large airliners for the domestic and international flight sectors. Airbus has an extended family of aeroplanes based on the same framework and, thus, requiring only one type of license to operate all variants (e.g., A318-321, A320E, A320neo). Especially domestic low-fare airlines favor operations of only one family of aeroplanes to cut cost for maintenance and operations as well as increased flexibility for crew training and assignment. Airbus’ major success with the A320 family was the A320neo where more efficient engines reduced fuel consumption, emission, and noise (Airbus, 2019).

The Boeing 737 MAX project started on August 30, 2011, when Boeing under the pressure of their customers (airlines) and competitors (Airbus) decided not to develop a new aeroplane type but re-engineer the Boeing 737 aeroplanes with better fuel efficient engines. The project was thought of as a masterpiece as the new fuel efficient but larger in diameter engines initially resulted in difficulties due to the lower space under the wings and the changed aerodynamics during certain flight maneuvers. Boeing obtained (Federal Aviation Administration) FAA certification on March 8, 2017. The first delivery of Max 8 aircraft was to Malindo Air on May 6, 2017. The new Boeing 737 MAX was considered similar to other aeroplanes in the product family (Boeing 737),
thus airline pilots and crew members did not have to go through a time- and cost-intensive training program but could use digital training material as a source for handling differences.

When the project was launched, the initial aim of Boeing was to achieve 16% lower fuel consumption than Airbus A320eco and 4% lower than the A320neo through its newly designed engines. In terms of sustainability this was set to achieve less carbon emission and quieter engines.

In both crashes, the MCAS software was identified as a critical cause. Originally implemented to compensate for the changed aerodynamics problems resulting from a rushed re-design to retrofit larger engines in the Boeing 737 family, it relied on sensor data to be activated and take over control from the pilots. For both crashes, a combination of errors in the software, ineffective warning about wrong sensor reading, and lack of proper training is supposed to be the cause for the dramatic outcomes and the long-term grounding of the Boeing 737 MAX worldwide.

**Failures and Deception**

Regarding DIM, the corporation Boeing could be considered in the “Loss of Market” state when the project for the Boeing 737 MAX started. Here, Boeing negatively impacts on stakeholders (airlines) with no immediate response to the A320neo. The intended project objectives to develop a new plane failed to regain the anticipated impact with the stakeholders as it would not be economically feasible (negative impact on the TBL dimension). Boeing decided, despite the technological challenges, to refurbish the existing Boeing 737 with advanced engines; including the choice to cover problems in aerodynamics with software “patches”. The misinformation about the severity of the decision and potential risk was part of the design stage of the project.

![Deception Impact Model](image-url)

**Figure 4:** Deception Impact Model (left) and example for project expectations and trajectory for deception (right)
Figure 4 shows an anticipated position in the “Loss of Markets” state with an expected trajectory for the project, gain on the TBL dimension resulting from the new Boeing 737 Max) as well as having a competitive response to the A320neo. The number of orders and positive introduction confirmed the expected trajectory to the “Maturity” state; until the first incident raised negative publicity. Further, risk implications can be mapped in DIM to visualise the impact of the occurrence of a particular risk. For example, r1 represents an increase in sustainability (e.g., lower fuel consumption) but acceptance by the stakeholders (airlines, customers) is decreasing. According to revealed information after the crashes, Boeing considered that case but decided to deceive the airlines with multiple actions; see below. Figure 4 is representing the project design stage; during the project implementation the position, as well as risks and expected impacts, have to be updated.

The project Boeing 737 Max caused multiple problems throughout the product life cycle, from changing the sustainable objectives of a new plane to satisfying customers regarding a short time to market and replicating the product family extension for lower operating costs. Without replicating the full reports on this case, we depict critical incidents to demonstrate how the DIM can map Boeing over time.

In the production phase of the project, one of the main suppliers of thrust reversers for the engine, the GKN, was not able to fulfil the demand in the short period of time, Boeing switched to Spirit Aerosystems who is the main manufacturer of Boeing fuselage. Supplier problems showed throughout the implementation of the project; confirming the initial rush to regain competitiveness without including suppliers for the feasibility of production rates (increased from 42 in 2017 to 57 in 2019) to fulfil the customer demand (airlines)). The discrepancy between the design and production phase of the project should have been detected in the testing and certification stage.

During the testing and certification phase of the project, the FAA approved the product without much testing. The following problems were detected in the certification process. The process, on the other hand, shows the intention for deception by Boeing:

- one of Boeing’s partner, CFM International, notified Boeing during testing of potential quality issues of the engine manufacturing. Boeing largely ignored them.
- during the certification process, FAA delegated parts of the inspection to Boeing or Boeing staff working for the FAA. The main reason was time pressure, lack of qualified FAA staff, and budget to evaluate the Boeing 737 MAX.
- creation of the MCAS software to fix problems with the aerodynamics.
- insufficient testing of the MCAS software; resulting in interfering with the pilots.
- lack of redundancy for critical sensors; supportive systems sold as extras
- no training for the pilots on the critical MCAS software (or information about it).

In summary, the following trajectory for Boeing 737 MAX case can be mapped in DIM (Figure 5).
Conclusion and Research Outlook

As shown through the Boeing 737 MAX case, the integration of sustainability perspectives including a societal perspective, having a management for stakeholders approach, applying TBL, and taking a values based approach to projects with project management tools provides a sustainable framework for developing impact models such as DIM. The Boeing case depicts the need for more research on mapping organisations in DIM and understand their trajectory to identify cases of deception before the damage to the TBL has happened. Boeing is one of many organisations in the recent past to admit taking advantage of disguising their malicious actions in complex supply chain networks.

This paper introduces the DIM for sustainable project management. The ongoing research is looking further into quantifying the positioning on the three dimensions in DIM using big data analytics for identifying anomalies in the literal search for the needle in the haystack.

Abstract

Using a practice lens, we investigate the role of project team members’ actions in constructing the social order and aligning inter-organisational elements to achieve digital congruence when implementing a digital and systemic innovation in construction projects, namely Building Information Modelling (BIM). We use a theory-building qualitative research design to induce a propositional theoretical model of key actions enacted in practice (e.g. technology-information management process basis alignment, knowledge integration) that contribute to a successful implementation of BIM. Our findings and the applied practice-based ontological approach extend existing literature by revealing some key conditions underlying how the phenomenon is constituted in practice.

Keywords: Systemic Innovation, Digital Transformation, Project-based Inter-Organisational Networks.

Introduction

Project-based industries, such as the construction industry, are amongst the largest in the global economy (Taylor and Levitt, 2004) and are major contributors to the global gross domestic product (GDP). The slow rate of innovation and low productivity in the construction industry, however, have been historically problematic (Hall et al., 2018). Certain types of innovation, such as systemic innovations, which affect inter-firm processes and redefine how work is done (Hall et al., 2018), are even less frequently implemented in project-based industries, such as construction (Arnold and Javernick-Will, 2013). Nevertheless, this type of innovation has a huge potential to offer productivity gains (Alin et al., 2013; Lindgren, 2016; Hall et al., 2018).

Given the relevance of the construction industry to the global economy and in an attempt to foster innovation in the sector and increase productivity, governments from different countries have included the digitalisation of the construction sector as a part of industry-wide development strategy agenda. Building information modelling (BIM), a type of systemic innovation (Alin et al., 2013; Lindgren, 2016), sits at the heart of
digitalisation in construction. BIM can be defined as the use of a shared digital representation of a built asset to facilitate design, construction and operation processes in order to form a reliable basis for decisions (The British Standards Institution, 2019). BIM is expected to bring major productivity improvements to the industry (Alin et al., 2013).

The digital delivery of projects through BIM is an important emerging phenomenon because as a systemic innovation, it alters the nature of the work of project-based firms and the relations in a project network (Lobo and Whyte, 2017; Papadonikolaki et al., 2019). Research on systemic innovation implementation in construction projects has sought to understand the influencing factors and enabling/required conditions for a successful implementation of systemic innovation in projects (Taylor and Levitt, 2007; Alin et al., 2013; Lindgren, 2016; Hall et al., 2018), such as practices that should be used to enable the multi-firm process of systemic innovation (Hall et al., 2018) and new capabilities that construction firms need (Lobo and Whyte, 2017). In the case of BIM as a systemic innovation, in particular, some international standards recommend information management processes and activities when managing information in projects with the use of BIM (The British Standards Institution, 2019). Existing research and industry standards have therefore focused primarily on the what of systemic innovation implementation and the conditions under which this change is accomplished successfully. Comparatively, how the implementation itself unfolds has been less explored. Understanding how systemic innovation unfolds in practice (Hall et al., 2018) and how it is enacted by people are important, as this is a determinant of the performance of systemic innovation implementation (Alin et al., 2013).

Actually, the majority of existing studies have considered aspects related to systemic innovation in project-based networks and, more specifically, BIM implementation, as entities or things that exist outside the practices and processes of those who enact them. Ongoing calls in the project-based literature have been made for more empirical investigation from a practical perspective and from within, with the aim of better understanding what occurs in practice in projects (Blomquist et al., 2010; Lalonde et al., 2012; Padalkar and Gopinath, 2016) and increasing the relevance of project management research to practice (Floricel et al., 2014; Clegg et al., 2018).

Therefore, we apply in this study a practice lens to investigate the implementation of BIM as a digital and systemic innovation in construction projects. More specifically, we focus on understanding how the alignment of inter-organisational elements following BIM implementation (e.g. process, technologies, structure), namely digital congruence in projects (Kane et al., 2016), occurs from a performative perspective. The practice lens facilitates a theoretical understanding of the constitutive role of project team members’ actions in constructing the social order and aligning inter-organisational elements to achieve digital congruence (Kane et al., 2016) when implementing BIM in a project. We analyse the black box of what happens in the process of implementing a systemic innovation and aligning inter-organisational elements, aiming to answer the following research question: How do project team members’ actions bring about digital congruence in construction projects?

We conceive of BIM implementation and achieving digital congruence in construction projects as both a set of rules aiming to establish social order in projects, making the conditions, work and human behaviour when managing information in projects more predictable and as an outcome that emerges from the application of these rules and alignment of inter-organisational elements over project lifetime. In other words, we draw on the recursive nature of action and social order and their mutual constitution (Giddens, 1984).

Framing the phenomenon from this perspective seeks to contribute to the project management literature in two main ways. First, this study is grounded in the need for research drawn from practice and the need for a plurality in perspectives on project work
that reveals the *lived experience* in projects (Van der Hoorn and Whitty, 2017). Second, understanding systemic innovation, more specifically, BIM implementation, in a project as a process that people enact involves a new ontological perspective. Calls in the project management literature have been made for theorising from new ontological perspectives to provide a more detailed understanding of phenomena as a result of a better understanding of their different facets (Joslin and Muller, 2016).

We begin by positioning the practice lens applied in this study, followed by a description of the research design. We use a theory-building qualitative research design to induce a propositional theoretical model of key actions in order to achieve digital congruence in BIM projects. We then discuss how the practice lens applied in this study allows us to add to existing research.

**Theoretical Framework**

Although project management research streams are based on assumptions of practices, the practice itself has been taken for granted in the project management literature (Hallgren and Soderholm, 2012). Scholars have acknowledged that many of the normative and traditional contributions to project management research are insubstantial in terms of understanding what occurs in projects (Blomquist et al., 2010; Floricel et al., 2014). More research on what project members do in projects is needed, rather than more research on the confirmation of best practice models (Blomquist et al., 2010; Lalonde et al., 2012).

Actually, the proponents of a project-as-practice approach argue that both practical and theoretical advances can result from studying the concrete actions of project participants (Floricel et al., 2014). These theoretical and practical developments can result from applying a practice-theoretical framework in the following three ways (Feldman and Orlikowski, 2011): i) through an empirical focus on how people act and the importance of practices in the ongoing operations of organisations, ii) through a theoretical focus on understanding the relations between the actions people take and the structures of organisational life and iii) through a philosophical focus on the constitutive role of practices in producing organisational reality. Through a philosophical paradigm, the project phenomenon is considered the sum of the actions of the people involved (Van der Hoorn and Whitty, 2017).

The philosophical approach, although less explicit in the use of practice theory in projects, is based on the premise that social reality is made up of practices (Feldman and Orlikowski, 2011). This approach is applied in this study to investigate BIM implementation and the alignment of multiple inter-organisational elements within multiple project team members’ actions distributed across time and space. We use this philosophical approach by considering that BIM cannot be separated from project team members’ actions when working in a BIM project and from the changing social ordering of inter-organisational elements’ alignment produced by these members. In other words, we argue that BIM implementation (information management process using BIM) is not a discrete entity; rather, it is constituted within practices. Through an *ethnography of BIM*, we identify some of the key practices that socio-materially configure it, as explained next.

**Research Design**

Given the nature of the research question, we apply a qualitative method, which is also strongly associated with the practice turn lens (Van der Hoorn and Whitty, 2017). Ethnography is a popular method in practice research (Blomquist et al., 2010). Moreover, calls have been made for rich ethnographic studies when investigating practices in projects, with the aim of understanding human action and managerial action in concrete project situations (Lalonde et al., 2012). We therefore draw on the ethnographic data of eight construction projects at different lifecycle stages by using a from-within (capturing
the experience of those involved in it) and in-the-flow (studying the phenomenon whilst it is being enacted) approach to capture the aspects of digital congruence over time and across projects and to identify project team members’ actions making up such configurations.

The fieldwork was carried out over 10 months (2018–2019), during which the first author of this paper was involved and immersed in the projects, playing the role of observer-as-participant (Bryman and Bell, 2011). The eight analysed projects involved new and refurbished educational facilities in two large organisation estates. All projects were digitally enabled projects, i.e. BIM projects. Estate organisations’ projects were selected through purposive sampling (Bryman and Bell, 2011). As the goal is to investigate BIM as a systemic innovation and to identify project team members’ actions that bring about digital congruence in construction projects over the entire asset lifecycle, we looked for BIM projects in which all stakeholders involved in the building’s lifetime (e.g. client, facilities manager) were a part of the project team, aiming to identify the roles and actions taken by all members when enacting BIM. The collected data include project documentation, semi-structured interviews, access to organisations’ intranet, meetings and workshops, as summarised in Table 1.

For each project, there was interaction with project personnel (e.g. the project manager, the lead designer, the information manager, the contractor, the facilities manager), who were selected for their potential to provide insights into the digital delivery of the project. Table 2 gives more details of the meetings, workshops and interviews associated with each project.

Our analysis followed the principles of grounded theory, starting with a detailed empirical reading and progressing to greater generality (Mantere et al., 2012). It started with a fine-grained reading of the data or a microanalysis of them (Strauss and Corbin, 1990). We used NVivo software to catalogue and code the data. Our first round of coding
focused on identifying descriptions that indicated the *praxis* undertaken by different project team members when working in a BIM project. Then, informed by our research focus, we concentrated our subsequent analytical efforts on identifying some categories of *praxis* that make up digital congruence in projects leading to successful BIM implementation. We derived propositions on some key practices enacted by project team members that led to successful BIM implementation and digital congruence in projects, as discussed in the next section.

Results
As acknowledged in existing literature, systemic innovations require related and complementary innovations (Lindgren, 2016). BIM implementation entails interrelated changes in existing processes by incorporating information management activities. It also requires changes in project structure and the use of new technologies and new skills. Our findings reveal that, in general, BIM is successfully implemented if there is congruence amongst the asset/project strategy, information management processes and activities, BIM skills, information management roles (structure) and BIM technologies as explained next by some of our propositions. That is, the systemic innovation is successfully implemented if an alignment exists amongst the new aspects related to the systemic innovation implementation itself, besides the alignment of the innovation with the existing project structure and existing work practices, as highlighted in existing literature (Taylor and Levitt, 2007; Alin et al., 2013).

Our data reveal a range of actions undertaken by multiple actors to promote the alignment amongst the inter-organisational elements leading to successful BIM implementation. Some of the actions that we have identified are related to the digital set-up of the project. For example, according to existing standards for the information management process using BIM (The British Standards Institution, 2019), one of the first information management activities is the definition of the information requirements by the client, considering organisational, project and asset information needs (i.e. the strategy). The client, however, may not have the experience or knowledge necessary to establish these requirements in a way that the information deliverables will be just enough and in the right format to support relevant decisions over the asset lifecycle and operational phase of the asset, even if an information manager is involved in the process. Therefore, aiming to guarantee the production and delivery of only essential information at the right time and in the right format, our data reveal practices that lead contractors are undertaking to align information production process and deliverables with the needs at the operational phase of the asset and its overall strategy: ‘When we get on board, one of our first actions is to speak with the facilities management system provider and facilities managers in order to identify information requirements. So, then, we can select our suppliers’.

Our data also show that successful implementation requires the client or another representative to take action to specify the information requirements and the level of information for such requirements in order to align the production of the information model and information deliverables considering each lifecycle stage’s needs, as well as to consider the procurement route: ‘So, if the way of procuring would have to change, I think it’s then good for the client to understand what the contractor might want so that it’s embedded in the contract of the design team from the start and doesn’t require rejigging, rehashing’. When the information model is produced in a way that it does not consider the needs of the next project stage, there may be issues, as noted by a contractor: ‘I think it’s fair to say that effectively, we’re taking bits of that, but we have to remodel a large proportion of it to suit how we actually want to use the project’.

Current literature posits that when tasks are more interdependent, the diffusion of a systemic innovation decreases (Lindgren, 2016). We propose, however, that if aligning actions are taken, such as the ones previously described, a systemic innovation, such as BIM, can be successfully implemented, even if the degree of interdependency is high:

**Proposition 1:** BIM is successfully implemented when digital set-up actions are taken to ensure that information production and information deliverables are in alignment with the needs of project lifecycle stages, from design to operation of the asset.
The data also reveal that an alignment should exist between the BIM technologies intended to be used over the project lifecycle and the way the information models are produced, i.e. the information production process: ‘I think 4D is there and has been there, and it’s been used. I think it needs to come with a warning because you wouldn’t 4D everything to the last screw, so it needs to be used for a defined purpose; either it’s general presentation or it’s very specific areas, but if you’re doing 4D, for example, you need your model to be built in the way your programme is built’.

Actions should be taken by project team members to align the information models with the technologies to be used, when necessary, as noted in one of the projects: ‘Look at energy or thermal modelling. So, if you’ve got your building modelled as it is, you can’t just press a button and put it into your thermal modelling software because the software won’t understand any clashes; you need and certain M&E consultancies have developed scripts that basically take this rather complex model of a building and turn it into something that can be digested by the thermal modelling software and then to do something’. Project team members also mentioned that there should be an alignment between the way the information models are produced and the intended use of multiple BIM technologies: ‘In the same way for the 5D. You know, they need to be split in a way that is costed. Now, sometimes, these ways do not match with one another, so what you need for 4D might contradict with what you need for 5D, which is, I would say, another story, another challenge for that’. Basing on these findings, we propose that the practice of aligning technologies and information management processes is critical:

**Proposition 2**: BIM is successfully implemented when actions are undertaken to align the technologies intended to be used with the information production processes and the deliverables.

Our data also show that actions to support knowledge integration, i.e. the process of combining disparate bits of specialist knowledge into a collective knowledge product (Ali et al., 2013), have been undertaken. Contractors are taking actions to align technology use across different disciplines, aiming to avoid interoperability issues, integrate different knowledge pieces properly and increase collaboration: ‘At the technical kick-off, the contractor and sub-contractors were talking about what version of Revit everyone will be using and said, “Right, who has got the lowest version of Revit?” And I think it was 2017, with the engineers saying, “Right, everyone is going to do 2017”; architects are already on 2018. It doesn’t matter. You will use 2017 for this until everybody is ready to go forward’. Basing on our data and consistent with the finding of Alin et al. (2013), we propose the following:

**Proposition 3**: BIM is successfully implemented when actions to integrate knowledge across different disciplines are undertaken.

Additionally, contractors are acting to guarantee the proper alignment between the information management processes and the BIM skills required for the project. Aiming to align the skill bases across the supply chain, some contractors are taking actions to engage the supply chain in aspects such as the information exchange process by using a common data environment: ‘We have supply chain days. They come into our regional offices. We talk about how BIM will affect the projects coming up’. Another contractor also noted the following: ‘Our supply chain partners play a pivotal role in our ability to deliver a BIM project, so we play an active role in training and upskilling supply chain partners. We hold regular training sessions for our supply chain and encourage a collaborative environment to stimulate the sharing of knowledge and expertise’.
Moreover, when a misalignment occurs between the information management processes and BIM skills, such as in the case when suppliers or sub-contractors with the required BIM skills could not be appointed for some reason, contractors are taking other actions to align the process with the required skills: ‘Our procurement strategy is to go for smaller, local companies, so we need to bring in a coordination company that’s going to put the duct work contractor, the pipe work contractor, the electrical containment contractor, all of their information potentially’. Therefore, although previous research has suggested that a large span (i.e. when many different boundaries of an inter-organisational network are affected) influences the diffusion of a systemic innovation (Lindgren and Emmitt, 2017), we propose that through skills–process alignment actions, such as the ones previously discussed, a systemic innovation can be successfully implemented, even in cases of a large span, such as in the case of a BIM project:

**Proposition 4**: BIM is successfully implemented when skills–process alignment actions are undertaken.

In summary, our data demonstrate that BIM implementation is thoroughly constituted within practices, i.e. it is not independent or fixed. Although standards provide useful guidelines, successful implementation is a result of BIM enacted in practice. The identification of some practical actions related to a successful BIM implementation drawn from real experience is useful for both systemic innovation in projects and the BIM literature, as discussed next.

**Discussion**

The practice-based ontological perspective used in this study allows us to extend existing literature in different ways.

First, existing literature on systemic innovation has posited that a successful systemic innovation implementation is governed by the existence of an agent who promotes project network change (Taylor and Levitt, 2007) and that a change in regulations is a key point for innovation (Lindgren and Emmitt, 2017). By considering that BIM implementation cannot be considered separate from the practices and processes of those who enact them and that as a phenomenon, it is constituted by contingent practices, we reveal through our findings that implementation success is also dependent on the actions of project team members, i.e. the success of a systemic innovation is dependent on how it is socio-materially configured. Moreover, existing studies have argued that some actions are necessary to align the misaligned innovation with the existing work task allocation of the project network (Alin et al., 2013). We argued that actions to align the components of the systemic innovation itself are also necessary, as previously discussed, such as alignment amongst tasks and technologies across different project lifecycle stages.

Second, from a theory building on a project-as-practice perspective, the use of a practice lens allows us to understand why and how BIM implementation and the information deliverables are successful even when some of the rules and conditions aiming to establish social order in projects when managing information in projects that are more predictable are not present (e.g. Project 3). The practice approach allows us to demonstrate that actually, a successful BIM implementation is also a result of project members’ actions and not just the implementation of standards. It points to a different way of thinking about BIM implementation, emphasising management interventions not highlighted in existing literature. The practice lens also offers valuable insights into practical actions or mechanisms that support the innovation diffusion, extending existing research on the conditions and factors that underlie systemic innovation implementation and diffusion in projects (Taylor and Levitt, 2007; Lindgren, 2016).
Furthermore, recent studies in the BIM literature have acknowledged that research thus far has emphasised mechanistic conceptions of BIM technology adoption that focus implementation efforts towards technology (Dowsett and Harty, 2018; Papadonikolaki et al., 2019) and that important links between implementation practices and outcomes are still missing (Dowsett and Harty, 2018). The propositions identified through a practice perspective, therefore, provide insights into such links. Finally, our findings also extend previous BIM research on the role of actors in driving BIM implementation (Vass and Gustavsson, 2017) by demonstrating that actually, their actions affect the performance of the innovation implementation. These findings also contribute to project-as-practice more specifically governance-as-practice literature (Brunet, 2019) by revealing that what is actually done by different actors influences the performance of the systemic innovation implementation.

Conclusions
Although BIM has become a popular paradigm in construction, recent studies have demonstrated that in practice, firms still struggle to implement and work in a BIM environment and that the managerial aspects of BIM implementation remain underdeveloped. By using a practice lens and identifying propositions on actions that underlie successful BIM implementation, we aim to contribute to practical knowledge on how BIM unfolds in practice. Our findings offer insights into practical actions that should be taken by practitioners.

Recent studies have recognised that a more comprehensive understanding of the phenomenon through practice lenses arises from the application of two perspectives and that further methodological, theory, and/or philosophical triangulation in project management research is needed. Therefore, the propositions identified in this study—drawing on ethnographic data—are just the first step in a mixed methods research design aiming to provide a more practice-relevant understanding of the phenomenon. One of the limitations of the qualitative phase of this study may be the focus on projects in the UK only, although it provided a realistic representation of the phenomenon being studied. By using triangulation to increase reliability, however, a new research method and data sources will be applied in a second stage of this research.

Abstract

This paper investigates the effect of tax reduction policy and completion risk sharing policy on the investment decision of the private investor in the public-private partnership project. The results manifest that: first, both incentive policies can promote the private investor to invest in the project earlier; second, the optimal debt level is not affected by completion risk sharing policy but displays a U-shape relationship with the incentive ratio under tax reduction policy; third, tax reduction policy can induce private investors to invest in the project a longer time. These results can help the government to make a better incentive policy.

Keywords: Public-private partnership, Tax reduction, Completion risk sharing

Introduction

To release the financial burden of government, attracting private investors to invest in infrastructure development through public-private partnership (PPP) has been a hot topic (Zhang et al. 2015, Wang et al. 2018). However, because of the large investment scale of the infrastructure, various unpredicted risks are involved. It is necessary for government to provide some incentive policies to increase the investment confidence of private investors (Park and Chang 2013, Soumaré 2016). One of the key factor that defer private investors from investing in the PPP project is the completion risk (Chan et al. 2014, Mouraviev and Kakabadse 2014). Under the PPP model, it is the private investor who is responsible to construct and operate the project (Zhang et al. 2015, Wang et al. 2018). Once the construction of the project cannot be completed on time, private investors may suffer a great loss. Therefore, one way that government can use to promote private investors to invest in PPP projects is to share the completion risk with them (Chan et al. 2014, Mouraviev and Kakabadse 2014). The other key factor that influences the investment decision of private investors is the profitability of the project. Because the main purpose of private investors to participate in the project is to make money, if the
infrastructure project cannot meet their requirement of internal rate of return, private investors will not be willing to invest in the project (Takashima et al. 2010). To increase the attractiveness of the infrastructure project, government usually provides some governmental guarantees in the PPP contract, e.g. the minimum revenue guarantee, the debt guarantee and the minimum traffic volume guarantee (Feng et al. 2015, Li and Cai 2017). Besides, government can also provide tax preference for the infrastructure project to attract the private investment. It is important for government to know how these incentive policies may influence the investment decision of private investors, so that a right incentive policy can be used in the right situation.

Some scholars have investigated the government support policy in PPP projects. Takashima et al. (2010) built a real options framework and analyzed how the degree of government guarantee and the cost sharing policy influence the investment timing of the private sector in public-private partnership (PPP). They concluded that when the guarantee of the government is large and the cost sharing rate is low, the private firm exercises the investment option earlier under the firm-maximum policy than under the value-maximum policy. Soumaré (2016) compared loan guarantee and direct investment through public-private partnership (PPP) under the perfect and asymmetric information situations respectively. The author argued that loan guarantee is better than direct investment for government under the perfect information situation, while this implication is mitigated under the asymmetric information situation due to the so-called plum problem. Feng et al. (2015) studied the impact of three types of governmental incentives, namely the minimum traffic guarantee, the minimum revenue guarantee and the price compensation guarantee, on the investment behaviour of private sectors, including the toll rate, the road quality and the road capacity. Shi et al. (2016) supposed that the government guarantee can serve as an instrument to induce the private sector to reveal true cost information under asymmetric information situation. Li and Cai (2017) investigated the impact of government incentive on the investment behaviour of the private sector under demand uncertainty. Although many governmental incentive policies in PPP projects have been investigated, the study related to the completion risk sharing policy and the tax reduction policy is still lacking. This study fills this knowledge gap to help government have a better knowledge about the influence of different incentive policies on the investment decision of the private investor, so that a better incentive plan can be made in PPP projects.

Modelling

The investment decision analysis of the private investor without any governmental incentives

This section provides a benchmark for further analyzing the influence of tax reduction policy and completion risk sharing policy on the investment decision of private investors. Suppose the cash flow of the project $X$ satisfies $dX = \mu Xdt + \sigma XdZ^0$, where $\mu$ means the expected rate of return of the project, $\sigma$ represents the volatility of the cash flow, and $Z^0$ satisfies a Wiener process. Because private investors have a minimum revenue requirement for the project, they will not invest in the project before the cash flow of the project reaches a threshold value $X_I$. On the other hand, private investors usually set up a special purpose vehicle (SPV) to construct and operate the PPP project and have limited liability for the project. When the project cannot make ends meet, private investors will abandon the project. In other words, there exists a cash flow threshold value $X_D$, when
the cash flow value is below this threshold value, private investors will withdraw from the project. Suppose the total construction cost is $I$, the debt capital used in the project is a tax-deductible perpetual coupon bond with coupon $C$, the risk-free interest rate is $r$, and the tax rate is $\tau$.

During the operation period, the project value is denoted as $\bar{V}_o(X)$, the debt value is $\bar{D}_o(X)$, and the equity value is $\bar{E}_o(X)$. As in the study of Dixit et al. (1994), the equity value $\bar{E}_o(X)$ satisfies the following differential equation:

$$\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{E}_o(X)}{\partial X^2} + \mu X \frac{\partial \bar{E}_o(X)}{\partial X} - r \bar{E}_o(X) + (1-\tau)(X-C) = 0 \quad (1)$$

Two boundary conditions need to be satisfied:

$$\bar{E}_o(X_D) = 0 \quad (2)$$

$$\left. \frac{\partial \bar{E}_o(X)}{\partial X} \right|_{x=x_D} = 0 \quad (3)$$

The first boundary condition captures the fact that private investors will abandon the project when their equity value equals 0 (the value matching condition). The second condition manifests that the threshold value should be optimally determined to maximize the total equity value of private investors (the smooth passing condition). Combining with the non-bubble condition used in the study of Dixit et al. (1994), the expression of the equity value $\bar{E}_o(X)$ can be derived.

$$\bar{E}_o(X_D) = \frac{1-\tau}{r-\mu} X - \frac{1-\tau}{r} C - \left( \frac{1-\tau}{r-\mu} X_D - \frac{1-\tau}{r} C \right) \left( \frac{X}{X_D} \right)^{\beta_2} \quad (4)$$

$$X_D = \frac{r-\mu}{r} \frac{\beta_2}{\beta_2-1} C \quad (5)$$

Where $\beta_2 = \frac{1}{2} - \frac{\mu}{\sigma^2} - \sqrt{\left( \frac{1}{2} - \frac{\mu}{\sigma^2} \right)^2 + \frac{2}{\sigma^2}} < 0$. According to the expression of the threshold value $X_D$, it can be seen that a larger debt capital value will make private investors abandon the project earlier.

The value of the project $\bar{V}_o(X)$ satisfies the following differential equation:

$$\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{V}_o(X)}{\partial X^2} + \mu X \frac{\partial \bar{V}_o(X)}{\partial X} - r \bar{V}_o(X) + (1-\tau)X + \tau C = 0 \quad (6)$$
When private investors withdraw from the project, the project asset will be transferred to the debt holder. Since there are fractions during the transfer process, a fraction of the cash flow value \((\alpha X_D, 0 < \alpha < 1)\) will be lost. Therefore, the project value at the threshold value satisfies \(\bar{V}_o(X_D) = \frac{1-\alpha}{r} X_D\). Combining with the non-bubble condition used in the study of Dixit et al. (1994), the expression of the project value \(\bar{V}_o(X)\) can be derived.

\[
\bar{V}_o(X) = \frac{1-\tau}{\tau r - \mu} X + \tau C \left( \frac{1-\alpha}{r} \frac{1-\tau}{r-\mu} X_D - \frac{\tau}{r} C \right) \left( \frac{X}{X_D} \right)^{\beta_2} 
\]

(7)

Private investors need to determine the capital structure of the project by maximize the project value, namely,

\[
\text{Max}_{C'} (\bar{V}_o(X)) \quad (8)
\]

Solving this maximum problem, the optimal debt level of the project can be expressed as

\[
C^* = \frac{r}{\tau - \mu} \beta_2 - 1 AX \quad (9)
\]

Where ‘*’ means the optimal level, and \(A = \left( \frac{\tau - \beta_2 + (\tau - \beta_2)(1-\alpha)\beta_2}{\tau} \right)^{\frac{\beta_2}{\beta_2}}\). Denote \(P = \frac{r}{\tau - \mu} \beta_2 - 1 A\), then the optimal debt level can be expressed as \(C = PX\). Furthermore, the threshold value and the project value can be expressed as \(X_D = AX\) and \(\bar{V}_o(X) = BX\), respectively, \(B = \frac{1}{\tau - \mu} (1-\tau + \tau A). It can be seen that both the optimal debt level and the threshold value are a linear function of project cash flow value.

Before private investors make investment, there exists completion risk in the project. Suppose the probability that completion risk could happen is \(\rho\), the project value is \(\bar{V}(X)\). Then, \(\bar{V}(X)\) satisfies the following differential equation:

\[
\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{V}(X)}{\partial X^2} + \mu X \frac{\partial \bar{V}(X)}{\partial X} - r\bar{V}(X) + (1-\rho)\bar{V}_o(X) - I = 0 \quad (10)
\]

Besides, two boundary conditions need to be satisfied:

\[
\bar{V}(X_I) = (1-\rho)\bar{V}_o(X_I) - I \quad (11)
\]

\[
\frac{\partial \bar{V}(X)}{\partial X} \bigg|_{X=X_I} = (1-\rho) \frac{\partial \bar{V}_o(X)}{\partial X} \bigg|_{X=X_I} \quad (12)
\]
Just like the above analysis, the first boundary condition is the value matching condition, and the second boundary condition is the smooth passing condition. It can be derived that the expression of the project value satisfies:

$$\bar{P}(X) = \frac{I}{\gamma_1 - 1 \left( \frac{X}{X_f} \right)^{\gamma_1}}$$  \hspace{1cm} (13)

$$\bar{X}_f = \frac{\gamma_1}{\gamma_1 - 1 (1 - \rho) B} I$$  \hspace{1cm} (14)

Thereinto, $$\gamma_1 = \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma}\right)^2 + \frac{\mu^2}{\sigma^2} + \frac{1}{2} - \frac{\tau}{\sigma}} > 1$$. It can be seen that the investment threshold value $$\bar{X}_f$$ increases with the construction cost $$I$$ and completion risk probability $$\rho$$.

The investment decision analysis of the private investor under tax reduction incentive policy

This section will investigate the influence of tax reduction incentive policy on the investment decision of private investors. Suppose government promises to give $$\delta$$ percentage of tax benefits back to private investors during the operating period. We need to estimate the tax benefits first. The tax benefits (denoted as $$G(X)$$) satisfies the following differential equation:

$$\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 G(X)}{\partial X^2} + \mu X \frac{\partial G(X)}{\partial X} - rG(X) + \tau(X - C) = 0$$  \hspace{1cm} (15)

Combining with the boundary condition $$G(X = C) = 0$$ and the non-bubble condition, It can be derived that the expression of tax benefits satisfies:

$$G(X) = \frac{\tau}{r - \mu} X - \frac{\tau}{r} C - \frac{\mu}{r(r - \mu)} \tau C \left( \frac{X}{C} \right)^{\beta_2}$$  \hspace{1cm} (16)

Under the optimal debt level $$C^* = PX$$, and denote $$Q = \left( \frac{\tau}{r - \mu} - \frac{\tau}{r} P - \frac{\mu}{r(r - \mu)} P^{1 - \beta_2} \right)$$, it can be derived that $$G(X) = QX$$.

Then, the equity value of private investors $$\bar{E}_o^i(X)$$ satisfies:

$$\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{E}_o^i(X)}{\partial X^2} + \mu X \frac{\partial \bar{E}_o^i(X)}{\partial X} - r\bar{E}_o^i(X) + (1 - \tau)(X - C) + \delta QX = 0$$  \hspace{1cm} (17)

Suppose the threshold value that private investors abandon the project in this situation is $$X_D^i$$, the expression of $$X_D^i$$ satisfies:
\[ X_D^1 = \frac{r - \mu}{r} \left( 1 - \tau + \delta Q \frac{1}{\beta_2} \right) - 1 C \] (18)

It can be easily demonstrated that \( X_D^1 < X_D \), which means that tax reduction policy can effectively keep private investors invest in the project a longer time. Besides, the larger degree of tax reduction (\( \delta Q \)), the smaller threshold value (\( X_D^1 \)) that makes private investors abandon the project.

In a similar way, the expression of the optimal debt level \( C_1^* \) can be derived:

\[ C_1^* = \frac{r - \mu}{r} \left( 1 - \tau + \delta Q \frac{1}{\beta_2} \right) A_i X \] (19)

where \( A_i = \left( \frac{\left( r - \beta_2 \right) \left( 1 - \tau + \delta Q \right) - \left( \tau - \beta_2 \right) \left( 1 - \tau + \delta Q \right) \right)}{r \left( 1 - \tau + \delta Q \right)} \right) \). Denote \( P_i = \frac{r - \mu}{r - \tau} \frac{1 - \tau + \delta Q \beta_2 - 1}{\beta_2} A_i \), then \( C_1^* = P_i X \). It can be found that there exists a threshold value \( \delta = \frac{\left( r - \mu \right) \left( 1 - \tau \right) \left( 1 - \beta_2 \right)}{r \left( \tau - \beta_2 \right) \left( 1 - \delta \right) - 1} \), when it is satisfied that \( \delta \leq \delta \), the optimal debt level decreases with the tax reduction ratio; otherwise, when it is satisfied that \( \delta > \delta \), the optimal debt level increases with the tax reduction ratio. The expression of the project value and the threshold value (\( X_D^1 \)) can be expressed as \( V_o(X) = B_i X \) and \( X_D^1 = A_i X \), respectively, \( B_i = \frac{1 - \tau + \delta Q}{r - \mu} (1 + \frac{1 - \tau}{r} A_i) \).

Before private investors make investment, the project value \( \bar{V}_i(X) \) satisfies:

\[ \frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{V}_i(X)}{\partial X^2} + \mu X \frac{\partial \bar{V}_i(X)}{\partial X} - r \bar{V}_i(X) + (1 - \rho) \bar{V}_o(X) - I = 0 \] (20)

Combining with the value matching condition and the smooth passing condition, the expression of the investment threshold value \( \bar{X}_i \) can be derived:

\[ \bar{X}_i = \frac{\gamma_1}{\gamma_1 - 1} \frac{r - \mu}{r - \mu - 1 \left( 1 - \rho \right) B_i} \frac{1}{r} r - 1 I \] (21)

It can be demonstrated that \( \bar{X}_i < \bar{X}_i \), which means that tax reduction policy can effectively motivate private investors to invest in the project earlier.

The investment decision analysis of the private investor under completion risk sharing incentive policy

Under completion risk sharing incentive policy, suppose government promises to reimburse a share of construction cost (\( \delta_0 I, 0 < \delta_0 < 1 \)) to private investors once the completion risk happens, which does not affect the investment behaviour of private
investors in the operation period. The project value ($\bar{V}_1(X)$) before the investment is made satisfies:

$$\frac{1}{2} \sigma^2 X^2 \frac{\partial^2 \bar{V}(X)}{\partial X^2} + \mu X \frac{\partial \bar{V}(X)}{\partial X} - r \bar{V}(X) + (1 - \rho) \bar{V}_0(X) - (1 - \delta_0 \rho) I = 0 \quad (22)$$

Combining with the value matching condition and the smooth passing condition, the investment threshold value can be derived:

$$\bar{X}^2_i = \gamma_i \frac{r - \mu}{\gamma_i - 1} \frac{1 - \delta_0 \rho}{(1 - \rho) B} \frac{r - 1}{r} I \quad (23)$$

It can be demonstrated that $\bar{X}^2_i < \bar{X}_i$, which manifests that completion risk sharing policy can also effectively promote private investors to invest in the project. Besides, when the completion risk probability satisfies $\rho \leq \frac{1}{\delta_0} \frac{B_i - B}{B_1}$, the investment threshold value under tax reduction policy is lower than that under completion risk sharing policy, namely $\bar{X}^1_i < \bar{X}^2_i$; otherwise, when the completion risk probability satisfies $\rho > \frac{1}{\delta_0} \frac{B_i - B}{B_1}$, the investment threshold value under tax reduction policy is larger than that under completion risk sharing policy.

The Numerical Analysis

This section examines the property of the model with a numerical analysis. The value of the basic parameters are determined based on data from project finance for capital-incentive investments (Sarkar 2012, Soumaré 2016). $r = 0.05$ for the risk-free interest, $\mu = 0.02$ for the risk neutral expected rate of return, $\sigma = 0.2$ for the volatility of the cash flow, $\tau = 0.4$ for the tax rate, $\alpha = 0.1$ for the degree of the transfer loss. Assume the total construction cost $I = 2$ (million) and the initial cash flow value $X = 0.1$ (million), the value of them can be changed without any influence on the result.

The influence of incentive policies on the investment threshold value.

Figure 1 displays the influence of tax reduction policy and completion risk sharing policy on the investment threshold value of private investors. It can be seen that both policies can effectively incentivize private investors to invest in the project earlier. The relative effectiveness of two incentive policies depends on the value of the completion risk probability, the incentive ratio, and other project parameters. When the completion risk probability is relatively large ($\rho > \frac{1}{\delta_0} \frac{B_i - B}{B_1}$), completion risk sharing policy is more effective to promote private investors to invest in the project (as is shown in the left figure); otherwise, when the completion risk is relatively small ($\rho \leq \frac{1}{\delta_0} \frac{B_i - B}{B_1}$), tax reduction policy is more effective to motivate private investors to invest in the project (as is shown in the right figure)
The influence of incentive policies on the optimal capital structure of the project. Figure 2 shows the influence of tax reduction policy and completion risk sharing policy on the optimal capital structure of the project. It can be seen that the optimal capital structure of the project is not affected by completion risk sharing policy. However, under tax reduction incentive policy, the optimal debt level increases with the incentive ratio when the transfer loss is relatively large ($\alpha = 0.1$), and decreases with the incentive ratio when the transfer loss is relatively small ($\alpha = 0.01$). This results manifests that government should be aware that inventive policies may not only influence the investment threshold value of private investors, but also change the capital structure of the project. If the purpose of government is just to induce private investors to invest in the project earlier, completion risk sharing policy should be first considered.

The influence of incentive policies on the exit threshold value of private investors. Figure 3 depicts the influence of tax reduction policy and completion risk sharing policy on the exit threshold value of private investors. It can be seen that the exit threshold value keeps unchanged under completion risk sharing policy, but decreases with the incentive ratio under the tax reduction policy. The result suggests that if government intends to induce private investors to invest in the project a longer time, tax reduction policy should be first considered.
Conclusion
This study investigated the influence of tax reduction policy and completion risk sharing policy on the investment behaviour of private investors, including their investment threshold value, optimal capital structure and exit threshold value. The results manifests that: first, both incentive policies can effectively reduce the investment threshold value of private investors; second, the relative effectiveness of two incentive policies depends on the value of the completion risk probability, the incentive ratio, and other project parameters; third, the optimal debt level is not affected by completion risk sharing policy but displays a U-shape relationship with the incentive ratio under tax reduction policy; finally, tax reduction policy can induce private investors to invest in the project a longer time. These results can help government to better arrange the incentive plan in the PPP project.

Abstract

Adopting new technologies brings competitive advantage for organisations. One of the leading innovations in the construction industry is Building Information Modelling (BIM). Organisations need to make major changes to benefit from the BIM adoption. This paper first conducts a literature review to investigate different approaches to the BIM implementation. A conceptual framework is then proposed, based on Organisational Learning theory. This framework reveals how organisations can be involved in the process of learning so as to change the different social, structural, and procedural components of their organisations to effectively implement BIM.

Keywords: Organisational Learning, Technology Implementation, Building Information Modelling (BIM)

Introduction

Pursuing new technologies is essential for organisations to sustain their competitive advantage (Tippins and Sohi, 2003) through process and product improvement and the resultant market benefits (Edmondson et al., 2001). One of the pioneer technological innovations in the construction industry is Building Information Modelling (Lu et al., 2015) which can enhance project management and outcomes (Chien et al., 2014).

BIM is defined as a set of policies, technologies, and processes for managing the design and data of a construction project through its lifecycle (Succar, 2009). BIM provides a data-based virtual model of the building project, facilitating the distribution of information and knowledge management in the project (Deshpande et al., 2014; Meadati and Irizarry, 2010). BIM enables information sharing and communication dispersion to reach an effective and multi-lateral interaction between different specialists involved in the project such as engineers, suppliers, contractors, and the client (Sackey et al., 2015).
BIM involves a shared database which contains all the information of the components of the virtual model, and this can be used in further analyses and evaluations of the project, such as energy consumption, project time control, project cost estimation, and identification of design and execution errors affecting the time, cost, and quality of the project (Bryde et al., 2013; Mihindu and Arayici, 2008; Succar, 2009). Using BIM has been found to reduce project cost and completion time, to improve output quality, and to facilitate communication and coordination between project members (Bryde et al., 2013). Because of these advantages, construction companies have been encouraged to adopt and implement BIM.

Despite the advantages, recent studies have shown that implementing BIM as a new technology is challenging (Chien et al., 2014). Almost 90% of the organisations which already use BIM still need to undergo major changes in their implementation strategy to benefit the advantages of BIM (Sackey et al., 2015). Organisations need to reengineer their structures, processes, policies, and people to reap the advantages of BIM implementation (Eadie et al., 2013; Liu et al., 2017; Rezgui et al., 2013; Samuelson and Björk, 2014).

The underlying principle of change is “learning” (Bresman, 2013; Crossan et al., 1999) which can explain the dynamics of change. Organisation learning helps us to understand the process through which new actions and routines can be adopted (Edmondson et al., 2001). Also, the learning concept plays a vital role in defining the result of IT implementation (Tippins and Sohi, 2003). In other words, when a new technology interrupts the current operating routine of an organisation, the organisation should go through a learning process so as to adopt the new routines effectively (Edmondson et al., 2001).

This paper aims to focus on the literature concerning how organisations in the construction industry learn to use BIM optimally for increasing project productivity. In this paper, the 70 articles recognized by Olawumi et al. (2017) for “learning, adoption and practice” are analyzed and compared. After the literature review, a conceptual framework regarding the organisational learning process in the implementation of BIM will be proposed.

**Literature review**

**Definition of BIM**

BIM is one of the most recent developments in the architecture, engineering, and construction (AEC) industry (Kim, 2012). BIM is defined as a set of policies, technologies, and process for managing the design and the data of the project through its lifecycle (Succar, 2009). This information and communication based technology (Bråthen, 2015; Froese, 2010; Xu et al., 2014) allows specialists in the construction project to make a virtual model of the building. This virtual model contains the geometry of the building project as well as the related data which can be used in the construction, fabrication, and procurement activities (Eastman, 2012). The BIM database can be a platform for storage and distribution of data and information during different phases of the project such as design, construction (Deshpande et al., 2014), and even facility management and maintenance (Froese, 2010; Lindkvist, 2015).

The use of BIM has been found to lead to economic and non-economic benefits. Economic outcomes include increased efficiency, profitability, and cost savings, and the non-economic results comprise increased skill and ability, increased decision quality, and improved business processes (Lindblad and Vass, 2015).
To achieve these benefits of using BIM, organisations should be prepared to undergo a major paradigm shift (Giel and Issa, 2016; Kim et al., 2016) where all the components of the organisation need to be aligned to the new working platform created by BIM.

**Approaches to BIM implementation**

In recent years, the amount of organisations using BIM has increased, and there has been a rise in the number of studies addressing different aspects of BIM implementation (Olawumi et al., 2017; Santos et al., 2017).

Olawumi et al. (2017) conducted a literature review of BIM related research, covering 445 articles, forming a baseline for understanding the different approaches to BIM adoption and its accomplishments in the construction industry. In this study, the authors categorized the papers, based on the subject in 10 different groups and evaluated them with regards to the project type influenced by BIM and the funding resource for BIM research. Their findings show that one of the main research categories, comprising 70 papers, is “learning, adoption and practice”. This category includes 11 different themes (Olawumi et al., 2017), viz.,

- BIM usage and adoption
- BIM curriculum development
- Construction stakeholders’ BIM adoption strategies
- BIM teaching and support
- Drivers of BIM adoption
- Cost-benefit analysis of BIM implementations
- BIM adoption barriers
- BIM standardization and intellectual property rights
- Competency assessment
- BIM ethics and professionalism, and
- Practice paradigms and governance approach.

None of the 70 papers proposed an implementation framework which, as Olawumi et al. (2017) believed, could empower the process of technology adoption.

As a further categorisation, the above papers in the “BIM learning, adoption & practice” category can be classified into two main groups regarding the application of BIM, viz., in the education field and the construction professional use of BIM.

In the first category, the use of BIM in the education field, there are two groups of research. One group, studies on teaching BIM in the universities, suggests methods and frameworks to review the curricula of universities and to include courses which train students in the usage of BIM (Pikas et al., 2013; Sacks and Pikas, 2013; Sampaio, 2015; Solnosky et al., 2014; Wu and Issa, 2014). It is advocated that students learn to work with new software, follow new procedures in the lifecycle of the project, and develop their soft skills so as to work in collaborative environments with other members of the projects (Pikas et al., 2013). In the other group, BIM is considered a tool which can accelerate the teaching of construction units (Gnaur et al., 2015; Kim, 2012; Sacks and Barak, 2010). For example, BIM helps students to understand construction details (Kim, 2012) and help them to develop their collaborative skills (Gnaur et al., 2015).

From the growing attention in the subject of BIM education, there is an inference that there is a shortage of graduate engineers who are able to work in the BIM context (Wu and Issa, 2014). This present deficiency creates problems in organisations within the construction industry (Matthews et al., 2018) where there is an expectation of these companies’ ability to work on projects in the BIM environment. To cope with this deficiency, the responsibility of the process of learning BIM skills seems to have shifted
from universities to construction organisations. People in organisations should be encouraged to work with each other (Tsai et al., 2014) to cope with both technical and nontechnical issues (Gu and London, 2010), and to change their attitudes toward collective work (Liu et al., 2017).

In the second category, the construction professional application of BIM, studies consider the different aspects of BIM adoption in organisations. For example, some studies measure the benefits of using BIM in different stages of the project lifecycle (Eadie et al., 2013); recognize the BIM adoption success factors (Tsai et al., 2014), or barriers (Chien et al., 2014); factors affecting the decision to adopt BIM (Kim et al., 2016); cost-benefit measurement of BIM implementation (Giel and Issa, 2013; Lu et al., 2014); and, regulations and intellectual property rights in BIM (Fan, 2014). These studies scrutinize some aspect of the BIM implementation and address the “what” questions of BIM implementation. They do not go deeper to understand “how” the implementation of BIM occurs.

However, some papers address the BIM implementation process with a deeper perspective. Some of these in-depth studies discuss the change strategies considering the structure of the organisation and the training plan of BIM implementation (Ahn et al., 2016). Some others developed decision frameworks for BIM adoption considering different levels of the construction industry (individual, organisation, inter-organisation) (Samuelson and Björk, 2014) and based on BIM implication concerns (strategic goals and domain, work road map, technical provisions of BIM and partner assessment) (Gu and London, 2010). Even though these studies try to help AEC organisations understand the requirements of the BIM implementation, they do not explain the dynamics of BIM adoption process.

Sackey et al. (2015) take a step forward and claim in their in-depth case study that what matters in the implementation of BIM is the placement of people in the learning loop. People must learn how to execute the optimal BIM and achieve the desired results. Nevertheless, based on organisational learning theories for successful implementation of BIM, in addition to individual learning, organisations should learn too (Senge, 1990). Despite the importance of organisational learning in the technology implementation (Roberts et al., 2017; Robey et al., 2000; Tippins and Sohi, 2003; Woldesenbet and Klay, 2016), the learning process seems to be neglected in the BIM implementation studies.

To shape the conceptual framework, a mind map of the literature review which shows the relation between different notions of the research is presented (Figure 1).

This paper aims at providing a conceptual framework based on the organisational learning perspective to address the implementation process of BIM as an IT solution in construction organisations.

Theoretical background and conceptual framework
The purpose of having a conceptual framework is that it “lays out the key factors, constructs, or variables, and presumes relationships among them” (Miles and Huberman, 1994, p. 440). In other words, the conceptual framework gives a structure of the concepts and their relationship and shows how ideas can be related one to another within the framework (Grant and Osanloo, 2014).

There are no best theory/theories to be selected as the basis to shape the conceptual framework, and it is the responsibility of the researcher to choose a theory or theories aligning the study’s purpose, research question, and design (Grant and Osanloo, 2014). Since the goal of this research is to include concepts of organisational learning in the implementation process of a new technology in the construction industry, the conceptual framework can be established based on Organisation Learning theory.
Organisational learning
Learning is the process of enhancing the capacity to perform efficient functions (Kim, 1998). Learning is a set of activities including knowledge acquisition, information distribution, and information interpretation which consciously or unconsciously affects the changes in the organisation (Templeton et al., 2002). Learning can occur in different levels such as individual, group, and company. Individual learning is the main component of organisational learning. However, organisational learning is not equal to the sum of the individuals’ learning (Fiol and Lyles, 1985; Kim, 1998). Organisations need some methods and techniques to facilitate learning and the transfer from individual level to organisational level (Gieskes and ten Broeke, 2000).

The main concept of individual learning is “mental model” (Kim, 1998) or “frame” (Edmondson, 2003). The mental model or frame demonstrates individual perspective of the world and how a person gives meaning to new material. Each mental model is a set of viewpoints or beliefs and activities. Organisational learning happens when individual mental model or frame reaches to a collective level and shapes the shared mental model. To make a shared mental model, it is essential to make individual mental models explicit. Using particular language or tools can accelerate the process of sharing individual mental models. When the shared mental model is shaped, it is independent of any specific individual one (Kim, 1998).

In the case of technology implementation, people should get involved in the actual experiments and practices to build up a new frame about the aims and patterns of work emerging with the new technology (Edmondson, 2003). They should try to expose their mental model through actions and communication to shape the shared mental model.

In the following, the conceptual framework (Figure 2) regarding the process of organisational learning will be presented.
Conceptual Framework
As stated above, BIM is an innovative development which affects all the aspects of the construction industry. Researchers have studied BIM implementation process from different perspectives. The organisational learning aspect is the fundamental issue in technology implementation process but this has been overlooked (Woldesenbet and Klay, 2016). To fill this gap, this paper presents the BIM implementation conceptual framework, based on the organisational learning theory literature review (Figure 2).

Figure 2- Conceptual framework based on literature review

BIM, as a technology and innovation in the construction industry, calls for change (Davies and Harty, 2013). The starting point of the change in organisations is people. There are various external and internal drivers affecting the decision of change. People may decide to adopt a new technology based on various drivers and different factors such as prior belief, the amount of information available, and costs (Young, 2009). Straub (2009) claims that three main categories of characteristics may affect the adoption or diffusion of a new technology. These categories are personal traits which push people to seek change, innovation characteristics such as the ease of use of the new technology, and the working context. (Link 1 in Figure 2).

In the next step, the decision to adopt a new technology should be operationalized through infusion and implementation of the technology in the organisation. Here, the leader’s attitude towards the new technology can be a critical point in the learning process. Leaders can reframe mental models of the people with their powers to interpret the implications of new technology. People tend to consider the action and the word of the leader more than those of peers and colleagues (Edmondson, 2003). Whether leaders consider the new technology as simply a “plug-in” which may improve their traditional way of work or consider the new technology as a “new innovative project” (Edmondson et al., 2001), this can affect the framing of individual mental model and learning process in the organisation. This is important because the way users comprehend the technology’s “pros” and “cons” affect the way they respond to the new technology implementation (Edmondson, 2003) (Link 2 in Figure 2).

The next step is to make a shared mental model regarding the use of new technology. Shared mental model consists of shared belief and activities. When the foundation of shared belief enlarges in the organisation, the capacity of the organisation to action
efficient coordinated activities increases accordingly. This is similar to the routines and actions being the auto reflection of beliefs (Kim, 1998). Based on this assumption, making shared belief regarding the new technology is an important step in organisational learning. The shared belief or understanding regarding the new technology can be achieved through communication, and the active participation of all the team members in the activities (Crossan et al., 1999). Active engagement in the practices and free communication throughout the implementation help people to obtain a better understanding of their roles and responsibilities in the technology implementation process (Edmondson et al., 2001).

Amoako and Salam (2004) further support the assertion that a shared belief is a key driver to implementing new technology in organisations. Shared belief regarding the benefits of the new technology can be facilitated through training and communication and can ultimately affect the ease of use and perceived usefulness of new technology (Link 3 in Figure 2).

There is a mutual relationship between organisational learning and IT implementation. Robey et al.,(2000) believe that the successful implementation of IT not only needs organisational learning but can also facilitate organisational learning. They indicate that IT can facilitate learning by providing virtual presentations, diagrams and pictures, and bring a collaboration atmosphere in a virtual environment. BIM, as an information-based technology, provides facilities such as easy access to information, virtual visualizations, and knowledge repository. These attributes in the project context, enhance the capacity of organisations to absorb new knowledge and transfer information efficiently which in turn increases the capability of learning organisations (Link 4 in Figure 2).

**Conclusion**

In the construction industry, BIM has recently been introduced as a communication and information technology (Bråthen, 2015; Froese, 2010; Xu et al., 2014) which can increase the capacity and capability of organisations to execute construction projects and enhance their outcomes. However, BIM as a new technology can disrupt the current procedures and strategies of organisations, as well as their social climate. Organisations which seek to realize full benefits of new technology implementation should change their structure, processes and strategies (Weston Jr, 2001). Organisational change occurs through learning (Styhre et al., 2004). Learning is the main element of consideration in technology implementation in organisations (Edmondson, 2003; Peansupap and Walker, 2005; Woldeisenbet and Klay, 2016) and is the means to review and change organisational strategies (Crossan et al., 1999). Technology users should learn how to work with others through new patterns of work that emerge from new technology implementation (Edmondson, 2003). Thus, organisations wanting to adopt BIM, should go through an organisational learning process to be able to use the new technology effectively (Tsai et al., 2014).

To adopt a new technology effectively, both social and technical aspects of the implementation process should be addressed. The team members should reach a shared belief about the usefulness of BIM to be able to use it and share data in the BIM context (Samuelson and Björk, 2014). It is not enough to provide access to the shared database of the projects’ documents, as the users should be conscious of the purpose underlying the implementation of a new approach. In previous studies, some of the technical and non-technical issues of the BIM implementation process were addressed (Gu and London, 2010). In addition, the importance of people learning as the fundamental concept of BIM implementation was argued (Sackey et al., 2015). However, there has not been a
framework to look at the implementation process from the point of organisational learning. This paper has tried to fill this gap by proposing such a conceptual framework.

Discussion

There are some pertinent factors which are not discussed in the proposed framework and these should be considered in the learning process of BIM implementation in further research. One of these factors points to external stakeholders. Governments, as an external influencer, can play a vital role in the implementation process, expanding the use of BIM across the construction industry (Bygballe and Ingemansson, 2014). For example, the Australian Cooperative Research Centre for Construction Innovation (CRC CI) found that investment in the BIM implementation program helped construction organisations to refine their routines and increase their capacity to acquire knowledge and improve their capabilities so that the national benefit increased (Kraatz and Hampson, 2013).

Another factor is the role of top management. Although the implementation process may seem bottom-up at the initial phase, the role of top management in implementation of a technology in the organisation is crucial (Tsai et al., 2014). Top management of the organisations should provide individuals with formal training and build the atmosphere of free communication which would then increase the collaboration and coordination among personnel and help them to reach a shared belief regarding the use of the technology.

The above factors may very well affect the learning process in different contexts and should be included in future studies.

Abstract

The objective of this paper is to extend the understanding of process improvement project failure by systematically reviewing the research on project failure and develop research propositions and a future research agenda. In total 118 papers on general- and process improvement projects are reviewed for contributions on project failure. This review reveals three categories in project failure research that lead to research propositions. The first category consists of the causes for project failure and their relative importance, the second category is about causality and relatedness between project failure factors and third and final is research on project failure mitigation strategies.

Keywords: Process improvement project, Project failure, Systematic Literature Review

Introduction

The organizational task of operations management is commonly divided into directing, designing, delivering and finally developing the operations (Slack et al. 2018). The task of developing the operations entails the continuous pursuit of improvement in both processes and products, generally embodied by process improvement projects based on established improvement methodologies such as Lean, Six Sigma, Total Quality Management and Lean Six Sigma (Antony, 2009).

To date many organizations have achieved significant results with the implementation of process improvement projects (e.g. Lucier and Seshadri 2001 for General Electric; Dedhia, 2005 for Samsung Electronics, American Express, Du Pont and others). Despite the reported successes there has also been criticism on the results of improvement project implementations (Easton and Rosenzweig, 2012). These mixed results about the effectiveness of process improvement project implementation provide the motivation for this systematic literature review.
In many industries and organizational domains organizations are operating, changed and improved by project based activities (Lundin & Söderholm, 1998). In this systematic literature review, research on process improvement project failure and general project failure from operations management and adjacent disciplines such as information systems, information technology and engineering are reviewed. Questions we seek to answer are: What characteristics do improvement projects share with general projects, what are common themes that are known to cause project failure, and what are the implications of the findings on project failure research to date for process improvement project failure research?

**Characteristics of process improvement projects**

Operations management research to date has focused on the unique characteristics that are essential for success of process improvement projects. These are for one a clear focus on project goals (improvement of the critical dependent “Y” metric) that drives and encourages learning about the problem at hand and the organizational context (Linderman, 2003, Easton and Rosenzweig, 2012). Secondly the use of improvement specialists that are trained in a structured improvement method (such as the DMAIC structure for Six Sigma) and operate in a parallel project organizations (Schroeder et al. 2008) is recognized. Finally the prioritized selection and contribution of improvement projects to corporate strategy realization (McAdam and Lafferty, 2004), leadership support (Schroeder et al. 2008) and selection of suitable methodology frameworks for specific improvement objectives (Pyzdek and Keller, 2014) are recognized characteristics of successful improvement projects.

Comparing the definition and characteristics of general projects to improvement projects reveals many similarities. First the research on the characteristic of general projects similarly defined that projects are executed by temporary parallel organizations (Lundin & Söderholm, 1995) that are structured to perform a set of activities and create a unique result, with limited resources and a predetermined beginning and end (Gilbreath, 1986). Widely adopted criteria to define the success of a project similarly entail a costs, quality and or time metric associated with execution, also known as the Iron Triangle (Atkinson, 1999). Commonly a project is defined as being temporary, with an explicit beginning and end, and similarly to improvement projects is not a routine operation. Projects are similarly going through a certain life cycle, which commonly includes the four stages of conceptualization, planning, execution and implementation and finally termination (Adams & Barndt, 1983). As projects are often defined by boundedness in time, their structure and composition varies. General project organizations similarly have teams with specific expertise, and project- size and complexity can vary across industries (Radas & Bozic, 2012). Organizations can either implement in-house projects or outsource the execution of projects (Brady & Davies, 2004) and projects can have either a functional structure or matrix structure which runs across various functional units (Larson & Gobeli, 1989).

Hence improvement projects and general projects have many similar characteristics. Main differences lay in the explicit recognition of in-house or outsourced execution of projects and project governance structures. By means of a systematic literature review methodology that is described next we review and discuss the dominant project failure research themes and distil propositions for future research on process improvement project failure specifically.
Systematic review methodology

The systematic literature review methodology that is applied is based on the suggestions by Webster & Watson (2002) and Tranfield et al. (2003) which are the basis for the research methodology and presentation of results (figure with process flow of systematic review process available). The search for publications on project failure started with the keywords “project” and “fail” or “failure” in publication titles in the Google Scholar-, Web of Science-, the EbscoHost- and the Scopus journal database. After duplicate checks the initial sample comprised 877 articles for which a quick scan for inclusion and exclusion criteria in both titles and abstract was performed (table with criteria available).

After the first round of selection, 118 peer-reviewed publications remained for further consideration. Secondly a complete article read was performed and based upon the in- and exclusion criteria 22 more articles were excluded from the sample. Premier reason for exclusion in this stage is identification of research that addresses the failure of initiatives (projects), for instance in developing countries. Finally the rigorous search and selection procedure resulted in 96 articles that are part of this systematic literature review. Then research database with article citations was set up and the process of extracting relevant information from the sample of articles commenced. The information of interest from the articles per article in a data spreadsheet is recorded. To ensure the validity of this humanly performed data collection- and coding process, the information of interest was coded by making use of pre-defined labels (author, author profile, country, year, title, journal, finding, methodology, type and industry). After each round of coding, a second researcher independently validated the coding for error-sensitive information (author profile, journal finding and methodology). Conflicting coding results were discussed and resolved, thereby enhancing reliability of the resulting database (Chugh & Wang, 2015).

Descriptive analysis of the data

Distribution of research papers over time

With an increasing trend the average number of publications steeply rose from 1998 – 2004 to noticeably more articles per year during 2005 - 2016. The majority of the mostly cited articles stems from 2005 or after that, which signals the growing research interest in project failure (figure available).

Geographical distribution of research papers

The geographical distribution of the publications in shows that the Unites States (N=39, 41% of total sample) is the leading continent were research has been performed, followed by Europe (34%), Asia (17%), Middle East (5%) and Africa (3%). The earliest studies originated from North America whereas Europe entered into project failure research in 1995 (Beynon-Davies, 1995) (figure available).

Distribution of research methodologies

Results show that research on project failure is mostly performed by case-based research methods (N=31, 32% of total sample) (figure available). Also empirical research has received good attention from researchers (32%), which is mostly based on cross-sectional surveys from project managers and executives. Cross-sectional research was represented far more than longitudinal research in the empirical researches in the sample. In more recent theoretical studies, project management literature has been
linked with mainstream management theories (such as stakeholder-, institutional-, organizational- and agency theory), which signals maturity of the research area.

**Distribution of research papers based on industry**

Most research originates from the public sector (20%), professional services (18%) or covers multiple sectors (12%) (table available). Research papers that covers multiple sectors are predominantly surveys aimed at project practitioners. Project types that are predominantly represented in the sample comprise Information Technology (IT) (33%) and Information Systems (IS) (23%).

**Distribution of research papers across journals and author profile**

The research on project failure has been published in management and technically orientated journals. The top five publishing journals account for about 25% of the total publications, and the top twenty accounts for about 50% (Figure available). This indicates a wide range of journals that are publishing on project failure.

**Critical analysis of the review**

Systematically studying the existing literature review has revealed a taxonomy whereby the results and the propositions for future research are discussed. The categories that are discussed are (1) the types of project failure factors and their relative importance, (2) how project failure factors are related by topic and in time and (3) before, during and after the project failure mitigation strategies.

**Project failure factors**

The largest and most researched category in the sample is on project failure factor identification. Project failure factors are primarily established through empirical and case-based research and are discussed per category (Table 1).

Prior research on project failure factor identification (detailed discussion of review available) listed in Table 1 revealed whether a failure factor appeared significant in research. More recent research has recognized the relative importance of project failure factors. A distinction is made between critical- and catalysing failure factors, whereby the latter are not sufficient on their own to induce project failure, but does contribute to project failure if other factors coexist. Review of the literature yields a fragmented and inconclusive understanding of the relative importance of project failure factors. Critical project failure factors identified are software development difficulties, management capacity and procurement methods (Brown, 2001), poor project planning and project management and control issues (Yeo, 2002), stakeholder capabilities and fit between technological solution, and strategy and cultural fit (McLaughlin, 2009), organizational structure (Elkadi, 2013) and project planning, team experience and poor initial- and often changed designs (Nguyen & Chileshe, 2015).

Reviewing the literature on criticality of project failure factors shows agreement on the existence of critical failure factors, though ambiguity on the origins of critical project failure factors (e.g. in- or outside the sphere of influence of the project organization). There is a predominant focus on failure factor that originate within the project organization (the project managerial and the technological categories, see Table 1) and less focus is on failure influenced by forces outside of the project organization (the organizational and external categories) which leads to the following proposition for future process improvement project failure research.

Proposition 1: Failure factors that originated from within the project organization have a stronger positive influence on the likeliness for process improvement project failure than failure factors that originated outside the project organization.

Interdependency of project failure factors
Recent research has started to address the interdependency of project failure factors, mostly hypothetical and based upon author experiences (Lehtinen et al. 2014). One important reason for the scarce empirical research to date is that researching interdependency and causality is requiring a post hoc reconstruction of a string of events. Research methods that are being applied comprise case study research based upon causal mapping (Ackermann & Eden, 2005) and interpretive structural modelling (Hughes et al. 2016). These methods in itself are subjective due to partial reports of the involved actors and provide an inevitably selective presentation of the events (Brown & Jones, 1998). For instance, Brown & Jones (1998) found that the narratives of project failure is simplifying events (to produce a coherent interpretation) and is attributing causes to elsewhere (to fate or the action of others). Hence, multiple researches have proposed models of interdependency, though all the following discussed researches refrain from conclusive results.

Causality is being proposed by Belassi & Tukel (1996), whereby five exogenous project failure factor categories (factors related to the project manager, the project team members, the project, the organization and the external environment) are expected to influence four endogenous failure factors (client consultation and acceptance, project manager performance, project estimates and availability of resources) that are expected to determine project failure. Poon & Wagner (2001) researched the application of Critical Success Factors (CSF) on project outcome and similarly find that factors related to the project (adequate sponsorship, adequate resources and the link to (strategic) business objectives) are important in causing project failure. Research by Cerpa & Verner (2009) finds that fundamental in the chain of causality are project managerial factors, being unrealistic delivery date, project resource underestimation, inadequate
risk management and overburdening of project staff. Additionally, Lehtinen et al. (2014) found that a lack of cooperation, weak task backlog, and lack of software testing resources were most influential for project failure. Hughes et al. (2016) discussed how driving project failure factors are in the project managerial domain, being executive support and project sponsorship, size and complexity and whether a pilot and initial project evaluation was performed.

Reviewing the above literature for interdependency of project failure factors shows a pattern of initially project managerial failure factors and causes for failure in predominantly the earlier project phases (e.g. definition of objectives, ensuring sufficient resources and sponsorship, application of project management methodology). Research by Ahonen & Savolainen (2010) corroborate the likeliness of serious mistakes before a project has started as sales, negotiations and project start-up processes are full of opportunities for project failure. Hence there is agreement on the existence of interdependency between project failure factors, though there is ambiguity on the origins of the independent (the causing) project failure factors. Reviewing the literature reveals a pattern of predominantly project managerial failure factors that originate in early project phases, which leads to the following proposition.

Proposition 2: Project managerial failure factors in early phases of the project lifecycle have a stronger positive influence on the likelihood for process improvement project failure than project managerial failure factors in later phases of the project lifecycle.

Mitigation strategies for project failure factors

Knowing what project failure factors are likely to disturb project execution is raising the need for project failure mitigation strategies. Research into project failure has identified mechanisms that allow for before-, during- and after-the project failure mitigation.

Before the project failure mitigation strategies: Known preventive factors for project failure are skill gap identification and training programs for project sponsors, -managers, -members and -stakeholders to ensure technical competency (Kilkelly, 2011) and intercultural competency (Kealey et al. 2005). For preventing project failure due to suppliers Chen et al. (2010) propose to use contracts wherein suppliers agree on the costs and penalty (calculated based on the probability of failure) when they fail to deliver as promised. Jørgensen (2014) proposes that project failure can be predicted by the failure rate of previous projects by the provider and suggests that increased emphasis on low price and project size increases the risk for failure. Clear and shared understanding of the project scope must be in place through transparent and effective communication in the early stages to reduce the chances for project failure (Gray and Anantatmula, 2009).

During the project failure mitigation strategies: While the project is in execution mode, close monitoring of progress allows for learning at regular intervals or following significant events (Robertson & Williams, 2006). To do so, Dalcher (2003) proposes a five step feedback loop and Matta & Ashkena (2003) propose small projects that quickly deliver mini versions of the bigger project’s end result to ensure fast feedback. In a typical improvement project execution stage, a reporting system is designed to meet the needs of the organization (Snee and Hoerl, 2018). Abdul-Rahman et al. (2012) suggest that strategies related to user involvement and project-planning and communication are most influential in preventing failure and Janssen & Klievink (2012) advocate the guiding use of enterprise architecture structures. Research by Vit (2011) suggests that project failure is hard to detect and prevent as different mechanisms such as the rules, cognitive routines and ideological pressures of an institutional environment
can override technical and economic rationality. Chen (2015) proposes that occurring project failure can be detected by monitoring seven performance factors. When project failure is imminent and commitment to project success is failing Keil & Robey (1999) showed that actions to turn troubled projects around are redefinition of the project and its objectives, improvement of the project management methods applied, and a change in project leadership. For project leadership, Jani (2008) found that when project managers believe the failing project is under their control it is unlikely they recommend alternative courses of action other than continuation. Jani (2011) found that project managers are likely to underestimate endogenous (within the project) risk factors and point to a ‘self-efficacy’ bias, where project managers with a higher self-efficacy underestimate the risks of a troubled project. Additional research by Ivory et al (2005) has proposed implications for management in complex-project failure situations, being multi-nodality (design intervention at differing hierarchical levels), top-down and bottom-up intervention (allow for flexibility of local response to emerging problems) and the requirement for organizational slack (ensure availability of time and resources).

After the project failure mitigation strategies: The element of learning and the execution of retrospectives is named often as after the project failure mitigation strategy (Bierwolf, 2016), such as cognitive- and causal mapping (Robertson & Williams, 2006; Ackermann & Eden, 2005) and decomposition of a project in a complex set of linear and non-linear interactions (Ivory et al. 2005). Learning at the individual, team and organizational levels is essential for the sustainable deployment of process improvements projects (Antony and Gupta, 2018). Sauser et al. (2009) suggest that adopting contingency theory will enhance project failure understanding. The researchers advocate that what works well in one situation may not work in another, and therefore engagement in after the project learning should be characterized by a contingency perspective.

Reviewing the literature on project failure mitigation reveals a predominant focus on learning and adaption, before the project (training) while the project is in execution (feedback mechanisms) or after the project (evaluations and retained learnings) which leads to the following proposition for future research.

Proposition 3: Presence and use of mechanisms that allow for frequent evaluation, learning and adaption negatively influence the likeliness of process improvement project failure.

Conclusions, future research agenda and limitations
Managers and practitioners that are confronted with the task of managing projects may find direction in the typology of project failure factors and the consecutive strategies for project failure mitigation. Certainly many idiosyncratic causes for project failure will exist, however improvement project management is better served when managers and practitioners have a grasp of the known mechanisms underlying project failure.

The review identified predominantly cross-sectional and case study research methods that have yielded a list of project failure factors, mostly in the project managerial sphere of influence. Subsequent research has identified the level of criticality and causality between project failure factors and the project phases where project failure factors start to emerge. Conclusively we see a growing interest in explaining project failure while it is happening and future research methods should focus on better understanding project failure as it unfolds by for instance process study research methods (Langley, 1999).

Contingency factors that are identified in research to date are organizational culture, politics, organizational structure and other external factors such as regulatory requirements and the influence of external parties. Explanation of improvement project
failure through the research lenses of contingency- (Hofer, 1975) or stakeholder theory (Freeman, 1994) is especially valuable for creating a better understanding of effective project leadership behaviours in different organization context where for instance differences in strategy, technology and size are expected to affect improvement project outcome.

Theoretical streams of research can further enhance the understanding of process improvement project failure. The organizational behaviour literature provides insights in the internal dynamics and functioning of project teams (Hackman & Wageman, 2005) and can contribute to a better understanding of project failure. Research that presumes more fundamental management theories such as the resource-based view (Wernerfelt, 1984) or dynamic capabilities (Teece et al., 1997) will be particularly valuable in exploring the interrelatedness of the project organization with the broader organization and how this is affecting improvement project failure (Chandrasekaran et al. 2016). Such research can establish new and different conceptions of project failure beyond the traditional failure factors and develop more refined contingency frameworks.

Additional future research lies in several directions, being the research methodologies applied and the types of improvement projects for which failure factors are being studied. Furthermore, most of the studies that have been conducted on project failure factors have limited cross-cultural perspective and are based mainly on data from the United States and Europe, have focused mainly on the public- or professional services sector or have focused predominantly on IT and IS types of projects.

This systematic literature review has limitations. Discussions and conclusions on project failure research is based upon our sample, which is a product of the research methodology applied and journal databases wherein the search is performed, and is therefore limiting the generalizability of our findings. Also we acknowledge that project failure is a label we have chosen after initial exploratory research. Publications that apply different labels to similar concepts may thereby be missed and not included in our sample.

Purchasing and Procurement
Abstract
This paper object is to study factors of purchasing and supply management performance in project business. In project business where the usage of external suppliers is extensive, supply chain effectiveness and procurement are one of the key capabilities influencing on the project outcomes. This paper focus on exploring the drivers of purchasing and supply management performance in the project business environment. The paper applies quantitative methodology and survey data. The initial finding of the study is that supplier relationship management (SRM), purchasing policies, and supply chain risk orientation predicts significantly purchasing and supply management performance in the project-based companies.

Keywords: Supply chain, Purchasing performance, Project business

Project Business, Purchasing and Supply Management
A project is a typical form of organizing operations and searching for efficiency in operations. Projects are often considered as dynamic and complex activities within a period of time and unique, one-off settings. Project characteristics include a specific goal, specified resources (people and budget) and clearly defined schedule. The complexity of a project derives from its size, value and the number of personnel involved and things like uniqueness. Furthermore, projects carry inherited risk and uncertainty because of their temporary nature (Baily et al., 2008). Even though project management is widely studied research field, only a few researches has attempted to focus on project business as a research field. Artto and Kujala (2008) have research the topic considering the number of involved firms and projects to compile four distinctive management areas of project business:
(1) management of a project; 
(2) management of a project-based firm; 
(3) management of a project network; and 
(4) management of a business network.

In this study focus is on several firms’ contributions to projects as nowadays not all tasks are done within one firm and therefore projects often include many companies. Moreover, project business is a part of business that relates directly or indirectly to projects that involve a firm or several firms (Artto and Wikström, 2005). From this perspective project business in this study is understood in context of the third and fourth management areas; “management of project network” and “management of a business network”

Project business differs from standard manufacturing business drastically as projects are often considered as dynamic and complex activities within a period of time and unique, one-off settings. Furthermore, projects carry inherited risk and uncertainty because of their temporary nature (Baily et al., 2008). Also projects often include many companies as nowadays not all tasks are done within one firm. In this respect it is no wonder that studies have found that purchasing and supply management can have a major impact on the success of project business (Eriksson and Westerberg, 2011). There are, however, several challenges how to perform effective purchasing in projects. The success of the overall project is in many cases highly dependent on the success of purchasing activities and performance of selected suppliers. In large industrial projects parts of the engineering may be done by external parties as well as components and parts that are critical for the end result. At the final phase the installation often is done by the collaborating companies having expertise in these activities.

In the project management literature, purchasing is seen as a one part of the scheduling challenges. It is also suggested that time-critical purchases should be included into the overall schedule and these should be observed strictly. In addition, these factors high monetary value of project purchases makes these purchases strategically important for firms and their supply chains. Consequently, this dependency sets companies vulnerable to supply chain disturbance and risks. It has been explored that the economic consequences of supply chain risks can be vast (Norrman and Jansson, 2004).

**Project Purchasing Performance Factors**

In several studies, purchasing and supply management had a major impact on the success of the project business (e.g., Ahola et al., 2008; Eriksson and Westerberg, 2011). Furthermore, a transparent purchasing process is critical for the success of a project (Bing et al., 2005). However, an integrated supplier network and close supplier relationships have not yet been widely adopted in project business (Crespin-Mazet and Portier, 2010), and numerous barriers to pursuing effective purchasing in projects have been reported in the previous literature (Akintoye, 2010).

There are, however, several challenges how to perform effective purchasing in projects. The nature and type of the project, for example, the length and location, can be critical factors from the perspective of supply management. The success of the overall project is in many cases highly dependent on the success of purchasing activities. In many projects the whole projects time span from initiation to the end include companies and experts from different areas.
Supplier Relationship

In supply management, several arguments favor integration. Economies of scale and increased efficiency help management establish a global supply view and deepen their knowledge of the supply market. Integration allows the available supply management skills to be used efficiently and knowledge to accumulate internally. Furthermore, integrating supply management is a prerequisite for cost-effective partnering with suppliers, in developing new products with suppliers and in global supply management (Leenders and Blenkhorn, 1988; Faes et al., 2000; Quintens et al., 2006). Moreover, knowledge of the supply markets and a strong power position in negotiations require more coordinated supply actions (Matthyssens and Faes, 1996).

In project business predictability and reliability are found to be the explanatory factors of project performance. According to Cheng and Carillo (2012) research, a supplier partnership can enhance operational efficiencies, but partnership alone does not guarantee an increase in revenue. Moreover, according to Walker and Nogeste (2008) stakeholder influence on project procurement delivery (how well the project met stakeholders needs) clearly indicated the importance and high impact of project stakeholders to project management success. Therefore, standardization of suppliers will lead to better results (Micheli et al., 2008) and experience former work relationships is an element that reduce supplier risks (Veres, 2009). These findings support the relevance of collaborative relationships in improving project business performance by bringing supplier reputation and perceived risk together.

Supplier Collaboration

Another research angle is the project management literature and how it deals with purchasing. In this field, studies and understanding are lacking, as stated by Venkataraman (2004). In the project management literature, supplier and purchasing issues are dealt within the project risk management chapter or ignored almost completely. Although adopting and implementing complete SCM-related strategies is quite prevalent in retail and the manufacturing industries and the benefits are well understood, project-based organizations have lagged in accepting and using such strategies. There is an urgent opportunity to adopt the practices of total supply chain management to reduce inefficiencies, and optimize value (Venkataraman, 2004). In this, procurement department play key role in managing the multifaceted aspects of supplier collaboration. According to Veres (2009), supplier recommendations or good references suggest less risky cooperation. On the other hand, Patrucco et al. (2019) found that attractiveness functions as a key variable to manage buyer-supplier relationship and that customer attractiveness is not only related to innovation performance but also positively affects costs offered by suppliers to buyers due to supplier collaboration and transparency.

Risk Orientation

In the project business environment, different project characteristics moderate between purchasing procedures and project performance. The more challenging the project characteristics (complexity, customization, uncertainty over value/size and time pressure) are, the more the cooperative purchasing procedures improve overall project performance (Eriksson and Westerberg, 2011). Hence, risk management is a significant element of a firm’s strategic supply management. Zsidisin (2003) divides the supply risks to the sources of risks and to the outcomes following the risk incidents. Decisions regarding the sources of risks and their outcomes are highly critical in nature and, thus, risk management should be considered
as a significant element of strategic supply management. As Smeltzer and Siferd (1998) state, substantial risks are more likely to occur when purchasing is not included in the strategic planning process.

These studies have shown that purchasing and supply risk management has a major impact on the success of the project. Furthermore, an integrated supplier network and close supplier relationships have not been widely adopted in project business. However, studies examining the main barriers to and challenges of purchasing in the project business environment could not be found. Hence, clearly, a research gap exists.

Project risks are associated with different project characteristics: therefore, project purchasing can on the one hand cause huge problems to projects and on the other hand be a major source of business success to a company. According to (Shishodia et al. 2018) projects comprise of “numerous geographically dispersed but interdependent activities, suppliers, and stakeholders that are exposed to different types and degrees of risks.” Therefore, proper supply chain risk identification can help to identify non-fit projects and increase proactiveness to overcome foreseen difficulties. Also, an increased understanding of the key supply chain risks will lead to the formulation of more realistic plans and expectations (Rudolf and Spinler, 2018). Risk management is therefore major area for investigating supply management performance. Managing procurement risk not only need to mitigate the risk of price and lead time, but also need to have sophisticated analysis to realize the correlation between supply risk and profit impact – and by that, to decide the appropriate procurement strategy (Hong et al., 2018)

**Sustainability and Code of Conduct**

Sustainability aspects have had growing importance in the supply chain risk management. Sustainability practices have an important role in managing non-compliance and economic and reputational damage (Hofmann et al., 2014). Companies that are aware of sustainability-related risks will often use codes of conducts with their suppliers (Hoejmose and Adrien-Kirby, 2012) for managing supplier relationships and in ensuring the sustainability of suppliers. Code of conducts include the utilization of different certificates and standards for environmental management or securing the social responsibility (Marshall et al., 2015). Furthermore, code of conducts reflects the values a company applies to its business and expects its suppliers to follow these values and requirements. Supplier code of conducts are especially needed in project business where supplier relationships are typically discontinuous and relationships can be in inactive phases that can often last several years.

**Purchasing policies**

It is stated that the purchasing strategy selected in projects affects value creation. Short-term value elements have product focus and a competitive tendering basis whereas long-term value elements in projects focus on relationships with customers and suppliers and innovations (Ahola et al., 2008). In the project business environment, various project characteristics moderate purchasing procedures and project performance. The more challenging the project characteristics (complexity, customization, uncertainty value/size, time pressure) are, the more cooperative purchasing procedures improve overall project performance (Eriksson and Westerberg, 2011).

Because projects are unique, one-off settings and carry inherited risk and uncertainty because of their temporary nature (Baily et al., 2008) decentralized purchasing in projects
and competitive tendering is the prevailing practice in buying companies. Thus, the firms’ motive of buying determines which purchasing strategy it uses (Svahn and Westerlund, 2009).

Research Approach
A survey was conducted to collect data from companies engaged in project business in Finland. The main industries included were machinery and mechanical engineering, marine and MRO industry, and construction and civil engineering. A total of 99 responses were received yielding a satisfactory response rate of 37% per cent (99/265). The collected data were analyzed with quantitative methods. The results showed that the level of supply strategy and capability increase risk management in firms. Furthermore, it can be concluded that from the total cost elements - the cost before purchasing and after it - are related with risk management whereas actual purchasing costs such as price, transportation and ordering do not impact on risk management. In addition, it is found that the project length influences risk management. The survey instrument items are presented in Appendix 1. The main latent constructs include Purchasing Policies, Risk Management orientation, Supplier relationship management (SRM) and Purchasing Performance. The Likert scale (1-7) was used for assessment of the survey items.

Survey instrument
We validated the survey measurement model by measurement reliability, validity of the factor structure, and discriminant validity (Henseler et al., 2009). Construct reliability (CR) and the average variance extracted (AVE) were used to assess the measurement reliabilities of latent construct by average variance extracted (AVE) (Fornell and Larcker, 1981). The measurement reliabilities are illustrated in Table 1, which shows that all of the latent variables had decent reliabilities for further modeling and analysis. According to Kline (2011), the CR coefficient should exceed .50 to indicate acceptable if the model validity otherwise is good. The CRs of the latent constructs were varying between 0.87 and 0.93 indicating acceptable level, we analyzed the measurement model (factor structure) by significance of factor loadings, reliability, and validity. We also assessed the cross loadings between latent factors.

All loadings in the measurement model were above 0.4, which can be regarded as acceptable (Hair et al. (2016). AVE convergent validity values were greater than 0.50 for all measured latent factors implying acceptable construct validity (Fornell and Larcker, 1981). Furthermore, we used the square root of AVE (i.e., Fornel-Larcker criterion) (Henseler et al., 2015) for evaluating the heterotrait-monotrait ratio of correlations (HTMT) of the measurement model. According to criteria (Henseler et al., 2009) if the HTMT value is below 0.90, discriminant validity has been established between two reflective constructs. There are no correlations higher than 0.5 manifesting in a good discriminant validity of the measurement model.

Analysis of paths in the Research Model
We analyzed the main effects in the model based on the hypotheses 1–3. In the analysis, the bootstrap the resampling of the data was repeated 5000 times (basic bootstrapping) in the analysis, which is adequate for estimating the parameters in the model (Henseler et al., 2009; Kline, 2011). We tested and validated the quality of the structural model through the explanatory power and path significances.

The r-squared for the latent variables in the path model were “Purchasing Performance” = 0.55, “Purchasing Policies” = 0.39, “Risk Management Orientations” 0.57, and Supplier Relationship Management “SRM” = 0.21. Overall, it can be stated that the explanatory power
of the model is satisfactory, regardless of the relatively low sample. The model is relatively capable of predicting purchasing performance in the studied environment.

The tested path model (see Fig. 1) shows that all of the latent constructs “Purchasing Policies” and “Risk Management Orientations” 0.57, and Supplier Relationship Management “SRM” had a strong direct influence on the “Purchasing Performance”. There were also interesting indirect paths that are regarded significant. According to analysis “Code of Conduct” influence significantly on both “Purchasing Policies” and “Risk Management Orientation”. Furthermore, “Risk Management Tools” influence significantly on “Risk Management Orientation”. Thus both “Purchasing Policies” and “Risk Management Orientation” mediating role in the research model between variables. Finally, our model indicates significant relationship between “Supplier Collaboration” and “SRM” and indicates positive mediating role between “supplier Collaboration” and “Purchasing Performance”.

Research Findings
The results of the empirical survey study conducted in the project-based industries in Finland indicated the factors that explain the purchasing performance in the project business. Based on the finding of the empirical study, Supplier Relationship Management (SRM), purchasing policies, and supply chain risk orientation predicts significantly to the purchasing and supply management performance in the project-based companies. It is surprising how purchasing tools and code of conduct (sustainability) have no straight impact on purchasing performance in project business context. However, this finding is in line with the literature; uniqueness and complexity of a project requires more relationship and previous experience from suppliers (SRM) and different approach in purchasing and supply management. Supplier Relationship Management itself might work as a risk management method but as the results
indicates, risk management objective is evident in procurement performance. Project business literature also supports risk management high agenda in project management and project performance. Collaboration with suppliers did not showed direct influence on the purchasing performance, however, the study showed partial evidence that SRM mediates the relationship between supplier collaboration and purchasing performance.

**Conclusion**

From the perspective of purchasing and supply management, project environment creates various challenges that should be understood better. The aim of the empirical study is to explore the factors affecting to the supply management performance in the project-oriented companies. Firstly, the aim is to investigate the supply management characteristics in the project business. Secondly, the objective is to study the relationship between supply management practices and organization on the purchasing and supply management performance. In this paper we highlighted the challenges of purchasing in project business context, contemporary issues.

Our study provided some interesting findings related to purchasing performance in a project environment. Supplier Relationship Management (SRM), purchasing policies, and supply chain risk orientation predicts significantly to the purchasing and supply management performance in the project-based companies were found to have high impact on projects’ outcome. Overall, the research findings correspond with the literature review. Projects uniqueness, dynamic and complex activities sets challenges to procurement. Procurement should at the same time mitigate risks by exploiting well known and well performing supply base but still try to search for better cost from novel suppliers (transactions) at the same time. Taking this into consideration, procurement should involve several external resources such as suppliers and subcontractors to ensure performance and expected project outcome. Hence, procurement in projects reminds more management of a business network rather than transactional buying adopting risk management procedures. The research results suggest that procurement performance in project business is a field to pay attention to.

**References**

## APPENDIX 1– Survey Instrument

### Purchasing Policies – Policy (1-7 scale)
- Corporate policies related to purchasing activities are well established and documented
- Corporate policies give guidance and direction to purchasing activities
- A comprehensive purchasing ethics policy exists and is widely communicated
- Supply management practices conform to corporate policies
- The purchasing process is well documented
- Written procedures cover purchasing documents such as forms, orders, and legal contracts
- Written procedures also exist for MRO, emergency and extraordinary purchases

### Risk Management Orientation – RiskMgmt (1-7 scale)

*How much do you pay attention to the following risks in your business?*
- Country risk (politics, economy, social stability)
- Financial risk (loans, collateral, investors, interest rates, currency fluctuations)
- Delivery risk (because of the supplier)
- Business relationship risk (contract violation, knowledge leak, negotiation power)
- Risk related to a third party (transport, sub-contracting)
- Risk related to corporate social responsibility (CSR, social, ecological and economic responsibility)

### Supplier Relationship Management SRM – SRM (1-7 scale)

*Evaluate how well supplier relationship management is conducted in your company*
- Daily routines and operations with suppliers are well performed
- The supply chain is managed holistically
- Building of trust-based relationships is the goal
- Suppliers are treated ethically and all contracts are legal
- Information is readily shared and communication is open between the supplier and buyer

### Purchasing Performance - PurchPerform (1-7 scale)

*Please evaluate how well the following statements describe the performance of supply management in your company.*
- The products the supply management has purchased meet well the given requirements/specifications
- The products the supply management has purchased arrive/are produced in time as agreed
- Supply management does not exceed the given target costs
- Supply management does not exceed the given inventory level targets
- Internal customers are satisfied how their problems are dealt with in supply management
- The contracts negotiated by the supply management meets well the different needs
- Supply management delivers relevant information to its interest groups
- Supply management delivers high quality products and services
An empirical investigation of the drawbacks of SME-friendly public procurement policies:  
The UK experience

Abstract

The paper explores the potential weaknesses and limitations of key policy measures implemented to support SMEs in public procurement in the UK. We conducted semi-structured interviews with a sample of SME owners/managers competing for public contracts within North West NHS Trusts in England and evaluated the data through qualitative thematic analysis. The five key themes that emerged from the data through the process of inductive coding are: 1) implementation and compliance issues, 2) experiential barriers, 3) participation is not a given, 4) unattractiveness, and 5) inability to maximise policy benefits. This paper contributes to the emergent SME-public procurement nexus discourse.

Keywords: SMEs, public sector, procurement.

Introduction

An important aspect of UK government policy is to increase SMEs participation in public procurement. The government previously set a target of 25% of public sector procurement spending to reach SMEs by 2015 (Department for Business Innovation and Skills, 2013). Several policy measures are being implemented across public organisations to achieve this target; the most notable ones are the rule that requires public organisations to eliminate Pre-Qualification Questionnaire (PQQ) for small value contracts, the prompt payment rule, division of contracts into lots, establishment of contracts finder, acceptance of consortium bidding and promoting of subcontracting opportunities. Despite the growing adoption of these policy measures (Loader, 2018), the latest available data shows that SMEs are still under-represented in public procurement markets.

For example, data published by the UK government (Cabinet Office, 2017; Cabinet Office, 2018) show that public sector spending with SMEs fell to 24% in 2015/16 and 22.5% in 2016/17, respectively. If this trend persists, the government is off-track to reach its latest plan of directing 33% of public procurement spending to SMEs by the end of 2022 (Home Office, 2018). Therefore, key policy measures being applied to promote SME participation in public procurement should be reviewed to ensure that they remain relevant and effective. Research conducted by Loader and Norton (2015) in the UK’s
Heritage sector, revealed that SMEs would prefer to deal directly with the procuring authorities rather than acting as subcontractors to larger firms or forming consortia to boost their tendering capabilities. However, the authors did not provide much detail about the reasons for this preference.

To address this gap, we examined issues that SMEs face regarding key policies implemented in public organisations in the UK. First, we conducted a review of relevant literature to identify studies on measures designed to help SMEs improve in public procurement in the UK. These included relevant articles published in academic journals, policy notes, consultation papers, guidance documents, press releases and other government publications. Six most frequently cited measures identified in the literature were examined through empirical data collected from SMEs supplying NHS trusts in North West England. The findings include five key themes derived through qualitative analysis of empirical data. We provide a discussion of the findings and highlight the implications for theory, practice and policy.

SMEs participation in public procurement in the UK

The political push for making public contracts more accessible to SMEs stemmed from the adverse effects of the 2008 global economic recession (Flynn et al, 2013). The recession restricted access to finance for small businesses, leading to decline in cash flow and subsequent negative effects on sales and profit margins (Prince et al, 2013). Since then, increase SME access to public procurement has been a key commitment of the UK government. Consequently, a major consideration for policy makers and experts has been to leverage the public procurement spending for promoting growth in the small business sector.

In a comprehensive review of current evidence, Loader (2013) discovered low involvement of SMEs in public tendering in the UK over a twenty-year period. The author also found that there has been no significant improvement in the success of SMEs winning public sector contracts. Although it can be argued that Loader’s finding is no longer current, there is paucity of evidence to prove that the situation has improved significantly since then. Results of another study conducted around the same year by Federation of Small Businesses (FSB) provide a clearer picture, concluding that 78% of SMEs had not bid or worked on public sector contracts (FSB, 2013). The FSB is the biggest pressure group influencing government policy in the interest of small business owners in the UK. It has a panel membership of 6,394, all of whom were invited to participate in the survey.

Similar findings emerge in a more recent report by Minority Supplier Development UK (MSDUK), demonstrating that SME participation in public procurement in the UK is amongst the lowest in Europe (MSDUK, 2014). Researchers (e.g. Loader and Norton, 2015; McKevitt and Davis, 2015) have linked the low participation of SMEs in public procurement to several barriers. Various policy measures have been adopted to address these barriers, which we shall discuss in subsequent sections of this paper. Yet, there is not enough evidence to suggest that efforts to help more SMEs bid for public sector contracts is yielding the expected outcomes. Government spending with SMEs fell from 27% to 22.5% between 2015 and 2017 (Cabinet Office, 2018).

Barriers facing SMEs in public procurement in the UK.

An early attempt to consider the challenges faced by SMEs competing for public sector contracts in the UK was by Glover’s (2008) committee review. A key finding of this review was that SMEs do not have access to information on available public contract opportunities in the UK. This is because individual public organisations used to advertise
contract opportunities on their own websites, which might necessitate SMEs to use their limited time and resources in searching for tenders on various web-portals. Since then, there has been increasing interest by researchers to understand the barriers facing SMEs in public procurement. We have summarised some of these in Table 1.

Table 1 - Key barriers facing UK SMEs in public procurement

<table>
<thead>

<th>SMEs key challenges in public procurement</th>
<th>Sample literature</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transparency issues: lack of access to information about existing contract opportunities</td>
<td>Glover (2008)</td>
</tr>
<tr>
<td>Lack of, or insufficient skills to develop winning bids: e.g. legal, administrative, customer services, IT skills</td>
<td>Karjalainen and Kemppainen (2008), Freshminds, 2008, Loader (2011)</td>
</tr>
<tr>
<td>The size of available contract opportunities: contract value is sometimes unattractive, contract duration is short, and the sizes are too large, discouraging SMEs from participation</td>
<td></td>
</tr>
<tr>
<td>Overly prescriptive requirements: technical requirements are too high, and the specification is inflexible</td>
<td>Yukiko (2014),</td>
</tr>
<tr>
<td>The procurement process is cumbersome: tendering process is time consuming; involving too much paperwork and unrealistic tender timescales</td>
<td>Loader (2011), Pickernell et al (2011),</td>
</tr>
<tr>
<td>Pro-large-business culture of public buyers: preference for incumbent suppliers, rationalisation of supply base and emphasis on cost savings</td>
<td>Loader (2013)</td>
</tr>
<tr>
<td>Slow payment: delays in payments to contractors and sub-contractors</td>
<td>Loader (2015)</td>
</tr>
</tbody>
</table>

The UK government has designed several policy measures to tackle these barriers. We have identified six notable measures that are being implemented in public organisations including the NHS, to help support SMEs in public procurement. These are included in UK public procurement regulations, consistent with European Code of Best Practices Facilitating Access by SMEs to Public Procurement Contracts, and Public Contracts Directive, 2014/24/EU. In Table 2, an attempt will be made to summarise these key measures along with the barriers around SME participation in public procurement which they seek to mitigate.

Table 2 - Liking policy measures to barriers facing SMEs in public procurement in the UK

<table>

</tr>
<tr>
<td></td>
<td>redcuting the administrative burden placed on bidders • Make the supplier eligibility criteria less difficult to meet, • Allow bidders to self-certify their ability to meet the required selection criteria (e.g. financial and insurance requirements).</td>
<td>financial capacity that are disproportionate to the value/size of the contract opportunities (Pickernell et al, 2011).</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>2. Prompt payment rule</td>
<td>Designed to: • Alleviate the impact of prolonged delay in payment under public procurement contracts (Nicholas and Fruhmann , 2014). • Impact on the cash flow of contractors and help subcontractors to be financially healthy (Rostek, 2015). • To inspire existing/potential contractors to be on the lookout for new contract opportunities (National Audit Office, 2015).</td>
<td>• SMEs are discouraged from participating in public tendering because they perceived that public sector organisations delay payments to their contractors (Preuss and Walker, 2011). • There is a widespread concern about delay in payments to contractors and subcontractors (Loader, 2013).</td>
</tr>
<tr>
<td>3. Consortium bidding</td>
<td>Designed: • To enable SMEs improve technical capability and increase resource through collaboration • To allow two or more SMEs to pool knowledge together or combine unique expertise to submit high quality bids (EU, 2009). • Drive skills transfer among firms forming a consortium to deliver contracts (Palacios-Marqués et al, 2015) • Reduce geographical immobility of contractors for delivering (Competition &amp; Consumer Protection Commission, 2014).</td>
<td>• Bidders with little/no experience of public tendering are also expected to demonstrate a track record of performance in similar contracts (Loader, 2013). • Lack of ability to meet the resource and capability requirements to participate in public tendering (Loader, 2013) • SMEs performance in public tendering is impeded by lack of resources namely legal, customer services, IT skills marketing, administrative and human capital resources (e.g. Karjalainen and Kemppainen, 2008).</td>
</tr>
<tr>
<td>4. Contracts finder</td>
<td>Designed to: • Make contract opportunities more • Enable prospective bidders to keep an eye on forthcoming tender opportunities</td>
<td>• Lack of awareness of opportunities and insufficient communication with the public procurement officers (GHK, 2010).</td>
</tr>
</tbody>
</table>
Research Methodology
The purpose of this research is to examine the opinions of SMEs supplying NHS organisations in the North West of England, regarding key policy measures implemented to improve their participation in public procurement. The analysis unveils issues and concerns that should be addressed to improve effectiveness of policies designed by the UK government to support SMEs bidding for and winning public contracts. A qualitative research approach has been adopted to help us unearth SMEs’ experiences and thoughts about these policy measures.

We conducted semi-structured interviews with 25 SMEs, located in the North West region of England, who act as suppliers to different NHS trusts and have some knowledge of public procurement policies for small businesses in the UK. The North West is the 3rd biggest of the 9 regions, accounting for 13.7% of the total annual healthcare spending in England (Full Fact, 2018) and was selected because the authors can gain...
access to NHS trusts in this region and obtain information about SME suppliers that can be recruited as participants in this study. Using existing contacts with relevant NHS trusts, we selected the sample firms from their database of suppliers.

Data collection
In depth interviews were conducted with the manager or owner of each firm to obtain data. These were structured to determine experiences of tendering for contracts within the NHS, and issues of concerns about the supporting policy measures. We began the interviews by asking participants to share their stories of how they started their business and came to be a supplier to the NHS. This allowed them to elicit their experiences willingly in an informal setting, following the narrative conversational style recommended by Edwards and Holland (2013). Although the questions were structured to maintain focus, the interview process was flexible (Silverman, 2010), enabling better conversation about different policy measures to support SMEs in procurement. Not only does this approach allow participants to show knowledge of these policies, it enables them to express opinions and develop arguments about the benefits and drawbacks of implementation.

All interviews were conducted face-to-face on the premises of each firm so that participants can feel more comfortable to express their experiences and opinions. The interviews were jointly conducted and recorded by the first two authors after obtaining the interviewees consent. The third author took notes to capture important information during the interviews and transcribed the recorded interviews with the support of the first author.

Data analysis
Transcripts from qualitative interviews were analysed using thematic analysis (Miles, Huberman and Saldana, 2013), to help us make sense of the data. We conducted inductive coding of textual data to identify, categorise and discuss themes that represent the drawbacks and limitations associated with six policy measures designed to support SMEs in public procurement in the UK, namely 1. Elimination of PQQ for smaller contracts, 2. Prompt payment rule, 3. Consortium bidding, 4. Contracts finder, 5. Division of contracts into lots, and 6. Sub-contracting. After each author finalised their coding, the themes were compared, any inconsistencies that occurred were debated and resolved. Themes were then adjusted where necessary before full analysis. This process has two advantages; first, it enabled us to guarantee inter-coder reliability and validity given the extent of agreement between the different coders (Weber, 1990). Secondly, it enhances the extent to which the final coding results represents what we intend to measure. The findings of our analysis are presented and discussed in subsequent sections of this paper.

Participant firms' characteristics
To gather the relevant data and determine representativeness, firms in the sample were required to have experience of competing for contract opportunities in the NHS and have not more than 250 employees. Hence, all firms that participated in this study can be classed as SMEs based on employee numbers, in accordance with the UK government’s definition of SMEs (Wand, 2014). In addition, we identified the varied characteristics of the sampled firms before presenting the findings, by distinguishing them according to size: namely micro-sized (with less than 9 employees), small-sized (less than 50 employees) and medium-sized (having not more than 250 employees). Apart from the number of employees and firm size, the locations and industry sectors attest to the
diversity of the firms. Although we do not include these firm characteristics in our data analysis, in line with the qualitative nature of the study, they suggest the possibility to examine SMEs’ different experiences of the various policy measures to help them improve participation in public procurement.

Results

Five key themes emerged from our qualitative data to represent the limitations of policy measures designed to support SMEs in public procurement in the UK. These are discussed below under the following subheadings: implementation and compliance issues, experiential barriers, participation is not a given, unattractiveness, and inability to take full advantage of the policies.

Implementation and compliance issues

Lack of implementation and non-compliance are the most common issues raised by participants about all the policy measures examined in this study. This was most likely caused by the lack of penalties or consequence for non-compliance, the negative attitude of public buyers towards small suppliers and a desire for cost savings in procurement process, which may not materialise through buying from small firms. For example, some (15) participants reported that tender specifications are still frequently skewed in favour of large firms, irrespective of whether the tender is divided into lots or not. Our findings support previous research that policy actions to support SMEs in public procurement remain “more rhetoric than reality” (e.g. Flynn and Davis, 2015).

Experiential barriers

The fact that NHS organisations seek suppliers with a proven track record of success in contract delivery was another important concern expressed by participants in this study and identified as a major drawback of SME-friendly procurement measures. This suggests that despite the supporting policies that are being implemented, firms without public tendering experience are still not likely to compete effectively against large firms who have dominated the public sector market (Loader, 2013). We argue that this is a key issue that cannot be ignored because it can potentially discourage start-ups or new SMEs from seeking public contracts. If bidders are always required to have previous experience of supplying the public sector to qualify as contractors, it is nearly impossible for young SMEs (or start-ups) to win contracts.

Participation is not a given

The idea that key policy measures do not guarantee participation and success in public tenders was another issue raised by our respondents. For example, there were concerns that dividing contracts into small lots does not preclude competition between small and large firms. Irrespective of size, all firms are required to contend against each other in the tendering process. This suggests that efforts to open the public procurement market to competition (Thai, 2006), could have a negative impact on effectiveness of SME-friendly policy measures. This finding supports the initial argument by Andrecka and Trybus (2017) that public procurement reforms, particularly in EU countries like the UK, cannot be regarded as actions favouring the small business sector.

Unattractiveness

Evidence from this study reveals that participants have apparent lack of interest in subcontracting. The finding is consistent with previous research (e.g. Loader and Norton, 2015) that SMEs supplying the UK’s heritage sector would prefer to contract directly
with public organisations rather than via the Subcontracting route. Our results, however, shed more light on this by identifying the probable reasons for this disinclination for taking part in subcontracting opportunities. These include unfair treatment by prime contractors, risk of losing intellectual property and lack of transparency in the selection process.

**Inability to take full advantage of the policies**
The underutilisation of policy benefits was identified as another factor limiting the efficiency of the policy measures. This point was raised in relation to Consortium Bidding, Prompt Payment Policy and The Contracts Finder. Some participants expressed a lack of understanding of how to form a consortium when bidding for contracts. The problem of identifying which firm to collaborate with when bidding for a public contract was also mentioned. Furthermore, most NHS trusts use electronic invoicing solutions to pay suppliers, which may pose challenges to some SMEs who have limited ICT capability. A similar issue was raised about the online portal used for contracts advertisement (i.e. Contracts Finder).

**Discussion**
We examine the potential drawbacks and limitations of policy measures being implemented to facilitate SMEs participation in public procurement in the UK, from the experiences of firms supplying NHS trusts in North West England. Our findings reveal some factors which might explain why UK government policies have not been yielding the expected results in terms of increasing SMEs share in public sector spending. First, the findings suggest that government should increase efforts to bridge policy–practice gaps by introducing stricter penalties for noncompliance and incentives to increase enthusiasm for SME suppliers to the public sector. Secondly, SMEs as potential beneficiaries need to develop the necessary capabilities to maximize policy benefits, e.g. by leveraging social media for networking to share information, knowledge and experiences about public tendering, as well as explore potential partners for consortium bidding opportunities. The evidence generated from this study offers new insights into factors that can potentially affect the effectiveness of SME-friendly procurement policies in the UK.

**Contribution to knowledge**
Previous research (e.g. Kidalov and Snider, 2011) have claimed that government policies and actions for promoting SME participation in public procurement are ineffective and their implementation is more "rhetoric" than reality (Flynn and Davis, 2015). However, many of these studies did not attempt to explain the reasons for this. The paper contributes to knowledge in this area by highlighting key issues that need further attention, to translate government policy intentions around SME participation in public procurement into expected outcomes.

**Implications for research**
Researchers can build on the findings in this paper to formulate hypothesis to test different ways in which government policies might be modified or changed to demonstrate better outcomes for SMEs in public procurement markets.
Implications for practice
The findings can guide policy makers and public procurement managers in identifying where modifications and improvements of existing policy measures are needed for promoting SME participation in public procurement.

Limitations
Our findings are based on a qualitative study conducted in one of the nine regions of England, which limits its generalisability. Notwithstanding, the evidence gathered from the experiences of SMEs supplying NHS trusts in North West England provide insights into areas of focus for translating policy to reality, particularly about SMEs participation in public procurement.

Conclusion
The overall conclusion from the study is that while SME-friendly procurement policies of the UK government seem good in principle, it is not a given that implementation will yield expected results. This is because there are several limitations which can make the policies inadequate and ineffective.

Abstract

Buyer-supplier relationship performance is significant in industrial markets. While the extant literature points to the importance of interpersonal trust mechanism for a long-term buyer-supplier relationship, we propose that more informed supplier ‘brand representatives’, rather than traditional sales representatives, can improve the quality of information that is transferred between suppliers and buyers. We conducted in-depth interviews and collected survey data from procurement managers in Australia. We found that suppliers’ brand representatives significantly and positively influence buyer’s trust through their communication of both functional and emotional roots of trust.

Keywords: Interpersonal Trust, Buyer-Supplier Relationship, Risk Reduction

Introduction and Literature Review

The development and maintenance of trusting relationships between buyers and suppliers plays a critical role in enhancing the competitiveness and efficiency of manufacturing processes. The decision-making process for procurement personnel – understanding suppliers’ products and services and supplier selection – involves a significant amount of uncertainty (Devaraj et al., 2012, Riedl et al., 2013). Because of the asymmetric nature of information and new transactions, developing trust reliably, can be difficult (Zhang et al., 2011, Zaheer et al., 1998). One way in which suppliers can more credibly and efficiently communicate the nature of their business, and reduce buyers’ procurement risk, is through supplier’s brand (Leek and Christodoulides, 2011).

We propose that more informed supplier ‘brand representatives’, rather than traditional sales representatives, can improve the quality of information that is transferred between suppliers and buyers. We also propose that trust in supplier brand representative has both functional and emotional roots. Brand representatives can transfer information that goes beyond basic product details, and which more effectively informs whether trust will
develop in the relationship. This in turn reduces overall risk for buyers, thus improving the efficiency of the procurement process.

Method

Given the limited empirical work on the role of brand representatives in B2B markets, exploratory research was undertaken. Scholars recommend a qualitative research phase where extant research may be inadequate (Venkatesh et al., 2013). Nine in-depth interviews were conducted with procurement managers from a variety of manufacturing organizations including footwear, chemical, automotive, and steel amongst others. This was followed by administering a survey collecting data from Australian senior managers responsible for purchasing or recommending products to their organizations.

Measurement items for trust in brand representative and its antecedents were generated using existing scales and based on the interview phase by following procedures recommended for operationalization and measure development (Churchill, 1979, DeVellis, 2012). A total of 204 completed questionnaires were collected.

Result and Discussion

Results confirmed hypotheses developed and pointed to the importance of proposed relationships. Consistent with the extant literature (Dowell et al., 2015, Homburg et al., 2011), our findings suggest that trust in a supplier’s brand representative has both functional and emotional roots. The positive direct relationships that emerged between these factors and trust in brand representative were substantiated. Further, trust in brand representative was found to reduce buyers’ risk, thereby enhancing relationship loyalty, which is consistent with similar findings (Nicolaou et al., 2013).

The extant literature has underscored the complexity of the concept of trust and the shortcomings of its operationalization (Seppänen et al., 2007). In line with research advocating the multi-dimensionality of trust (e.g. Butler, 1991, Singh and Sirdeshmukh, 2000), our findings contribute to theory by providing empirical evidence that trust in brand representatives has both functional and emotional roots. This study further demonstrated the critical role of brand representatives in directly and indirectly influencing trust development between buyers and suppliers during the procurement process, reducing risk and enhancing relationship loyalty.

Our study suggests several managerial implications. First, as B2B brands continue to grow in importance, managers should be aware of the strategic role brand representatives can play in articulating a brand promise during the procurement process. Our findings support prior propositions regarding the importance of human representatives in B2B markets when engaging with customers (Lynch and de Chernatony, 2007). Second, our findings show that brand representatives play a central role in improving buyers’ understanding of suppliers.

What is the right purchasing portfolio model for your purchase?

Abstract
Purchasing portfolio models (PPM) are the number one tool for purchasers and various versions exist that help to increase the effectiveness of the function. Yet, PPMs are also criticized for being too simplistic. This study aims to provide a more differentiated approach to PPMs by considering the objective of a purchase. Employing mixed methods drawing on scenario-based survey data and 29 interviews (41 cases) this research explains how for a given objective different PPMs might be suitable. In doing so, we not only add important insights to PPM theory, but also help practice to increase the usefulness of portfolios.

Keywords: Purchasing Portfolio Models, Objectives, Mixed Methods

Introduction
Purchases cannot be managed uniformly (Ateş et al., 2015) due to a diverse set of strategies and tactics that may apply for various purchases (Hesping and Schiele, 2016). Purchasing portfolio models (PPMs) are the number one tool for purchasers to differentiate purchasing approaches due to their simplicity and flexibility (Montgomery et al., 2018). By segmenting purchases into prototypical sourcing categories PPMs allow to derive suggestions on how to manage a purchase in the most suitable way. However, applying strategies in practice is frequently not that simple as there is often more to consider in categorizing purchases than a single PPM can offer (Hesping and Schiele, 2016). As such, identifying further differentiation possibilities drawing on PPMs could help to progress the field of purchasing.

One fruitful avenue for differentiation is the objective of a purchase (i.e. the envisioned accomplishment) such as cost savings, delivery performance, innovation or quality improvements (e.g., Lee and Drake, 2010). Previous research considering the purchasing objective shows that purchases can be clustered based on the importance of a purchasing objective (Luzzini et al., 2012) or that the objective affects the structure of the supply base (Ateş et al., 2015). Furthermore, Pagell et al. (2010) observe that purchases focused on sustainability do not follow the proposed approach of the original Kraljic PPM. A question that arises is: why use a PPM as a starting point in categorizing purchases (as suggested by e.g., Olsen and Ellram (1997)) rather than considering other aspects (e.g., the objective) up front? To advance the ways purchasing can add value to an organization we ask: to what extent and how does the objective of a purchase influence the choice of the most suitable PPM?
While PPMs are not a theory in itself, they have the key component of a theory as they help to allocate limited resource in the proper manner to increase performance (Pagell et al., 2010). As such, by addressing the above research question we not only contribute important practical, but also valuable theoretical insights. In particular, drawing on mixed method data, we address the lack of a sound theoretical background, a proper framework, and usable metrics regarding PPMs (Luzzini et al., 2012). In doing so, we contribute important new insights to the field of purchasing on how to allocate resources in the most effective way by differentiating the operationalization of PPM dimensions so that PPMs can be used in their true intention.

Theoretical Background

Purchasing Portfolio Models

PPMs allow firms to develop differentiated approaches for various purchases while reducing administrative complexity and increasing the effectiveness of available resources (Montgomery et al., 2018; Olsen and Ellram, 1997). The basic idea of PPMs is to categorize purchases based on two dimensions (each assessed from low to high) into four homogenous categories; individual categories require a similar management approach for which norm strategies are recommended (Hesping and Schiele, 2016). The most acknowledged and established PPM in theory and practice is the Kraljic Matrix (1983) (e.g., Ateş et al., 2015; Montgomery et al., 2018). Based on the underlying dimensions of the importance of the purchase and the complexity of the supply market the Kraljic PPM distinguishes non-critical, leverage, bottleneck and strategic category items with non-critical and leverage items requiring a transactional, and bottleneck and strategic items a relational approach (Lee and Drake, 2010; Olsen and Ellram, 1997). The transactional versus relational approach has been further linked to aspects of dependence as Caniëls and Gelderman (2007) found relatively high buyer’s dependence for bottleneck and strategic items and relatively low dependence for non-critical and leverage items. As such, the Kraljic (1983) PPM allows an organization to maximize purchasing power and value while minimizing supply risk (Padhi et al., 2012) i.e. to match external risks and opportunities with internal needs of the firm (Dubois and Pedersen, 2002).

Efforts to operationalize the dimensions of Kraljic, have led to many extensions of the PPM since 1983 (Luzzini et al., 2012) (see also Table 1). These PPMs derive the same four categories, but with different means to get there: they adjust one of the PPM dimensions. Olsen and Ellram (1997) change the complexity of the supply market to the difficulty of managing the purchasing situation. In doing so, they add more detail and focus to the dimension. Gelderman and Mac Donald (2008) and Padhi et al. (2012) consider profit impact and supply risk in an alteration to Kraljic. A different PPM is introduced by Bensaou (1999). His portfolio focuses on different types of relationships using buyer’s and supplier’s specific investments as dimensions. Bensaou recommends investing into relationships for the categories of strategic partnership and captive buyer while focusing on transactions for the market exchange and captive buyer quadrants.

While the overall usefulness of PPMs is widely acknowledged (e.g., Caniëls and Gelderman, 2007; Padhi et al., 2012) these models are not without criticism. In particular, the simplicity of the models and the difficulty of operationalizing and choosing dimensions have been highlighted (Dubois and Pedersen, 2002; Luzzini et al., 2012; Olsen and Ellram, 1997). Moreover, the origins of PPMs date back to a time when purchasing was mainly focused on costs. Since then, it has long been acknowledged that the value of purchasing to an organization goes beyond costing savings such as contributions to innovation (Ateş et al., 2015). Hence, Lee and Drake (2010) propose that purchasing approaches need to be aligned with the competitive objective of a firm.

**Purchasing Objectives**

In its origin, purchasing was expected to minimize the costs of a purchase related to unit price, total cost of ownership (TCO), processes, asset utilization (Ateş et al., 2018). Yet, today it is well acknowledged that purchasing is more than achieving cost efficiency, but also quality, innovation, sustainability or delivery performance (Ateş et al., 2015; Lee and Drake, 2010; Luzzini et al., 2012; Pagell et al., 2010). Purchases conducted with a quality
objective are concerned with the conformance to specifications and meeting customer expectations (Luzzini et al., 2012). This can include sustainability goals that are also based on compliance and conformance (Luzzini et al., 2012). While innovative purchases are often linked to improving introduction rates and timing of new products/services (Ateş et al., 2018), purchases with a delivery performance goal concern speed, reliability and availability of the product/service (Lee and Drake, 2010; Luzzini et al., 2012).

The different purchasing objectives can predict differences in purchasing practices (Hesping and Schiele, 2016). For instance, previous research has shown that objectives can affect the structure of the supply base (Ateş et al., 2015) and that in some purchasing categories one objective is more important than others (Luzzini et al., 2012). Yet, it was also found that buyers sometimes use the same purchasing practices and strategies across all Kraljic quadrants (Ateş et al., 2015; Lee and Drake, 2010). This indicates that PPMs do not seem to serve their purpose in creating uniform management categories. At the same time, however, current PPM approaches consider the objective of a purchase secondary to the categorization based on two dimensions, even though it seems that different strategies need to be employed depending on the objective. As such, considering the objective of a purchase up front, before categorization, might allow to differentiate dimensions that are important for an objective and as such suggest different PPMs for different purchases. Accordingly, the aim of this study is to explore to what extent and how the objective of a purchase influences the choice of the most suitable PPM.

Methodology
We conducted a two-step mixed method research approach and study purchases (unit of analysis) with different objectives. The first step was exploratory with the aim of investigating different aspects that could allow for a more differentiated approach to PPM. The objective of a purchase, product vs. service characteristics and the buy class were included in this first step as possible differentiation factors. We conducted 15 interviews in eight large organizations (X, A-G) asking each interviewee about two different purchases in the last 12 months. The analysis of this data showed that the objective was the main aspect to focus on when looking for differentiation in purchasing approaches.

In a second step, we engaged with two large organizations (X and Y) in-depth collecting an additional 14 interviews as well as scenario-based survey data. We once again asked purchasers to recall two specific purchases made in the last 12 months and asked questions about applied strategies, the evolution of the purchasing process and reasons behind choices made. We sought out an even spread of objectives (innovation, cost, quality, delivery performance) over the 28 purchases following a theoretical replication logic. We further included those cases of the first step in the data analysis that yielded additional insights. This allowed us to analyze 41 cases: 9 cost focused purchases (C1-9), 14 quality focused purchases (Q1-14), 8 innovation focused purchases (I1-8) and 10 delivery performance focused purchases (D1-10). Table 2 gives an overview of the cases in the context of the organizations and interviews collected. In both the first and second step, all interviews were recorded, transcribed and coded following good standards of qualitative data analysis (see Miles and Huberman, 1994).

Additionally, we collected quantitative data of 52 purchasers (80% of the populations of purchasers in organizations X and Y, 80% male, 96% Dutch). Participants were asked to rate the importance of portfolio dimensions (see third column Table 1) in four scenario-based purchases (Rungtusanatham et al., 2011), each with a different objective. In our scenarios we asked the participants to act as the purchaser responsible for the sourcing of four modules of a combiner project for MachineTooling, a manufacturer of high-end agricultural machinery: straw walker (quality), grain tank (cost), driver’s cab...
(innovation), engine (delivery performance). We first provided a general scenario description and then asked questions about the importance of the portfolio dimensions (constructs were based on multi-item measures using a 7-point Likert scale from 1, not important at all to 7, very important) per module (module sequence was at randomized). All items were based on existing scales in the literature or were developed using conceptualizations of the literature (see Table 1). Except for difficulty of managing the purchase dimension (Cronbach alpha of 0.675) the Cronbach alpha scores are all above 0.7, indicating satisfactory levels for internal consistency reliability. We tested whether portfolio dimensions were considered more important within a certain performance objective (i.e., differences within objectives) using a paired sample T-test (see Table 3).

**Findings**

In line with the aim of this study, the quantitative data show to what extent portfolio dimensions are important within objectives. These results are depicted in Table 3. Following, we present the findings of the qualitative data along the purchasing objectives. In doing so, we first outline the main mechanisms identified and then link it to the PPM dimensions to be able to explain how the objective of a purchase influences the choice of a suitable PPM while also reflecting on the significance levels of the quantitative data.

Cost
We identify two re-occurring themes in the qualitative data for cost-focused purchases: issues around dependence (number and availability of sources) and linked to that financial concerns (benchmarking, competitive bidding, switching costs, TCO). More specifically, we find that when there is little dependence on suppliers (i.e., many alternative options available) our data suggest that buyers tend to “create a supply base from which you can draw” (C6) and “play the game of negotiation with the suppliers […] reasonably hard” (C2) as “they [suppliers] think twice, before they do something wrong” (C3). The low dependence on a specific supplier allows buyers to not only apply competitive bidding, but also to benchmark other aspects of the purchase (e.g., quality or delivery performance) while ensuring “that we can complete that project within the budget.” (C1). “If you have three or four parties that offer [product], well, then you have one or more samples taken so you can [endurance] test them” (C6). This purely transactional approach changes slightly if there are many alternative suppliers in the market but a need to commit to a dependent, single sourcing relationship e.g., IT solutions or energy supply. While for such purchases benchmarking and competitive bidding are used to determine the lowest TCO, more attention is paid to relational aspects to mitigate the increased dependence. The data indicates that once a dependent relationship is established, or in the case of high dependence from the outset, a relational focus is much more important as “it is much easier, if things don’t go well” (C4).

As such, the analysis of the interviews confirms the findings of the quantitative data that considerations of supply risk/complexity are significantly more important than other portfolio dimensions when purchasing with a cost focus. The qualitative data show, that this is due to concerns of dependence. We find that if a buyer can choose between many alternative supplier (i.e. low supply risk) competitive bidding and benchmarking are used to keep TCO low. Accordingly, next to supply risk the data indicate that strategic importance (based on financial concerns) needs to be considered for cost-based purchases, which was found to be more important than other dimensions, but with no significance in relation to others in the quantitative data. In line with the quantitative results that show that the difficulty of managing the purchasing situation as well as buyer- and supplier-specific investments are significantly less important, we see no indication in the qualitative data that purchasers pay attention to these aspects.

Delivery Performance
The analysis of the data shows, that there are two underlying reasons why purchases are focused on delivery performance: availability (number of sources) and timing (risk). More specifically, we find that in eight out of ten delivery performance cases the number of alternative suppliers available to supply a product/service is limited. This is according to our results either due to product (D6, 9), supply market (D1, 4, 5, 7, 10) or environmental characteristics (D8). The data indicate that the product, supply market and environmental characteristics that make availability difficult and the resulting dependence on suppliers often means that purchasers aim for long-term relationships. “We’ve seen that [market pressure] coming pretty soon, so we quickly concluded a long-term contract with the suppliers” (D7). The aim for long-term relationship due to concerns in availability is opposed to concerns of timing. In D3 we find that time is essential due to risk concerns: “...you want the goods to be there at the right time, but you don’t want the goods to stay there for a week, for example. Then you only run the risk that it will be stolen, broken or damaged.” In case D2 timing is important too, here however, linked to a change in legislation which meant that a purchase for a simple product with high availability of alternative suppliers had to be done focusing on delivery performance
rather than costs. Hence, the mechanisms of cost focused purchases competitive bidding and benchmarking were applied. Accordingly, also in D2 and D3 underlying environmental conditions make delivery performance the main objective, yet it does not lead to the need for long-term relationships as dependence is limited. As such, the qualitative data highlight the importance of the difficulty of managing the purchase as a portfolio dimension for delivery performance focused purchases. This is different to the quantitative results that show that this dimension is not significantly more or less important than others while highlighting that supply risk/complexity is significantly more important. At the same time, we find in the qualitative data that supply risk/complexity arises from the difficulty of managing the purchase as it causes supply risk/complexity, eliminates alternatives of supply and leads to an overall low number of alternative suppliers.

Furthermore, we find in all cases that focus on availability (D1, D4-10) that disruptions in supply will cause higher TCO than paying a higher price upfront. This was highlighted extensively throughout the cases, for example: “The only interest we had was to secure supply. So we didn’t really care about price or contractual conditions. It was all about availability.” (D10). In D1 transportation modes are changed from 2.5 months shipping to 1 week flying to ensure availability. This adds 3000€ in comparison to 10-20000€ per hour in case the company is not able to deliver to its customer. These examples illustrate the strategic importance portfolio dimension for availability related delivery performance purchases. This is different to the quantitative data that found the strategic importance dimensions to be neither significantly more nor less important than other dimensions related to delivery performance. At the same time, in line with the quantitative data that shows that buyer- and supplier-specific investments are significantly less important, we see no indication in the qualitative data that purchasers payed attention to these aspects.

**Innovation**

The analysis of data highlights the importance of investments and commitment for innovative purchases. Consequently, we find that even when there are many alternative suppliers available competitive bidding is not used. It appears that this is due to the fact that in all innovation cases specialist knowledge is required: organizations realized that they need the help of a supplier to innovate as the product/service entailed technical complexity “so high that we couldn’t put it down on paper ourselves” (I11) or “so specific, it was really hard to make a complete specification from scratch” (I7). Accordingly, the characteristics of the innovate purchase were “so customized that they were looking for a supplier that was willing and interested in co-development in a partnership” (I1). A focus on a one-on-one relationship was highlighted throughout the cases “especially if you want to achieve innovation together” (I6). “We found this supplier and together we developed their processes to be able to produce this product” (I8). Beyond seeking a close relationship and as the previous quotes indicate, all cases but I2 engaged in co-development. We find that such co-development requires buyer- as well as supplier-investments. “We flew in ‘the knowledge’ and they had to do some small investments [in their production facility], but they’re really seeing that is was for a good outcome.” (I8) Similarly in I3 they "brought in a lot of knowledge and expertise, but the supplier also had a lot knowledge and expertise" (I3). As such a partnership might go as far as being “so transparent that you tell them what the budget is and what the planning is and then ask them if they can do something with it” (I3) and lead to high dependence “because those [products] are really very specific to us so we were really tied to that supplier” (I3).
Given these aspects, we find that risk assessment, in terms of the size of the supplier or their financial status, is more important than competitive bidding. Particularly the size of the supplier kept emerging from the data. On the one hand, we find that it was considered a "risky situation, because it was a really small supplier, and really dependent on us" (I8). “For those very large parties, on the other hand, I had the idea: I’m just one of many parties, so how fast are you going to run (work) for me (doubts)?” (I2). In essence, what emerged from the data is that “you should look for a party that is technically skilled, but still has the interest to do such a development trajectory” (I1). However, different to cost and delivery performance focused purchases this finding seems to not link to dependence, but rather to ensuring commitment (i.e. supplier investments).

The qualitative findings show that innovative purchases are always strategically important and that the difficulty of managing the purchase is a given due to the product characteristics. Furthermore, concerns about supply risk/complexity are not highlighted as in the search for customized solutions organizations often aim to develop one-on-one relationships. Hence, organizations are less troubled by the amount of alternative suppliers and dependence. Similarly the quantitative findings for these three dimensions show that neither is significantly more or less important than others. Additionally, the quantitative findings demonstrate positive but non-significant importance of buyer- and supplier-specific investments. This is underlined by the qualitative data. Buyers seek out suppliers that can commit to the innovation and are willing to co-develop with both parties investing time and resources to find a feasible solution.

Quality
The data indicate two re-occurring aspects for quality focused purchases: product characteristics (conformance to specifications) and the importance of the purchase. More specifically, we find that for quality focused purchases specifications are of immense importance as “delivering not according to our ‘specs’ is non-negotiable” (Q13). In all cases the data show that the type of product/service and the need for quality lead to complex and detailed specifications. “Think about five binders of specifications, very detailed” (Q12). Different to innovation focused purchases, these could, however, be derived completely internally. At the same time, similar to delivery performance focused purchases the product characteristics in all cases had a large influence on the purchasing approach as conformance to specifications was key. We find one-on-one relationships in most of the cases (Q1-4, 6-9, 12); in some it was highlighted that no matter how many suppliers are available a single supplier was preferred to ensure “there is also a lot of good support and guarantee from the supplier” (Q8). The data indicate that organizations only deviate from this if one supplier cannot ensure availability in terms of quality and/or quantity. However, also environmental factors such as natural deviations (Q10, 13, 14), consumer trends (Q14), weather (Q2) or safety (Q9) seem to play a role in defining and ensuring quality. Hence, the qualitative data support the findings of the quantitative in highlighting that the difficulty of managing the purchase is significantly more important than other portfolio dimensions when focusing on quality.

A second aspect that became apparent in our data is that fact that the strategic importance of quality focused purchases seems to be high throughout all cases as “if one [product] is missing we cannot run the furnace” (Q10) or “if the [products] are not running well, the complete line isn’t running well either. So it has a pretty high impact” (Q11). The strategic importance of quality focused purchases was evident in the use of cross-functional teams with close collaboration between purchasing and other departments and the involvement of higher management in the purchasing process: “In the end we went to the supplier with our COO and the CPO” (Q5); “Even the board
members and stakeholders in the UK are needed for that [consent] [...] it was myself and the CEO of Europe doing the final negotiation.” (Q12). Furthermore, the strategic importance of quality focused purchases also became apparent in the fact that organizations engaged in extensive site visits (Q1, 3, 8, 10), asked suppliers for a pilot (Q1, 4) or required certificates/ inspections to proof quality (Q2, 3, 10).

As such, we find similarly to delivery performance focused purchases that the strategic importance and the difficulty of managing the purchasing situation are important PPM dimensions to consider for purchases with a quality objective. As a matter of fact, it appears that quality cases are often linked to delivery performance. In 10 out of the 14 quality cases delivery performance was close to if not of equal importance to quality. We find that this was often linked to the strategic importance of the product/ service meaning that if it was not available at the right time (“one day late means one year late” (Q1)) within the specified quality, production might stop or a window of opportunity would be missed. This is in sharp contrast to the quantitative data where results indicate the strategic importance PPM dimension is significantly less important than other dimensions. Yet, given the extensive reference to the strategic importance of the purchase and overlap with delivery performance objective (findings), we consider it vital.

Discussion and Conclusion
The goal of this study was to explore to what extent and how the objective of a purchase influence the choice of the most suitable PPM. While practice and most research (e.g., Ateş et al., 2015; Pagell et al., 2010) draw on the well-established Kraljic Matrix, we find that when considering the objective of a purchase upfront, his PPM is not the most convenient for all purchasing situations. Rather, depending on the purchasing objective different PPMs are appropriate as depicted in Table 4.

The results of this study allow us to address some of the shortcomings of current PPM theory in terms of their simplicity and their operationalization of dimensions (e.g., Dubois and Pedersen, 2002). In particular, while a wealth of PPMs have been based on Kraljic (1983) trying to extent and operationalize PPM dimensions, our findings indicate that it is not about a single operationalization of a dimension, but more about a differentiated selection of operationalization for purchases with various objectives. This is reflected in the suggestion that for cost focused purchases the original Kraljic PPM seems most suitable, but for purchases focusing on delivery performance or quality Olsen and Ellram’s (1997) PPM with the modification of one of the PPM dimensions appears to be more appropriate. Furthermore, this study extends and compliments previous research considering purchasing objectives (e.g., Lee and Drake, 2010). In particular, the findings of Ateş et al. (2015) show that the structure of the supply base for innovation focused purchases is somewhat contradicting with recommendations derived from the Kraljic
PPM. One explanation for this could be, that a different PPM should have been used, based on our findings Bensaou (1999), differentiating buyer- and supplier-specific investments. Additionally, we compliment the findings of Luzzini et al. (2012) by linking their defined purchasing strategies in terms of competitive priorities to specific PPMs. These insights also provide valuable guidance to purchasing managers on how to best allocate their scarce resources.

In conclusion, insights from this study contribute to a differentiated approach in PPM theory. In particular, we show how PPMs can be used more holistically and at the same time more tailored to the specific category being managed. While the link to purchasing levers/strategies is missing in this study it offers an interesting and valuable avenue for further research.

Integrating small and startup suppliers in the supply base: The role of innovation intermediation

Abstract

Buying organisations aiming to leverage the innovation potential of small and startup suppliers may face challenges related to increasing supply base complexity, and to the ability of small firms to engage effectively given their limited scale, resources and knowledge. One possible solution is innovation intermediation. Drawing on an in-depth case study, we show how innovation intermediaries support and connect small suppliers to buyers, while managing trade offs (innovation vs. cost and risk) involved in supply base management. However, intermediaries’ impact can be limited by behaviours, goals and incentives within buying organisations that are less conducive to small supplier-led innovation.

Keywords: innovation sourcing; startup suppliers; innovation intermediaries

Introduction

This paper investigates how innovation intermediaries contribute to innovation sourcing by supporting innovative small firms and startups to become suppliers to large buying organisations. Existing literature on innovation sourcing is mainly concerned with how large focal firms utilise their suppliers’ capabilities, integrating them with internal resources and knowledge to drive innovation performance (Lawson, Tyler et al., 2015). Buying firms are assumed to be in control of the innovation process and to actively manage supplier involvement, but they may be underutilising the technological potential of innovative small firms and startups as possible new suppliers (Narasimhan and Narayanan, 2013). Existing research tends to focus on existing suppliers and supply networks (Nair et al., 2016), and there is limited knowledge of the process by which buyers integrate, manage and develop startup suppliers in the context of innovation sourcing (Wagner et al., 2017).

Although buyers can benefit from forming relationships with startups and small suppliers of technological solutions to fulfil their unmet needs, interactions with such small firms are challenging, given their lack of scale and resources (Arjbjørn and Paulraj, 2013). In addition, engaging directly with innovative small suppliers means that a buying firm has to expand its supply base and deal with a more heterogeneous and diverse set of suppliers. While this increasing complexity in the supply base can have a positive impact on supplier-led innovation (Choi and Krause, 2006), it may also undermine transaction
cost reduction and relational benefits associated with long-standing supply-base reduction strategies.

One approach that buying firms can follow to manage these trade-offs and to structure interactions with small firms is to use the services of innovation intermediaries, but their role is little understood in the context of innovation sourcing. In this paper, we draw on the innovation intermediation literature (Howells, 2006; Kivimaa et al., 2019) to answer the following research question: How do innovation intermediaries support small supplier-led innovation whilst managing complexity in the supply base of a buying firm?

**Literature review**
This section synthesises literature on innovation sourcing, supply base management, and innovation intermediation to develop the analytical framework of the study.

**Innovation sourcing**
Existing literature on innovation sourcing and supplier involvement in NPD stresses how focal buying firms combine their innovation inputs and capabilities internally with those of their suppliers to drive innovation outcomes (Oke et al., 2013). Literature on supplier involvement has long emphasised a buyer’s ability to control the innovation process and to involve its suppliers as and when required (e.g. Lawson, Tyler et al., 2015). Key process issues include the exact timing of involving suppliers (Zhao et al., 2014), the stage of the NPD process at which to involve them (Wowack et al., 2016), and the extent of supplier involvement (Koufteros et al., 2007). Overall, this line of research stresses the importance of developing a structured approach to supplier involvement and of effectively managing supplier relationships (e.g. Van Echtelt et al., 2008).

In keeping with the above, recent studies of supply chain innovation highlight the role of firm- and network-level attributes. For example, buying firm’s absorptive capacity, supplier’s innovativeness and supply network accessibility and interconnectedness can all have a positive influence on innovation performance of a focal firm (Narasimhan and Narayanan, 2013; Bellamy et al., 2014).

Overall, the empirical literature appears to converge to the conclusion that effective management of supplier involvement contributes to significant performance benefits in terms of reduced development time and cost and improved product quality (Van Echtelt et al., 2008). However, it is less clear whether involvement of existing suppliers is beneficial in cases of high technological uncertainty or radical innovation requirements. In such contexts, it may be more effective to involve new suppliers and benefit from their diverse knowledge (Johnsen, 2009). Involving new suppliers in innovation activities influences the structure and management of a buying firm’s supply base.

**Supply base management and innovation**
The design and management of a firm’s supply base structure is a key strategic sourcing issue (Gadde and Häkansson, 1994). Conceptually, the supply base refers to a lower unit of analysis as compared to the supply chain or supply network (Lu and Shang, 2017). According to Choi and Krause (2006), the supply base is the part of the supply network that the focal firm manages actively through contracts and purchased products, materials and services. In practical terms, a focal firm will be mostly active in managing its first-tier suppliers. However, the supply base need not be restricted to first-tier suppliers, as a buying firm can also actively manage interactions and control relationships with its second- or third-tier supplier (Choi and Hong, 2002).

The existing literature has identified a number of dimensions determining the supply base structure of a buying firm. Gadde and Häkansson’s (1994) early treatment, for
instance, referred to the number of suppliers, and the way these suppliers are organised (e.g. existence of tiers in the supply base). Subsequent literature has emphasised complexity as a way to construe supply base design and management decisions (Choi and Hong, 2002; Bode and Wagner, 2015). This is because the notion of complexity combines structural (e.g. number of suppliers in the supply base) and behavioural or relational elements e.g. interactions among suppliers of a focal firm (Lu and Shang, 2017).

Choi and Krause (2006) use the term ‘supply base complexity’ to refer to the number of suppliers a focal firm actively manages, the degree of differentiation among suppliers, and how inter-related suppliers are. The larger the number of suppliers, and the higher the differentiation and inter-relatedness among suppliers, the higher the level of supply base complexity. Ates et al. (2015) have contributed two additional characteristics determining supply base structure: contract duration (time dimension) and supplier information sharing (transparency dimension), as these two characteristics can affect cost and innovation performance outcomes sought by a buying firm.

One strategy buying firms can deploy to manage supply base complexity is reducing the number of suppliers they actively manage (Cousins, 1999). Such supply base reduction or rationalisation strategies are grounded on arguments regarding the need to reduce administration costs, although such arguments have been long been disputed (e.g. see Gadde and Håkansson, 1994). In other words, reducing supply base complexity by rationalising the number of suppliers a buying firm deals with helps to reduce transaction costs (Choi and Krause, 2006).

Beyond transaction cost considerations, supply base design and management decisions can influence innovation outcomes. Working with fewer suppliers may positively contribute to innovation performance in that closer relationships with these suppliers incentivises them to invest in new technologies or to share knowledge with the buyer (Ates et al., 2015). On the other hand, supply base reduction strategies may entail opportunity costs related to the loss of knowledge and resource advantages that pertain to a buying firm interacting with a larger, more diverse set of suppliers (Gao et al., 2015), including small firms (Narasimhan and Narayanan, 2013). Indeed, Choi and Krause (2006) suggest that reducing supply base complexity may reduce the focal firm’s ability to tap into supplier innovation, as they posit a positive relationship between supply base complexity and supplier innovation: the higher the number of differentiated and closely related suppliers, the higher the potential for supplier-enabled innovation. Key factors influencing supplier-led innovation include the ability of suppliers to network with each other and share information and resources, the level of supplier autonomy, and buyer direction to innovation activities of suppliers (Choi and Krause, 2006).

Reducing the supply base may also increase supply risk due to dependence on fewer supply sources, thus making buyer efforts and investments in supplier development relevant (Choi and Krause, 2006). Supplier development programmes can positively contribute to innovation sourcing when buying firms invest in developing supplier technological capabilities and creativity (Lawson, Krause et al., 2015). As part of their supply base management efforts, buying firms can also intervene to suggest collaboration or integration of smaller suppliers (Choi and Krause, 2006), they can directly manage and control relationships with second- or third-tier suppliers (Choi and Hong, 2002), or they can delegate responsibilities for supplier control to first-tier suppliers (Cousins, 1999).

Research focusing on supply base design and management has not explicitly considered how small or startup suppliers may influence supply base complexity. Such a focus is particularly relevant in innovation sourcing settings, as small suppliers and startups can be a valuable source of technological novelty and radical innovation ideas (Wagner et al., 2017). At the same time, engaging with small suppliers is challenging as
they often lack scale and resources required (Arjbjørn and Paulraj, 2013). Buying firms may not have the time or resources to explore how such (potential) suppliers can contribute to product or process innovation, and they may not be willing to invest in their development. From a supply base complexity perspective, engaging with small firms and startups is likely to increase complexity not only because of an increase in the number of suppliers a firm is dealing with, but also due to increasing supply base heterogeneity (Ates et al., 2015). Small and startup suppliers tend to be different from established, larger suppliers in terms of size, culture, management style and practices, and governance structure (Kull et al., 2018), hence increasing the degree of differentiation in the supply base (Choi and Krause, 2006). One approach that buying firms can follow to structure interactions and relationships with innovative small suppliers and startups is innovation intermediation, a concept originating in innovation policy and management studies.

The functions of innovation intermediation

An inherent characteristic of innovation intermediary organisations is their ability to broker connections and facilitate interactions between buyers and suppliers of innovative technologies, products and services (Edler and Yeow, 2016; Kivimaa et al., 2019). Research on innovation intermediation collectively stresses the multiple roles that intermediaries assume as part of the innovation process (Howells, 2006). The empirical literature has examined a diverse set of intermediary organisations spanning from public organisations and government-affiliated agencies, to research and technology organisations, web-based business platforms, and consultancies and other types of knowledge intensive business services (e.g. Klerkx and Leeuwis, 2008a; Colombo et al., 2015). These intermediaries can either operate across industries or have a narrow remit e.g. promoting innovative solutions in the energy sector (van Lente et al., 2003). They can provide their services either to the buyer side or the supplier side, as evident in the literature (Howells, 2006).

Innovation intermediaries perform various functions in supporting buyers and /or suppliers of innovation. They contribute to definition of unmet needs and requirements, articulate demand for innovative solutions, perform horizon scanning and promote appropriate technological options (Kivimaa, 2014; Klerkx and Leeuwis, 2008b). They can also assist in filling managerial gaps related to innovation project management and innovation adoption (Bessant and Rush, 1995), and may also provide access to funding necessary to set up and execute R&D and innovation demonstration projects (Polzin et al., 2016). Additional functions that intermediaries can fulfill include processing and (re)combining knowledge from several sources, matchmaking to connect suitable partners, commercialisation support, and validation and evaluation of technological innovations (e.g. Howells, 2006; Lichtenthaler, 2013).

The empirical literature suggests that intermediaries operate both in private and public sector settings. In the specific context of health innovation procurement and adoption processes, for instance, Edler and Yeow (2016) show how the intermediaries involved filled important capability gaps of the public buying organisation with regard to definition of unmet needs, analysis of supply options and innovation promotion and adoption. Although this research stream, overall, stresses the positive role of intermediaries in the innovation process, the performance impact of such interventions is less evident. In addition, the literature suggests that perceptions regarding neutrality and impartiality of intermediaries, and their ability to continue operating in spite of financial, institutional and policy-related constraints have a bearing on their impact (Klerkx and Leeuwis, 2008b).
Research method
We adopted a single, embedded case study design (Voss et al., 2002) to develop an in-depth understanding of how innovation intermediaries contribute to involving, developing and managing small and startup suppliers as part of innovation sourcing initiatives. Our research setting is the supply chain of the UK National Health Service (NHS). The NHS is a large buying organisation attempting to engage actively with startups and small firms and to leverage their technological potential to improve patient outcomes and reduce service costs.

The innovation intermediary in focus, henceforth referred to as InnoMed, is one of the 15 regional innovation agencies known as Academic Health Science Networks (AHSNs), whose remit is to spread innovation in the health and care system "at pace and scale". InnoMed, like other AHSNs, is funded by NHS England and the UK Government Office for Life Sciences and operates based on a five-year licensing commitment agreement with NHS England (which was recently renewed).

Case selection followed a purposive sampling logic (Patton, 1990). We selected the NHS as our empirical setting since in the UK public health and care system innovation procurement and adoption is, at best, challenging. In this context, intermediary organisations assume an important role in supporting buyers and/or suppliers and in accelerating innovation development and adoption (see Edler and Yeow, 2016). We selected InnoMed due to its various support programs for small and startup firms.

Crucially, the embedded case design allowed the analysis of InnoMed’s roles and contribution to the NHS’ innovation sourcing efforts, as well as studying a sample of 20 small and startup suppliers as recipients of InnoMed’s support. The majority (17) of these firms operate in the 'MedTech' and 'Digital Health' segments of the health and life sciences sector in the UK. The other three firms operate in different areas e.g. mental health. Table 1 provides an overview of the innovative solutions of the studied firms.

Data collection involved 32 semi-structured interviews with innovation intermediary staff, founders/executives of small firms and startups, and NHS procurement professionals. The interviews covered multiple themes such as the types of support that InnoMed provides, suppliers’ perceptions of the quality and impact of InnoMed’s support, and of the NHS as a (potential) customer. The interviewees were also asked to offer their views and opinions on challenges related to innovation procurement and adoption. To complement and triangulate interview data, we analysed in excess of 20
documents (e.g. hospital procurement strategies, InnoMed reports and presentations) and other sources of publicly available data (e.g. AHSN Network communications, health policy reports). We used the ATLAS.ti software to analyse and code the data, and to identify key themes in the data.

**Findings**

This section presents the analysis of the case. Table 2 summarises the key findings regarding the innovation intermediary’s functions, the nature and impact of the support it provides to small /startup suppliers, and implications for the NHS’ supply base management.

Case analysis suggests that InnoMed performs, on behalf of the NHS, several functions as part of the innovation sourcing process. The intermediary contributes to identifying and articulating the unmet needs of patients /citizens and of the health and care system, which innovative solutions could help fulfill. While this occurs primarily at regional level given that InnoMed’s health innovation remit concerns a specific UK region, the intermediary contributes to definition of unmet needs nationally. InnoMed performs technology horizon scanning activities and plays an important role in identifying solution options and potential suppliers that could help meet the needs of the NHS. The intermediary also assumes a matchmaking role, introducing potential small suppliers and startups to hospitals and other healthcare providers (e.g. GP clinics) that face problems that these small suppliers could help solve. In addition, InnoMed performs a validation function by evaluating and vetting products and promoting to the NHS the most promising solutions. The NHS also benefits from the ability of InnoMed to receive, combine and share knowledge about national health innovation trends and to raise awareness regarding high-impact innovations developed at other parts of the country.

<td><strong>Impact of support and related challenges</strong></td>
<td>Some evidence of small /startup firms generating NHS contracts and sales. However, in general the rate and pace of adoption of small firm-led innovations by the NHS is rather low. Multiple challenges e.g. NHS procurement goals and incentives; supply risks and cost-to-serve related to dealing with small /startup suppliers.</td>
</tr>
</tbody>
</table>
The empirical evidence shows that a central duty of InnoMed is to provide support to small firms and startups that have the potential to become new suppliers to the NHS. This support takes multiple forms, as interviews with both InnoMed staff and small /startup firms revealed. The intermediary evaluates early on in the engagement process the technological solution, the business model and /or the sales approach of the firm, depending also on the company’s stage of maturity in relation to the process of product development and commercialisation. InnoMed’s feedback to firms can result in redirection of the small firm’s innovation efforts to match better the NHS’ unmet needs. InnoMed brokers connections between small firms and clinicians and decision makers in hospitals. It also performs a wider networking function by connecting small /startup suppliers to each other, as well as to other (larger) suppliers of complementary products and technologies.

Another key area of support is contributing to knowledge and capability development of small /startup firms through the organisation of education workshops (e.g. on health economics, NHS governance systems) and through one-to-one coaching and expert advice (e.g. regarding the sales approach and NHS procurement procedures). A key goal of InnoMed is making startups commercially astute and helping them to navigate the complexity of the NHS, and that of its procurement and supply procedures. InnoMed also provides finance-related support mainly by signposting funding opportunities and providing funding-related advice, and less frequently by directly funding promising innovation projects. InnoMed is also involved in setting up clinical trials or demo projects, which enable small suppliers to generate required evidence to validate and certify their medical devices /solutions.

In terms of the impact of InnoMed’s contribution, there is evidence to suggest that small /startup firms that receive support have succeeded in penetrating the supply base of the NHS and to secure contracts and sales. More specifically, of the thirteen studied companies in the sample that already have a developed product /solution, nine of them have generated NHS sales, while the other four are in the process of doing so. Seven small /startup firms from those interviewed are still in the process of developing or validating their solutions, and therefore it is premature to evaluate the impact of InnoMed’s support in terms of NHS sales and company growth.

However, interviews with all stakeholders suggest that, more broadly, the rate and pace of adoption of small firm-led innovations by the NHS remain rather low. There are several reasons for this, such as InnoMed’s limited ability to influence innovation adoption decisions. Another challenge is the lack of meaningful engagement of NHS procurement professionals with small /startup firms, and with the intermediary’s efforts in infusing new products and technologies into the NHS more broadly. A key related finding is that the NHS procurement system’s objectives and incentives are not aligned with InnoMed’s agenda. Specifically, the NHS’ centralised procurement function as well as procurement teams at hospital level operate based on stringent annual cash-releasing savings targets. These targets incentivise awarding multi-year contracts to large suppliers, and working with established suppliers to drive cost efficiencies. Procurement directors at hospitals seem to be less well-disposed toward dealing with small suppliers, not least due to considerations of supply capacity and cost-to-serve an order (a key NHS procurement criterion), which tends to be higher when dealing with small /startup firms.

Regarding the implications of InnoMed’s involvement for the NHS’ supply base management, the analysis suggests that innovation intermediation can be an effective approach to managing trade-offs between innovation and risk /transaction cost outcomes related to supply base expansion. Specifically, engagement with an increasing number of small firms and startups, through InnoMed, increases the NHS’ ability to leverage the
(radical) innovation potential of these suppliers-in-the-making. At the same time, InnoMed appears to mitigate certain types of supply risk (mainly product quality risk) and to reduce transactions costs related to innovation process interactions by vetting solutions and promoting to the NHS small suppliers that hold high promise. However, this approach does not seem to address other aspects of supply risk (small supplier scale/capacity) and transaction costs (cost-to-serve orders), as analysed above.

**Discussion and conclusions**

The empirical findings suggest that innovation intermediaries serve as a means for the identification and exploitation by buying organisations of new technologies, products, and services that can potentially improve quality and reduce costs. The case reveals the multiple ways through which intermediaries can support small firms and startups and help them to penetrate the supply base of large buying organisations, in this instance the NHS. It also highlights, however, the challenges associated with influencing mind sets and behaviours within large buying organisations in relation to small/startup suppliers considering also diverse goals and misaligned incentives between different functions.

The study contributes to existing research on innovation sourcing and supply base management in multiple ways. First, it extends existing research on innovation sourcing by focusing on the approaches buyers may use to manage the involvement of startup suppliers (e.g. Wagner et al., 2017). More specifically, we highlight the role and potential impact of an intermediation model of innovation sourcing. We demonstrate how innovation intermediaries can contribute to innovation sourcing efforts of a buyer by: a) identifying and involving small and startup firms and connecting them to the buyer, b) educating and supporting the development of small firms and startups as potential suppliers, and c) supporting these small suppliers to overcome innovation adoption barriers within the buying organisation, and to penetrate the supply base of the buyer. In other words, we show how innovation intermediaries work to link in small and startup suppliers. This is different from existing innovation sourcing literature which largely presumes that buying firms engage and interact directly with their supply base or supply network (e.g. Oke et al., 2013).

Second, the research stresses the mechanisms underlying the support and development of small firms and startups as suppliers that could potentially penetrate the supply base of a buying organisation. Existing literature on innovation sourcing and supply base management implicitly assumes that it is the *existing* supply base and suppliers that contribute to innovation (e.g. Choi and Krause, 2006), and ignores the role of *suppliers-in-the-making*. Comparatively, our study offers insights into how small firms and startups can become suppliers of innovative solutions to a buying organisation, and contributions of innovation intermediaries in this process.

Third, the study highlights the involvement and potential impact of small firms and startups as *new* (to the buyer, at least) suppliers. Existing research on supply base design and management has underplayed the influence of small /startup suppliers in relation to a buying firm’s innovation strategies, and the implications for supply base complexity. In this study we emphasise the contribution of innovation intermediation in relation to the above issues. Using intermediaries to go beyond the existing supply base and to develop relationships with small /startup firms as potential suppliers can be an effective way to manage supply base complexity: by reconciling requirements for innovation on the one hand, and transaction costs and risk on the other. Being knowledgeable about the buyer’s unmet needs, innovation intermediaries can provide some direction to startups’ innovation efforts. Through their networking function, they can also strengthen the interconnectedness of these small suppliers-in-the-making. Both aspects can in turn foster
an environment of innovation (Choi and Krause, 2006). Overall, intermediaries offer a way of orchestrating the buyer’s supply base expansion to pursue innovation goals in a way that mitigates some types of supply risk and transaction costs (e.g. by vetting and promoting only highly promising suppliers and solutions). However, such an orchestrating role may be limited by an overemphasis on price and short-term cost savings within the buying organisation.

The study is based on a single case focusing on a rather peculiar (and public sector) context, which potentially limits the transferability of findings. Further empirical research cutting across public and private sector supply chains is needed to build a more comprehensive theory regarding the role of innovation intermediaries in innovation sourcing initiatives. In addition, the empirical study has not explicitly addressed the dynamics of the process by which small firms and startups get involved, develop and potentially penetrate the supply base of buying organisations. Process-based studies, of longitudinal nature, would be suitable for pursuing this future research avenue.

Reliability and Maintenance
Causal based spare parts forecasting exploiting product-in-use data: a mixed method case study in a heavy vehicle aftermarket context

Joakim Andersson, (Joakim.andersson@chalmers.se)
Chalmers University of Technology, Division of Supply and Operations Management, Gothenburg, Sweden and Volvo Group Trucks Operation, Service Market Logistics

Abstract
The purpose of this paper is to find relevant relations between spare part types and explanatory factors, as well as evaluate propositions regarding improved forecast accuracy by applying regression methods on the demand by using the explanatory factors. The analysis reports both promising and expected results, mainly an improved forecast accuracy applying regression-based forecasting with explanatory factor. Although some of the findings requires further research. This model and the process used could serve as a foundation for other companies striving for enhancing their spare parts forecasting capabilities.

Keywords: Spare parts, Demand forecasting, Connected vehicles, Internet of things, Product-in-use data

Introduction
Internet of Things (IoT), smart devices, increased computing capabilities (faster hardware, smarter software etc.) and the vast amount of internal and external data available (Kache and Seuring, 2017) are amongst the key drivers of the ‘big data’ revolution. For automotive manufacturers, a ‘connected vehicle’ generates a vast amount of data that is captured Traditionally, spare parts forecasting research has focused on improving time series forecasting methods using the historical demand solely (Bacchetti and Saccani, 2012). The main problem with these models is that they do not consider the underlying demand, which is the need for exchanging spare parts in a maintenance or repair context (Romeijnders et al. (2012). Several studies show that there is a potential to base spare parts forecast on causal relations with explanatory factors, such as sensor data, fault codes, mileage, running hours and installed base (product-in-use data) instead (Van der Auweraer et al., 2019, Andersson and Jonsson, 2018). Furthermore, contextual factors such as life cycle stage, demand pattern and specificity (Huiskonen, 2001) is expected to influence the potential of causality of the underlying explanatory factors positive effects on predicting the future demand.

The purpose of this paper is to find relevant relations between spare part types and explanatory factors, as well as evaluate hypotheses regarding improved forecast accuracy by applying machine learning methods to predict the demand utilizing these explanatory factors. The empirical analysis is based on case data, both qualitative and quantitative
data, from the aftermarket service of a global heavy vehicle manufacturer. Furthermore, this paper sets out to categorize the spare parts based on variables explaining the underlying demand and develops a generic process on how a causal based forecasting process can be developed.

**Literature review**

The focus of this paper is to study utilization of explanatory factors (product-in-use data) in causal based forecasting for heavy vehicle spare parts. Causal based forecasting is closely related to installed based forecasting (Auweraer et al., 2019) or leading indicator forecasting (D’Amuri and Marcucci, 2017).

**Causal based forecasting methods**

Various regression methods with exogeneous, explanatory variables have been used for a long time in econometric analysis. For examples of methods, see e.g. Hansen (2017). To predict spare parts demand, some research applying causal based methods with regression techniques are for example: Hua et al. (2007) describe a method applied in the process industry combining regression analysis of explanatory variables correlated with non-zero demand within the lead time and bootstrapping. Ghobbar and Friend (2002) propose a method predicting the demand interval for aircraft spare related to operating usage and the spare part life cycle, Dekker et al. (2013), describes different install base forecasting methodologies. They propose to use the failure rate, use of planned preventive maintenance (PM) and by collecting data from remotely monitored machines (CBM). Fritzsche et al. (2014) aims at optimizing the total maintenance cost, but particularly in an airline industry context. Their concept, called: prognostic health management (PHM), is using data such as; performance degradation, physical degradation, vibration and usage-based factors. The data produced by on-board sensors, monitoring data and data from previous maintenance and inspections are then used to produce the status and prediction of next maintenance occasion. In a paper by Andersson and Jonsson (2018) it is proposed that positive performance effects on spare parts forecasts are expected for medium to high frequent demand, especially in phase-in situations.

**Product-in-use data**

The explanatory variables in forecasting are the underlying factors causing the demand. For spare parts these underlying factors are closely related to the maintenance and repair need. For the automotive industry we adopt the definition of product-in use data for description of the explanatory, demand driving variables. (see table 1, Andersson and Jonsson, 2018).
According to e.g. Huiskonen (2001) also the classification variables, such as demand pattern, life cycle stage and type of spare part, should have an impact on the causation between the underlying variables and the demand.

**Methodology**

*Data collection*

This paper draws upon results from a case study in a heavy vehicle aftermarket context comprising of both qualitative and quantitative components. Since the possible explanatory factors (available product-in-use data elements) encompass more than 3000 data elements, it was necessary to reduce these in order to make the quantitative analysis feasible.

The qualitative study was guided by RQ1: What data has a potential impact on the demand for different groups of spare parts for heavy vehicles? To find relevant explanatory factors with a potential impact on the demand, meetings and interviews with maintenance engineers and workshop managers were carried out. The outcome of this qualitative data collection was to use data on the fault codes that have the highest impact on the demand, as well as average driving distance and operating time per vehicle. To determine which fault codes to use, the correlation between demand and number of vehicles reporting the various fault codes were used. Due to the great amount of data the top three fault codes were selected to be included in the quantitative analysis. The selection of spare parts to include were guided by the proposal from e.g. Boylan and Syntetos (2008), and Axsäter (2007) who suggest a potential improved forecast using explanatory variables for phase-in parts. To test this proposition, spare parts with an age less then five years were selected. Additionally, spare parts with too low demand and intermittent demand patterns were excluded. An arbitrary selection was made, in order to make the forecast analysis feasible, in discussion with data scientists at the case company, resulting in the exclusion of spare parts with less average demand per period during the last year than 1.5 pieces and with number of periods without demand less then 4.

In order to create a dataset appropriate for analysis of the causality of the explanatory factors on the demand (the causal based forecast model), data from several large databases

Figure 1: Description of the data collected for the forecast model
This data was merged into a data file and used as input to the forecast model, containing the following fields: spare part number, period number, demand, fault code frequency 1-3, average distance per vehicle and average operating time per vehicle. Number of spare parts are 611, number of periods are 65.

Data analysis
The beforementioned data was used to analyze RQ2: What is the performance effect of causal-based forecasting using product-in-use data in an aftermarket setting? By applying a multivariate linear regression method, a causal-based forecast was calculated and compared to a set of traditional forecasting methods in a forecasting competition (Makridakis and Hibon, 2000), evaluating the result using Mean Absolute Percentage Error (MAPE) and MAE (Mean Absolute Error), see Kim and Kim (2016). The applied regression model used the explanatory variables in a stepwise approach, i.e. for each added variable the adjusted R square value was compared to the previously calculated value. Moreover, an analysis was performed to classify spare parts into groups (Huiskonen, 2001) based on the categorical data (e.g. life cycle and demand frequency), determining which forecast model has the best fit, i.e. lowest MAPE and/or MAE.

As part of RQ2 the quantitative analysis aims at testing the following hypothesis: Positive performance outcome can be achieved by combining multiple causal-based forecasting interventions using product-in-use data (a) between different life-cycle phases and, (b) with time-series methods.

Finally, a causal based forecasting process is developed and validated with demand and inventory specialists and data scientists at the case company. To predict the forecast one period ahead we used an autoregressive forecasting model, using demand as well as exogenous variables.

Pre-mature analysis of the data showed that no well-performing general regression method was to find, i.e. due to differences in the slope and intercepts for individual spare parts. As a consequence, an individual model had to be created for each spare part. The autoregressive equation has the following form: \[ Y_{it} = \alpha_i + \beta X_{it} + \epsilon_{it}. \]

Results
Initial findings of the hypotheses testing analysis (RQ2) show promising results for five product groups (spare parts) using the explanatory factors: mileage and fault codes. The findings draw on the result from explorative studies and aims at increasing the scope, both in terms of relevant product groups and number of spare parts in the sample, as well as in terms of developing the analytical forecasting method. Preliminary tests at the case company show that the potential effect of causal-based forecasting is highest in the phase-in stage in the product life cycle (0-5 years), which is in-line with conceptual causal based forecasting studies (e.g. Andersson and Jonsson, 2018).

The forecast analysis using fault codes with the highest correlation with demand and operational data, also comparing with traditional time series forecasting methods gives the following result, presented three different stages in the life cycle (table 3):

</tbody>
</table>

The forecast accuracy of the model (MAPE and MAE) clearly shows improved performance of the model. First, we can see that the simple linear regression model outperforms both the single and double exponential models. Secondly, for the series with a three- and five-year history, MAE shows an increased forecast performance for each added explanatory variable, although the forecast accuracy measured with MAPE shows improvements for the model adding fault codes one to three, but no improvements due to adding the variables distance and time. Since MAE (measured as an average over all forecasts) is sensitive to large errors that typically are more common for spare parts with high demand, it is difficult to draw any conclusion just by that. This result needs to be examined more in detail to see where and for what type of parts the errors are better or worse. However, the forecast accuracy measured by MAPE could be considered more trustworthy since it is scaled and expressed as a percentage error.

For the series forecasted and measured after one year the results show an improved accuracy, both with MAE and MAPE, for each added explanatory variable. What stands out with this result is the rather high-performance effect when the last variable was added (average time). This result is most likely an effect of a high interaction between vehicle usage and a willingness to maintain and repair a new vehicle. Still it remains further analysis to statistically prove that proposition.

In order to see the effects of the causal forecast model on spare parts with different demand frequency, frequency classes were created and the result (see Table 4) is also presented for these classes. The frequency classes are: 1) slow moving parts with an average demand per period < 5, 2) medium frequent parts where the average period demand is between 5 and 25, and finally, fast moving spare parts where the average period demand > 25.

</tbody>
</table>

For medium and fast-moving spare parts, the regression model with explanatory variables outperforms the traditional times series methods. Furthermore, the result is improved for each explanatory variable added. For slow moving parts, both the traditional methods show better result than the regression methods. Moreover, the more frequent spare parts are the better the forecast gets (measured by MAPE of obvious reasons), which is not a surprise. The same improvement is seen for both single and double exponential smoothing methods.

Based on the qualitative data collection we also performed tests with the same regression methodology as previously described. The expectations of these analysis were high since the fault codes in this case were derived from experience by maintenance specialists and technicians. However, we could not see any significant improvement of the forecast in this case, so no details of that analysis are presented here.

**Discussion and conclusion**

The results showed some expected results and some that were unforeseen upfront. The impact of the fault codes regarding different length of the time series were partly as expected (three and five years of history. However, the negative impact on the operational variables (driving distance and driving time) needs further research. It could be due to covariance with the other explanatory variables, i.e. the fault codes. More surprising was the improvement of the forecast accuracy for the one-year time series when adding the last variable (driving time) to the analytical model. Also this finding requires further analysis and research. A possible explanation could be that the vehicle owners are more compliant to maintenance recommendations in the very beginning of the life cycle.

Regarding the analysis divided by the frequency of the spare parts it is showing promising results according to the a priori expectations.

One unexpected outcome in the analysis were that no improvements could be seen for spare parts with qualitatively judged fault codes. In order to analyze the root cause of that result, a deeper study is needed, invoking both statistical analysis and discussions with maintenance specialists and field technicians.

The study contributes to the spare parts forecasting field by presenting a detailed empirical analysis of real product-in-use data and its impact on spare parts forecasts. Furthermore, a proposed process/framework for choosing types of spare parts feasible for causal-based forecasting and usable relevant data has a practical relevance for firms that wants to develop their forecasting process for spare parts using product-in-use data. The proposed process contributes to the calls in the literature to conduct practically relevant
and empirically based studies on forecasting using explanatory factors (Auweraer et al., 2019). We are now working on further developing and testing the causal-based forecasting model in relation to the purpose. The final part to propose a process/framework for matching forecast method and spare parts is developed in interaction with the case company.

Public Procurement of Railway Infrastructure Maintenance: A Linear Regression Analysis

Jens Aldenlöv (jens.aldenlov@ltu.se)
Luleå University of Technology, Department of Business Administration, Technology and Social Sciences, 971 87, Luleå, Sweden

Abstract

Swedish railway infrastructure maintenance has been outsourced through gradual exposure since 2002. The idea behind outsourcing was to reduce cost and improve efficiency. However, railway maintenance cost has increased faster than railway maintenance operations, resulting in neglected railway maintenance. Since railway operation is governed by the contract design the purpose of this paper was to explore the relationship between contract design and maintenance outcome within Swedish railway infrastructure maintenance. To explore this relationship linear regression analysis was used. The result indicates that asset knowledge and accessibility to the track are important to consider for improving maintenance operations.

Keywords: Public Procurement, Railway Maintenance, Contract Design
Introduction

Railway maintenance outsourcing has been a popular choice for European countries during the last decades. One motivation behind the outsourcing decision is to reduce overall cost without jeopardizing track quality. According to Odolinski and Smith (2016), outsourcing through gradual exposure has reduced cost by 12 per cent in Sweden. Gradual exposure creates a learning process for railway custodians regarding both procurement strategies and contract design (ibid.). However, large changes in the contract design can only occur during the procurement process not during the contract period, since the law of public procurement only allows for smaller changes (Lagen om offentlig upphandling [LOU], SFS 2016:1145). Smaller changes include unpredictable circumstances, minor additions and changes as well as change of contractor (ibid.). However, the contract is arguably fixed during the contract period, making design especially important. Hence, there is a need to understand the impact of contract design on maintenance outcome.

In Sweden, railway maintenance has been outsourced through gradual exposure since 2002, with the last contract exposed to competition in 2013. Due to expensive machines, there is a high economical barrier for maintenance companies to enter the market (Lingegård, Lindahl 2015). Therefore, the railway maintenance market in Sweden is oligopolistic, that is, it only involves a few actors. Alexandersson and Hultén (2007) indicates that a market with few actors open for more negotiation then actual competitive tendering during a procurement process. However, governments often try to avoid such collaboration techniques (i.e. negotiations) during a public procurement process (Meehan, Ludbrook et al. 2016). Another unique characteristic in a client-contractor relationship in maintenance is that the infrastructure already exists. Usually client-contractor relationships involve construction of infrastructure (sometimes including maintenance). When the infrastructure is new the knowledge about the condition is high, and the predictability for maintenance needs is also peaking. However, most railway infrastructure is several decades old, complicating maintenance requirement predictions. Hence, an accurate description of the condition of the railway infrastructure is needed. Without accurate knowledge of the railway infrastructure there is a risk of inaccurate contract design (Olsson, Espling 2004), causing a misalignment between infrastructure condition and contract design (Andersson, Hultén 2016). Andersson & Hultén (2016) suggest that Swedish railway maintenance costs are increasing four to five times faster than railway operations, caused by a misaligned governance structure of railway maintenance, costing up to 2 billion SEK annually. Governments need to better understand the effects of procurement strategies and contract design, especially since railway maintenance has received little research attention. Hence, the purpose of this paper is to examine the relationship between contract design and maintenance outcome.
Theoretical perspective

Maintenance Contracts

The purpose of a contract is to have a written agreement between different economic actors on a subject that they may have a different perspective on (Borg, Lind 2014). However, it is difficult for the client to design a contract that minimizes its cost without changes to the overall quality of the railway infrastructure. While minimising cost and maintaining asset quality, the contractor's payment should be sufficient enough to minimise moral hazard (Borg, Lind 2014), something that is hard to achieve in practice. The contract design within railway infrastructure maintenance depends on the asset knowledge and pricing of these assets (Olsson, Espling 2004). Cross (1988) mentions three factors that affect maintenance services; pressures for reducing costs; reorganization to allow an improvement of the service given; withdrawal from providing a particular service towards introduction of suppliers (i.e. outsourcing of the maintenance service). Today, client organizations often try to find an optimum between cost control and operational improvements through outsourcing. Contracts need to specify the content of service as accurately as possible in order to design financial incentives (Rahman, Chattopadhyay 2010, Olsson, Espling 2004, Tarakci, Tang et al. 2006), otherwise there is a risk of conflicts (Abdi, Lind et al. 2014, Borg, Lind 2014). In Sweden, the overall contract describes a function that the contractor has to satisfy, e.g. the track should be available for traffic 24 hours every day of the year. However, the working instructions for each railway asset are specific resulting in procurement of a contractor that only follows specification (Lingegård, Lindahl 2015). Creating a situation where the contractors have freedom to organize the maintenance activities (i.e. logistical solutions), but not the maintenance itself.

Pricing and payment are sources for conflict in contract situations (Abdi, Lind et al. 2014) and as such, the payment scheme must be designed carefully (Borg, Lind 2014). The careful consideration in designing this payment schemes is of vital importance to minimise conflicts and to distribute the right amount of risk. Simplified, there are two types of pricing; fixed-price and actual cost. Fixed price is simply fixed payment for the maintenance activities. Actual cost is payment according to reality, including factors such as time, personnel and equipment. Railway maintenance contracts in Sweden have, of course, a mixture of the two payment types. However, Sultana et al. (2013) mentions problems with such traditional way of contacting and procuring. Procurement of the lowest cost may result in a neglect of quality for the reduction of cost. The client has to ensure, by either inspections or governance, that the quality is not jeopardized.

Partnering in railway maintenance contracts has been used in the Swedish contracts. The main idea is to make contacts more flexible to change by close cooperation between client and contractor (Abdi, Lind et al. 2014). By close cooperation, the aim is to drive innovation, increase productivity and implement new ways of working (Eriksson 2015). The client is expected to drive both the partnering process and the knowledge transfer by encouraging to partnering activities (Havenvid, Hulthén et al. 2016, Olsson, Espling 2004). However, clients have had problems with both understanding and implementing
partnering (Eriksson 2008). Because railway maintenance is complex by nature, there is a need for partnering in such an environment (Pesämaa, Eriksson et al. 2009). Olsson and Espling (2004, p. 245) mentions four key factors to partnering within railway infrastructure maintenance: requirements for partnering; partnering process; success elements; measurements. Requirements for partnering handles the complexity of the project (i.e. complex projects requires more partnering). Partnering process handles the type of collaboration and has to be driven by the client (Eriksson, Larsson et al. 2017, Eriksson, Westerberg 2011). Success elements regard knowledge transfer of tacit knowledge between maintenance personnel and honest communication. Measurements regard the performance of the contractor and should be done in such a way so that the client can assess both the railway assets and the contractors’ performance, agreeing with the findings of Sultana et al. (2013). However, Tadelis (2012) suggest that the law of public procurement hinders the partnering process. He argues that the flexibility of the partnering process is difficult since larger changes cannot be done due to the law. Partnering can be used in any type of contract (Borg, Lind 2014) and the law of public procurement can be managed (Abdi, Lind et al. 2014).

Methodology
The case study was related to Trafikverket (Swedish transport administration) and empirical data was mainly collected from two sources. One source is the contract data base, where the contracts and their design are described together with additional information such as contractor and covered geographical area. The other source is LUPP, which is Trafikverket’s tool for business intelligence within the maintenance area, i.e. SAP BusinessObjects. Through LUPP information about events that occur can be collected. Examples of information that have been used in this study is the occurrence of faults, which can be related to the spatial domain (e.g. contract area and track section), the temporal domain (e.g. year, month, week and day), the system domain (e.g. track, signalling and power supply). Also time measures related to corrective maintenance activities initiated by occurred faults can be extracted, e.g. time to respond and be at the location, active maintenance time, and total correction time. Also consequences due the faults, such as number of disturbed trains and delay times can be extracted. The two sources of data are then related to each other by specific contracts as the common denominator. Hence, in this way the contract design are related to the occurred events and its consequences within the geographical area that the contract covers. Data was exported from LUPP and the contract data base to Excel, where they were combined by the logic described above. Thereafter, the combined data base was imported to statistical tools such as Minitab for linear regression analysis.

Collected data covers the time period of 2010-2017. The lower limitation is based on the coding structure of occurred events, which was changed by STA in 2009. This means that data before 2010 is difficult to compare with later data. The upper limitation of 2017 is due to the fact that whole years were preferable to be used within the study. 22 out of 34 different contracts from different regions in Sweden were collected and analysed to be able to connect to the maintenance data. These contracts are procured under different times and contain both high and low amount of traffic.
Contract data were qualitative and describes for instance contractor name, contract type, length of contract, type of pricing, etc. Most of the data were in written form and had to be manually transformed to a data sheet. LUPP data were quantitative and describes number of inspections, error reports, inspections errors, response time, repair time, train delays, etc. LUPP data were connected to the contract data via contract number and track section number to create one common database. Most of these quantitative measurements can be affected by the maintenance contractor. However, some of them can be disrupted by external factors. These external factors could be age of the track, condition of the track, traffic intensity, animal or vegetation. There is also a gap of information between maintenance outcome and maintenance activities. The railway assets condition could have been improved by either reinvestment or maintenance actions. However, this information is not available in the LUPP data, causing uncertainties regarding the estimates of asset condition.

Data analysis
Railway maintenance contracts in Sweden contain many work descriptions and regulations regarding how maintenance should be performed. Since contractors are obliged to follow these regulations, contractors can, in practice, only affect logistical solutions. By logistical solutions we mean how contractors get to the railway tracks and how they organize maintenance activities. Hence, response time to corrective maintenance was selected as response variable for the regression analysis. However, there are some aspects that need to be considered. Firstly, larger contact areas will have a longer response time, simply because of geographical distances. To accommodate for these geographical differences the response time was divided by the length of the track section. Secondly, the contact state that contractors cannot exceed a fixed response time without receiving a fine. These fixed response time are adjusted according to traffic amount, i.e. a track section with heavy traffic have a lower time limit before a fine. Since this paper seeks the outcome of maintenance activities derived from the contract, this aspect is noted but not adjusted for in the regression model.

When the response variable has been selected the data must be cleansed of errors and irregularities. Firstly, response time plus repair time of more than one day or negative amount of time was removed ($t < 1$ and $t > 1441$ minutes). This limitation accounted for around 13 percent of the data. Secondly, the data is divided into 64 different railway assets. To determine what asset types that are relevant for a regression analysis a pareto-chart was constructed, Figure 1.
Figure 1 - Pareto chart displaying the total amount of error reports divided into the 64 different asset types

Seven of the 64 railway assets are responsible for 75 percent of all errors on the railway tracks. Three of these seven was selected for the regression analysis: Switches and Crossings; Track; Level Crossing. These three was selected because they are primarily affected by the contractors’ maintenance activities and can be reduced by preventive maintenance. Because there is a significant difference in repair time between these three assets, they have to be analysed independently.

From discussions with experts in the field they gave a unanimous view that it takes three years for a contractor to establish themselves within the contract. Therefore the data was divided into two observations (where possible), one during the first three years and one during the last three years. Of the 22 contract, 10 were able to be divided into two observations. Another aspect of a three year average is the reduction of seasonal dependence. Maintenance during winter conditions takes longer than during the summer. Also, contracts in the north have a longer winter period than contracts in the south of Sweden. By having a three year average this effect is reduced.

An initial residual analysis concluded that the response was not normal distributed. To resolve this issue the response was transformed by a logarithm transformation. The residuals then took a more normally distributed form. This indicates that the normal distribution assumption cannot be discarded, making the regression analysis valid. Non-significant regressors were then eliminated by backwards elimination with a level of 10%.
Findings
The result from the three separate regression analysis determined that four regressors had a significant correlation with response time; number of operating places; number of safety inspections; contract area and track classification. Each data point is the average response time of a track section over a period of three years. The result indicates that more operating places and safety inspection could result in a lower response time for the contractors. The $R^2$ values were 71.54% (Track), 63.37% (S&C) and 76.56% (Level Crossing), with a significant p-value for the models (all $\leq 0.05$) there is a statistical significant relationship between the variables.

Discussion
From the linear regression analysis two continuous variables were significant (number of operating places and number of safety inspections) and two categorical variables (contract area and track classification). When selection response time as the response for the linear regression analysis we initially had two considerations, seasonal and traffic variation. Seasonal variation was adjusted for by using a three year average. Traffic variation was associated with the track classification and was not adjusted for in the model, since we are seeking the relationship between contract and maintenance. Therefore, the two categorical variables were not surprisingly significant for the response. Since the contracts regulates the response time according to the track classification, it would have been a surprise if the variable was not significant. The same argument can be made for the contract area, since there is a difference between contract areas in both the contract themselves but also in geography (e.g. seasonal variation). Although contract area and track classification was expected the results indicate that there is a difference between the contract areas in Sweden. As previously stated, since 2013 STA has moved to a more standardized approach for maintenance contracts in Sweden. The result of this paper indicates that maintenance contracts need less standardization and more individualization. The contract for each contract area should be designed according to the preconditions for the specific area. However, more research is needed to determine this relationship.

Number of operating places is strongly connected to the length of the track, i.e. a longer track section will have more operating places. To simply construct more operating places on a smaller area is therefore not the solution. However, the result does indicate the importance of logistical solutions (as were one of our prerequisites) by the active contractor. When procuring new contracts, number of operating places can indicate the accessibility to the tracks for a contractor. Track sections with high accessibility can have a stronger connection with maintenance outcome, and be more favorable for a contractor to place a bid, although more research is required.

Arguably there is a connection between individual contract design and track accessibility. Today, contractors receive a fine if they exceed a preset limit for the response time. This limit is mostly regulated according to the track classification, rather than existing accessibility. Since number of operating places had the strongest correlation with response time of the four significant factors, accessibility should have a
strong effect on maintenance outcome. This result further emphasizes the need for individualization of the maintenance contracts.

Number of safety inspection was significant in all three regression analysis, with more inspections leading to a lower response time. One interpretation of the significant correlation could be that the contractor that preforms more inspections can use the opportunity to fix issues directly, reducing the inspection time. However, the same argument can be made for maintenance inspections, which were included in the linear regression analysis. Maintenance inspections did not have a significant correlation with the response. The differences between these two types of inspections are that safety inspection are much stricter and follow a detailed instruction from the client. Maintenance inspections are described as a more “gut feeling” approach, and result differ between the technicians preforming the inspection. Due to the more technical focus of a safety inspection the reason behind the correlation can be in the learning process for the contractor. By performing many technical safety inspections the contractor gains knowledge about the asset condition. With this increased amount of knowledge the contractor can plan and predict maintenance more efficiently. Also, the contractor learns the geography of the track and where the assets are. This in turn can reduce the response time for corrective maintenance activities.

Conclusion
This research is a first step of investigating the relationship between contract design and maintenance outcome using linear regression. In this paper three separate linear regression analysis was performed on maintenance and contract data for three asset types: track, S&C and Level Crossings. With response time as response four factors had a significant correlation with the response in each of the three linear regression analysis: contract area; track classification; number of operating places and number of safety inspections. Contract area and track classification were expected to be significant, since response time is regulated via fines in the contract. However, the factors number of operating places and safety inspections were not expected. The results indicate three primary conclusions; individual contract design; accessibility to the track and asset knowledge.

Since the response in the linear regression analysis was response time for corrective maintenance, there is still a need for more research to create a larger picture. However, the research does agree with previous findings of individual contract design (e.g. Abdi, Lind et al. 2014) and the importance of asset knowledge (e.g. Espling, Olsson 2004). For railway clients the procurement and contract process should value asset knowledge, both in-house and by their contractors. With accurate asset knowledge the contract should be designing individually based on the prerequisites of the contract area. By doing so there is a possibility of the increased efficiency of predicting and planning maintenance activities.

Future research should conduct additional analysis on other response variables (e.g. repair time). Response time is only one aspect of the contractor’s ability to conform to the contract design. To fully understand the relationship between contract design and
maintenance outcome, additional variables should be explored. Also, a multivariate analysis (e.g. principal component analysis or cluster analysis) could be beneficial to explore the relationships between the different variables in the dataset.

Acknowledgements
This work is funded by the Swedish transport administration (Trafikverket) and the research council for environment, agricultural sciences and urban development (FORMAS, reference number: 2015-119). Their support is acknowledged and greatly appreciated. We also like to acknowledge the consultant firm Prifloat AB that has provided data material and insightful discussions to this study.

Abstract
This paper presents graphical methods for monitoring, diagnostics, and prognostics of the condition of railway infrastructure as support to maintenance planning. The paper also uses graphics to aid univariate, bivariate and multivariate analyses of large datasets of secondary data for linear asset condition assessment in the temporal and spatial domains. We present graphical methods useful for evaluating how the asset degrades and how maintenance actions affect the track condition within different time horizons. Hence, the infrastructure manager and the contracted entrepreneur can share a common view of the asset’s current and future condition, as well as maintenance effectiveness.

Keywords: Graphical methods, Prognostics, Railway infrastructure

Introduction
In Sweden and elsewhere, condition assessments are increasingly often used for decisions on when and where to maintain different systems of the railway infrastructure, e.g. power supply, signalling, track, and catenary systems. Special measurement trains that regularly measure important variables are currently the predominant way to perform inspections to obtain condition measurement data for the track and the catenary systems. The infrastructure manager or contracted entrepreneurs plan for the needed maintenance when measures surpass certain threshold limits. The importance of the variable and the severity of the deviation from the designed limit dictates the time bounds before actions are required, as well as the type of action itself. In Sweden, such times can range from acute, requiring immediate corrective traffic management and maintenance actions, up to planned maintenance actions within three years after detection (Stenström, 2015). Thus, measurements trigger much of the maintenance and its planning. If the timetable (i.e., set 18 months before execution) does not allow inclusion of the required maintenance, there is a significant risk that the required maintenance action disturbs the railway traffic, requiring line shutdowns, train delays or cancellations. Condition measurements are thus of utmost importance. However, current diagnostic practice only uses measurements from the last passage of the train to monitor the asset’s current condition.
However, to use only the last measurement makes the maintenance decision more susceptible to measurement uncertainty. Uncertain measurements do on the one hand force the infrastructure manager to lower maintenance threshold limits to maintain low system risks for accidents due to undetected faults. On the other hand, this practice increases the false alarm rates.

Additionally, many maintenance actions may themselves reduce the life of the infrastructure items (Arasteh Khouy, 2013; Famurewa, 2013), so the maintenance cost is not limited to the replacement costs of items worn by use and of costs for personnel and machinery (Patra et al., 2009). One example is ballast tamping; an action performed to realign the track. Tamping involves lifting the rails and sleepers while pushing a fork like equipment into the ballast beside the sleepers. The forks will then vibrate, which will fluidise the ballast so that it will flow in under the sleepers. When the machine lowers the track, tamped segments will be higher, which will hopefully reduce some geometry faults. Tamping is expensive, and the vibrating forks crush some of the ballast rocks, reducing ballast life and at the same time producing fine material, which reduces the dewatering properties of the superstructure. A rule of thumb used by the Swedish Transport Administration is that the ballast can withstand ten tampings before it needs replacement or ballast cleaning; maintenance actions that are classified as reinvestments and should improve the condition in such a way that it is considered to restart the life cycle of the ballast.

In the north of Sweden, geometrical deviations may indeed be real, but temporary. A temporary displacement of the track may be due to ground frost, which in turn, is a condition that is due to water in the superstructure or substructure. Hence, a temporary speed restriction until conditions settle may be the proper action for some geometrical deviations, rather than to perform maintenance and possibly worsen the situation. Underestimating (false alarms) or overestimating (undetected faults) will both degrade the condition decision quality thus increasing cost and degrade system usability. (Bergquist & Söderholm, 2012, 2014)

Better data analysis and better asset condition knowledge thus become essential. When the maintenance personnel acquire asset condition data, they usually screen them for causes for alarm, that is, to check whether some assets need attention shortly. Those areas where there is an acute need, or where it is evident that things are about to become acute are further studied, and those areas will be scheduled for maintenance. The rest of the measurement data will likely be stored away for later reference. However, an approach that stops with storing data for later without anyone analysing them is only a waste of storage space. A better way is to use data to help gain an understanding of the asset condition and how the condition changes over time. Data analytics in general (Levrat et al., 2008; Karim et al. 2009) and the reoccurring measurements allow for time series estimations of how the track conditions evolve (Bergquist and Söderholm, 2016). Additionally, it is possible to display, extract and analyse vital information from large datasets. Hence, condition assessment based on proper methodologies and technologies could substantially reduce maintenance-related costs and increase infrastructure capacity while maintaining traffic safety (Arasteh Khoy et al., 2014; Soleimanmeigouni et al., 2018).

Aim
This paper aims to demonstrate how graphic representations and modelling may aid monitoring, data quality assessment, diagnostics and prognostics of the track condition to support asset management maintenance planning.
Method
The method we use is to study stored condition monitoring data for asset measurements, and here we study railway track geometry data.

The studied case, the Boden – Luleå track section
The data for this study stems from measurements of the Swedish Iron ore line. Measurement cars measure the geometry with some regularity and with current regulations, the measurements are performed six times yearly. Four different measurement trains and trollies produced the data between 2007 and 2018. The measurement trains and trollies have somewhat different measurement performance and measurement profiles, such as top speed of measurements, and they have different axle loads.

The studied track section 119 links the cities of Boden and Luleå and is 35 km in length. Besides the Luleå and Boden stations, the section also has stations at a regional hospital in Sunderbyn, a freight terminal station in Gammelstad and a commuter station at Notviken. Track 119 is relatively straight and does not include short radius curves. The track is a single track with meeting point sidetracks, and both passenger and goods traffic use it. Track 119 is a heavy haul line classified to handle a maximum of 32.5 metric tonnes axle load.

Dataset issues
The data analysis of historical data usually starts with an analysis of the data itself; that is, a study of the data quality. One way of discussing big data is the 4V-model of Katal et al. (2013), comprising of data volume, velocity, variety and value. To those, a fifth V have been added, veracity (e.g. Lukoianova & Rubon, 2014). The value of the data depends on their trustworthiness. The dataset in this paper relates to numerical data, in which data veracity may refer to erroneous measurements, and the objectivity of the data and the collection systematics are not problematic per se. However, the veracity may be hurt from poorly calibrated or faulty instruments, erroneous data pre-processing and erroneous data positioning when several data sources are combined to one dataset.

Data may thus be erroneous, may be missing, and measurement data always contain noise. In all likelihood, the data needs cleaning before the data quality is sufficient for the analysis task. Often, the quality will remain too low, for instance, because of a too low information-to-noise ratio even after the analyst has cleaned the data. The risk that the database does not contain all that is relevant to the goals of the study is always present. Assume that the analyst will use the data for a regression task to find correlations among properties or variables. If the database lacks information about important events, the regression analysis will, at best, be poor or fail to find significant correlations. At worst, the correlations will be strong and significant, but pointing in the wrong directions. Data correlations may just be reactions to an external, but unknown signal, so rather than each other’s causes, both are reactions to the underlying event.

The analyst extracting data from numeric databases should be aware that the data often is secondary, i.e. it was collected for other purposes than the intended goals of the present analysis. Using secondary data means that the analyst must scrutinise the original objectives to see if they interfere with the questions that the analyst is trying to answer. If the original goal may have been to supply measurements for a highly critical process where accuracy is paramount, and where one would like to spot any errors immediately, great trust in the data may be warranted. Even so, also safety-critical data contain errors that are readily obvious when they are scrutinised from a new vantage point. The analyst must also check the appropriateness of the data from other viewpoints, such as if the
statistical properties of the data are compatible with the necessary analyses techniques that are to be employed. Poor accuracy may also result from organisational gaps, for instance, because the user of the data has not made the data supplier aware that there are issues with them. Such issues may, for instance, not being forwarded to the correct recipients since the information channels are not working correctly. Proper use of the statistical methods relies on the assumption that data are independent and normally distributed. Data seldom are, but one can often salvage datasets where these assumptions are violated by choosing proper statistical tools or data transformations.

Data quality assurance in the studied case
The data for the current graphical approach to railway track condition monitoring entails many of the previously discussed issues. They are secondary data since they were sampled to evaluate the current asset status, rather than to form the basis for condition prognostics, that is, for forecasting purposes. The ultimate purpose of the analysis is to forecast asset conditions with enough accuracy so that appropriate maintenance planning can commence far enough into the future so that train schedules are not disturbed.

While this distinction between assessing asset condition and obtaining condition data useful for forecasts may seem like a minor one, there are issues with the data that a diagnostic analysis of the current asset status will not reveal. Diagnostics of the current state assessment is a snapshot of the asset condition, but it is not a motion picture, whereby one could estimate how the condition will develop over time. Prognostics require both. The measurement trains measure with differing times between measurements, and the measurements need to be linked together to evaluate the speed of change of the measured property. A reasonable way to do this that will allow for is to estimate conditions within regular intervals, based on some method, for instance by using interpolation of historical data, for instance using splines, linear regression, or just to use the latest measurements as the best estimated for the condition at a specific time. All methods have their strengths and weaknesses. Here we used averaging of measurements obtained within the latest quarter to estimate the condition, due to simplicity and extrapolation stability.

To link measurements over time means that one needs to certify that the second record relates to the same asset or asset segment as the first record. Better still if measurements have been obtained with the same equipment and personnel, with updated calibrations. To acknowledge such errors, one needs a frame of reference, that a single measurement will not provide. It is, therefore, not surprising that condition datasets obtained for a particular asset within a short time difference can differ substantially due to measurement issues rather than condition variation. Maintenance personnel did not find such issues when they only used the last and most current measurements.

Positioning is, due to the linking of measurements in time, a central property. Since we are discussing railway assets that often remain in position for tens of years (for instance track) and sometimes hundreds of years (for instance, bridges and tunnels), one may assume that positioning is trivial. If the spatial information of the data is correct, it probably easy to link measurements. If not, the analyst needs to use some strategies for overcoming the spatial errors to estimate the speed of change of the properties. In the studied case, positioning errors have been considerable, and the strategy to overcome them has been to use data binning to split the track into segments long enough for failures to have a high probability of falling into the same segment during consecutive measurements, see also Bergquist & Söderholm (2012, 2015).
Another potential difficulty is that some external disturbances have affected the asset or the measurement equipment between measurements, which would lead to errors in the rate of asset degradation. Usually, maintenance prognostics aim to predict when the condition of the asset has degraded to such a poor state that it needs maintenance. The degradation rate of the asset property is, therefore, often what one seeks to combine this information with the state itself for condition predictions. However, sometimes the recorded asset condition has improved between measurements. Some of these unexpected events may be due to maintenance actions that one can find in other databases. If there is a viable reason for an improved asset condition, the proper way to handle things could be to remove prognoses until the deterioration rate is reasonably stable. A procedure to monitor improvements could include triggering alarms for larger improvements than a threshold level based on the expected normal variation. Improvements that are larger than what can be expected just by measurement uncertainties and which cannot be explained by external factors would mean that the current model is not valid for describing current data. In the case of the subarctic railway track maintenance studied here, such improvements that are known to influence readings could be ground frost effects, maintenance or due to changes of the measurement equipment such as calibrations. Some detective work may reveal the actual causes. Generally, events that are due to pure measurement errors, such as zero recordings, are easy to find and remove.

Other unusual observations may also be easy to determine as erroneous, such as when the recordings are orders of magnitude different from the regular measurements. A multivariable bi-variate scatterplot as depicted in Figure 1 is useful to get an overview of the data. Two of the studied variables, two standard deviations of twist with 3 m or 6 m base has had several recordings stemming from another distribution, which is an illustration of the data with different orders of magnitude. The twist fault that can lead to derailments and it is thus safety critical and regularly measured. Figure 2 shows this deviation in detail. The twist data also contains zeros, which given the segmentation approach and the standard deviation studied here used is almost impossible, and the analyst should remove such observations. The time interval where ground frost events are likely should be possible to estimate for railways using local knowledge.

Figure 1. Matrix plot of some measured track properties important for railway track safety, equipment reliability and passenger comfort. Note that the twist measurements split correlations into two groups.
In many cases, strange observations will remain mysterious. The analyst should consider all possibilities and consequences for keeping or disposing of the strange data where the culprits are not obvious. If, for instance, the intended use of the data is condition prognostics, a restart of the prognostic model could help, depending on the model design.

For track geometry conditions, the maintenance itself will often unsettle the track superstructure. The first or first few measurements after maintenance may indicate that the superstructure geometry is well within its targets, but then the conditions may degrade rapidly until the superstructure has obtained a new, predictable, deterioration rate. If this happens, it may be advisable to restart the model. If the empirical prognostic model uses recent data to estimate future conditions of the property, the model is likely to generate poor predictions until the asset has settled. In the track case, a steady condition deterioration indicates that that the track has been subjected to sufficient transported weight or temperature variations for the ballast to wiggle into a more stable configuration.

Figure 2. Histogram of the 6 m twist standard deviation reveals that two distributions have been combined, one centred just above zero. Further studies show that part of the data has a mean that is orders of magnitude lower than the rest, which indicates erroneous measurements.

Seasonal effects may be necessary to include in the prognoses models. As already stated, reoccurring events such as winter frost may influence conditions. Geometrical conditions after the spring thaw or the autumn frost seasons may improve by themselves until the next measurement since frost is a function of the local water content of the substructure and temperature. Frost may, therefore, affect the track substructure or superstructure differently with considerable local variation; differences that dissipate as the frost thaws or has settled over the whole track segment. Temperatures themselves are also important as they force the material to expand and contract, causing stresses in the linear assets due to different thermal expansion coefficients.

All of the above effects can be studied using time series plots. Figure 3 shows a time series plot of one of the critical geometrical properties, twist over 3m. The figure displays both the measurement data (circles) and quarter means (crosses). The figure also shows a Kalman filter model including a prediction confidence interval for the model based on the variation in the sample, as well as an upper confidence interval of the model data. The Kalman filter is based on the quarterly average since the sampling is not regular. The measurement frequency is too low and too irregular, so the model does not allow a standard seasonality component of the time series, but the Kalman filter is used to assess the current state but also predict future conditions. The model does in this case a poor job of estimating the data behaviour. The vertical dashed lines represent known maintenance (tamping). The twist variable must not exceed certain threshold values for comfort and
safety, so large absolute values are problematic. The expectancy is that maintenance will reduce the absolute twist, at least in the short term. Studying the observations in this plot reveals that in 2009, the absolute value decreased without obvious reasons. Since the model needs to have some degree of robustness against random variation such as measurement noise, it did not respond to the rapid decline, nor did it pick up the rapid degradation rate between 2010 and 2015. The 2009 improvement suggests some maintenance action that was not recorded in the data. Interestingly, the 2013 tamping does not appear to have improved the twist. A speculation is that the degradation rate has lessened as a result of the tamping. The 2014 tampings did, however, reduce the absolute value of the twist. Judging from the data, it appears that the situation again improved in 2016, so it is possible that had been maintained or that there was something done with the measurement equipment, but this is not clear from available data. Another possibility is that the track measurement systems were updated or calibrated during these episodes. The situation improved again in 2017, to such a large extent that the model had automatically restarted.

**Graphical condition assessment and prognoses**

Graphics that are pictorial representations of data have the inherent property that they can make complex phenomena more easily interpretable (see, e.g., Bergquist & Söderholm, 2012, 2015). We will here discuss pictorial representations of data in the form of 2D heatmaps, and use colours to represent dimensions beyond the 2D imagery. Figure 4 shows a heatmap of data representing the condition of the track twist.

Figure 4 shows railway twist, here the 6m twist. The vertical axis represents the spatial information, and the horizontal axis represents the temporal information. The colours of the heatmap denote the twist values. The plot was created in R, using the ggplot2 package and the geom_tile command. The colours appear as streaks of mostly orange or yellow from left to right. The figure represents quarterly averaged data from ten years. The horizontal segmentation is a representation of 200 m segments of the track section. The data for the maximum twist of the segment constitute the foundation for the model output, and the maximum twist values are those that are essential for safety concerns. Figure 4 does not show maintenance actions, but all segments were tamped at least three times.
The observations have been segmented into bins representing maintenance classes, where dark green represents segments and times where the maximum 6 m twist for the segment was lower than the stipulated maximum for new tracks. Many conditions are worse than new, but they are still not of any concern (below the PLAN limit). Worse still are segments that are above the PLAN limit, which means that the maintenance organisation should consider maintaining the segment. The plot also shows even further degradations. When the track conditions have surpassed the UH1 (maintenance 1) limit, the maintenance organisation is required to plan maintenance so that they have performed it before the condition has reached the next level, UH2 (maintenance 2). If the condition exceeds the UH2, the maintenance organisation is required to maintain immediately. If the condition surpasses the KRIT (critical) limit, the track manager needs to close the track or impose speed restrictions until conditions have improved.

It is possible to add another layer to the plot, showing the performed maintenance, and Figure 5 shows the plot with a maintenance layer added. In this figure, it is clear that problematic segments usually remain as problematic even after tamping, since the colour remains the same.

The use of a geographical map for localisation purposes is attractive for linear assets such as railway track, but also for localising point assets (e.g. switches and crossings, bridges, and level crossings) as part of the infrastructure. Hence, a combination of heatmaps and geographical maps are useful for maintenance planning purposes. The use of GIS-applications and layers can also be used to integrate further information about the track surroundings that are useful for diagnostic and prognostic purposes, e.g. soil and water conditions. Furthermore, data about the weather should be useful for diagnostic and prognostic purposes. One example is the temperature, where low temperatures increase the risk for rail break and high temperatures increase the risk of buckling.
Microsoft Power BI Desktop can also use R scripts and allows the user to run a collection of R packages for graphical presentations and analyses. This feature also allows for zooming, and Figure 6 shows an interactive display, allowing the user to zoom in on particular periods and track segments. In this plot, the colours are auto-scaled, from green in the colourmap representing segments with little gauge variation, to red where the variation is considerable. The Plotly package in R can also produce an interactive plot.

Another source of information that should be valuable when performing diagnostics and prognostics is the actual maintenance actions done on a segment (Arasteh Khouy, 2013; Famurewa, 2013). However, when dealing with the basic maintenance contracts, this information is stored locally within each contract (often in scanned PDF within a Share point solution) and not easily accessible for aggregated analysis. Appropriate usage of a standardised maintenance system (e.g. Maximo) should enable a more comprehensive analysis of performed maintenance actions (see, e.g., Al-Chalabi, 2018). The inspection system Bessy (e.g. inspection occasions and inspection remarks), the fault
reporting system of Felia (e.g. faults, repair times, and repair actions) also contain some useful additional information about maintenance actions and the asset condition. The asset register (BIS) also contains some information that might be useful for analysis purposes, e.g. type of items and installation year. The relevant age of infrastructure items can be calculated by a combination of the calendar time and the yearly tonnage.

Contributions
The datasets that the measurement trains produce are large and riddled with defects, and things to consider for sifting out the relevant results are presented. The graphical plots show that some maintenance actions are not effective, that there are underlying factors that make some track segments to outperform others, that continue to be troublesome despite repeated maintenance actions. Such sections that have been troublesome for years may eventually need non-standard corrective maintenance or reinvestment stand out in the spatiotemporal graphical overview. The findings show that a proper analysis may reveal how much a maintenance action improves the asset condition, not only directly after the action, but also if the long-term deterioration rate is affected. Hence, both the infrastructure manager and the contracted entrepreneur can share a common view of the asset’s condition and maintenance effectiveness as a basis for continuous improvement.

Abstract

While the attention for Condition-Based Maintenance (CBM) has been growing, both academically and in practice, many organizations are struggling with the adoption and deployment of advanced condition monitoring technologies. The purpose of this research is to develop a CBM Maturity Model and CBM Maturity Assessment that can aid asset owners and maintenance managers in the development of their CBM practices. The maturity model, assessment instrument and assessment procedure have been developed with and tested at two large asset owners in the Dutch process industry following the design science methodology.

Keywords: Condition-Based Maintenance, Maturity model

Introduction

Condition-Based Maintenance (CBM) is one of the means to optimize the utilization and useful lifetime of our current asset base and thereby, to make our industries more sustainable. CBM aims to predict future malfunction of an asset by monitoring several conditions (e.g., temperature, vibrations), so maintenance can be executed at “just the right time” (Jardine, Lin & Banjevic, 2006).

In recent surveys in northwest Europe up to 60% of organizations indicated they have concrete plans or intentions to use predictive maintenance in the near future (PwC & Mainnovation, 2018). In those same surveys, only 11% of organizations indicated they are already employing predictive maintenance practices. In reality, many organizations are struggling with adopting advanced condition monitoring (CM) technologies (PwC & Mainnovation, 2018) and, when adopted, with fully diffusing these technologies throughout the organisation (Van de Kerkhof, Akkermans & Noorderhaven, 2016). Unfortunately, there is a lack of relevant, actionable guidance for industrial maintenance organizations to meet their maintenance ambitions (Bokrantz, Skoogh, Berlin & Stahre, 2017), as well as a lack of understanding of what optimal usage of CBM entails for maintenance organizations (Tiddens, 2018).
Maturity models are helpful tools for addressing these issues (Wendler et al., 2012). Based on the assumption of predictable patterns, maturity models represent theories about how organizational capabilities evolve in a stage-by-stage manner along an anticipated, desired, or logical maturation path (Pöppelbuß & Röglinger, 2011). In general, the term ‘maturity’ refers to a state of being complete, perfect, or ready (Schumacher et al., 2016). The main purpose of maturity models is to help an organization or entity reach a more sophisticated maturity level (Mittal et al., 2018), by enabling the organization to assess the as-is situation, by picturing the desired ‘final’ stage of maturity and by providing guidance on how to improve (Wendler et al., 2012).

Although the maturity concept emerged out of quality management (Shewhart, 1931), the first instruments with maturity stages building on each other were developed by Crosby (1979: quality management process maturity grid) and Nolan (1979: maturation of data processing). The development of maturity models really took off since the Software Engineering Institute introduced the Capability Maturity Model (Paulk, Curtis, Chrissis & Weber, 1993). Since then, the maturity concept has been widely applied across many domains, such as software development (e.g., Haase, 1996; Subramanian, Jiang & Klein, 2007), project management (e.g., Kerzner, 2002; Hilson, 2003; Pennypacker & Grant, 2003), knowledge management (e.g., Hsieh, Lin & Lin, 2009; Khatibian, Hasan & Abedi, 2010), and many more (see Wendler et al., 2012 for an overview). Recently some maturity models have also been developed in fields that are related to CBM, such as digitalized manufacturing (e.g., Mittal, Khan, Romero & Wuest, 2018), big data (e.g., Comuzzi & Patel, 2016), asset management (The IAM, 2016), and reliability-centred maintenance (Hauge & Mercier, 2003). Yet, an actual CBM maturity model is still missing.

In this paper we aim to develop a descriptive maturity model (Pöppelbuß & Röglinger, 2011) for the deployment of Condition-Based Maintenance by (the maintenance organizations of) asset owners in the process industry. The main purpose of this descriptive maturity model is to enable asset owners and their maintenance managers to assess their current practices and capabilities. The outcomes of these assessments can then be used to create improvement plans. To achieve these objectives, the maturity model (the reference model) is translated into an assessment instrument and accompanied by an assessment procedure. Hereby we answer the call for relevant, actionable guidance for industrial maintenance organizations (Bokrantz et al., 2017).

**Methodology**
We have adopted the design science paradigm (Hevner, March, Park & Ram, 2004) for developing and evaluating the maturity model, the assessment instrument and the assessment procedure. Typically, design science research seeks to create innovative artefacts that are useful for coping with human and organizational challenges by following an iterative process of development and testing (Hevner et al., 2004). Our methodology, as depicted in Table 1, is based on the procedure of Becker et al. (2009), who have translated the design science principles into a dedicated procedure for the development of maturity models. Following the recommendations of Wendler et al. (2012), we have applied a combination of multiple methods in different research states to evaluate the maturity model’s completeness, validity, usefulness and ease of use. Specifically, the study has been performed in three consecutive phases: (1) scoping, (2) development and testing of the maturity model, and (3) development and testing of the assessment instrument and assessment procedure.

</table>

The maturity model and assessment method are developed in cooperation with two large asset owners in the Dutch process industry: Tata Steel and BP. Seeing practice impact in new ways, we followed a leading pathway (Simsek, Bansal, Shaw, Heugens & Smith, 2018), working with Tata Steel’s central domain expert to establish the research design, as well as the first version of the maturity model, the assessment instrument and the assessment procedure. Most focus group sessions, as well as the practical setting evaluation, have been held with domain experts from these organizations. To safeguard the external validity of the developed maturity model, additional focus group sessions have been held with domain experts from other asset owners and knowledge institutes in the Netherlands.

**Scope**

In the first phase, scoping, we evaluated the practical and theoretical need for the development of a new maturity model. The theoretical need was assessed by identifying calls for research and guidelines (Bokrantz et al., 2017; Tiddens, 2018) and by reviewing existing maturity models – no maturity model yet existed for the usage of CBM. The practical need was assessed by interviewing managers and domain experts from the organizations involved in our research program, asking whether or not and how a maturity model would aid them in improving their CBM practices. The results from both endeavours confirmed the need for a CBM maturity model.

Then a focus group session was held with maturity model experts and domain experts from Tata Steel to define the problem, the design requirements, the development strategy, and the future user group.

**Development of maturity model**

The maturity model has been developed in four consecutive steps. First, we have reviewed the structure and content of existing and accessible maturity models – from
scientific journals, conference proceedings, and knowledge institutes, as well as Tata Steel’s prior developed maturity models – to identify what structure best fits the application of CBM by asset owners and to ensure a structural fit with Tata Steel’s maintenance related maturity models. The content of the maturity model was developed first and foremost by studying scientific literature and reports, books and guidelines from knowledge institutes, and by reviewing interviews with domain experts that had been held before within the research program (139 at Tata Steel, 154 at BP, 32 with other asset owners and service providers). The few gaps that initially remained were closed by performing (5) additional interviews with domain experts.

After the first version of the maturity model had been developed, 12 focus group sessions were scheduled with domain experts from the two asset owners and two knowledge institutes (see Table 2). The participants for the sessions were selected as such that, as a whole, their knowledge covered all maintenance disciplines and all types of CM technologies, and the key stakeholders within the organisation were represented (maintenance, operations, projects, IT, R&D).

During these sessions participants were asked to evaluate the maturity levels (would you add/remove levels, would you adjust the description of levels? If yes, why and what/how?), the categories (would you add/remove/adjust categories? If yes, why and what/how?), and the description of each category-level combination (would you adjust the description? If yes, why and how?), based on the evaluation template of Salah et al. (2014). All sessions were recorded and transcribed.

After the sessions the written feedback was aggregated per maturity level, category and description. All feedback that was considered relevant was used to adapt the first version of the maturity model into the second version. This was done primarily by the main researcher, in accordance with Tata Steel’s central domain expert.

As the final step, a survey was sent to all participants of the focus group sessions to evaluate the maturity model’s relevance (the elements are relevant to CBM maturity), comprehensiveness (all elements are included), accuracy (elements are correctly assigned to maturity levels) and mutual exclusiveness (elements are clearly distinct), following the evaluation format of Salah et al. (2014).

**Development of assessment method**

The assessment method consists of an assessment instrument and an assessment procedure that describes how the instrument should be used. The design specifications for both were determined in focus group sessions with future users at Tata Steel and BP. As Tata Steel’s central asset management department had over 10 years of experience with developing maturity models and performing maturity assessments, we could build on their instruments and procedures for designing the CBM Maturity Assessment.

After development, two assessments were performed to test the usefulness and ease of use of the assessment instrument and procedure, one at Tata Steel and one at BP. In these assessments we followed the prescribed procedure. Both sessions lasted 2 hours. At the end of each session, the participants received a survey to evaluate the usefulness
and ease of use of the assessment instrument and procedure, following the evaluation format of Salah et al. (2014).

**Findings**

We define CBM maturity as a state in which a ‘facility’ (an organizational subunit) makes optimal usage of CBM. In particular, when a facility has reached CBM maturity, the facility applies the optimal combination of CM technologies (that are currently available) to all assets that could benefit from CBM and optimally uses the information provided by these CM technologies.

According to the domain experts, a facility is the most meaningful unit of analysis in the process industry: for most sites the entire production process is too large to manage by a single production and maintenance department, thus the organization is divided into smaller teams, each responsible for a subset of the asset base. A facility is the organizational unit that is responsible for managing their subset of the asset base, such as a production line or cracker unit. Each facility has their own production teams, maintenance team(s) and management.

It should be noted that the exact features of the optimal state of a facility are likely to differ per facility and change over time. First, the applicability and usefulness of CBM is dependent upon the characteristics of the assets (e.g., degradation mechanisms) and the production process (e.g., consequences of breakdown). Secondly, new CM technologies and the capabilities of existing CM technologies are still being developed. To stay mature, the organization thus needs to keep track of changes in their asset base and innovations in CM technologies, and adapt their CM technology portfolio accordingly.

**CBM Maturity Model**

In our observations of CBM practices and in line with maintenance (e.g., Macchi & Fumagalli, 2013; Hauge & Mercier, 2003) and asset management maturity models (e.g., The IAM, 2016; Volker, Van der Lei & Ligtvoet, 2011), we identified five logical states of using CBM. In the first state, CBM is not used, for example because assets are not maintained. In the second state, CBM is used reactively. None of the assets are monitored structurally, but when an operator or a maintenance technician encounters an anomaly with an asset, an external CM service provider is asked to properly investigate the asset in order to better prepare maintenance activities.

In the third state, CBM is used structurally and planned, mainly to improve the efficiency of maintenance. In this state, the organization has built some internal capabilities with easy-to-learn and easy-to-use CM technologies (Nicholas, 2016) and uses CBM to reduce corrective and periodic maintenance activities.

In the fourth state, CBM is used proactively to increase the reliability and productivity of (mainly important) assets. Here the organization has decided to invest more heavily in CBM and has started experimenting with multiple hard-to-learn, hard-to-use and specific CM technologies, for example in a dedicated Condition Monitoring Program. Better equipped CM specialists have become important partners in reliability improvement initiatives, as insight into the assets’ condition aids in identifying why the assets failed. In this state, the higher costs for CBM are justified by even higher gains from reliability and asset productivity improvements.

In the fifth state, CBM is used optimally, or World Class, to increase the value realised from the asset base. Here the facility has ramped up all successful CM technologies, while maintaining the exploration for new CM technologies. The facility has embraced asset management (as described in ISO 55.000) and information about
the assets’ condition has become an essential component of many asset management decision processes, including optimization of production, inventory management, project prioritization, and designing new assets. Because processes become more stable and predictable now, the facility starts actively reducing buffers, such as redundancy and stocks. To facilitate this, CM teams have gained a central position in the organization and have become well-connected to knowledge institutes, equipment and CM technology manufacturers and specialist CM service providers.

Through our studying of the diffusion of CBM practices (Van de Kerkhof et al., 2016), a literature review and additional interviews at Tata Steel and BP, we distilled twelve categories of elements that are required to perform CBM successfully. These categories describe characteristics of the technology, the organization or the people involved.

In the technological realm, five categories were relevant. First, the category CM technologies describes what CM technologies are used by the organization and how they are used, starting off with ad hoc and infrequent inspections and moving towards high-frequent and automated measurements. Second, the category Assets describes to what assets CBM is applied, starting with the assets that are easy to monitor, but incorporating more and more assets for which the highest value of monitoring can be attained towards higher maturity levels. The third category, Decisions, describes what decisions are (also) based on information about the assets’ condition, starting with maintenance decisions only, but moving gradually towards other asset management decisions as well. The fourth category, Data, describes what data are needed to be able to perform the CM analyses and make the decisions thereafter, including for example master data, financial data, failure data, production data, and environmental data. The fifth and last technological category, IT-infrastructure, describes the characteristics of the IT-infrastructure, starting with stand-alone systems for each CM technology, but moving towards a standardized IT-infrastructure that enables smooth ramping up of successful CM technologies.

Also in the organizational realm, we identified five main categories. The category Strategy and goals describes the strategy of the organization (or facility) and the main KPIs for the facility, moving from minimizing maintenance costs to improving reliability, production and the value realised from assets. The category Structure describes how the monitoring is organized, first relying mostly on external CM service providers, but moving towards a structure in which centralized and decentralized CM teams work in close cooperation with specialist external CM service providers. The category Budget and capacity describes what budgets and capacities are reserved for condition monitoring, CBM, experimenting with new CM technologies and maintaining adopted CM technologies, moving from no or very limited budget and capacity to structural and dedicated budget and capacity for each of these purposes. The category Processes and documentation describes the processes and documentation that are used for the CBM practices, gradually defining processes and documentation for monitoring and decision-making, for experimenting with and implementing new CM technologies, and for evaluating and managing the CM technology portfolio. Important documentation includes standard CM reports, maintenance concepts, CM concepts (how an asset type is monitored), a list of critical assets, and an overview of what CM technologies are applied to each asset. The final organizational category, Governance, describes how the CBM practices are governed, including defined procedures, specified acceptance criteria, certification of CM specialists, formal agreements about data rights and responsibilities, and obligations for project managers to consider CM technologies in their projects.
Finally, we classified two categories that focus on the characteristics of the people involved in the CBM practices. First, the Knowledge, skills and abilities of those people is one of the key determinants of the success of a CBM practice. Specifically, domain knowledge about the asset and its (production) context – what is ‘normal’, how can it fail, what influences degradation, how does degradation influence production – and proficiency with CM technologies are determining the quality of analyses and decisions. Second, the Culture of the organization has to match the CBM practices for the practice to be sustainable. Typically organizations progress from a firefighting culture towards a bureaucratic culture, after which the organization can transition to a reliability and asset management culture.

In addition, multiple maintenance managers indicated during the domain expert evaluation that the rationale was lacking in the first version of the CBM Maturity Model: “why should our facility aim pursuing a higher maturity level?” Therefore we added one category to the maturity model: Value. This category describes the primary gains that can be realised at each maturity level, going from better and more efficient maintenance to increased productivity and return on assets. The design for the CBM Maturity Model is shown in Table 3.

CBM Maturity Assessment
The assessment instrument and procedure are designed as such that they can be integrated in Tata Steel’s assessment program. This program focuses on facilitated and self-assessments to aid facilities in improving their asset management practices. Specifically, the assessments help in understanding how well a facility performs certain asset management practices, in identifying gaps, in creating improvement plans, and in transferring knowledge between facilities.

The design of the assessment instrument is displayed in Figure 1. For each of the twelve categories, the assessment group can assign the best fitting maturity level (score and description). When selecting a score, the group has to present evidence that supports their choice, such as data or references to documentation, interviews or
observations. If the maturity level’s description doesn’t perfectly match their current situation, they can outline the differences in the comments. The scores are automatically converted into a vertical spider diagram, making it easy to see what categories are at a lower-than-desired maturity level.

![Diagram](image-url)

*Figure 1 – Design CBM Maturity Assessment instrument*

In the practical setting evaluation it was confirmed that the assessment can best be performed with an independent facilitator who understands the CBM Maturity Model, clarifies descriptions with examples, and challenges the participants to get a shared and correct view of the situation.

The assessment procedure consists of six steps. First, the facilitator and the facility’s initiator (often a management position) agree on a plan for carrying out the assessment, including the date, who is going to participate, and whether or not a preparatory session is required. If so, a brief CBM awareness session is held for the assessment’s participants two weeks prior to the assessment. Then, secondly, the CBM Maturity Model is shared with the participants about one week prior to the assessment. This gets the participants thinking about the topic and their maturity already, and it speeds up the introduction during the assessment session.

The third step is the assessment itself, guided by the facilitator. The ambition is to get a common shared view on the maturity of each element in the assessment. If the group does not reach a consensus or the score is in between two scores, the lowest score is to be selected. In these cases, the comments box is used to explain the score. It was noted by the practitioners that low scores are at least as valuable as high scores, since these provide opportunities for improvement. These scores were supported by comments as well, so that it was easier to define the steps to improve the maturity in the next step.

In the fourth step, the facility’s management translates the assessment results into an improvement plan. At this stage it is sufficient to have a prioritised list of improvement areas, rather than a detailed plan. If needed, the facilitator can support in this step, but the facility’s management should take responsibility for drafting and executing the improvement plan. Then, in the fifth step, the facilitator and facility’s management decide upon a realistic timescale for re-assessing, dependent on the planned improvement process.

Lastly, after each assessment process, the facilitator reviews the assessment process and communicates learning points to the people who were involved in conducting the assessment and to the people who will be involved in setting up and facilitating future assessment sessions.
Conclusion

The CBM Maturity Model provides scholars with more insight into the multi-faceted nature of CBM and, when used by practitioners, shows the areas asset owners have most difficulties with. This can guide future (practice-oriented) research. Managers from asset owners can use the CBM Maturity Model’s assessment instrument and assessment procedure to assess their as-is situation and derive opportunities for improvement.

Abstract

This paper aims to explore and compare national and international food retailers in terms of analyzing and examining linkages between innovation and sustainability performance at three levels: actor, dyad and network in order to examine food supply chains. The research applies a comparative study across those food retailers. Qualitative multiple cases are applied to provide a more holistic view of similarities and differences in innovation in food supply chains and how they are linked to sustainability performance. The research reveals key themes of innovation that are implemented to support retail firms and how these innovations are linked to sustainability performance.

Keywords: Sustainability Performance, Retail Supply Chain, Food Industry

Introduction

The importance of enhancing sustainability in supply chains has escalated significantly over the last decade (Petljak et al., 2018). As organizations face challenges concerning sustainability and global competitiveness, they come across increasing demands to reduce costs, improve customer service and reduce harmful environmental influences to ensure the continuity of supply chains (Barnes and Liao, 2012). In this context, we consider food retailers. There are challenges faced by these retailers, hence there is a need to understand the similarities and differences between national and international food retailers linking innovation and sustainability performance and examining
this link at the three levels of focal actor, dyadic relationship and chain networks (Yakovleva and Flynn; 2004; Awaysheh and Klassen, 2010; Esfahbodi et al., 2016).

In this study’s empirical context, the Jordanian food supply chain, the retail sector is increasing due to high demand for food supplied by large and well-established retailers (MoA, 2018) and the population growing rapidly, especially in urban areas within the country and also having several nationalities who have moved from neighboring countries (DoS, 2018). Therefore, international food retailers are establishing branches across Jordan.

In prior research, there is limited theoretical understanding of the link between innovation and sustainability performance in retail supply chain at the actor, dyad and network levels (Yakovleva and Flynn; 2004; Esfahbodi et al., 2016). Therefore, it is important to understand the innovation in supply chains and its link to economic, social and environmental sustainability challenges that retailers face (Awaysheh and Klassen, 2010) at international and national levels. Moreover, the implementation of innovative practices and activities require both types of firms to effectively manage innovation and any barriers from their supply chain dyads and networks (Petljak et al., 2018). Thus, the research aims at examining the linkages between innovation and sustainability performance at international and national retailers at the actor, dyadic and network levels, to better examine retailers’ practices in food supply chains. Hence, the following research questions are addressed:

1) What are the contextual dimensions for innovation in a food supply chain?
2) How do international and national retailers implement innovation dimensions and technologies at actor, dyad and network level to enhance sustainability?

**Literature Review**

**Innovation Perspective**

Innovation in supply chains is “the creation of new combinations. These new combinations can be a new product, a new technology for an existing application, a new application of a technology, the development, or opening of new markets, or the introduction of new organizational forms or strategies to improve results. This means that an innovation can be not only a new product, but a new production process, a far-reaching re-organization of production and distribution, […]” (Omta, 2002, p. 73). Food supply chains induce innovation by means of technology, either adapted or invented, including product technology, information technology, process technology, transportation technology, standards and systems (Trienekens et al., 2003; Rueda et al., 2017). An effective way to generate sustainable practices with technology in the food supply chain does not build on a completely “new” set of skills (Shah et al., 2017). To understand the innovation perspective, three components, product, process and organizational innovation, are explained in order to explore and compare how retailers implement innovation to enhance sustainability performance.

Product innovation is concerned with “developing new products, staying competitive and seizing market opportunities, responding to external demands, competing in niche markets, capabilities and competencies, and engaging in ecopreneurship” (Klewitz and Hansen, 2014). It involves the replacement of raw materials with sustainable materials, as well as energy saving...
properties or sustainable product characteristics that respond to customer, buyer, or future developments (e.g. Behnam et al., 2018). Enterprises can utilize their uniqueness to compete in niche markets, for instance their ability and flexibility to respond swiftly to different demands in the market (Jenkins, 2009). Enterprises are capable of taking hold of market opportunities with environmental product innovation, for example via product differentiation (e.g. Martín-Tapia et al., 2010; Bellamy et al., 2014).

Process innovation consists of the subtopics of “economic benefits, response to external pressures and anticipation of regulatory changes, adoption of new technologies, pollution prevention/recycling/waste management/resource efficiency as well as capabilities and competencies” (Klewitz and Hansen, 2014). In that way, enterprises attain economic benefits through cost saving in their production processes, among others (e.g. Behnam et al., 2018). From external pressure or expectation of regulatory alterations, enterprises benefit from innovations in their procedures, whereby they minimize material usage, consumption of energy and waste, generally, moving in the direction of cleaner and more eco-efficient production. Enterprises improve their environmental performance, gain economic benefits, and engage in pollution prevention through eco-efficient practices. Eco-efficiency can even aid towards further radical process and ultimately product innovations (Michelsen and Fet, 2010).

Organizational innovation is commonly known as a firm-level style of innovation in management initiatives (Anzola-Román et al., 2018). Organizational innovation “means the implementation of a new organizational method in the undertaking’s business practices, workplace organization or external relations. Changes in business practices, workplace organization or external relations that are based on organizational methods already in use in the undertaking. As well as changes in management strategy, mergers and acquisitions, ceasing to use a process, simple capital replacement or extension, changes resulting purely from changes in factor prices, customization, regular seasonal and other cyclical changes” (Union, E., 2006). Organizational innovation improves creativity enhance enables the development of technological innovations (Mothe and Nguyen, 2010). Organizational innovation is recognized as a source of competitive advantage and supports technological innovation in a context of enhancing sustainability and increasing competition (Sapprasert and Clausen, 2012; Anzola-Román et al., 2018).

Food Supply Chains
“Supply Chain Management (SCM) is the integration of key business processes from end user through original suppliers that provides products, services, and information that add value for customers and other stakeholders” (Global Supply Chain Forum in (Lambert and Cooper, 2000, p. 66). SCM as encompassing four distinct echelons: internal supply chain, the dyadic, the chain and the network (Harland, 1996). SCM emphasizes in the ways by which firms make use of their suppliers’ processes, technology, and capability to enhance competitive advantage. Most food supply chains tend to involve the following stages: origin of the resource, agricultural production, primary processing, further processing, final manufacturing, wholesale, retail, food service and domestic consumption (Hugos, 2018). According to Revoredo-Giha et al. (2012), a supply chain is seen as a network of organizations or actors that have economic and social relationships that

---

---

3
allow the working of the supply chain to produce goods and services. This shows that there are three different levels of supply chain: actors, dyadic relationships and network, helping enterprises (e.g. focal firms) link innovation orientation and sustainability orientation in a food supply chain (e.g. Gómez-Cedeño et al., 2015).

A focal firm can be defined as the one that is responsible for the direct link with the end-customers; at the same time it has direct and indirect links with different actors across the supply chain such as wholesalers, retailers, packaging providers and distributors (Hugos, 2018). As actors change their roles across the supply chain levels, they may face opportunities and/or risks (Beske and Seuring, 2014). The major focus of the focal firm is based on how to link the supply and demand, focusing on the product value (Aarikka-Stenroos et al., 2014). In this study, the retailer of meat supply chain is the focal actor.

![Figure 1 - Focal Actor](Source: Frostenson and Prenkert, 2015)

Dyadic relationships can be defined as the interactions of actors amongst each other to create a more collaborative dynamic and facilitate innovation (Wilson, 1995; Michalski et al., 2018). The relationships developed between the retailer as a focal actor and other actors have become a high priority, as they are either vertical or horizontal relationships (Petljak et al., 2018). In these relationships, “Issues of trust and risk can be significantly more important in supply chain relationships, because supply chain relationships often involve a higher degree of interdependency between companies” (La Londe, 2002, p. 10). Omta (2002, p. 75) defines a network as “all of the actors within one industrial sector, or between related industrial sectors, which can (potentially) cooperate to add value for the consumer.” In fact, there is a lack of research on SCM from the perspective of retailers (Petljak et al., 2018). Retailers are acknowledged as an important actor in the supply chain that contributes to change (Lehner, 2015). Addressing retailing’s innovation and sustainability, the “...food retailing is very important because of time pressure due to perishability, the need of cooling and the related waste management challenge” (Petljak et al., 2018, p. 2). Several authors (e.g. Lambert et al., 1998; Michalski et al., 2018) have suggested fundamental aspects for how and why channels are structured and created. Hence, the supply chain structure is the network of actors that forms relationships between members of the supply chain (Michalski et al., 2018) to facilitate innovation in food supply chains.
Research Methodology

Research Design
This is a qualitative case study and examines socially constructed dynamic reality (Creswell, 2007). Through an in-depth, comparative study of two food retailers (international and national), this study is to understand the linkages between innovation and sustainability performance at the actor, dyadic and network levels, to better examine food supply chain chains (Yin, 2018). After reviewing literature, a multiple case study strategy is applied since rich findings are needed to maximize reliability and validity. As a comparative study, case studies were conducted and later compared the findings. Several sources of secondary data were analyzed such as retailers’ websites, sustainability projects and related past surveys. For the primary data collection, multiple cases of interviews and observations were compiled during January 2019. A method of analytic generalization is followed, where a prior developed theory of innovation perspective is utilized as a template to compare the empirical findings (Bryman and Bell, 2015). The unit of analysis is the meat supply chain of retailers, specifically beef products.

Sampling, Data Collection and Analysis
Multiple cases of two large food retailers, where R1 is an international retailer and R2 is a national retailer. For each case, five face-to-face semi-structured interviews were conducted, giving 10 interviews in total. The cases followed a snowball sampling, where managers recommended several different relevant managers from the retailers (Patton, 2015). Those managers were supply chain managers, hygiene and safety managers, fresh food managers, product development managers and managers of sustainable sourcing. The multiple case strategy was conducted to understand similarities and differences in the themes (Yin, 2018) between international and national retailers from the innovation perspective in food SCM at the actor, dyad and network levels. This is to explore and explain their links to innovative technologies and in turn to sustainability performance. Each interview of 60 minutes was conducted voluntarily, voice recorded and later transcribed. For each case, three observations of 60 minutes were performed (Yin, 2014), where the researcher attended one meeting combined with field tours as a non-participant at both retailers, including the actor level (the retailer), the dyad level (retailers with a direct relationship) and the network level (retailers with an indirect relationship). These actors were chosen to be observed to create multiple sources of evidence to support the interviews’ findings (Aarikka-Stenroos et al., 2014). The slaughterhouse, beef distributor, beef packaging and a government body, were chosen to be observed based on a convenient sample.

Ethical consideration was applied throughout this study. Thematic analysis was followed to group themes and indicate contextual dimensions from the collected data in order to enhance the thoughts and provide meaningful findings (Miles et al., 2014). NVivo was used to organize, store and retrieve the research data (Bazeley and Jackson, 2013).

Findings and Discussion
Several key dimensions emerged during data analysis in association to the key themes of innovation in relation to enhancing sustainability performance at the actor, dyadic and network levels, to better examine food supply chain. This is in line with prior research that emphasized the significance of innovation at their retailer in order to be successful and overcoming any challenges (Omta, 2002; Bellamy et al., 2014). As supported by R1, Product Development Manager, “I
believe that our innovative ideas are what keeps us thriving in our competitive market and seizing market opportunities.” This is also supported by the observations conducted at R1 and R2. Table 1 represents the key dimensions for the innovation themes that emerged. These were clustered into three key themes, product, process and organizational innovation.

</table>

Contextual dimensions leading to perceive innovation at actor, dyadic and network level in the supply chain were identified (Table 2). Previous research highlighted the importance of innovation in an organization, at the actor level, but there was a lack of research at the dyad and network level in order to have a greater involvement of all the members across the supply chain and enhance
social, economic and environmental sustainability in SCM (Bellamy et al., 2014; Behnam et al., 2018).

Table 2 demonstrates the level of innovation implementation at the actor, dyadic and network level, in relation to achieving sustainability in SCM. R2, Product Development Manager highlighted, “We believe for our retailer to be successful in achieving sustainability we need to be differentiated in our competitive market and be as innovative as possible”. Though it was identified that at the actor level, innovation is applied well, at the network level is lower. R1, Supply Chain Manager explained, “Our company has tried many times to collaborate with the government with several ideas and programs such as hygiene issues, recycling, and certificates; however very rare cases have been applied with very little resources. I believe that if more joint programs are implemented between us this will encourage us to be more innovative and sustainable.” Therefore, the results revealed enhancing sustainability performance in SCM is achieved when innovation is successfully implemented at actor, dyadic and network level. Based on the results of this study a comparison between Retailer 1 and Retailer 2 was conducted. It was found that Retailer 1 implements innovation more than Retailer 2, as it is an international organization that adopts and adapts international ideas and concepts hence has a wider opportunity to implement them in a developing country.

*H= High, M= Medium, L= Low (These are measured on a three-point scale (high, medium and low). Based on the level of implementation of innovation at actor, dyadic and network level. Further information is available upon request).
Retailers implement innovative technologies at actor, dyad, and network levels to achieve sustainability in food supply chain. This study has illustrated that some actors across the supply chain implement more than others depending on their implementation of innovation; they integrate more dimensions. R1, Head of Sustainable Sourcing explained, “We always work to be a part of the whole supply chain as this will bring sustainable benefits for all of us. For example, we are not computer connected via ERP between the Food and Drug Association, hence delaying inspections, trainings, etc. So it would be great if someone came up with an innovative idea to overcome this challenge.” In addition R2, Hygiene and Safety Manager highlighted, “Our transportation vehicles between us and the meat suppliers are very innovative. The vehicles are refrigerators and have a cooling tracking device which track the temperature of the refrigerator as the meat is being transported. This allows us to make sure that the temperature is in the appropriate range.” R1, Supply Chain Manager explained, “Our retailer and the other actors in our supply chain are concerned with the economic situation in Jordan. We have a variety of prices for meat and other products, we try our best to be innovative even with cost.” This is supported by the observations conducted at R1 and R2. Table 3 demonstrates that actors across the supply chain implement innovation more than others, where Retailer 1 compared to Retailer 2 implements innovation more.

Conclusion

The interest of sustainability in food SCM in research is growing especially in the innovation perspective (Behnam et al., 2018). This study concluded the significance of implementing innovation, either product, process and organizational innovation, in order to enhance sustainability performance at the actor, dyad and network level. Key contributions to knowledge
will be a theoretical association to understand how to enhance innovation in SCM from the perspective of innovation. Key implications made for retailers are to support their employees to be innovative and to understand the different types of innovation technologies that they can adopt or adapt at different levels in order to enhance sustainability. From the empirical context view, this research contributes to critically examine the food supply chain context in a developing country, Jordan, and in a retailing industry. A limitation to this study is conducting interviews only with the retailers; a suggestion for future research is to conduct interviews with all the actors across the supply chain to gain a more holistic picture of how to enhance sustainability in SCM at all three levels from the perspective of innovation.

Optimal sourcing strategies of fresh agricultural product retailers

Jing LIU
Ludong University, China

Qile HE (qile.he@coventry.ac.uk)
Coventry University, UK

Abstract:
This paper models the optimal sourcing strategies of fresh agricultural products among alterative sourcing strategies of retailers based on the scenario of a supply chain of one retailer and two suppliers. The retailer can choose from two types of suppliers – preservation effort supplier and non-preservation effort supplier – to maximize profit. Based on numerical examples, the optimal retailer sourcing strategies are explored under two scenarios: the traceable scenario and the non-traceable scenario. The results offer insight for retailers, regulators and consumer groups on how to encourage quality sourcing practices, so that to maximize food quality in the supply chain.

Keywords: Fresh agricultural products, Preservation efforts, Sourcing strategy

Introduction
In recent years, consumers’ requirement for fresh agricultural products (FAP) has grown significantly due to concerns about food safety, food quality and healthier diets (Soto-Silva et al., 2016). Retailers are the final link in the food supply chain serving consumers. Their sourcing strategies can have major impact on the quality and safety of the food in the supply chain. Previous studies suggest that intrinsic factors, such as contracts (Yang et al., 2017), retailer’s corporate social responsibility (Maloni and Brown, 2006), and management’s perceived risk (Fearne et al., 2001) play important roles in the sourcing strategy of retailers. In addition, extrinsic factors such as inspection policies (Omari, et al., 2018), monitoring (Srbinovska et al., 2015), regulations (Kraft and Raz, 2013), as well as cost of violations, willingness-to-punish for violations, and willingness-to-pay for responsibility are also highlighted (Guo, et al., 2015). Limited previous studies considered more comprehensively the contributing factors of the retailer’s optimal sourcing strategy of fresh agricultural productions, and hence the focus of this paper.

This paper focuses on five factors which affect the sourcing strategies of retailers of fresh agricultural products: (1) consumers’ quality-sensitivity; (2) level of preservation
effort of suppliers; (3) risk of food safety incidents; (4) potential price premium; and (5) level of potential penalties for unsafe products. The retailer can choose one or more suppliers in its sourcing portfolio to maximize its profit. To understand the mechanism of optimal sourcing strategy of retailers, we focus on two scenarios. The first being the traceable scenario, within which suppliers and retailers implement traceability systems designed to track the quality of the products for optimization purposes (Aiello, et al., 2015). The second being the non-traceable scenario, within which food products are non-traceable due to lack of labeling and supplier information (Saak, 2016).

This study intends to answer two questions: (1) what are the key factors and how do they determine retailer’s optimal sourcing strategy? (2) how can retailers optimize their sourcing strategies to ensure higher food quality and higher profitability? We applied the deterioration inventory model to determine the order quantity of fresh agricultural products either with preservation or without preservation. Retailer’s optimal sourcing strategies under the two traceability scenarios are determined and the expected profit associated with each scenario is derived using MATLAB. The sensitivities of key model parameters are analyzed to investigate their impact on the optimal sourcing strategy.

**Model development and analysis**

**Assumptions**

Before model formulation, the following assumptions are imposed:

a) Demand rate $D$ is a known constant (Dye, et al., 2007).

b) A supply chain of one retailer and two suppliers of different preservation efforts are considered, one being a supplier with preservation efforts and the other being a supplier without preservation efforts. The two suppliers are the same in all respects except for preservation efforts. Because of the investment in preservation efforts, the supplier with preservation effort has a higher cost and product per unit price.

c) During the replenishment period $[0, T]$, there isn’t replacement and treatment for the deteriorated products (Teng, et al., 2016).

d) Consumers have equal willingness ($p$) to pay for the FAP.

**Model formulation**

The following is the forecast model of retailer’s order quantity of FAP. Using above assumptions, the inventory level of the retailer is described by the following differential equation (Dye, et al., 2007):

\[
\frac{dI(t)}{dt} = -D - \lambda I(t) \quad (0 \leq t \leq T) \quad (1)
\]

FAP are necessities of living, thus in the absence of unexpected events, the demand rate $D$ is relatively stable within the order period, hence market demand

\[
Q = \int_0^T D \, dt = DT.
\]

$\lambda$ is the deterioration function of FAP, where $0 \leq \lambda \leq 1$. $I(t)$ is the inventory level at any time $t$, $0 \leq t \leq T$.

We then construct the preservation decay function $\theta(t) = \theta^t$, $0 < \theta \leq 1$, which
indicates the freshness of FAP. If $t = 0$, hence $\theta(t) = 1$, which means the products are in the freshest state when the supplier sells the product to the retailer. $\lambda(t)$ denotes the loss caused by natural and human factors such as temperature, handling, simple packaging, extrusion, and transportation from the initial stage of the order cycle to the retail process. Suppose $\lambda(t) = -ln\theta \cdot \theta^t$, where $\theta \to 1$, $ln\theta \to 0$, $\lambda \to 0$, so $ln\theta$ can be used as a coefficient to describe the loss rate of FAP.

If there are no preservation efforts, we have deterioration function $\lambda_l(t) = -ln\theta \cdot \theta^t$, with the boundary condition $l_t(T) = 0$. Solving the differential equation (1), we get the inventory level $l_t(t)$. When $t = 0$, the retailer’s order quantity for each cycle in the case of no preservation efforts $Q_l = l_t(0)$, and inventory cost of the retailer during the order cycle $T$ is $H_l = h_l \int_0^T l_t(t) \, dt$, $h_l$ is retailer’s inventory price per unit without preservation efforts.

If there are preservation efforts, a preservation effort factor $\alpha$ ($0 < \alpha < 1$) is introduced. The smaller the value of $\alpha$, the better the effect of preservation. Then $\lambda_h(t) = -\alpha ln\theta \cdot \theta^t$, we get the inventory level $l_h(t)$. When $t = 0$, the retailer’s order quantity for each cycle in the case of preservation efforts $Q_h = l_h(0)$, $H_h = h_h \int_0^T l_h(t) \, dt$, $h_h$ is retailer’s inventory price per unit with preservation efforts.

**Sourcing strategies under the traceable scenario**

We will explore when each of these sourcing strategies will be optimal.

**Single channel low-cost (SCLC) sourcing**

Under this strategy, there is a single sourcing channel for the retailer, which can choose to purchase all FAP from the low-cost supplier without preservation efforts. Therefore, retailer’s order proportion $q_l = 1, q_h = 0$. Those FAP are prone to spoilage and corruption due to the absence of preservation efforts. If the consumer purchases this kind of products, there are two possible consequences to the retailer: a decrease in demand and an increase in cost. The former consequence is due to consumers who experience food safety incidents stop purchasing the product, a proportion ($\epsilon$) of consumers known as “quality-sensitive” respond to the incidents by withdrawing from the retailer and purchasing from other retailers. The latter consequence is due to penalties ($\kappa$) charges from the food safety incidents. Consequently, the expected profit of the retailer under this sourcing strategy is:

$$
\Sigma_l = Q\gamma(1 - \epsilon\eta)(p - c_l) + Q(1 - \gamma)(p - c_l) - Q\eta\kappa - c_l(Q_l - Q) - H_l
$$

(2)

In the above formula (2), $c_i$ is purchasing price per unit, subscript $i = l$ represents no preservation efforts, subscript $i = h$ represents preservation efforts. $p$ is average price per unit. $\eta$ is the probability of complaints due to food safety incidents without preservation efforts ($0 \leq \eta \leq 1$). $\gamma$ is the proportion of quality-sensitive consumers who are willing to pay high prices ($0 \leq \gamma \leq 1$). The first part of formula (2) is the
profit that the retailer obtains from the quality-sensitive consumers. The second part is the profit from the non-quality sensitive consumers. The other three parts are the violation cost, deterioration cost and inventory cost, respectively.

**Dual channel (DC) sourcing**
Under this strategy, retailer source from two types of suppliers simultaneously. Low-cost FAP are sold to the ordinary consumers at the price $p$, high-cost FAP are sold to quality-sensitive consumers at a higher price than $p$, then the retailer reaps the price premium ($p_r$). Hence, $q_l = 1 - \gamma, q_h = \gamma$. The expected profit of the retailer is:

$$\Sigma = Qy(1 - \eta)(p + p_r - c_h) + Q(1 - \gamma)(p - c_l) - Q\eta\kappa - (1 - \gamma)c_l(Q_l - Q) - \gamma c_h(Q_h - Q) - (1 - \gamma)H_l - \gamma H_h$$  \hspace{1cm} (3)

**Single channel high-cost (SCHC) sourcing**
Under this strategy, the retailer only sources from one channel, that is, high-cost supplier with preservation efforts. The order proportion is $q_l = 0, q_h = \gamma$. The retailer is now only selling to quality-sensitive consumers and gains the profit from price premium. Thus, the expected profit of the retailer is:

$$\Sigma_3 = Qy(p + p_r - c_h) - \gamma c_h(Q_h - Q) - \gamma H_h$$  \hspace{1cm} (4)

**Single channel high-cost mass-market (SCHCMM) sourcing**
Under this strategy, the retailer sources FAP from the preservation supplier and sells FAP to two types of consumers (quality sensitive and not quality sensitive) at the same price $p$. In this case, the expected profit of the retailer is:

$$\Sigma_4 = Q(p - c_h) - c_h(Q_h - Q) - H_h$$  \hspace{1cm} (5)

According to the above description of sourcing strategies, Figure 1 graphically shows the relationship between sourcing strategies and order quantity.

![Figure 1- Relationship between sourcing strategies and order quantity](image)

**The optimal sourcing under the traceable scenario**
Based on the four possible retailer sourcing strategies discussed above, we now explore when these strategies will be optimal. A key factor that determines this is whether
customers are willing to pay more than the incremental cost of preservation efforts, i.e., whether \( p_r \) is greater than \( \omega = \frac{c_h(Q_h - Q) - c_l(Q - Q) + H_h - H_l + c_h - c_l}{Q(1 - \eta)} \), which is the cost difference between preservation effort supplier and non-preservation effort supplier.

The retailer’s optimal sourcing strategy under the traceable scenario are as follows:

**Proposition 1.**

(i) If \( p_r < \omega \), and \( Q_h c_h - Q_l c_l > Q \eta_\kappa + Q \gamma \varepsilon \eta (p - c_l) + H_l - \gamma H_h + \max [Q \gamma p_r - (1 - \gamma) (Q p - Q_h c_h - H_h), 0] \), single channel low-cost sourcing strategy is optimal;

(ii) If \( p_r > \omega \), and \( \eta_\kappa (p + p_r - c_h) + \eta \kappa < \frac{1 - \gamma}{Q} \min \left[ (Q p - Q_l c_l - H_l), (Q_h c_h - Q_l c_l + H_h - H_l) + \frac{Q}{1 - \gamma} p_r \right] \), the dual channel sourcing strategy is optimal;

(iii) If \( p_r > \frac{1 - \gamma}{Q} (Q p - Q_h c_h - H_h) \) and the strategies of (i) and (ii) aren’t optimal, the single channel high-cost sourcing strategy is optimal;

(iv) If \( p_r < \frac{1 - \gamma}{Q} (Q p - Q_h c_h - H_h) \) and the strategies of (i) and (ii) aren’t optimal, the single channel high-cost mass-market sourcing strategy is optimal.

We observe some customers value quality and might pay a premium for it. As a result, the retailer must decide whether to source some or all of its FAP from a preservation supplier and what price to charge customers. If the willingness of consumers to pay for the preservation efforts is small, i.e., \( p_r < \omega \), dual channel sourcing strategy can never be optimal. Sourcing from non-preservation supplier occurs if the loss in profit from quality-sensitive consumers and penalties due to food safety incidence are less than the incremental cost for preservation efforts. Proposition 1 shows that even if the willingness of consumers to pay for the preservation efforts is low, the retailer may still source from the preservation supplier despite the seeming unprofitability. Results are due to the reduction in penalties.

**Proposition 2.** If \( p_r < \omega \) and \( Q_h c_h - Q_l c_l < Q \eta_\kappa + Q \gamma \varepsilon \eta (p - c_l) + H_l - \gamma H_h + \max [Q \gamma p_r - (1 - \gamma) (Q p - Q_h c_h - H_h), 0] \), the optimal sourcing strategy may change from single channel low-cost to either single channel high-cost mass-market or single channel high-cost with the increase of \( \gamma \). The retailer may reduce the order quantity from the preservation supplier at a turning point \( \gamma = \frac{Q p - Q_h c_h - H_h}{Q p_r + Q p - Q_h c_h - H_h} \), meanwhile, the optimal sourcing strategy may change from the single channel high-cost mass-market to the single channel high-cost.

When \( \gamma \) and \( p_r \) are small, the retailer may choose single channel high-cost mass-market for fear of penalties caused by food safety incidents and quality-sensitive consumers withdrawing from the retailer sourcing from the non-preservation supplier. As \( \gamma \) and \( p_r \) increase, the premium obtained from quality-sensitive consumers is more attractive to the retailer. The retailer raises price to reap the premium to achieve higher profit. Therefore, the optimal sourcing strategy may change from the single channel high-cost mass-market to the single channel high-cost. Non-sensitive consumers are
expelled from this market, causing the retailer to reduce the order quantity of preservation supplier from $Q$ to $\gamma Q$, as shown in Figure 1.

**Proposition 3.** $Q_h$ will decrease sharply and $Q_l$ will increase sharply, if the optimal sourcing strategy transfers from single channel high-cost mass-market to dual channel and $\gamma$ increases from less than to greater than $\frac{Q_h c_h - Q_l c_l - Q_H + H_h - H_l}{Q_H(p + p_r - c_h) + Q_H c_h - Q_l c_l - Q_P + H_h - H_l}$ with the increase of $p_r$.

Proposition 3 shows that the retailer following the dual-channel sourcing strategy can obtain more profits from quality-sensitive consumers than following the high-cost mass market sourcing strategy. However, the dual-channel strategy has more order quantity from the non-preservation sourcing supplier which leads to the reduction of freshness of the whole supply chain, as shown in Figure 1. Retailer’s optimal sourcing strategies are determined by both proportion of quality-sensitive consumers ($\gamma$) and potential premium ($p_r$) rather than by only one or the other. Therefore, there is a risk of reducing the freshness of the whole supply chain by increasing the proportion of quality-sensitive consumers or the willingness to pay for the preservation efforts (price premium) to influence the retailer’s sourcing strategy.

**Proposition 4.** Whether $p_r > \omega$ or not, as long as $\kappa$ is large enough, the optimal sourcing strategy may be single channel high-cost mass-market or single channel high-cost. Although the retailer may reduce the order quantity from the preservation supplier, the retailer will not increase the order quantity from the non-preservation supplier. Therefore, increasing penalties or the intensity of disclosing violations will have a positive effect on promoting the freshness in the supply chain.

**Sourcing strategies under the non-traceable scenario**

Under the non-traceable scenario, there is a lack of information sharing between retailers, suppliers and consumers. Therefore, it is difficult for consumers to tell whether FAPs were supplied with preservation efforts. Food package and label will be the only source of information for consumers to tell different FAPs. There are two typical sourcing strategies, high-cost sourcing and double-label selling (HSDS) strategy and low-cost sourcing and double-label selling (LSDS) strategy.

*High-cost sourcing and double-label selling (HSDS) strategy*

Under this sourcing strategy, the retailer will source from the supplier with preservation efforts, but will label some products with preservation logos and some products with ordinary logos. Retailer sells the FAP with preservation logos at a higher price due to better market recognition or media coverage. Hence, the expected profit of the retailer is as follows:

$$\Sigma_5 = Q[\gamma(p + p_r) + (1 - \gamma)p - c_h] - (Q_h - Q)c_h - H_h$$ (6)

If quality-sensitive consumers are so sophisticated that they find it unfair to buy high-priced FAP, therefore, they will switch to purchasing products with ordinary logos.
because the quality of the products with preservation logos and ordinary logos is the same.

**Low-cost sourcing and double-label selling (LSDS) strategy**

Under this strategy, there is a single sourcing channel for the retailer, and all FAP are sourced from non-preservation supplier. However, as a fraudulent behavior, the retailer may label some FAPs with preservation logos to capture the premium. Thus, the expected profit of the retailer is as follows:

\[
\Sigma_6 = Q\gamma(1 - \eta)(p + p_r - c_l) + Q(1 - \gamma)(p - c_l) - Q\eta\kappa - (Q - Q)c_l - H_l
\]  

(7)

**Proposition 5.** Under the non-traceable scenario, high-cost sourcing and double-label selling strategy is optimal, if 

\[Q_h c_h - Q_l c_l < Q\gamma \eta\eta(p + p_r - c_l) + Q\eta\kappa + H_l - H_h;\] and the low-cost sourcing and double-label selling strategy is optimal if 

\[Q_h c_h - Q_l c_l > Q\gamma \eta\eta(p + p_r - c_l) + Q\eta\kappa + H_l - H_h.\]

**Numerical analysis**

In this section, some numerical examples are developed to analyze the results in different sourcing strategies proposed.

**The influence of \(\gamma\) (proportion of quality-sensitive consumers) and \(p_r\) (potential price premium) on the sourcing strategy**

The sensitivity of some key parameters of the model (\(\gamma\) and \(p_r\)) are discussed. We consider the following data set (Wang and Dan, 2015): \(D = 1; T = 10; c_l = 0.2; c_h = 0.5; h_l = 0.1; h_h = 0.015; p = 1.5; \kappa = 3.2; \eta = 0.1; \alpha = 0.8; \theta = 0.95; \varepsilon = 0.2.\)

![Figure 2 - \(\gamma\) vs \(p_r\) (Green Lines are the demarcation lines of each source strategy)](image)

Under the traceable scenario, the optimal sourcing strategy is the single channel low-cost, if \(\gamma\) and \(p_r\) are small, as shown in Figure 2 (a). The optimal sourcing strategy has to be changed to single channel high-cost mass-market and finally to single channel high-cost with the increase of \(\gamma\) to 1. We found that the retailer may source from the preservation supplier at a higher price even if consumer willingness-to-pay for
preservation is low. When \( p_r \) are bigger, the optimal sourcing strategy has to be changed from the dual channel to the single channel high-cost with the increase of \( \gamma \). These results are in line with Propositions 1, 2 and 3. Under the non-traceable scenario, the optimal sourcing strategy may be transformed from LDS to HSDS with the increase of \( \gamma \) and \( p_r \), as shown in Figure 2 (b).

The influence of \( \epsilon \) (proportion of quality-sensitive consumers withdrawing from non-preservation efforts market) and \( \eta \) (risk of food safety incidents due to non-preservation efforts) on the sourcing strategy

We consider the following data set (Wang and Dan, 2015): \( D = 1; T = 10; c_t = 0.2; c_h = 0.5; h_l = 0.1; h_h = 0.015; p = 1.5; \alpha = 0.8; \theta = 0.95; \gamma = 0.3; p_r = 0.38; \kappa = 0.3 \) (and 2.3).

![Figure 3 - \( \epsilon \) vs \( \eta \) (Green Lines are the demarcation lines of each source strategy)](image)

Under the traceability scenario, when \( \epsilon \) and \( \eta \) are small, the optimal sourcing strategy is the dual channel sourcing strategy, as shown in Figure 3a and 3b. With the improvement of consumers’ quality awareness, consumers’ complaints may also increase due to deterioration of FAP (\( \epsilon \) and \( \eta \) increase). Therefore, the retailer has to change their sourcing strategy to reduce risks. Under the non-traceability scenario, with the increase in \( \epsilon \) and \( \eta \), the optimal sourcing changes from LDS to HSDS, as shown in Figure 3 (c and d). This is because the increase in \( \epsilon \) and \( \eta \) leads to increased operating cost and risks of the retailer, hence the benefits from LDS cannot offset the penalty and complaints. The higher the penalty, the greater the order quantity from the preservation efforts supplier.
The influence of $\alpha$ (preservation efforts factor) and $p$ (average price) on the sourcing strategy

We consider the following data set (Wang and Dan, 2015): $D = 1; T = 10; c_1 = 0.2; c_h = 0.5; h_l = 0.1; h_h = 0.015; \theta = 0.95; \epsilon = 0.2; \eta = 0.1; \gamma = 0.5; \rho_r = 0.38; \kappa = 3$.

![Figure 4 - $\alpha$ vs $p$ (Green Lines are the demarcation lines of each source strategy)](image)

The result shows that, preservation efforts level ($\alpha$) is an important factor affecting the retailer’s profit. The bigger $\alpha$, the lower the preservation efforts level. Under the traceability scenario, SCHC is the optimal strategy if $p$ is small. This is because the price premium from quality-sensitive consumers is more attractive. The optimal strategy changes from SCLC to DC and SCHCMM with the increase of $\alpha$. There is no obvious difference between the preserved and non-preserved agricultural products if $\alpha$ is low, so retailer can capture more profit by SCLC. With the increase of $\alpha$, deterioration loss is reduced and the risk of food safety incidents is lower, so DC and SCHCMM become the optimal strategies. Under the non-traceability scenario, similar to the traceability scenario, the optimal strategy is changed from LSDS to HSDS with the increase of $\alpha$.

Conclusion

This study shows the optimal sourcing strategies FAP retailers under different traceability scenarios. This study also illustrates the importance of key factors played in the retailer’s optimal sourcing strategy. Basically, the findings suggest that consumer-oriented promotion approaches of retailers (i.e., focusing on increasing consumers’ potential price premium or increasing the proportion of quality-sensitive consumers) can have a negative impact on retailers’ order quantity from suppliers with greater preservation efforts, and hence worse freshness and food quality in the supply chain. On the other hand, higher penalty levels and more exposure to risk of food safety incidents by retailers will lead to increased order quantity from suppliers with greater preservation efforts, and hence higher food freshness and quality in the supply chain.

However, simply relying on increased regulation does not address the root of the problem. Among the five factors ($\gamma$, $p$, $\alpha$, $\epsilon$ and $\eta$) examined in this paper, only $\alpha$ is within the control of retailers. Therefore, retailers should cooperate with suppliers to find a good way, for instance, to set up risk sharing and benefit sharing mechanism to
enhance preservation efforts that would improve profitability, quality and freshness of the FAP in the supply chain.

Abstract

This paper explores the uncertainty related to medium-term engineering needs considering sales and operations planning (S&OP). The areas of uncertainty and how they are addressed by S&OP are investigated in an engineer-to-order setting. Uncertainties stem from customer orders and critical competences and are minimized through integrating engineering resource planning into S&OP sub-processes and organization, and through explicating methodologies using IT tools that also support scenario planning. To improve the effect of S&OP, measuring short- and long-term performance is recommended, and aligning S&OP with the bidding and organization development processes is important. Future research may replicate this study using multiple cases.

Keywords: S&OP, Case study, Engineer-to-Order

Introduction

This paper focuses on the requirements put by engineer-to-order (ETO) environments on the sales and operations planning (S&OP) process. The ETO planning environment has several challenges. The competition in ETO markets is based on providing substantial customization beyond standard product options to embrace very heterogenous customer needs. Allowing product customization in conjunction with incoming customer orders, contracts or inquiries requires intensive and frequent engineering work whereby new or existing products and manufacturing systems are either developed or adapted.

Providing the required engineering competences to conduct the engineering work is crucial to compete on contracts and to successfully deliver orders. Competence requirements change overtime as the heterogeneous ETO market needs evolve. Also, availability of engineering resources and expertise vary. Moreover, obtaining critical engineers is often expensive and takes relatively long time. Therefore, in ETO environments, the criticality of engineers needs to be identified and managed at the tactical planning horizons, i.e. within the scope of S&OP.

Several studies related to the resource-based view (RBV) depart from a strategic perspective to address critical resources as sources of sustainable competitive advantage
(e.g. Kraaijenbrink et al., 2010). How to plan critical resources within tactical terms in ETO environments is however still lacking. Therefore, we explore how ETO business characteristics put requirements on and can be handled by an S&OP process.

S&OP is an aggregate planning process that – through cross-functional integration – seeks to balance demand and supply within tactical timeframes (Jonsson and Holmström, 2016). However, limited number of S&OP studies deal with ETO environments (Kristensen and Jonsson, 2018). To the best of our knowledge, no study addresses how S&OP manages the uncertainties associated with the dynamic medium-term needs of engineering resources in an ETO environment. Therefore, to fulfil the purpose of this study, two research questions are formulated as follows:

- RQ1: Which areas of uncertainty can be related to engineering resources within the S&OP process in an ETO environment?
- RQ2: How does S&OP manage the dynamic medium-term needs of critical engineering resources in an ETO environment?

**Conceptual framework**

Sales and operations planning (S&OP) integrates the plans for sales, supply, and production into an overall aggregate plan (Noroozi and Wikner, 2017) and aims at balancing the targeted customer demand, shaped by marketing and sales functions, and the supply capacity, shaped by procurement and operation functions (Jonsson and Holmström, 2016). Therefore, S&OP is defined as: “a business process that links the corporate strategic plan to daily operations plans and enables companies to balance demand and supply for their products” (Grimson and Pyke, 2007, p. 33).

Although S&OP is simple in theory, companies vary in how S&OP is implemented. According to Danese et al. (2017), literature mainly addresses implementation that characterize four main S&OP maturity dimensions, including people and organization, process and methodologies, information technology (IT), and performance measurement.

In this paper, the definition of ETO production adopted by several researchers (e.g. Willner et al., 2016, Gosling and Naim, 2009) is applied as to be distinguished from make-to-order (MTO) production, which allows for limited configuration within a pre-defined solution space. Accordingly, ETO production is perceived as directly linked to a customer order with the decoupling point in the design stage dedicated to adapting products. This implies uncertainties affecting the S&OP process. However, ETO literature does not explicitly address the areas of uncertainty that influence critical capacity planning. Therefore, this paper addresses such areas of uncertainties drawing on their generic sources: customer demand and supply capacity.

The main source of uncertainty stems from demand. Depending on the depth of the product structure and the amount of jobbing needed to process such requests, ETO environments range from basic to complex settings (Hicks et al., 2001). In complex settings, individual customer orders typically require large investments in plants, machines, equipment, and engineering resources. Each customer order, inquiry or contract calls for careful considerations that may result in substantial consequences in terms of engineering resources. Therefore, ETO companies need to deal with several areas of uncertainty stemming from customer orders.

It is not unusual that the resource preparation process does not conform to the lead time requirements that ETO customers are willing to accept (Olhager et al., 2001), which is crucial in winning customer orders in addition to cost and quality. The competition enforces ETO companies to embrace more uncertainties related to resource requirements through – for instance – rushing up the acceptance to process inquiries without being carefully studied as customers need quick response. This explains the tendency of ETO
companies to build and maintain excessive capacities in a capacity lead strategy. Accordingly, ETO companies arguably need to deal with uncertainty areas stemming from critical competences.

Figure 1 summarizes the theoretical framework of the paper, which focuses on the interfaces between the generic process of S&OP and the specific areas of uncertainty embedded in ETO settings, which are empirically identified under the main categories of customer order and critical competence to answer RQ1. The arrows in the figure highlight the bidirectional focus of RQ2, where the influence of S&OP on the areas of uncertainty identified to answer RQ1 as well as the influence of these uncertainties on the S&OP maturity dimensions are addressed.

**Methodology**

To answer the research questions, an exploratory single case study was conducted at a leading multi-technology first-tier aerospace supplier. According to Yin (2017), a single case study can be used to represent a unique or extreme case. The uniqueness of the selected case stems from being an ETO-oriented firm that possesses a structured S&OP process that includes engineering resource planning.

Drawing on the conceptual framework presented in Figure 1, an interview protocol was developed to collect empirical data. The data was gathered through semi-structured interviews and process-related documents. In total six interviews were held with an average length of 100 minutes. Three interviews were audio recorded and conducted with one participant, while the other three interviews involved a relevant group of participants. The three group interviews were held with management representatives from the logistics and operations planning function. Then, an interview was conducted with the marketing manager, the S&OP coordinator, and a representative from the management team of the engineering function who is part of the S&OP development team.

The unit of analysis was the five main stages of S&OP including data gathering, demand planning, supply planning, pre-S&OP meeting, and executive S&OP meeting (see Wallace and Stahl, 2008). The data was elicited to explicate the uncertainties associated with engineering competences and how they were addressed throughout the process, i.e., identified, communicated and minimized.

Through content analysis, the collected data was analysed, and relevant constructs were identified after iterations of inductive coding (Glaser and Strauss, 2017). Through empirical evidences, areas of uncertainty associated with engineering competences were suggested as constructs under the main categories of customer orders and critical competences. The empirical data on how such areas of uncertainty were addressed throughout S&OP allowed for identifying several requirements for the process design.

Research quality was considered through neutralizing biases and ensuring transparency. Detailed documents describing the S&OP process at the company were
studied before interviews. The documents contained the latest update of the standardized process; the inputs, objectives, decisions, and outcomes of each activity; the methods, process and systems used to perform and support the activities; and the representatives from each function and the coordinators involved in each activity. This helped in mapping out the S&OP process at the case company to more effectively gather relevant data.

Interviews were conducted in a sequence that ensured logical data gathering through which the questions about specific areas were posed to the right respondents. S&OP is started by the marketing function to plan demand. This part was well defined and documented, and thus easy to start with to identify the uncertainties. Having done this from the demand planning perspective, the interview with the S&OP coordinator then helped to further explore and describe the issues from the supply planning perspective. Consequently, more holistic knowledge about the uncertainties related to the critical resources within the implemented S&OP was captured, which then helped to identify specific root causes through the interview with the engineering function. Finally, to avoid the single researcher bias, the interviews were transcribed by one researcher and analysed collectively based on the transcripts and the company documents.

Case description
The case company provides customized components to three aircraft engine manufacturers. The components are grouped into six main product groups, which are continuously adapted to new components originating from new contracts typically awarded after tendering. The designs of new components are iteratively specified and agreed upon with respective customers. The production processes need to be upgraded to deliver the agreed quantities and specifications according to the new contracts and life cycle plans. Usually, three main production development phases are followed for each life cycle plan. Small quantities are first produced in the production start-up phase, before the ramp-up, and finally, the termination phases. In the aerospace industry, even though the product lifecycle is relatively long, phasing in and out components is complex and requires unique engineering competences that may take up to two years to be fully prepared for proper utilization. Therefore, the case company incorporates activities in S&OP that specifically address the medium-term need of engineering resources.

The S&OP process is conducted with monthly planning buckets and planning frequencies, and with a planning horizon of 36 months. The main logic is that each product group puts forward the future demand and supply needs that are then reviewed and met by the related functions. Forecasts and demand plans are reviewed by marketing, engineering resource requests are reviewed by engineering, while internal and external capacity requests are reviewed by operations and supply chain. When the functions are unable to fulfil the requests within the present budget, escalations are made to the top management that respond through decisions during the S&OP meetings.

Analysis
Investigating where the need for engineering resources emerges within S&OP activities lead to identifying 11 areas of uncertainty (see figure 2), 5 of which are related to customer orders, while 6 of which are related to critical competences. The analysis of each area of uncertainty includes insights into the planning consequences. Then, the ways for how the S&OP process maturity helps to deal with such challenges are presented.

Five areas of uncertainty stem from customer orders including the source and timing of customer orders, customer order specifications, the probability of winning customer orders, and customer reliability. The S&OP process starts with each product group developing or updating the demand plan. Inputs from the bidding process (process for
screening and reviewing tender requests and preparing competitive bids) provide insights into the future potential customer orders. The sources of customer orders are three aircraft engine manufacturers. According to the marketing manager, the source of customer order can be an area of uncertainty for other ETO environments where more potential customers exist. However, since this does not apply in this case, it is difficult to foresee the consequences of having such uncertainty and how S&OP mitigates for it.

The marketing manager also emphasizes that the timing of customer orders is uncertain leading considerable consequences on engineering resource plans. Supposedly, learning about the accurate timing of customer inquiries as early as possible allows for higher resource utilization, and timely recruitment and preparation of engineering competences to fulfil the needs from bidding processes and subsequent engineering work.

The S&OP coordinator states that customers are typically uncertain about the detailed component specifications and quantities, which increases the uncertainty concerning the future amount and type of engineering work. Underdefined customer specifications also imply increasing the uncertainty concerning the coordination workload needed to compile inputs for engineering resource planning. In the first place, product groups are usually uncertain about if they will win future customer orders, which is why they tend to delay crucial decisions concerned with extending and upgrading the engineering resource base. The consequence is that top managers in the S&OP executive meeting approve the recruitment of critical engineers when the work for customer orders needs to start within less than 6 months, whereas the corresponding recruitment and preparation process may take more than a year until these engineers live up to the working standards.

According to the interviewees, customers sometimes transmit overestimates (approximately 10% more than the actual demand) as to mitigate the risk of scenarios where the case company runs into production disturbances. That is, customers enforce the case company to build excess capacity, but without sharing such costs.

To mitigate for the areas of uncertainty related to customer orders, the monthly S&OP cycle starts with gathering relevant assumptions from the product groups. The assumptions serve as a foundation for predicting the timing of future customer orders, customer order specifications, win-rate and customer reliability, not only based on figures (forecasts), but most importantly based on events. The assumptions are tracked, reviewed and updated throughout the consecutive S&OP events. The bases of the assumptions originate from the collaboration with customers, which is evident from the marketing team activities associated with the bidding process and the component life cycle reviews. The assumptions are also based on internal business intelligence that has been developed and accumulated over years. The marketing team – which is represented in each product group – then compiles the updates of the forecasts and assumptions prior the demand review that is conducted by the marketing manager who, in turn, validates the updates through questioning the reasons on which they were based. Consequently, the medium-term demand – in terms of the customer orders over 36 months – is updated and approved.

On the other hand, six areas of uncertainty stem from critical competences including competence type and quantities, the availability of internal and external competences, competence qualification period, and inter-resource equivalences. Product group takes the responsibility of detailing the consequences of the updated demand on tools and equipment, which in turn shapes the future need of production infrastructure and engineering competence. The product groups, through representatives from engineering and production functions – chief manufacturing engineers (CMEs) and chief design engineers (CDEs), respectively – define the specific engineering capacities required for production and product design. CMEs and CDEs rely on the inputs from the updated reviews of demand, tooling and facility. However, how such inputs are transformed into
**future needs of engineers** is not explicitly documented, but rather based on rules of thumb and personal experiences. Furthermore, the identified needs are often generic specifying high-level skills or expertise, which arguably increases the uncertainty about if these identified engineering resource needs perfectly match the actual need of the updated demand. Such uncertainty increases the possibility of having either under- or overcapacity in engineering resources. It is even possible to experience scenarios of both under- and overcapacity, where overqualified engineers (with broader skillsets than needed) are recruited, but still do not live up to the quantity needed to fulfill the actual demand. Here, the case company will incur the cost of excess capacity that is not well utilized, and the cost of potential delay in form of penalties, for instance.

CMEs and CDEs use a roadmap to visualize how the required engineers need to be aligned with the ongoing and future parallel projects. Moreover, they use a workforce planning tool to communicate the type and quantity of competences that will be requested from engineering by each product group. These requests are processed by the various engineering divisions given the internal competence availability. Similar to the way the engineering resource needs are identified, the engineering divisions assess the availability and suitability of internal competences against the requests raised by CMEs and MQEs from product groups. Controlling the availability of engineering resources is not different from other labour categories. That is, the uncertainty about engineering workforce availability rests in unforeseeable absenteeism due to, for instance, injury, sickness and contract termination. These risks are typically mitigated through building excess capacities whereby engineering assignments temporarily can be performed temporarily by one or more individuals. However, the suitability of available engineers compared to the requests is still based on subjective judgment, meaning that there is uncertainty about whether the internal resources being continually configured to best meet the future demand with maxim utilization and to avoid the scenarios of under- and overcapacity.

The engineering function consists of divisions. Each division identifies the types and quantities of competences that are lacking and escalate deficits to the higher management level. Here, the second-line managers, the head of engineering and the external resource manager address the different options to secure the supply of engineering workforce. This includes recruiting new engineers, acquiring consultants, and reorganizing the engineering resource base. The latter option is based on the outcomes of a parallel process for planning the organizational structure that is aimed at determining how the organization should evolve given the strategic business objectives. This includes foreseeing the probable changes in the resource base such as the retirements and promotions of individuals. Usually, the consequences of promoting a group of engineers on future demand are uncertain. However, the S&OP process and the organizational planning process are not formally or coherently linked to each other.

As for external resources, the case shows that there is always a lack of knowledge concerning the type and quantities of competences that can be found externally. Consulting and newly recruited engineers are different in nature, i.e. in terms of skills, expertise and personalities. Therefore, the time needed to prepare such engineers in line with the respective task requirements varies, meaning that the preparation period also represents an area of uncertainty. The interviewee from the engineering department emphasized that there is much uncertainty concerning how a group of engineers can be allocated in equivalent configurations of teams to produce the same effect, which allows for advantageous flexibility. That is, engineering resource planning within S&OP is mainly done through individuals from each division, which limits the visibility of the embedded flexibility and equivalences among engineers across the different divisions. The higher-level managers who review the respective plans still see this more
comprehensive picture of how all engineers are allocated. Again, these managers rely on their own experience and ad-hoc approaches to optimize such resource plans.

The case company partially measures the S&OP performance through indicators from few activities including forecast accuracy, customer scheduling adherence, inventory turnover, and service level. That is, the performance of S&OP as a whole is not measured due to the lack of consensus on the effect to be measured. Some participants consider the periods the S&OP process is able to address beyond the budgeted activities as an indicator, while others relate the S&OP performance to the progress made on strategic goals. On the other hand, the interviewees confirmed that the performance of S&OP had been assessed at least against maturity criteria to identify major gaps. Consequently, a dedicated team of 10 members prioritized the improvement of activities, which were not followed up according to an action plan in each S&OP cycle, but rather used as guidelines. Involving engineering in S&OP is an example of such improvements. Another example is improving the processing conditions and clarifying the descriptions of several sub-processes. The team continuously refines the data that should be prepared upfront before the executive S&OP meeting to enable quicker and better decisions. That includes how the data should look like as well as how and when the data should be communicated. Figure 2 presents the areas of uncertainty related to engineering resources and the S&OP activities through which these areas are captured and addressed (i.e. the grayed out cells).

![Figure 2 – Areas of uncertainties related to engineering resources within S&OP](image)

### Discussion

The case analysis explores how to manage ETO challenges in an S&OP process, in terms of **people & organization, process & methodologies, and performance measurement**. It also explores how the S&OP integration with other processes is important in this context.

As revealed from the case analysis, the frequent engineering changes caused by incoming demand calls for incorporating a function for identifying and tracking the medium-term needs of engineering competences in addition to what has been referred to in previous literature (e.g. Wallace and Stahl, 2008) as a traditional S&OP organization. By involving engineering representatives in the demand planning conducted by product
groups, the S&OP organization facilitates the translation of demand plans into engineering resource needs. However, within the engineering functional organization, the hierarchical gap between management levels can be reflected from limiting the respective cross-hierarchical communication to certain escalation conditions. When this applies, top managers are often not able to question such escalations and thus delay related decisions as they are not fully aware of the grounds on which the identification of engineering needs were based. This corresponds to a general need and absence of early communication of uncertainties and structured communication of assumptions as part of a demand management and S&OP process (APICS, 2019). We see that such need of early and structured communication is critical in ETO environments. In accordance with the cross-functional integration framework of Oliva and Watson (2011), we also see that S&OP may enable improved engineering information quality and constructive engagement even within the engineering function – cross-hierarchically.

As for the processes and methodologies used in S&OP, to address the uncertainty areas identified in Figure 2, the case company seems to rely on assumptions and implicit ad-hoc approaches. For instance, the translation of engineering workload requirements into man-hour per engineering skill is based on subjective judgements, rules of thumb, and personal experiences. Findings show that the uncertainties stemming from an ETO environment require more structured/advanced methods of capacity planning compared to other contexts. While such identification of engineering needs can be “good enough” as claimed by an interviewee, the lack of method transparency still hinders making quick decisions by higher-level managers and does not allow for establishing a consistent engineering planning process among product groups and engineering divisions. The lack of using systematic methods to plan capacity for job shops was also discussed by Tenhijälä (2011). This lack was attributed to the practitioners being often unaware of the possibilities RCCP methods can bring. Apart from that, there seems to be a strong requirement on the integration between the key sub-processes of S&OP (i.e. demand and supply planning) in ETO settings as to be able to run the S&OP cycle in a monthly basis despite the extra need of continually identifying engineering needs. The case company enables considerable integration between demand and supply planning through a matrix organization that takes the form of product groups, which in turn serve as collaborative cross-functional platforms. The cross-functional teams from the respective product groups are involved in almost all demand and supply planning events of S&OP, which ensures that both planning processes are somehow integrated throughout the process.

Information technology (IT) has been recognised in several S&OP literature as a key process enabler in many contexts, and the case analysis shows that ETO settings are not an exception. The case company dedicates internal databases of business intelligence and tools for competence road mapping and collaborative workforce planning, which is – according to the interviewees – far from being enough to deal with several ETO challenges. The dominant type of information that can be made available in ETO settings is highly descriptive due to the uniqueness and ambiguity embedded in demand. Manipulating and processing such type of information requires considerable manual human work as information systems are not yet mature enough to automatically arrange descriptive information into systematic codes (Evers, 2018). Instead, findings show that the information systems used in ETO environments for S&OP should at least enable intuitive explicating of the ad-hoc approaches used by individuals to define the required engineering workload given a certain demand, the required type and quantity of engineering competences given a certain workload, and the possible allocation(s) of competences to fulfil the requirements of a certain workload given their availability. Besides, ETO environments are surrounded with several risks and assumptions such as...
engineering critical resource absenteeism, and IT tools that support scenario planning is much needed under such circumstances. High-performing firms use scenario planning in S&OP (Danese et al., 2017). The scenario-planning support for S&OP in ETO settings also needs to enable modelling the consequences of recruiting new engineers, acquiring consultants, and reorganizing the engineering resource base as these activities are frequently performed. Consequently, our findings indicate relative high IT needs for S&OP in ETO settings, already on lower maturity levels.

As for S&OP performance, the case shows an evident lack where limited performance indicators are used such as scheduling adherence and forecast accuracy. According to Hulthén et al. (2016), the performance of S&OP can be measured through measuring the efficiency of, for example, respective meetings. Meetings are highly important to make timely decisions in ETO settings, especially when it comes to approving the recruitment of additional engineering competences. This is because certain engineering competences need long-lasting preparation and training before they can be properly utilized. The S&OP process in large is also more complex in ETO settings (e.g. more functions involved, more supply planning activities) which may motivate a need for measuring process efficiency.

Finally, the case emphasizes the importance of tightly integrating certain planning processes in ETO contexts. Since the majority of ETO markets are based on tendering (Hicks et al., 2001), the bidding process plays a crucial role in shaping the medium-term demand. This calls for having S&OP and bidding highly integrated. Similarly, the lifecycle of products also influences the timing and volume of future demand, which is extremely important for ETO environment as discussed earlier, and thus needs to be tightly integrated into S&OP. Apart from that, S&OP outcomes should be integrated into organizational plans as S&OP captures in a monthly basis the potential future competence gaps that the organizational plans need to be aligned with.

Conclusion
This study explores how S&OP manages the uncertainty associated with the dynamic medium-term needs of engineering resources in an ETO environment. A relevant single case study was investigated leading to three main areas of contribution. The first contribution is to the ETO planning environment. Eleven areas of uncertainty were identified and related to customer orders and critical competences, as shown in figure 2.

The second contribution is to explore the role of S&OP in relation to the identified areas of uncertainty. To mitigate for these areas of uncertainty, we explore the role and maturity dimensions of S&OP. The S&OP organization needs to integrate an additional function concerned with engineering resource planning. Such growth of the S&OP organization calls for more coherent integration of S&OP sub-processes that enables to run S&OP within reasonable timeframes. Arguably, this is possible through the early involvement of engineering resource planning actors in that cross-functional teams dedicated to measure and follow up the performance of demand and supply planning. The engineering resource planners need to explicate the approaches they use to identify the required engineering workloads and corresponding competences needed as a first step towards learning about and standardizing relevant know-how knowledge and best practices. In this respect, the IT tools used in S&OP should at least intuitively support such knowledge elicitation from individuals on top of the need to support reliable scenario planning capitalizing on companywide data. That is, in ETO settings, the need for IT and information sharing is relatively high even at lower S&OP maturity levels.

The study also identifies a need to continuously improve the short-term performance of S&OP through measuring the efficiency of the key events of the S&OP activities such
as important meetings. Within longer terms, the maturity assessments are suggested to identify the significant deficiencies and develop action plans accordingly.

The third contribution is related to the role of S&OP in other processes. The alignment of S&OP with the bidding process and organizational development seems to be highly important in ETO settings due to the recurring exchange of inputs and outcomes between these processes. Further, S&OP seems to have cross-hierarchical integrative potentials within large engineering organizations, which is manifested by improved information quality and constructive engagement and suggested for future research. Studying S&OP in other ETO settings with different complexity is also highly recommended to further explore, validate and generalize the findings of this study. Another trajectory is to more deeply study the requirements on and the potentials of one or more S&OP dimensions to manage one or more areas of uncertainty related to engineering resource planning.

Abstract

This paper is concerned with the reasons for not using and the perceived relevance of Sales & Operations Planning (S&OP) based on 156 full and useable answers to a questionnaire-survey distributed among Danish manufacturer. The more the respondents perceive the lack of knowledge S&OP the more they perceive the relevance of S&OP. Further, the more the respondents perceive unrecognized needs the less the perceived relevance of S&OP. Lack of implementation skills does not influence this S&OP relevance. The perceived relevance of S&OP influence only sales performance in terms of customer and delivery performance but neither operational nor financial performances.

Keywords: Questionnaire-survey, maturity, readiness, performance

Introduction

Sales & Operations Planning (S&OP) is a cross-functional process that aims to balance supply and demand typically with a tactical planning horizon from 3-24 months (Kristensen and Jonsson, 2018). Extant literature on S&OP is rich and is found in academic, grey and practitioner-oriented literature (Thomé et al., 2012; Tuomikangas and Kaipia, 2014). It contains a number of research contributions focusing on various maturity stages of S&OP (e.g. Danese et al., 2018; Grimson and Pyke, 2007; Wagner et al., 2014), technology implementation and outcome at the expense of drivers and antecedents that promote S&OP (Swaim et al., 2016; Qi and Ellinger, 2017). However, some literature has, in fact, focused on the antecedents for S&OP and success criteria for implementing S&OP (Boyer, 2009; Iyengar and Gupta, 2013; Lapide, 2014; Swaim et al., 2016) but are concerned with companies that already have decided to implement S&OP.

Literature focusing on the stages before implementation processes of S&OP is limited despite some practice-oriented literature (Tinker, 2017). Extant literature on S&OP is not
explicit about this pre-stage of S&OP but several sources justify this point of analysis (e.g. Stahl and Shedlawski (2012) on why companies do not choose to pursue S&OP due to catch-up) and Naslund and Williamson (2017) have investigated companies not operating with S&OP to identify the performance potential of such companies if implementing this tool. The S&OP maturity models by Danese et al. (2018) and Wagner et al. (2014) do contain a first step that equivilize with having no S&OP processes. However, this seems only to be mentioned and not further researched. It is interesting to analyze why S&OP not is implemented by companies since benefits apparently appeal to both sales, operations, and finance (Prokopets, 2012), and is a tool that can help tearing down the silos (Grimson and Pyke, 2007; Wagner et al., 2014), which may sustain dysfunctional organizations (Rangarajan et al., 2018). The S&OP literature also demands more empirical founded literature on S&OP issues (Ivert et al., 2015; Swaim et al., 2016; Pedroso et al., 2016; Thomé et al., 2012). A specific point of analysis is also to look at the firm size in the analyses. Further extant literature on S&OP is sparse on contributions having an explicit focus on small- and medium-sized enterprises (SMEs) (Kristensen and Jonsson, 2018; Stentoft et al., 2019).

Hence, the purpose of this paper is to advance the understanding and provide novel data of reasons for why companies are not using S&OP and what might be done to facilitate a better evaluation if the relevance of S&OP.

**Conceptual frame of reference**

This section argued for various reasons for not using S&OP. The section is based on inputs from literature (see Table 1) as well as from ten case studies concerning the whole process of initial clarification of what S&OP is through a decision to implement and develop the S&OP process to pilot and final operation (Stentoft et al., 2019) (see Appendix A). In the first meetings in these ten companies, discussed why S&OP was not part of their daily business and why they found it relevant for them to implement. Furthermore, this section also includes a brief sub-section about the performance outcome of S&OP.

**Reasons for not using Sales & Operations Planning**

**Lack of knowledge about S&OP**

Among possible reasons for not applying S&OP, the first plausible reasons are the lack of knowledge about S&OP. This knowledge-gap may take place both at the top management level as well among the organization in general. S&OP literature stresses the importance of top management support (Ivert and Jonsson; McLeod, 2012; Wallace and Stahl, 2008) when deciding and operating S&OP, which requires knowledge about it. Furthermore, it might be the case that top management or some from this group do know to S&OP, but that the organization does not. Literature, therefore also stress the importance to prepare the organization for the potential for such processes e.g. though training or other cross functional initiatives (Slone et al., 2010; Rangarajan et al., 2018). The lack of knowledge has also been discovered at the beginning of a large project following the decision-processes, planning, and implementation of S&OP in ten Danish manufacturers (Stentoft et al., 2019). In the first meeting with the companies, they were all asked about why they do not have a S&OP up running. In case 4, 9 and 10 it was experienced that no one in the top management knew about S&OP. However, in case 4 and 10 there was a S&OP knowledge among the middle managers who knew from past jobs and from their professional network. In case 3, 5, 8 and 9, we experienced a low S&OP knowledge level in the organizations, which all are SMEs.

Unrecognized need for S&OP

Another group of reasons for not using S&OP is concerned with an unrecognized need for S&OP. Muzumdar and Fontella (2006), for example, mentioned that many executives are unsure about S&OP and question why their company needs S&OP. This was experienced in case 4 (an SME) where the CEO expressed at the first meeting that S&OP was not needed because their business is so special. However, after some months, the COO and planning manager returned with an acceptance to be part of the overall project since they had convinced the CEO to start up the S&OP project. Another reason for not having implemented S&OP is a lack of S&OP readiness. In case 4, 6 and 10 such lack of readiness became visible in different ways. In case 4, the CEO’s articulated resistance led to a lower S&OP awareness among the sales and finance staff. In case 6, which is a large company, there was in the beginning a lack of buy in to process by sales. In case 10, there was a lack of readiness by some members of top management and middle managers due to unsolved issues with prioritization of time between daily operation and the S&OP process development. The uncertainty of the division of this work created a lower readiness. The last reason identified in this group may also simply be that managers cannot see that the benefits are higher than the costs of implementing and operating S&OP (Chase Jr., 2013; McLeod, 2012; Stahl and Shedlawski, 2012). This reason was also found in case 5, 8 and 9. In case 5, the sales staff was not motivated for the S&OP project and questioned that the benefits did not defend the resources that should be used. A similar situation was present in case 8, where sale also had reservations towards S&OP due to the extra workload. In case 9, the skeptics towards S&OP came from finance that extended the company’s decision process to join the project due to a perception that the outcome could not exceed the efforts put into the process.
Lack of implementation skills

The final group of possible reasons for not operating with a S&OP process is concerned with a lack of implementation skills. The first reason is here lack of resources. So, a company might have knowledge about S&OP and they have also recognized a need for S&OP but has not implemented it due to lack of resources. Having the resources necessary to first attend a S&OP project and afterward operate the process is crucial (Boyer, 2009; Dougherty and Gray, 2006; Pedroso et al., 2016). The resource issue also became visible in case 1, 5 and 9 and 10. In case 1, the top management and middle managers were aware of S&OP and its relevance for their company, and only two years before they decided to start up but did not start up due to lack of the right resources. In case 5, it became clear during the first meetings that the company had difficulties in initiating and implementing business projects due to a weak separation of operation and project work. Lack of resources to carry out S&OP projects was also mentioned in case 9 and 10. Finally, a reason for not operating with S&OP might be past negative experiences with unsuccessful implementations (Iyengar and Gupta, 2013; Lapide, 2005; Moon and Alle, 2015). Case 2, 6 and 7, which all are large companies, reported in the beginning that they had tried with S&OP before but failed with the implementation due to lack of top management support, lack of sales involvement and having a too short-termed focus.

Accordingly, we hypothesize that:

H1: Reasons and Relevance toward S&OP
a) Lack of knowledge toward S&OP influence the perceived relevance of S&OP.
b) Unrecognized needs toward S&OP influence the perceived relevance of S&OP.
c) Lack of implementation skills toward S&OP influence the perceived relevance of S&OP.

Performance outcomes of S&OP

Extant literature on S&OP is also concerned about how performance might be affected by S&OP (Swaim et al., 2016; Prokopets, 2012; Thomé et al., 2014; Tuomikangas and Kaipia, 2014). In literature, the performance effect is divided into sales performance (Swaim et al., 2016; Wagner et al., 2014), operational performance (Boyer, 2009; Thomé et al., 2012) and financial performance (Prokopets, 2012; Thomé et al., 2012).

Accordingly, we hypothesize that:

H2: Relevance toward S&OP and Performance of the firm
a) Perceived relevance of S&OP influence firm’s sales performance.
b) Perceived relevance of S&OP influence firm’s operational performance.
c) Perceived relevance of S&OP influence firm’s financial performance.

Method

This paper is based on the data from a questionnaire-survey carried out in the autumn 2018 in an investigation of reasons behind companies not applying S&OP. In total, 891 Danish manufacturing companies with 50 or more employees were contacted. 240 of the companies agreed to participate in the survey about reasons for not using S&OP. In total, 166 responded of which 156 respondents have provided full and useable answers leading to a response rate at 17.5 percent (138 SMEs and 18 large companies). The constructs that were chosen to measure the hypothetical model are built on extensive review of relevant literature. The construct reasons for not using sales and operations planning (S&OP) includes indicators like lack of knowledge, unrecognized needs, and lack of implementation skills. The construct relevance of S&OP is evaluated according to the answer provided by the respondents on a
5–point Likert Scale. The construct performance includes sales, operational and financial indicators (see Appendix B for the complete list of constructs and indicators). Sales performance includes customer, delivery, and sales performance. Operational performance includes operational cost, planning cost, and output cost. Financial performance includes net working capital and profitability.

Analysis
The analysis aimed at exploring the understanding of reasons for not using S&OP, the relevance of S&OP, and the performance implications. Exploratory factor analysis and linear regression were performed using SPSS 24 software. The validity and reliability of the measurement instrument were assessed. Tests for non-response bias (Li et al., 2016) and common method variance (Chang et al., 2010) were performed, and the results inform that it is not of major issue. The seven questions concerning the reasons for not using S&OP like lack of knowledge, unrecognized needs, and lack of implementation skills were built based on the existing literature and were sent to the respondents from three companies for validation. The respondents did authorize the appropriateness of the selected reasons for not using S&OP. Factor analysis was performed for the construct performance and the selected indicators for the projected factors were included for regression analysis.

Findings
Factor analysis was performed for the construct performance in terms of sales, operational, and financial. The result of the exploratory factor analysis (see Appendix B) indicated three indicators for customer performance (improved customer service level; improved customer satisfaction; and customer continued usage), three indicators for delivery performance (improved forecast accuracy; reduced stockouts; and improved time-to-market of new products/services), two indicators for sales performance (improved earnings and growth in market shares), one indicator for operational cost performance (lower purchase costs), one indicator for planning cost performance (a more stable production (fewer re-scheduling)), one indicator for output performance (an improved capacity utilization), three indicators for net working capital performance (lower capital tied up in inventories; improved accounts payable - extended payment deadlines to vendors; and improved accounts receivable - shortened period for customer receivables), and three indicators for profitability performance (improved return on investment; improved product profitability; and improved customer profitability). The selected indicators for the projected factors were included for regression analyses to test the proposed theoretical model.

Linear regression was performed to check whether the chosen reasons for not using S&OP positively influence the relevance of S&OP. The results indicate that lack of knowledge positively influence the relevance of S&OP (statistically significant at 95% level; p-value = .020) and unrecognized needs negatively influence the relevance of S&OP (statistically significant at 99% level; p-value = .000). The result also indicates that lack of implementation skills does not influence the relevance of S&OP. Hence, H1a and H1b are supported. Next, linear regression was performed to check whether the relevance of S&OP influences the performance of the firm in terms of sales, operational, and financial. In general, the relevance of S&OP negatively influences the sales performance (statistically significant at 90% level; p-value = .067). However, the relevance of S&OP does not influence the operational and financial performances of the firm. With reference to sales performance, the relevance of S&OP negatively influences the customer performance (statistically significant at 95% level; p-value = .021) and delivery performance (statistically significant at 90% level; p-value = .097). Hence, only H2a is supported. In addition, secondary data was gathered and analyzed to check whether relevance of S&OP influence...
last available three years income not influence income index and ROI performances. Since we believe that firm size plays a major role in S&OP implementation, the impact of firm size was investigated. The results indicate that firm size does not have a great impact (marginal impact 90%) on the relationship between reasons and relevance of S&OP.

Discussion
This research considers that lack of knowledge, unrecognized needs, and lack of implementation skills are the reasons for not using S&OP and perhaps about companies readiness for S&OP. The companies because of lack of knowledge toward S&OP are not able to realize the relevance of S&OP. Therefore, companies have to make a conscious effort in acquiring adequate knowledge to understand the relevance of S&OP and increase their readiness for using S&OP. Alike, companies should also begin acknowledging the unrecognized needs to realize the relevance of S&OP as well as to encourage the readiness for using S&OP. Further, the lack of implementation skills may not be important for perceiving the S&OP relevance and readiness. This research suggests companies to first unfold the appropriate knowledge through various internal and external sources. The acquired new knowledge will result in understanding the unrecognized needs to realize the relevance of S&OP and stimulating the companies readiness for S&OP. Undoubtedly, this will optimize the S&OP implementation skills. Regarding the performance, the less awareness of relevance toward S&OP results in more realization only toward sales performance. In particular, the relevance toward S&OP and companies readiness for using S&OP seems to be important for both customer and delivery performances. Whereas, the realization of relevance toward S&OP perhaps does not seems to be important for operational and financial performances.

This research increases firms’ consciousness toward the reasons for not implementing S&OP as a tool or concept. Lack of knowledge can prevail among both top management and middle managers in a company. However, knowledge can be captured either by internal ambassadors or external consultants or professional organizations. These sources will help to improve the knowledge level in terms of articles, professional network facilitated by organizations, and conferences related to S&OP. Unrecognized needs happen both when a company lacks knowledge and has adequate knowledge concerning S&OP practice. Therefore, engaging both internal and external resources and capabilities can originate a thirst for new knowledge to identify the unrecognized needs. This will, in turn, bring much more visibility to the benefits of S&OP implementation. When a company has identified relevant knowledge and unrecognized needs they still lack implementation skills because of no human resources and has tried earlier without success. This research recommends companies to do a complete analysis of the internal employees and available external resources to make an overview of how well they are managing their current jobs using available resources. Besides, they can try to reorganize the existing human resources to work with the implementation of S&OP. If companies have tried in the past without success then they need to think about the requirement for change management, emphasize working with the burning platform, try to change their approach (mindset), and try to involve strong change agents. Altogether, understanding the reasons for not using S&OP and solving them will increase the readiness for S&OP implementation. Even though, the relevance of S&OP is not found to influence on operational and financial performances, it is found that the relevance of S&OP impacts negatively on sales performance. This seems to underpin a perception of that companies find that there is a trade-off between implementing S&OP and sales performance. Our study doesn’t indicate the existence of such a trade-off, but may, in turn, be a reason why some companies see no need for S&OP and that lack of readiness exists in other companies.
Conclusion
This paper has set out to investigate possible reasons behind why companies have not implemented S&OP despite its accompanying benefits. Thus, we hypothesized that three groups of reasons for not have implemented S&OP affect the respondents’ perception of S&OP. Furthermore, we hypothesized that the perception of relevance influence sales, operational and financial performance in the company. The analysis found statistical evidence for supporting H1a and H1b i.e. that the lack of knowledge of S&OP and an unrecognized need for S&OP influence the perception of the relevance of S&OP. The more the lack of knowledge the more the respondents find S&OP relevant and the more an unrecognized need for S&OP the less perceived relevance for S&OP. In contracts, data does not find support for H1c. Lack of implementation skills does not affect the respondents’ perception of the relevance of S&OP. Regarding the relationship between perceived relevance and performance, we only found support for H2a i.e. the relevance of S&OP negatively influences the sales performance. Thus, the more perceived S&OP relevance the lesser the respondents perceive their sales performance which indicates that S&OP can be one among other factors that can help companies to improve their sales performance. Finally, the data did not find any support for a relationship between perceived S&OP relevance and operational and financial performance. Overall, the results seem not to differ with respect to firm size.

Implications for theory and practice
This paper has implications for both theory and practice. For theory, this study indicates a need for further practitioner-oriented research on antecedents for making decisions on S&OP. Is S&OP relevant to all business sectors? Such knowledge can be in the form of identifying contingencies and is as much important to know as it is to know drivers and barriers, performance outcome and success criteria and maturity models of S&OP. Next, future research can further explore the problem area with respect to firm size. Is S&OP, in fact, also relevant for SMEs? Recent research has found that S&OP is relevant for SMEs (Stentoft et al., 2019), but further research is needed. Finally, the focus on reasons for not operating with S&OP is closely related to readiness for S&OP, which is a topic that needs further exploration as a tool to be used in the decision-making process for initiating a S&OP project and thus is a preceding activity before the activation of S&OP maturity models. For practice, this study indicates a need to increase the knowledge level about S&OP among the top and middle managers. This can be done by professional organizations and/or management consultants. An increased awareness can help managers to make conscious decisions either to deselect or select S&OP as a mean to maintain or even enhance competitiveness.

Limitations and guidelines for future research
First, the questionnaire part is based on single respondents from each company. Future research can be strengthened by obtaining multiple respondents per company. Second, the qualitative part is limited to insights from 10 case studies. Future research can include more case studies to explore further reasons for not applying S&OP. Third, future studies should also include a more thorough theoretical underpinning of organizational readiness before implementation of S&OP. Fourth, this study did not focus on the various contingencies for companies being part of the research. Future, research can further investigate whether S&OP is deemed more relevant in some industries and/or with certain contingencies than others. Fifth, overall more research is needed into the limitation and the alternatives for implementing S&OP.

Abstract

Blockchain is a novel technology that shows great promise to disrupt many aspects of society, industry and supply chain. Supply chain applications of Blockchain, however, have been rarely discussed in the academic literature. This study investigates the effects of Blockchain on the customer order management process and operations. A Blockchain is programmed in a Large International Firm in a prototype study. Results show reduction on order processing times and costs.

Keywords: Blockchain, supply chain, operational performance

Introduction

Blockchain offers four unique and powerful characteristics – transparency, traceability, resilience and safety that other digital systems lack (Palfreyman, 2016). This is a decentralized database that append records. There is great interest in Blockchain due to its architecture of anonymity, security, transparency and reliability without requiring neither trust between the participants nor a regulating intermediary (Yli-Huumo et al, 2016). The information track record is held in a tamper-proof database available to be inspected on demand by interested parties (Swan, 2015). Supply chains are seen as one of the area most prone to disruption, due to its presently time-consuming and fragmented information tracking systems. Supply chain applications
of Blockchain, however, have been rarely discussed in the academic literature. To date there is not research on the effects of Blockchain in the customer order management process. This study investigates the effects of Blockchain on the customer order management process and operations. There is limited understanding on the use and benefits of Blockchain on supply chains, even less at processes level. The research question is What are the effects of the distributed ledger platform – Blockchain – on the operations of a supply-demand chain, particularly in customer order management?

**Literature**

A. **Blockchain Technology: A Distributed Data Ledger**

A Blockchain transaction generally starts when a party declares the transaction to the network, the receiving party broadcasts the acceptance of the transaction and the entire network participates in validating the transaction (Nakamoto, 2009). The transactions (or other pieces of information) are combined, recorded and cryptographically encoded into uniquely identifiable blocks, along with a pointer to the previous block and a timestamp. Many such blocks chronologically appended form a chain (Kruijff and Weigand, 2017). Each chain is initiated by a ‘genesis block’, hardcoded in the software, which is the only block that does not point to a previous block.

A block may contain a ruleset with additional conditions required to be fulfilled in order for the pieces of information be sent across the network (Kiviat, 2015). This functionality evolved into the concept of a smart contract, defined as executable code operating on the Blockchain to facilitate promises between untrusting parties (Alharby and van Moorsel, 2017).

B. **Blockchain Applications**

Blockchain is a revolutionary technology largely applied in finances, particularly in cryptocurrencies such as Bitcoin (Glaser and Bezzenberger, 2015; Holotiuk et al., 2017; Yermack, 2017) and smartcontracts (Alharby and van Moorsel, 2017). Outside cryptocurrencies, limited understanding on the uses of Blockchain is shown (Avital et al.2016; Risius and Spohrer, 2017).

Nowinski and Kozma (2017) foresee a trend that the research body on applications will explode in the following years. Applications could include services in supply chain management, insurance, digital knowledge management and e-commerce (Glaser, 2017). The majority of the applications of this digital technology is at a nascent stage. Few cases demonstrate the use of Blockchain, nonetheless learning from these applications has changed the way companies operate. From a practical perspective, the majority of companies are cautious in investing in Blockchain, while still keen to learn from proof-of-concepts that demonstrate the feasibility and benefits of this digital technology (McLannahan, 2016). Hence, the impact of Blockchain on business models remains highly interesting to both industrialists and scholars (Risius and Spohrer, 2017).

Beyond the financial applications (Brown, 2018), Blockchain is recently implemented and tested in few other contexts such as, health (Eklab et al, 2016), energy (Naudin, 2017), land registry (Landmateriet, 2017, (Vorick and Champine, 2014; Bocovich et al, 2017; Shieber, 2017), education (MIT, 2018), high-value assets (Everledger), data management (Zyskind et al, 2015), industrieland administration, Conoscenti et al (2016), food (Steiner and Bake, 2015), and other market-place economic models (Sun et al, 2016, McConaghy and Holtzman, 2015). However, the majority of these implementations are reduced to early Blockchain implementation stages with little information disclosed about the effects...
of Blockchain on their operations, performance and outcomes. Only few successful cases show the impact of the Blockchain technology on the business performance.

C. Blockchain in supply chains
Blockchain as an open platform that allows companies to build their own applications. Its versatility and vast array of applications inspires its use in the supply chain (Benkler, 2006). Companies are actively exploring how they can leverage Blockchain to innovate parts of their business operations under the form of ‘private’ Blockchains (Davidson et al., 2016), Private Blockchains do not require cryptographic incentives nor proof-of-work as public ones, but access is restricted to the chosen network and its information.

Reducing the complexity and lowering the technical barriers have contributed to the growing popularity of Blockchain. Thereby, it is foreseen that Blockchain will increasingly be in competition with existing organisations’ systems and eventually could pose a threat to them due to its potential to perform their tasks more efficiently or reliably (Davidson et al., 2016).

As most companies build and maintain their own supply chain management software, it is difficult to have a global view of goods status in today’s increasingly intricate supply chain networks(Gao et al, 2018).

It is hypothesized that the value-added from Blockchains resides on the companies’ internal value chain (Science, 2016). Blockchain could revolutionise the way supply chain works (Dickinson, 2016). Kshetri (2018) claims that supply chain is believed to be one of the promising and transformative non-financial applications of Blockchain. Bunger (2017) supports that an industrial use-case in supply chains can provide an early return on investment for Blockchain applications.

Currently, the foods and goods supply chains are leading the implementation of the blockchains. Cases demonstrate the implementation of blockchain on the main stream supply chain of cotton, coffee and other goods. These use Blockchain from the growing, producing to the processing, distribution and retailing stages of the supply chain. Four out of eight applied cases reported in literature have been used in the foods and goods supply chains. The rest are applications on diverse sectors such as the health and safety compliance, high value assets and automotive. Their Blockchain applications are limited to front-end of the supply chains such as, in distribution and retailing.

With the exception of the Everledger case, the maturity level of these blockchain implementations are at the proof of concept stage. Most of these successful pilot cases are waiting to be scale up to understand and study the full potential of the blockchain in their industrial contexts. To date there not academic studies that demonstrate the effects of blockchain implementations on punctuated stages of the supply chain. In response to these research gaps, this study investigates the effects of Blockchain on the customer order management process and operations. The next chapter set the method for building and programing the Blockchain and the analysis of the results. This paper ends with some conclusions and future research.

Method
The emerging nature of research on Blockchains in supply chains is formalized not long after 2015, where few studies were conducted beyond smart contracts in a supplier-provider context (Dickinson, 2016; Gao et al, 2018; Miau and Yang, 2018).

Given the emerging knowledge in this topic, an exploratory research method is chosen as the right methodological fit to investigate our line of enquiry (Edmonson and
McManus, 2007). An in-depth case study method is selected as the foundational method for this exploratory research.

A Blockchain is first programmed from scratch. Our study (Yin 2009) is set in an international industrial manufacturing company specialized in heavy-assets equipment. For the purpose of this paper, the company is named as ‘HAE’ (disguised name for the company). At HAE, an Enterprise Resource Planning (ERP), an in-house collaboration tool, an Electronic Data Interchange (EDI), Excel sheets, customer portals, and some others are used to manage customer orders. Customer orders are presently highly manual and time-consuming, hence there is a high investment and operating cost aimed at human resources. Additionally, due to the laborious manual activities required for each order, processing and response times are long.

Unit of analysis. To add a precise understanding to the existing body of literature and to control our study, we decided to focus the implementation and use of Blockchain a particular stage of the supply chain – the Customer Order Management. Customer order management was chosen because it is often seen as the bottleneck to all the information flowing from the early processes of a supply chain stages.

Data collection. The triangulation of data and information strengthen the validity and reliability of this research.

The direct data collection process consisted of more than 36 hours of direct contact:
1. Interviews face-to-face, over phone and Skype. with four out of six Account Coordinators for the customer order management department of the company, the Head of Supply Chain and the Head of Digital Transformation.
2. Shadowing customer orders by direct observation.

HAE Case

Identified Problems in the Current Processes
Looking into the problem further, there are several key issues that are evident in mapping the scenario.
1. Amending orders can take many days to be approved. Inefficient communication lines and inadequate scenario handlers, result on long period of time before an amendment to an order is approved and modified.
2. Multiple communication channels to place or change an order. Lack of standardisation is risky and causes inefficiencies in the system such as discrepancies in the data collected and possibility of errors down the line. This substantially increases customer frustrations and likelihood of disputes between the customer and supplier. e.g. traceability and accuracy of modifications are highly unreliable.
3. Multiple rulesets for different orders/customers.
4. Extensive manual work. The situation becomes complicated as there are multiple customers and a lot of manual work involved.
5. Multiple external customers. External customers need to feel in control, which is not possible when using this current centralised trust model.
6. Prolonged Grief. Grief’ is the terminology used within the Order Management department to refer to the inability to process an order due to incomplete or incorrect information. It is the source of many discussions and is a significant drain of time for the Account Coordinators.
Blockchain Prototype Building

In programming the Blockchain for HAE, the selection of the technologies for the particular company & clients’ needs is very important. This continues by building the architecture and the business network. Finally, developing the Blockchain Interactions for Placing and Amending Orders. To secure the programming quality, the ‘Test Driven Development methodology’ is followed.

A. Selecting of Technologies

• **Back-end Technology**
  The back-end is the part of the system that stores and processes information. Also known as the data access layer of a piece of software or the “server side”. It refers to everything that does not appear in front of the user.
  
  The back-end for this study is the Blockchain (which acts as the database). It is accessed via CRUD calls from a RESTful api. This layer is concerned with security, content management and ensuring there is an established connection with the front-end. The content that the customer requests is dynamic. A closed network Blockchain – is selected on the basis of its perfect fit for the tasks’ context and the simplicity of its use. After a long analysis of all options.
  
  The Hyperledger Composer and Hyperledger Fabric combination is by far the most suitable choice for programming our Blockchain prototype. This combination is selected because (a) its ability to create neat private blockchain networks and (b) the low barrier to entry, unlike the alternatives.

• **Front-end Technology**
  
  The front-end is the customer-facing interface (also called user interface), it is the one the customer uses to interact with the server. Also known as the presentation layer, this is concerned with usability, creative output and functional user experience. The user interface needs to ensuring that it is simple yet intuitive. The front-end communicates with the server by way of a RESTful api. Exposing a RESTful API on the back-end side is one of the most popular method for getting the front-end to communicate with the back-end. The back-end facilitate this communication by having a few endpoints that return responses as JSON objects.

  There are several options for the front-end framework. Each choice has some benefits and constraints.

  The Angular interface could be a great choice because due to the Open Source Yeoman code generator framework that allows the user to quickly create a skeleton; however, it is restrictive as it is not commonly used in industry. The Electron another fantastic open-source framework that can be used to create desktop GUI applications, but one of its main limitations is that user may prefer a more intuitive web interface. While HTML+CSS and Vue.js are both easy to pick up, however, the React is by far the most suitable interface because it is widely used in industry for rapidly prototyping web applications.

B. **Building the Architecture**

The system architecture has few components that must communicate seamlessly in order for the full-stack application to work. Figure 1 illustrates how a single client application is subscribed to the Fabric runtime. The full-stack Blockchain (mobile/ web/API) solution
contains the transaction logic that is executed on the Fabric runtime. Hyperledger Composer generates a business network archive. It runs on top of Fabric; i.e. the Composer SDK maps down to the underlying Fabric SDK.

The Hyperledger Composer permits the ability to develop core components in a ‘business network’, generates RESTful APIs that interact with customers applications and deploys the network to a live instance of a Fabric runtime. This composer offers superior integration capabilities possible by a LoopBack connector that exposes endpoints to the running network as a RESTful API, which in turn can be consumed by a customer application.

C. Coding the Blockchain

In maximizing the accuracy and efficiency of coding, we used the ‘Test Driven Development’ methodology. By following a continuous cycle– coding, testing and refactoring – its unit testing verifies individual units of code to ensure they work as intended. Thus, this methodology allows external developers to easily understand the codebase (Dingsøyr et al 2012).

The final version Blockchain-enabled Customer Order Management System for HAE (back-end and front-end applications) has more than 5000 of line codes and took 15 iterations. Two programmers: one focused on programming the Blockchain (back-end) and the second one for the customer interface (front-end). Figure 2 shows the coding for the process of placing an order.
Results and Findings

First, the Blockchain was programmed following the following steps: we started by mapping the information flow and take the specifications and routines. Then the selection of the digital technologies made us to identify and evaluate various technologies, to inform our selection – Hyperledger Composer and fabric. We built the Blockchain architecture. We programmed the Blockchain app for customer order management. To connect the Blockchain with the user, built a user interface. We worked in continuous communication and synchronization with HAE company. Each step was validated with the company and customers.

The results were validated in a further workshop with more than dozen HAE employees.

Findings

The following early findings from the analyses of our study are summarized here: The Blockchain implementation:

(1) Improve the efficiency in the order management process. The Blockchain Solution considerably improved efficiency of the order management process at the HAE company. While normally it would take 2-4 days for an order or modification to be processed and approved, the Blockchain Solution leads to instantaneous, automatic approval times (including the verification time against set rules). Improved efficiency, from 2-4 days to less than 1 minute.

(2) Improved Traceability of order placed and modified. The Blockchain Solution improved the traceability of orders placed/amended at the HAE company. The company never had this open detail of traceability of transactions in the past. Therefore, transactions such as placing and amending orders are traceable back to participants, date/time and detailed modifications – quantities, specifications, approvals, confirmations, etc. Moreover, Blockchain provides a Dashboard with real-time traceable status of orders to customers and employees.

(3) Improved the visibility of the order management process. The visibility of data is increased and safely opened to employees and customers’ employees in the supply chain.
by predetermined access rights for writing, viewing and/or accessing information. Our very early simulation analyses show that Blockchain improve the efficiency of some operations. 65% reduction in the processing time for Placing Orders and a 60% reduction in the processing time for Amending Orders from the current state to the mature Blockchain state and reduction of account coordinators from 6 to 2.

**Contributions, Limitation and Future Work**

This is the first study that demonstrates with real data from an industrial firm the reduction of operations, efficiency gains and human processing input savings by using Blockchain in customer order management. Moreover, this study extends the supply chain theory by analyzing the granular effects Blockchain to process level i.e. customer order management.

The effects of Blockchain on the customer order management shows that Blockchain:

- Consolidates a single point of entry for placing and amending orders.
- Removes the multiple check points.
- Reduces manual input into the orders.

**Limitations and Future Work**

This research is based on a single in-depth case. However, this study sets the precedent on the benefits of the Blockchain and has the scope to be tested in other context in future.

Quality Management for High-Contact Professional Service Firms: A Multiple-case Evidence from Indian Law firms

Dr. Anupama Prashar (anupama.prashar@mdi.ac.in)
Assistant Professor, Management Development Institute, Gurgaon, India

Prof. Jiju Antony (j.antony@hw.ac.uk)
(Professor of Quality Management, Heriot-Watt University)

Abstract

This paper presents an exploratory study to understand the distinctive quality dimensions of high-contact Professional Service Firms (PSFs). The paper is based on empirical evidences from multiple cases in leading Indian law firms. The paper adopted an exploratory, multiple, embedded and comparative case study design. The empirical evidence from multiple case studies in 10 law firms was used to explore the QM dimensions for PSFs. The results showed that QM in PSFs is a multifaceted and continuous process rather than a straightforward and episodic one. The findings reveal three distinctive dimensions of QM for PSFs

Keywords: professional service firms; quality management; service quality;

Introduction

Globally, the professional service firms (PSFs) are at an inflection point of growth, facing an ever more demanding clientele and ensuing pressures to cut prices and expand service value. For instance, the waxing client dissatisfaction with legal advisory services (or law firms) is evident from a worldwide stagnant growth in legal service demand (between negative 4% and positive 6%), declined lawyer productivity (from 134 to 122 billable hours) and reduced collection realization rates (from 94.6% to 89.1%) during the past decade (Georgetown Law & Thomson Reuters Legal Executive Institute, 2017). Yet, there is limited Service Operations Management (SOM) research to investigate what PSFs should do, and how they should be managed to achieve superior quality (Jayaram and Xu, 2016; Lewis and Brown, 2012; Goodale et al., 2008, Zhao et al. 2004; Harvey, 1990). The established service quality literature ascribed the inconsistencies in
PSFs’ service outcome to their emblematic operational characteristics viz. knowledge intensiveness, professional autonomy, altruism, self-regulation and customization (Lovelock, 1983; Schmenner, 2004). However, lately, even the most autonomous services of medical practitioners (Sabella et al. 2014), accountants (Jeffords and Thibadoux, 1993) and engineering designers (Boone, & Ganeshan, 2001) have recognized the economic benefits of a systematic implementation of customer-focused quality management (QM) systems and practices (work measurement, coaching, employee training and reward system to name a few) that have paid manufacturing sector off in a big way in the past (Flynn et al., 1994).

Considering the academic research on QM in PSFs, the recent editorial note for the special issue of Journal of Operations Management (JOM) on “Professional Service Operations Management” (Harvey et al. 2016) emphasized the role of client awareness and precision in the recognition of relevant service quality attributes. The authors also highlighted the role of proxy indicators of quality (such as partnership-based organization structure) in the firm’s service quality assessment. Additionally, the need for managing the network or interactive quality during the extended service delivery process typical to PSFs was also highlighted. A large part of service quality research on professional services is into modelling the client’s expectation-perception gap (Parasuraman et al., 1988; Zeithaml, 1988). There has been little focus on how PSFs should be managed to achieve superior quality (Zhao et al. 2004). A process-focused research for exploring such service provider’s activities, procedures and behaviours that drive the client’s expectations and/or perceptions during the extended service delivery process in professional services is scant in the literature (Svensson, 2006). Therefore, this paper presented an exploratory study to understand the distinctive quality dimensions for professional services followed by the development of a conceptual model for QM in PSFs. The study used empirical evidences from multiple case studies in law firms to examine the QM practices in high-contact PSFs. The study was narrowed down to a specific professional service sector (legal advisory services) in line with the past research (Brandon-Jones et al. 2016; Lewis and Brown, 2012), which established that sector-specific insights played a crucial role in deriving competitive advantage in professional services. Given the exploratory nature of the research, the study adopted multiple, embedded (Yin, 2003), and comparative (Dul and Hak, 2008) case research design to achieve the research objectives. This
qualitative research design was suitable to gain a holistic (systematic, encompassing and integrated) view of the context of study.

**Literature Review**

*Distinctive characteristics of PSFs and associated QM challenges*

PSFs are conceptualized as one service category in generic service typologies in the service marketing literature (Silvestro et al., 1992; Schmenner, 2004). For PSFs, these typologies have emphasized some shared operational characteristics such as high level of customer contact and labour intensity (Lewis and Brown, 2012). However, these typologies fell short in recognizing the distinct QM and operational (control) challenges related to programmability of tasks and measurability of outcome faced by various professional service providers (Goodale et al., 2008). Harvey (1990) emphasized that unlike other service firms, the nature of operations management decisions in PSFs are driven by the relative power of the three stakeholders i.e. the professionals, the clients and the top management (firm). In a study based on the evidences from a specific PSF setting (law firms), Lewis and Brown (2012) emphasized that unlike other service categories, in PSFs the professional-client exchange is asymmetrical and required varying degree of customization in process design for different clients; there are less variables involved in the processes, creating an opportunity for commoditization; and the notion of professional identity greatly influences the efficiency of a PSF. Based on an empirical investigation in Management Consulting firms, Brandon-Jones et al. (2016) demonstrated the need for a contingent approach towards management of operational quality in PSFs. The authors showed that both the firm-level (scale of operations, degree of specialization) and individual-level (leverage, partnerships) characteristics impact the planning and control of the professional service quality.

Researchers have extensively discussed the QM challenges in PSFs using theoretical and conceptual research approaches (Fischer et al., 2014; Goodale et al., 2008). Some of these challenges are high process variability (due to high level of customer contact); limited scope for standardization and automation (due to high level of customization and knowledge intensity of the processes); input/output based operational planning and control measures (hours billed instead of process measures); and limited emphasis on the internal quality monitoring (due to strong
influences of explicit code of conduct and implicit norms). Further, defining the direct QM measures for PSFs can be tricky due to disparate quality evaluation criteria adopted by the service provider and receiver (Haywood-Farmer and Nollet, 1994; Lehtinen and Lehtinen, 1991). Therefore, it is important for the professional service providers to understand the direct and indirect QM indicators and manage them effectively to warrant a satisfying client experience.

**Figure 1: Preliminary research model for QM in PSFs**

**Research Methodology**

The purpose of this exploratory study was to develop a conceptual model for QM in high-contact PSFs. Adoption of a qualitative research design was appropriate for the early stages of theory-building to achieve the research objective, considering the limited research done so far on the complex phenomena of QM in PSFs (Miles and Huberman; 1994; Siggelkow, 2007; Eisenhardt, 1989). The paper used multiple, embedded and comparative case-study research design (Yin, 2003; Dul and Hak, 2008; Silverman, 2002).

**Case Selection**
This study was conducted in the Indian legal service sector. The Indian legal advisory service sector is world’s second largest legal market (in terms of number of lawyers with 1.3 million lawyers) and is currently preparing for opening-up to foreign legal professionals (INBA, 2017; Chinna, 2012). For the exploratory study, the Indian legal sector was represented by 10 leading law firms with leverage ratio (i.e. number of non-partner lawyers to equity/salaried partners) of 8.5 to 3.3. All the selected firms were general partnership firms known for Corporate & Business Law advisory services (though these firms also offered advisory in mergers & acquisitions, insurance, tax, and capital markets) and were ranked in band 1 & 2 (law firm ranking from 1-6, 1 stands for best; ranking is based technical ability, professional conducted and other quality attributes) by Chambers and Partners (Chambers and Partners, 2017).

Data collection and analysis
The data was collected at multiple points in time in the selected case settings during the fall of 2017. The primary method of data collection was semi-structured or standardized open-ended interviews (Rubin and Rubin, 1995) using an interview protocol as the instrument. For a detailed description of case findings, multi-stage data processing and analysis process, suggested by Miles and Huberman (1994) was adopted.

Findings
The major findings regarding the design of QM activities in the case studies are summarized in Table I and Figure 2.

Discussion and Conclusion

Broadly, the empirical findings showed that the unique personnel (lawyer) and organizational characteristics of law firms make QM a multi-dimension and continuous effort rather than a straightforward and episodic process. This observation is in line with (Ritsema et al. 1992) the definition of professional service quality as a process of continuously meeting the specification agreed by the client and the professional, considering the efforts and anticipated outcome, and incorporating all the self-evident needs of both the parties. Additionally, the findings also support the observation by Harte and Dale (2005) that it is difficult to define quality measures and controls in professional services because of their highly intangible, labour intensive and customer-centric nature.

It was substantiated that external image/reputation (corporate quality), internal client interface & support process/procedures (interactive quality) and perceived value for monetary and non-monetary costs (physical quality) broadly cover the complete scope of quality management in PSFs (Lehtinen and Lehtinen, 1991). Further, for managing the corporate quality, the findings illustrated that projection of firm's 'corporate image' should be targeted especially at the client-market served (global and domestic corporate clients
in these cases) with thorough understanding of the competition. This observation is aligned with the argument by Jääskeläinen and Laihonen (2014) that lack of awareness about the alternative service providers makes the 'image and reputation' crucial in client's selection of professional services. In fact, managing partner in one of the firm with international reputation explicitly endorsed "the need to work on developing a brand identity" to attract corporate clients worldwide. Additionally, a great degree of creativity and diversity was observed in firm's choice of image-building solutions, owing to the regulatory restrictions on legal advertising (in India) (Figure 2). This observation is in line with Nachum's (1999) proposal that creativity and reputation are variables that drive a PSF's competitiveness. The observed solutions for image-building were not only driven by senior management (firm representation in prominent forums by partners) and dedicated internal teams (practice development team working on continuous personnel engagement) but also steered by specialized external professional (external PR arranges and realizes publicity opportunities for the firm). On the content of corporate image building activities, endorsement of firm's legal acumen (trainings/workshops on recent statute, representation in law conferences) emerged as the primary agenda followed by highlighting the social responsibility endeavours (pro-bono work in association with NGOs).

This paper contributes to the SOM theory by focusing on the operational quality aspects in PSFs from service provider’s perspective, which was mainly explored from customer’s perspective, so far. The paper contributes proven QM attributes and dimensions for PSFs to the existing knowledge base on operational control and QM issues unique to professional services (Brandon-Jones et al. 2016; Lewis and Brown, 2012; Holschbach and Hofmann, 2011, Goodale et al. 2008). An indirect control on firm’s image through a constant engagement of professionals (people outside the marketing function) emerged as the primary dimensions of QM in PSFs (Cameran et al. 2008). Further, the findings showed that an effective design of service encounters in PSFs is achieved through instilling tangible and intangible components in the client-interaction (including both front-end and backend aspects) (Ponsignon et al., 2011; Svensson, 2006). Finally, due to the ambiguity in the definition and scope of service outcome in PSFs, managing the perceived value of services vis-a-vis costs (and efforts) is crucial for these firms (Lapierre, 1997).

Abstract

This paper describes how customer journey mapping can support the business-to-business (B2B) sales process over the operational life of equipment and examines both the products and the services offered throughout the entire lifecycle. Three cases from industrial firms are described and compared with the literature. The analysis of the results of this study shows that while the current customer journey mapping is useful in a complex B2B environment, it is sub-optimal and changes are therefore needed to provide a tool that is more suited to this context. The study identifies key areas where improvements could be made.

Keywords: Product service system; Customer Journey Mapping; B2B Marketing;

Introduction

The sales process of industrial product-service systems is often very complicated compared to the sale of stand-alone products (Kowalkowski & Ulaga, 2017), making it even more important to address stakeholder needs proactively (Anderson et al., 2006; Cohen et al., 2006). Additionally, the procurement/sales process has been getting more complex according to Nicholas et al., (2017), who stated that more than six stakeholders are now involved in a typical purchase process. Customer journey mapping has been used successfully in business-to-consumer (B2C) environments (in both sales and execution) to understand and map B2C customers’ experience and to support the redesign of supplier processes (Lemon & Verhoef, 2016). As a Service Design method, it has been useful in these B2C markets; the methods help in understanding B2B environment although can lead to oversimplification. Complex B2B sales processes where the supplier is not directly selling to the 'end customer' can be very convoluted, with many layers and different roles and responsibilities (Anderson & Narus, 1999). For capital equipment with a long operational life, this process can be further complicated, while the introduction of digital solutions around the product-service system—to create more value for the customer—adds complexity to the sales process (Clarke, 2014).

Research question

The purpose of this paper, based on the problem described above, is to identify how customer journey mapping can be adapted to B2B businesses to support the sales and project execution
process over the operational life of the equipment. For business leaders who provide industrial product service systems this will offer tools that can support improved customer experience. The research question is:

- How can the customer journey mapping process be adapted for use in complex B2B product service system environments?

Literature review

The literature review describes the use of customer journey mapping and service blueprints, before moving to consider complex product-service systems (PSS) and servitization; it then moves to consider the marketing aspects of transactions between firms in a B2B environment.

Customer journey mapping and service blueprints

Customer journey mapping and service blueprints trace their history to 1984 when Shostack published the first scholarly article on the topic, describing a service blueprint as a tool to support service design and innovation. From this visual tool the customer journey mapping process has evolved (Stickdorn, 2011) providing two tools that complement each other for understanding and designing new services for individuals. The tools have been used in B2C environments and an example of a customer journey map is shown in Figure 1. An important prerequisite before starting any customer journey mapping process is to understand the transaction that is being investigated.

![Customer Journey Map](https://uxplanet.org/journey-mapping-is-key-to-gaining-empathy-1da5b54655e1)

Figure 1: A customer journey map for a B2C environment

Richardson & Li (2010) looked at improving the customer experience by improving touchpoints. This approach was taken further by Kalbach & James (2016) who describe using personas and empathy cards in customer journey maps to provide more insights into service delivery, in particular what is and is not important for the customer. Davey (2018) described a practical way to create customer journey maps. The integration of these ideas helps to improve customer intimacy, which is needed for Design Thinking approaches to improving experience (Dalton & Kahute, 2018). The actor personas here provide the basis for the innovation process and the subsequent service blueprints that can then be created. The visual approach to the customer journey helps to provide deep understanding of the customer experience (Lemon & Verhoef, 2016) and can act as the basis for innovation that can improve that experience.

Complex product service systems and servitization

The contribution of services to the success of a manufacturer’s business is frequently referred to as ‘servitization’ (e.g., Lightfoot et al., 2014). Kowalkowski et al. (2017) take this further by making it clear that servitization, including aftersales activities, is not a simple marketing approach but rather, fundamental to provide services that customers value, and support them (or the products they own) to achieve the outcomes that are important for them. All of these authors describe that much of the customer value from the service aspects accrues from intangible aspects, and that customer experience is one of the most crucial intangible aspects.
**Understanding firms and their buying processes**

Anderson & Narus (1999) highlight the importance of understanding firms, in particular: treating firms as individuals; the firm’s value creation processes; understanding a firm’s buying processes; and recognizing the roles of individuals within the firm in particular purchasing roles (e.g., initiator, influencers, gatekeepers, decider, purchaser and users). Within B2B marketing there is much discussion of “stakeholders” and maintaining relationships with them to improve sales effectiveness and relationships during project execution. Anderson et al. (2006) are also clear that value must be identified and developed for the customer in a B2B environment. Consideration of the stakeholders and the firm is discussed in the literature, as both influence each other and when providing a service or a sale the provider must understand both (Cohen et al., 2006). The importance of understanding the buying process (e.g., as a journey rather than a single event) is described by Viio & Grönroos (2016). The marketing literature goes further by stating that, in general, good customer experience and ongoing relationships between individuals in a supplier/buyer relationship increases the chance of repurchasing in the future. There are many differences between B2B and B2C marketing, but one of the starkest is that the number of stakeholders in a B2B transaction is significantly more complex than in a B2C transaction (Lilien, 2016). Nicholas et al. (2017) confirmed that the complexity of B2B transactions is increasing, with a growing number of stakeholders involved (+6.8) in the buying process; a number that rises with more expensive purchases. Sellers often come to the table late and do not take time to understand the buyer’s procurement processes. The solution proposed by Nicholas et al. is to make the buying process easier by simplifying and improving the buyer’s experience. This is achieved by matching the sales processes with the buyer’s procurement processes and providing the information they need at a particular point in time, rather than overloading them, allowing the offer to be ‘tweaked’.

**Research framework**

Individual case studies with reflections and cross-case analyses are an appropriate approach to qualitative research and are applicable to the development of a tool or integration of a new tool into an existing framework (Karlsson, 2009; Yin, 2009). Voss (2008) provides more guidance, with a cross-case analysis providing a valuable approach to study complex phenomena within their contexts (Baxter & Jack, 2008) to evaluate an existing process, to propose improvements based on the lessons learnt from the research, and then to build new theory. Effective dimensions are required for case analysis and cross-case analysis from the customer journey and marketing literature, along with a clear research question as an overall guide. In the case of customer journey mapping, the high-level dimensions identified from the literature are: context information; business process or transaction being mapped (Wellsandt et al., 2016); mapping process applied (Polaine et al., 2013); how were actors defined, personas developed, and company profiles created; insights into the customer’s processes (Nicholas et al., 2017); and general reflections.

**Methodology**

A case study approach was applied (Karlsson, 2009; Yin, 2009), with three cases to explore two mapping processes and a cross-case analysis to compare the findings with the literature (see Figure 3). The industrial cases were developed from three different projects where the aim of the customer journey mapping could be clearly defined. The case studies were selected to have the following traits in common: complex engineered products and their associated services; a long operational lifetime; and set in a business-to-business (B2B) environment. Three of the authors were involved, and observed the mapping processes.

The application of a cross-case analysis provides a framework (i.e., dimensions: objective of the mapping; processes mapped; regions; equipment lifecycle; mapping process; effectiveness of actor identification; development of actor personas; development of company profile; insight into customer processes and post mapping reflections) for structured reflections that distill lessons learnt from the three cases and provide a definite structure with a list of factors to be investigated.
From the results of the cross-case analysis, potential changes to the customer journey mapping process were identified to make it more applicable to complex B2B environments. The aim here was to extract the key lessons and points of difference to support customer journey mapping to be used in an industrial B2B environment.

**Results and initial analysis**

The cases examined in this paper come from capital equipment industries, providing product service systems as solutions over the whole operational life-cycle. All of the manufacturers in this study had direct access to the ultimate owner of the equipment. Two of the suppliers could be considered first-tier suppliers, whereas the OEM for the engine sub-system was a subcomponent supplier for the engine. In all three cases, the equipment was integrated into the customer’s process plant or a ship alongside equipment from other manufacturers. Typically, system integration was undertaken by an EPC contractor or shipbuilder who developed the whole system for the ‘end customer’ as a project. In each of the cases, given the long operational life of the equipment, there was a complicated cycle of ‘repair, refurbish, replace’ depending on the equipment upgrade cycle. The results of the study will now be described in three sections covering the work that was undertaken for each case, following with a cross-case analysis.

**OEM for glass manufacturing equipment**

Here two different journeys were created, one for the sales process of the original capital equipment, the other for sales of refurbishment services. Based on the two different customer journeys, a sales support handbook was developed.

Early in the mapping process, it became clear that the sales team did not fully understand the customer’s buying process. Although the sales process (both BOL and MOL) could be generically described, it was apparent that different firms had different approaches to the procurement process. At least five stakeholder groups were identified, with another 20 different individuals involved in the decision-making process. This complexity had not been seen clearly within the firm before mapping. The combined mapping of new equipment sales, aftersales and equipment refurbishment provided clear links between the three main sources of sales for the firm. In this case the sale of spares was not a major part of the revenue model. What became clear were the ‘trigger’ points for the initiation of refurbishment process – there was an agreement that this typically took place after six years of operation and that the sales process started informally after three to four years of operation. The mapping provided deeper insights into the customer’s two crucial buying processes: new equipment and refurbishment. The firm proposed adjusting their sales process to match the ‘generic’ buying process and improve the information flows to the customer with the aim of improving the sales hit rate. Figure 3 shows the high-level generic customer journey map for the sales process of new equipment. A detailed playbook for sales was one of the case’s outcomes.
OEM for paper manufacturing equipment
Customer journey mapping was developed for both the sales and the project execution process in Europe and in China. The lifecycle of a paper mill is typically over 30 years, based on continued equipment repair, refurbishment and upgrades to support market demands and safety requirements.

The mapping process defined descriptions of the role and responsibilities for each of the actors in a clearer form than previously, where the term “end user” was used to described many different actors involved in the process. A redacted extract from one map developed is given in Figure 5. Customer ‘trigger points’ for sales were identified more clearly with the mapping process than before. The complexity of the customer side of the process showed itself in this mapping, giving insights into which actors on the buyer’s side were leading the process, and at what point in the process they handed over responsibility to another actor. In this mapping process personas for individual actors as well as the company were developed, as it was considered that the cultural aspects of the firm affected the behaviors of the actors within the firm. Extending the mapping process into project execution provided insights to improve information flows and communication with the customers. Feedback from management stated clearly that matching the sales process to the buying process was important for them and that they expected sales performance to improve.

OEM for engine sub-system
The workshop was a one-day event with the aim of supporting the development of a web portal for customer and supplier use. Part of the output generated at the workshop is shown in Figure 6. The sales and the execution journey were mapped for both new equipment sales and equipment repair in the MOL. Personas were created for all key actors (buyer/user side and supplier side). Initially personas were created only for the buyer/user side, however having personas for all actors gave better definition to the journey map. Even simple personas were found to support discussions and helped to challenge assumptions. Much of the service delivery in this case
depended on third-party actors, and for the first time the firm created personas for these key third-party actors (e.g., freight forwarders). The most challenging aspect of the mapping was the buyer side processes, where there is limited understanding of all actors and their individual roles and responsibilities.

Cross-case analysis
In this section a cross-case analysis of the three cases provides reflections to support the development of a generic customer journey map more suited to application in complex product service systems. Table 1, provides an overview of the three cases considering: Objective of the mapping, Processes mapped, Regions, Equipment lifecycle, Mapping process, Actor personas, and Company profiles. The four key reflections from the three cases are also described in the table.

Figure 5. Photograph of the customer journey map from the workshop
Discussion
The discussion will first consider four critical aspects (i.e., actor identification, actor personas and firm profiles, customer process understanding, mapping process) and the points of clarification will provide the basis for the discussion. It will close with a proposal for a rebuilt customer journey mapping process for application in complex B2B environments.

Actor identification
It is important to recognize that some actors were very hard to pinpoint, yet their roles became clear during the mapping process. This stakeholder analysis, according to Anderson & Narus (1999), is one of the most crucial activities in developing insights into a firm and its decision-making processes. Appropriate communication with the different actors leads to improved relationships and has a positive impact on customer experience. In many B2B decision-making processes (Nicholas et al., 2017) there are key decision makers that need to be appropriately influenced. Here it is necessary to identify all the actors in the journey, on the supplier and on the customer side, since in B2B environments some of the key actors may be in third-party firms, making identification more difficult and requiring input from multiple sources for cooperation. However, identifying actors does not provide insight into their importance, and this should be considered in the building of personas.

Actor personas and firm profiles
In the B2B environment it was seen in the results that personas were needed for both internal and external actors and for every transition. The level of detail in each persona was a function of that actor’s role and their importance at a particular instance/situation. However, without profiles for the firms, development of actor personas and/or empathy maps was unsatisfactory. Profiles of the firms supported better customer understanding and even basic segmentation supported the development of more insightful personas; this could be from the fact that the firm’s culture plays a role in the behaviors of individual actors. Many different sources of information were used to create the firm’s persona; however group work with different people in a workshop environment was the most effective method for the development of personas, and this is in line with the literature (Lemon & Verhoef, 2016; Polaine et al., 2013; Richardson & Li, 2010). Having basic data in one place helps to ensure that everyone has a similar understanding of the customer firm.

Customer process understanding
This activity makes it possible to better match supplier interventions with buying activities and customer execution processes. The literature suggests that this improved understanding of customer processes is important both in the sales process and to improve the general effectiveness of communications. Often the term ‘fog’ was used to describe the customer’s process and through the identification of the actors and personas it is possible to ‘lift’ the fog and to make connections between different actors on the customer’s side in what are the customer’s backstage activities. It also provides insights where new (third-party) services are critical to a customer. The process of identifying and making the connections came from the initial front-line customer touchpoints where both the supplier and customer actors were first identified. From these touchpoints, using input from different people and assumptions, it is possible to build a picture of the customer’s backstage processes, albeit an estimated understanding. This imperfect view of the customer’s processes provided input into discussions that supported the further development of a deeper understanding; an approach that supported the breaking down of assumptions. Viio & Grönroos (2016) confirm the importance of repeating this to build a fuller shared understanding of the customer’s processes.

Mapping process
The mapping process was very complex when the whole equipment operational life cycle was considered (often over 25 years in duration). Development of some aspects (e.g., profiles of the firms) was more effective when started independently before returning to individuals for review, with the inputs then being synthesized into a coherent profile. The journey mapping process was
most effective when there was input from many people, and when it was coupled with iterations and reviews by the team who provided the input; this is in agreement with many scholars (e.g., Polaine, Løvlie, & Reason, 2013; Clarke, 2014; Kalbach, & James, 2016). The mapping helps to identify critical third-party actors as well as direct actors. Workshops were used to give a clear focus, with facilitation to ensure the quality of the output that could then be re-drawn into a more useable form. Interviews and drawing the map without iterations and input from others provided a woefully incomplete view of the journey. The use of templates helped with the mapping process to capture the appropriate information from the participants, although there is an associated risk of a desire to complete the template before moving to the next step. With effective iterations in place it was found to be more efficient to partially complete the template and to return later.

Suitability of customer journey mapping for application in complex B2B environments
The evidence from the cases and the cross-case analyses confirms that the B2B customer journey mapping process is far more complex than for B2C customer journey mapping. This has been shown to come from customers’ firms being more complex, with many different actors involved in the buying process. This is not new and has been seen in the literature (Anderson & Narus, 1999; Bitner et al., 2008; Kalbach & James, 2016), which says clearly that it is important to understand both the customer’s process and the ‘customer’ themselves. The mapping process is able to support this by providing a framework that allows the supplier to see through the ‘fog’ of the customer’s organization. This paper adopts the underlying assumption that understanding your customer and their processes and improving touchpoints (and hence communication) will lead to improved customer experience, and that this translates to improved revenues and lower costs associated with a particular customer. The research question asked what changes needed to be made to the CJM process to improve its applicability for use in B2B environments and the cases here shed light on the difference and propose a modified process, drawing on the existing customer journey mapping process, that has increased applicability to complex product service systems. A modified process is needed for the application of customer journey mapping in B2B environments and the three cases here provide some evidence that could underpin a reforming of the process for this purpose. A proposal for the process is given in Figure 6 which shows that the actors and their roles should be identified irrespective of the firm they are active in; then business profiles and actor personas should be created, and finally the customer journey map can be developed, showing the backstage/hidden actions as well as the visible actions and touchpoints.

Conclusion
The cases confirmed that customer journey mapping in a B2B environment is more complicated than in a typical B2C environment. However, customer journey maps (and the associated personas and business profiles) could be used for the new equipment sales process, service sales processes, and execution activities. This is mapping more than just the initial product sales but rather, all of the relationships and transactions along the operational life of the equipment. Doing this would provide a detailed understanding of the information flows required to support a proactive rather than a reactive sales process. The mapping creates deep insights into customers and how sales, products, and services are delivered to customers. According to the literature, this should improve customer retention, and sales volume and margins. When developing a customer journey map, the following tasks were found important to consider:

Suitability of customer journey mapping for application in complex B2B environments

Figure 6. Proposed framework for industrial B2B customer journey mapping process

Conclusion
The cases confirmed that customer journey mapping in a B2B environment is more complicated than in a typical B2C environment. However, customer journey maps (and the associated personas and business profiles) could be used for the new equipment sales process, service sales processes, and execution activities. This is mapping more than just the initial product sales but rather, all of the relationships and transactions along the operational life of the equipment. Doing this would provide a detailed understanding of the information flows required to support a proactive rather than a reactive sales process. The mapping creates deep insights into customers and how sales, products, and services are delivered to customers. According to the literature, this should improve customer retention, and sales volume and margins. When developing a customer journey map, the following tasks were found important to consider:
identification of the journey (including any triggers for new journeys, such as upgrades);
- identification of the actors and the key actors;
- creating business profiles and actor personas;
- co-creation of the customer journey and iterations to provide additional insights and to share lessons.

The limitations to this study are that a new proposed framework was not tested from the research. The framework should be tested thoroughly in different B2B environments to understand how it performs relative to the traditional customer journey mapping process. It is suggested that it should not diverge too far from that of the traditional B2C customer journey mapping process as this is well documented in the practitioners’ world.

Recommendations
It is recommended that a generic framework is developed and tested for this complex PSS environment in much the same way as for B2C environments. In practice, the framework could then be tailored for each firm, to support their processes. The framework could be integrated into sales support tools, such as customer relationship management. Additional testing of such a framework would be required, to understand its full applicability. Specific industrial recommendations are:
- integration of both sales and operation to improve customer experience;
- integration with marketing theory to support customer experience.
- the equipment’s operational lifecycle should be integrated to support trigger points.

Further research needs to be undertaken to understand the applicability of this work in different industrial environments, this should include:
- testing of the proposed framework for industrial B2B customer journey mapping;
- further integration of B2B marketing theory into the B2B customer relationships;
- further work on the trigger points that equipment can provide to reinforce customer experience.

Abstract

This paper reports on a longitudinal action research project conducted over three years within a medium-sized law firm. The focus is on high volume/low variety service processes which are considered a breakaway from the widely agreed typology of professional service generally characterised by high degrees of customer contact, labour intensity and customisation. Using customer contact as the central theme, this paper explains how a particular high volume/low variety legal service has been redesigned using a novel soft systems based intervention embedded into action research methodology. This research led to identification of key success factors and delivered improvements to service.

Keywords: Professional Service, Soft Systems Methodology, Action Research

Introduction

Professional services sector accounts for a significant portion of the UK’s economy and employment, and is one of the fastest growing sectors. Professional services such as law, accounting, medicine, management consulting, investment banking, advertising, engineering, architecture etc., are also considered to be knowledge-intensive and often presented as models of good practice for an increasingly knowledge-based economy.

Within professional services, legal services are considered as an exemplar (Nordenflycht, 2010), but even so are often criticised for being inefficient, ineffective and uneconomical in an increasingly competitive UK legal market (Falconer, 2005). Several studies indicate that little research has gone into development and application of Operations Management (OM) theory in the context of professional services, especially
A vast majority of literature surrounding law firms, focuses on change at an institutional level (Cooper et al., 1996; Sherer & Lee, 2002; and Pinnington & Morris, 2003). Based on these works and a wider literature review, there is little empirical research to draw conclusions about the operations management practices and challenges existing at the field level in law firms.

For example a recent in-depth case study conducted in a law firm explained how the firm adapted to endogenous and exogenous forces by embarking on an action research project (Clegg et al., 2019). The present paper aims to extend the research in this domain by exploring one particular service line within the high volume and low variety service range, the Wills and Estate planning service. High volume, low variety service processes are considered a breakaway from the typical notion of professional service that is generally characterised by high degrees of labour intensity, customer interaction and customisation (Schmenner, 1986; Lewis & Brown, 2012).

**Professional service operations management**

OM theory informs that professional service is one of the purest forms of service (Schmenner, 1986; Goodale, et al., 2008) and characterised by extensive customer contact, process customization, complexity and throughput variability. According to the taxonomy proposed by Nordenflycht (2010), delivering legal services is marked by the highest degree of professional service intensity compared to other professional services and is characterised by a set of three distinct features that include knowledge intensity, low capital intensity and professionalised workforce. Each of these characteristic features corresponds to different challenges and managerial implications. For example high knowledge intensity corresponds to challenges of directing, supervising and retaining employees. Other challenges such as inefficient processes are inherent to professional services in particular and services in general due to their distinct characteristics of customer contact, intangibility, inseparability of production and consumption, heterogeneity, and perishability (IHIP).

Yet, how these challenges manifest in practice at the operational level is a topic that has not been discussed widely, at least not in the legal services sphere. This paper aims to articulate some of the challenges inherent within High volume/low variety services within a law firm and presents how these have been addressed using a robust methodology rooted in systems thinking.

**Volume and variety at Lawyers Co.**

Lawyers Co. (LC) is a long established law firm in business for over 140 years and currently employing over 250 staff. LC is considered a full service law firm providing a variety of legal services grouped into 8 departments.

The volume and variety framework proposed by Hayes and Wheelwright’s (1979a, 1979b) along with Silvestro’ et al’s’ (1992) adaptions for services was used to categorise various services provided by the law firm to into two distinct groups as suggested in the framework (a) High Volume/Low Variety, (b) Low Volume/High Variety, as shown in Table 1.

High volume/low variety services can be organised and operationalised as service factories akin to what was proposed by Schmenner (1986, 2004). But there is no evidence on how and to what extent these service lines within a law firm can be redesigned into a service factory model of operations. In the following sections, a Will writing service which is part of the Private Client department at LC is analysed using a Service Blueprint (Shostack, 1984) to understand the existing service design and mainly to analyse the customer contact involved in this operation so that it can be redesigned for the better. Also, Harvey et al., (2016) argue that the presence of significant amounts of standard work inside the professional service space suggests an opportunity for deploying classic process analysis and improvement interventions from the OM literature.

**Customer contact in high volume/low variety services**

Customer contact (also termed customer involvement and customer interaction in OM literature) in the service delivery process is a source of complexity which negatively impacts on efficiency. Research informs that high contact processes are inherently inefficient and influence the outcome of that service, a feature that prominently distinguishes services from manufacturing (Chase, 1978; Shostack, 1984; Chase and Tansik, 1983). Similarly, Sampson and Froehle (2006) state that “with service processes, the customer provides significant inputs into the production process”, making this central to their unified services theory which proposes that the presence of customer inputs is a necessary and sufficient condition to define a production process as a service process. In understanding legal service processes, this definition is even more contextual and pertinent due to the high customer contact present at every step of the service delivery process. For example in a typical legal matter, from providing matter details to offering input at key stages and through to negotiating the settlement or alternatively appearing in the court, client is heavily involved in the service delivery process and accordingly shapes its output and outcome. Yet high client contact is mainly characteristic of only few service lines within LC and law firms in general, such as Dispute Resolution and Corporate Services which are marked by high complexity involving multiple stakeholders, information feedback loops and a variety of systemic success factors (Clegg et al., 2019).

In high volume/low variety service lines such as Wills and Estate Planning, Road Traffic Accident Claims, and to some extent in Commercial Property services and Family services, client involvement although present, is relatively low and punctuated throughout the service process rarely affecting the outcome of service.

For example in a typical matter involving Will writing service, client contact occurs in three to four instances – once at the beginning when making an enquiry, once in the middle when providing the personal details, also there can be a second contact here for
providing further details and once in the end for signing the will in the presence of a witness which is often done at the law firm offices.

An investigation into understanding the customer involvement in Will writing service at LC using the Service Blueprint has revealed two major fail points which needed to be addressed. Figure 1 provides a Service Blueprint that takes into account major activities in the process of delivering a Will writing service.

Figure 1: Service Blueprint of Will writing service

**Fail points**

As shown in the Service Blueprint in Figure 1, the two fail points occur at the stage of receptionist responding to initial enquiry by potential client (F1) and at the first client-lawyer meeting (F2). F1 denotes the wastage of opportunity for capturing client details by the receptionist and the lack of empowerment and training to carry out initial screening of the enquiry (for example finding out whether the client is ready to instruct the firm, or needs additional information before instructing the firm, or is simply shopping around for the lowest quote). Also F1 indicates that every enquiry that is routed to the lawyer in Private Client department is a potential waste or ineffective use of lawyer time – lawyer having to collect the personal details over the phone spending time which cannot be billed or recovered is a waste that can be eliminated. F2 indicates another redundant step in the process, collecting personal and case details at the first meeting, which can be altogether avoided if the client is willing to provide required details over the phone and submit documents over email – a waste that can be eliminated by providing alternative options to direct meeting. Besides these fail points, there can be several other systemic success factors that need to be understood before taking action for redressal.

**Using PrOH modelling methodology as an intervention for change**

To understand legal service operations and then enable improvements, systems thinking is used as a methodology, the principles of which have been widely applied to solve
complex real life problems in management, and to facilitate organisational change 
(Ackoff, 2006; Jackson, 2006). Within systems thinking a novel methodology known as 
the Process Oriented Holonic (PrOH) Modelling (Clegg, 2007) is used, which was 
developed from the principles of soft systems methodology (SSM).

The overall methodology aligns with that of the basic principles of SSM (Checkland 
and Poulter, 2006 pp. 11) as described in the following steps:

- identifying perceived *problematic real-world situation calling for action to 
  improve it* – for instance legal service operations within the context of recent 
deregulation and the need for delivering services that are more efficient, effective 
and economical.
- building *models of purposeful activity relevant to this situation* using PrOH 
  modelling
- employing a *process of using the models as devices to explore the situation 
  through PrOH Storyboarding workshops*
- conducting a *structured debate about desirable and feasible change* using action 
  research team meetings.

This research extensively used PrOH modelling methodology for modelling service 
operations within LC. It has been used to build models of legal processes in order to 
visualise the interactions between people, systems and other tangible and intangible 
entities involved in legal service delivery. Making use of the abstraction and enrichment 
principles laid out in the PrOH modelling methodology (Clegg, 2007), both high level 
and granular level models have been built and used in the process of making operational 
and cultural changes at LC.

PrOH enabled the modellers to engage with professionals in a knowledge-intensive 
environment through a structured process of enquiry which involved initial data gathering 
to build the model, a story boarding workshop to elicit ideas for improvement and change, 
leading to formation of action teams that were deployed in the process of *developing solutions 
and implementing changes* to process and practice. PrOH facilitated 
conceptualising, visualising, analysing and improving professional service operations 
that are inherently complex due to the factors detailed earlier in the paper such as client 
contact, labour intensity, customisation etc. A more detailed explanation of this 
methodology and the subsequent transformation similar to the one at LC has been 
explained in the recent paper by Clegg et al. (2019). In the present context of high 
volume/low variety services, an example PrOH model of the Will writing service is 
presented in Figure 2.

It might be argued why Service Blueprint alone was not sufficient for the purpose of 
analysing and redesigning the service operations at LC. It is very essential to understand 
that conventional process mapping tools would fail to model and elicit the intangible 
factors in the process such as success factors and also the multiple feedback loops as 
shown in Figure 2. Sampson (2012) argues that Service Operations Management (SOM) 
has not sufficiently contributed to research and practice. In spite of a plethora of ‘process 
mapping’ and ‘flow charting’ tools currently in use by both service and production 
operations professionals across the globe, Sampson advocates that there is an imminent 
need for new tools that help conceptualise, visualise and analyse service operations.
Figure 2: PrOH model narrating the high level view of delivering Will, Lasting Powers of Attorney (LPA) and Probate in the Private Client department at Lawyers Co.

Also process mapping techniques are criticised for being overly reductionist and reductionism is not appropriate for modelling human activity systems (HASs) (Checkland, 1981, p.52) such as legal services because hidden and emergent properties of systems and knowledge, their sub-systems and meta-systems, and respective knowledge, can be lost. Therefore PrOH model use can be thoroughly justified as the Systemic Success Factors of this operation have been captured in the model through consultation and workshop sessions based on the information provided by staff as well as
from the financial data provided by the firm’s Finance department. The success factors are considered for each element of the professional service triad, the Professionals (lawyers), Clients and the Firm as shown in Table 2.

**Changes implemented in the Private Client department**

As a result of the investigation and in conjunction with lawyers and support staff, various improvements have been made to the current process with the aim of eliminating fail points, improving utilization, productivity and also enriching the client’s experience of receiving the service, as presented in the systemic success factors table above. Improvements and changes implemented to the process also reflect the addressing of challenges presented in Table 2. The changes implemented in Private Client department can be categorised under three broad headings – process improvement, knowledge management and client service.

**Process improvement**

- The redesigned Will writing service as shown in Figure 3 clearly indicates the changes proposed to the process. The receptionist will make use of the newly created diary allocation system to route the call to the available case manager or schedule a telephone meeting with the client at a later date which imparts more certainty and speed to the process. At this stage, the receptionist can also collect personal information and input to the central client database which has proved cost effective as billable lawyer time is not spent on this administrative task. This is similar to the Mid Office concept discussed by Silvestro and Lustrato (2015) who argue that ‘if the mid office can facilitate high volume processing and scale economies in the back office, while also enabling service customization in the front office, then the mid office may offer a service configuration which supports mass customisation. In the case of LC the mid office is the case manager (paralegal) sandwiched between Reception (front
office) and the Lawyer (back office) who is now consigned to only review the draft will and not directly face the client in a Will writing service.

- New roles have been created not by adding members to the team but by effectively dividing work between the existing team. For example two administrative roles have been created by assigning one existing paralegal (legal executive) and upskilling one existing secretary to take on the roles of case managers as shown in the revised Service Blueprint in Figure 3. The designated case manager will be responsible for making contact with client, sending letters, drafting the will and ensuring matter closure. According to Bordoloi et al. (2019, pp. 262) a dedicated non-billable (or low charging) manager assigned to a group of professionals might bring down the utilization but will increase the efficiency and competitiveness of the group in the long run. The role of the highly-skilled lawyer has been limited to only reviewing the Draft Will thus spending less time in the process which leads to more profitability. Will writing is a fixed fee service and thereby benefits from reducing the cost, as the lawyer can focus on more complex, customisation-intense matters in Private Client department such as probate and estates planning which do not operate on a fixed fee.

- Customer contact has been decreased by reducing the number of face to face meetings which results in time savings (realised as lower cost) as well as improving efficiency.

Figure 3: Service Blueprint of the revised Will writing service at Lawyers Co. (all changes highlighted in red colour).

Knowledge management

- Information packs have been created which detailed the flow of events and processing involved in each service line within the department including the indicative prices. For example a standard information pack comprising of different services within Wills and Estates planning has been created which will be emailed or posted to clients according to their preference based on the telephone enquiry. New forms have been created such as the initial enquiry form which will directly feed into the firm’s central client data base.

- 12 standard letters have been drafted and made available to staff in the departmental folders electronically. These letters include follow up communication after the initial
enquiry, reminders for payment, reminders for information provision, instructions for will signing etc.

- 11 standard documents have been drafted and made available to staff in the departmental folders electronically. These documents include draft Will templates, Will explanation letter templates, instructions to execute Will and codicil etc. Notably, the newly created payment authorisation form eliminates idle time lost in waiting for the client’s payment before the lawyer/case manager begins to draft the Will. A checklist has been created which comprises of the list of various details regarding client’s personal wealth, family information etc. which allows the case manager to obtain all the evidence required to draft a Will at once.

**Client Service**

- Various client service protocols have been created such as the one for receptionist and case manager to deal with clients based on the initial enquiry type – those ready to make a Will, those requiring additional information before instructing the firm and those simply shopping around for the lowest quote. A diary allocation system has been proposed which allows the receptionist to schedule meetings in the diaries of the available case manager at the time of enquiry based on a distributed work load management system, which results in prompt service to clients whilst improving the utilisation rate.
- Training has been provided to these case managers using a robust manual newly created based on a typology of clients drawn by consulting senior lawyers in the team and corroborating with historic data on fee billed on a range of matters with differing complexity. In order to equip lawyers dealing with Probate matters where the relatives of deceased clients approach the firm for executing the will, bereavement training is provided to all lawyers in the department.

The Service Blueprints presented in this paper are only a high level representation of the process indicating major activities. Whereas detailed activities and steps in the process are mapped separately using Microsoft Visio, which are not presented here for reasons of brevity.

**Conclusion**

Although marked with several customer contact instances throughout the matter progression, drafting a legal will in most cases is a less complex operation compared to other legal services, and therefore can be potentially standardised. Also the need for standardising or productising this service is driven by the competitive market forces due to the threat from semi-qualified specialist will writers and ‘supermarket law shops’. The major challenges faced by Private Client department at LC have been understood and addressed using this action oriented research engagement.

This research highlights the merits of applying a soft systems based approach in a complex organisational setting which led to the elicitation of operational issues, followed by implementation of practical changes. By working closely with lawyers and support staff, several innovative solutions were designed, some of which have also been fully implemented.

This action research project indicates that despite high labour intensity and customer contact involved in delivering high volume legal services, there is considerable potential
for rationalising processes and improving efficiencies without disturbing but in fact improving the lawyer-client relationship, the sine qua non of a law firm.

Abstract
This study investigates the effect of service transition within traditional manufacturing companies on the job satisfaction of two functional groups of workers: salespeople and front-line service (FLS) employees. Although there is a growing body of work on the implications of service transition strategies for manufacturers performance, yet only limited attention has been given to how employees perceive of, and react to, such an important strategic redirection. We examine the effect of service infusion on the overall job satisfaction of sales staff and FLS personnel using data from an employee ratings company, with results showing differential effects.

Keywords: service operations, servitization, job satisfaction

Introduction
Over the last decade increasing attention has been devoted to manufacturing firms transitioning towards services – a phenomenon that is commonly known as ‘servitization’ (Baines et al., 2009; Vandermerwe & Rada, 1988). It entails manufacturing companies seeking to enhance their product portfolio by offering services and combining their products with services to create new offerings (Vandermerwe & Rada, 1988). Implementing a servitization strategy does not necessarily guarantee better performance (Gebauer et al., 2005). Recent studies suggest that significant initial investment is required (Visnjic Kastalli & Van Looy, 2013), that organizations need to reach a ‘critical mass’ for profitability from services (Fang et al., 2008), and that adding services does not linearly increase performance (Fang et al., 2008; Suarez et al., 2013; Visnjic et al., 2016). Although this is highly relevant, there is a need to take a step back and examine the implications of the transition upon the job satisfaction of employees. This aspect to date has been neglected in the extant literature. This is surprising as the performance of a firm will be in large part contingent on employee job satisfaction. So, whilst we have witnessed an ever-burgeoning literature on servitization, scant attention has been provided to how
service provision is actually impacting those that need to deliver it and their job satisfaction. In this paper, we examine the service transition and its implications upon employees. In particular, there is a need to examine the implications of a transition towards services upon frontline staff (FLS) that are responsible for day-to-day service related activities, and, in most cases, at the coalface with the customer. Of interest are also sales employees who traditionally in manufacturing firms are responsible for the sale of products, with the sale of support services that help with the functioning of the product (Gebauer et al., 2010). Changing the business strategy towards services entails changes to the ‘dominant mindset’, which means changes to the psychological contract (Rousseau, 1995). Routines and practices for selling products tend to have become embedded and are difficult to adjust, especially given sales are incentivized in a way that potentially privileges product sales. Change is difficult. Hence, asking sales to now promote and sell services, which in the past may have given away for free (Witell & Löfgren, 2013), is no simple task; such changes rarely play out smoothly.

Most studies tend to rely on primary datasets based on surveys administered to evaluate employee satisfaction. In recent times, with the onslaught of new platforms to voice their views (via ratings and/or qualitative responses), employees - and former employees - freely provide their input when it comes to job satisfaction (Conway, forthcoming; Stamolampros et al., forthcoming; Huang et al., 2015). Such data offers potentially novel insights that would not have been captured via in-company surveys. In this study, we draw upon a novel dataset of online ratings provided by current and former employees to the job listings website, Glassdoor Inc., to examine the impact of service transition on employee job satisfaction. In so doing, we aim to address the following research question:

1. What is the impact of service transition on employee job satisfaction?
   i. What is the impact of service transition on salespeople’s job satisfaction?
   ii. What is the impact of service transition on frontline service employee job satisfaction?

We thus contribute to the servitization discussion by, firstly, providing evidence of the impact of service transition on employee job satisfaction and, secondly, by identifying and discussing the differential effect of service infusion on sales and FLS personnel.

The remainder of the paper is structured as follows: next, the theoretical background is presented, followed by our hypothesis development. After which we present our research methodology, followed by the results of the study. Lastly, we discuss our findings provide some tentative concluding thoughts.

**Theoretical background and hypotheses development**

Job satisfaction is a heavily researched domain by organizational scholars. It is argued that job satisfaction is influenced by numerous factors (Lawler 1973; Ilies et al., 2009; Judge et al., 2017). Numerous studies have been undertaken with different theoretical underpinnings when it comes to job satisfaction. There exist a plethora of definitions, models and theories that attempt to explain job satisfaction. One of the most commonly used definitions in organizational research defines job satisfaction as “a pleasurable or positive emotional state resulting from the appraisal of one’s job or job experiences” (Locke, 1976, p. 1304). We will discuss some of the most prominent theories and models briefly below.

Arguably one of the best-known studies that explains job satisfaction being an outcome of the difference between expected and perceived rewards received in one’s place of work
(Lawler, 1973). In other words, it is rewards that meet expectations that drive job satisfaction, whereas rewards that do not meet expectations lead to dissatisfaction.

Hackman and Oldham (1976) proposed their job characteristics model. In this, they argue that core job characteristics seen as inherent in all jobs include skill variety, task identity, task significance, autonomy, and feedback which motivate employees towards desirable outcomes. When employees are able to use their many skills (i.e. skill variety) in order to complete a particular product (or service) (i.e. task significance), an employee will be able to attribute meaning and value to their work. When individuals have freedom (i.e. autonomy) to determine when and how they work, then they have a sense of responsibility and of being accountable for what they are trying to achieve because they have control of their job. When other organizational members – be they senior managers, supervisors, fellow employees, team members – provide input (i.e. feedback) on the (in)effectiveness it enables employees to improve. The model of Hackman and Oldham (1976) proposes that the strength of these relationships is moderated by an individual’s desire to derive satisfaction and personal growth and development, known as ‘growth needs strength’ (see also McClelland, 1987).

Herzberg (1966) proposed the two-factor theory to understanding the causes of individuals’ satisfaction. In this theory, job satisfaction and dissatisfaction are not considered to be two polar opposites on a single dimension nor an outcome of the same factors. Different factors thus are said to account for satisfaction and dissatisfaction. Job satisfaction is said to be an outcome of drivers known as motivators that result from the conditions of the job itself. Examples of motivators include things such as responsibility, advancement growth and recognition. The drivers of dissatisfaction are known as hygiene factors and are needed to ensure workers are content with their work.

Other notable work includes Karasek’s (1979) three-dimension demand-control-support (JDCS) model that explains the stress an employee encounters at work, emphasizing the situational predictors of job satisfaction (Karasek, 1979; Karasek and Theorell, 1990). In more recent times, Judge et al. (2001a; 2001b; 2017) consider the following to be important features of job satisfaction: promotions, pay, supervision, recognition, working conditions, the organization, management and coworkers.

Overall, it is fair to say there is no clear agreement as to what accounts for job satisfaction. Although there are some common drivers for job satisfaction, there are also different drivers and factors identified in the extant literature. This shows that there are a number of ways of understanding job satisfaction.

Next, we discuss service transition and its implication for job satisfaction for sales staff and FLS employees.

Service transition and job satisfaction
An extensive body of research claims that manufacturers are increasingly transitioning towards services and solutions as part of their offerings (Neu and Brown, 2005; Fang et al. 2008; Kowalkowski et al., 2012; Wise and Baumgartner, 1999; Storbacka, 2011). For example, the construction equipment company Caterpillar has increasingly infused services into its product offering - such as spare parts support, maintenance, “negative downtime” concept where customer only learns of an issue with equipment once it has been repaired – to meet customer needs. To date, much of the literature has focused on the strategic aspects of transitioning to service (Gebauer et al., 2010; Josephson et al., 2016; Patel et al., 2019), design considerations for firms (Foote et al., 2001; Davies et al., 2006; Raja et al., 2018), and financial performance (Eggert et al., 2014; Fang et al., 2008; Visnjic and van Looy, 2013; Visnjic et al. 2016; Visnjic et al., 2019).
Although the transition to services is an area that is receiving increasing attention, the pursuit of a service strategy and the implications this has upon employees has largely been neglected. It goes without saying that service transition is likely to have implications on the role of staff inside organizations. For example, salespeople who are accustomed to selling products will also be expected to promote and sell services. Although this may seem straightforward, it is anything but. Changing the routines that sales staff become accustomed to, measured upon are fraught with difficulties. In some cases, this has led to some arguing that firms are better off creating new service organizations with sales staff purely dedicated to selling service, or at least so that they are service-savvy (Reinartz and Ulaga, 2008; Ulaga and Loveland, 2014). Similarly, delivering service requires customer-facing FLS personnel. For many companies, they may already possess a field service workforce, though infusing greater service will mean expanding the demands that are placed upon the staff. In other cases, it will be a case or recruiting anew FLS personnel to meet customer needs and realize the service strategy. Of particular interest here is what such changes mean for employees in terms of their roles and resultant effect on job satisfaction for sales and FLS personnel.

We therefore examine the following hypothesis:

**Hypothesis 1:** As the level of service infusion increases, there will be a decrease in the job satisfaction of the non-customer facing employees

**Hypothesis 2:** There will be a U-shaped relationship between the level of service infusion and the satisfaction of salespeople

**Hypothesis 3:** There will be a U-shaped relationship between the level of service infusion and the satisfaction of salespeople

**Methodology**

**Sample and data collection**

The focus of this study is on manufacturing firms with primary 3-digit North American Industry Classification System (NAICS) codes between 333 and 336. These include manufacturers of machinery (333), computer and electronic products (334), electrical equipment, appliances and components (335) and transportation equipment (336). These are the industries in which servitization has been most prevalent according to the literature, seemingly due the properties of the manufactured products (relatively long-life and complex). The strict focus on manufacturing industries that are clearly conducive to servitization excludes companies that are practically unlikely to sell product-service offerings due to the nature of their products (e.g. paper product manufacturers), while it indirectly controls for industry-level factors that could confound the relationship between the extent of servitization and satisfaction with one’s employer.

Following prior research (e.g. Fang et al. 2008; Visnjic et al. 2019), as a proxy for the level of service transition of a manufacturer at any point in time, we compute their ‘service ratio’ (Fang et al. 2008). This is the proportion of a manufacturer’s total revenues in a year that comes from service activities. To obtain the required data, we use COMPUSTAT Business Segments because it provides time series of firm revenues from different business operating segments. For any given firm, the definition of the operating segments and the allocation of revenues between them is self-reported by the management team. Despite this disadvantage, this is the most common (and possibly, only) way to track a firm’s service transition over time. From the description of the operating segments and their associated NAICS code, we categorize them into service and nonservice, following the procedures specified in Visnjic et al. (2019). For a given firm in a given
year, the service ratio is the quotient of the division of the sales revenues from all service business segments by the total revenues.

To obtain measures of an employee’s satisfaction with their employer, we match our dataset with data supplied by Glassdoor, a job search engine and review website. We specifically utilize the ‘overall satisfaction’ rating, as well as satisfaction with four employment aspects: ‘compensation and benefits’, ‘career opportunities’, ‘work-life balance’ and ‘senior leadership’. All ratings range from 1 to 5, and we extract only those that come from employees (both former and current) of the manufacturers in our sample. Employee reviews begin in 2008, so this comprises the first period in our timeframe. We use the aggregate role categories, as specified by Glassdoor, to identify sales and frontline service employees, with all the rest being classified as ‘all other’ non-customer facing employees. Accordingly, roles such as ‘sales representative’ and ‘field sales manager’ are classified as salespeople, while ‘customer service’ and ‘field services’ are classified as frontline service employees.

Several variables that could affect both the extent of servitization of the company and the satisfaction of its employees, are included in the models as controls. These include firm size (total sales and number of employees), profitability (ROA), R&D expenditure, overall performance (Tobin’s Q), as well as industry (primary 3-digit NAICS code) and a linear time trend. Crucially, some manufacturers have begun their servitization ‘journey’ long before 2008, while others start reporting revenues from services only after 2008. We control for this using a dummy variable, as one could expect that the accumulated experience of providing product-service offerings (prior to the year we first start observing) may have helped senior management teams to implement policies and measures to address issues faced by their sales and service employees.

Analysis

As our dependent variables are naturally ordinal, the appropriate econometric models are the ordered logit and ordered probit. In the five models (one for overall satisfaction and one for each of the four separate aspects), the minimum number of observations (i.e. employee ratings) is 39822 (from 586 firms), and the maximum 41301 (from 595 firms). The 3-level categorical variable of job function enters our models as a set of two dummy variables, with the ‘all other’ category being the reference level. Crucially, to test our hypotheses, we interact these two dummies with the service ratio (and its quadratic term).

Results

Table 1 contains the main results of this work. The dependent variables in the five presented models are the ordinal scales of overall satisfaction (model 1) and the four separate aspects captured by Glassdoor: employee satisfaction with their compensation and benefits; the senior leadership in the organization; the career opportunities provided; and their work-life balance (models 2-5).

* $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$
The results can be summarized as follows:

- As service infusion increases, non-customer facing employees become increasingly unlikely to report a higher level of satisfaction with their compensation and benefits. There is no statistically significant effect of service infusion on the likelihood of higher overall satisfaction (or any other aspect).

- Compared to non-customer facing employees (the reference level), the likelihood that salespeople will report a higher level of overall satisfaction (and satisfaction with any other employment aspect) exhibits a (steeper) U-shaped relationship as service infusion increases. This is illustrated graphically in Figure 1, which presents the predicted probabilities of reporting a ‘5’ (the highest level) for the different aspects of employee satisfaction when the service ratio increases by 10% at a time. An interesting additional finding is that salespeople seem to be more likely to feel very satisfied when their employer is a pure product provider (service ratio = 0%) or fully ‘servitized’; namely, when the firm is 100% focused in either side of the product-service continuum.

- The form of the relationship between service infusion employee satisfaction FLS personnel with their employer is not significantly different compared to the base-level. However, they remain the most unlikely to report higher levels of satisfaction as service transition progresses (Figure 1) and seem to feel less satisfied with all aspects related to their employment. In addition, one can notice that for a fully servitized firm (service ratio = 100%), the predicted probability that a sales person will report a high level of satisfaction with any aspect of employment is about double compared to a FLS employee.

![Marginal effects of service infusion](image)

*Figure 1 – Marginal effects of service infusion*
Discussion and contribution

This study contributes to the emerging body of work examining the implications of service transition upon employees. Specifically, this work has implications for the design of sales and FLS roles, and how to manage these individuals during service transition. The results suggest a differential effect of service transition for sales and FLS personnel. It is noteworthy that for the sales personnel role, the firms have managed to, over time, address the initial drop in satisfaction. In contrast, the situation for FLS personnel roles is bleaker; especially when it comes to ‘compensation and benefits’ the results indicate that these employees are increasingly dissatisfied, with little sign of recovery. As such, we raise important questions for addressing the job satisfaction levels of all staff, but specifically those in FLS positions. We argue that low job satisfaction may explain the high propensity for those firms transitioning to services to experience difficulties or, in some cases, bankruptcy (cf. Benedettini et al. 2015).

Abstract

This research attempts to identify key staged-performance indicators from new service development stages and tie them to modes of innovation and performance. The empirical results indicate that three modes of innovation coexist in IT service innovation. The relationship between business model innovation and financial/non-financial performance is mediated by development and deployment performance. While development and deployment performance can mediate the relationship between process innovation and non-financial performance, they exert no mediation effect on the relationship between process innovation and financial performance. None mediation effect of development and deployment performance is found between product innovation and either financial or non-financial performance.

Keywords: modes of service innovation; service innovation stage; cost/time; functionality/service experience; financial/non-financial performance
Instruction
After decades of development, services have become the dominant sector and the most effective engine of the world economy, as evidenced by its 65.08% share of the world’s gross domestic product (The World Bank Data, 2017). Under this trend, numerous service firms emerge and manufacturing firms that historically focused on providing products begin to add accompanying services to their products for higher profit margins (Visnjic, Wiengarten, and Neely, 2016). Due to the unique characteristics of intangibility, heterogeneity, perishability, and inseparability of services, service demands are highly diversified, personalized, unstable, and unpredictable. Being continuously innovative is imperative for service firms to attract customers, gain competitiveness, and remain in business. However, from the back end, the outcome of service innovation is not that satisfactory as we anticipated. The success rate of service innovation is not high, and firms’ performance is not necessarily guaranteed by service innovation. The reasons for this tension between service innovation and its outcome may lie in the way of innovation performance measurement.

Firstly, after three decades of development, the studies of service innovation have expanded from broad in scope to specific in detail to bring about several key antecedents of service innovation performance (Storey and Perks, 2015). While those antecedents already cover multifaceted factors related to organization structure, organization strategy, innovation strategy, innovation efficiency, internal communication, external partnerships, and etc. (Storey et al., 2016), systematic examination between innovation success and modes of service innovation is less well understood (Wang et al., 2015). Since different modes of innovation have different objectives, appear in different domains, exhibit diverse innovativeness, require heterogeneous resources, involve distinct external partners, and are launched in different environments (Voss and Zomerdijk, 2007), the development patterns and performance outcomes derived from different types of service innovation are likely to be different (Avlonitis et al., 2001).

More importantly, although researches have already recognized that service innovation performance is a multidimensional concept (Cheng and Huizingh, 2014), historically, the majority of performance-related studies only focused on different dimensions of the final performance (either commercial success or strategic competitive advantage), ignoring important intermediate performance dimensions and their associations with final performance in the service innovation process (Storey et al., 2016).

Against this background, the purpose of this study is to answer the research question: “What is the staged performance model for different modes of service innovation?” That is, this research attempts to identify key staged-performance indicators derived from new service development stages and tie them to modes of innovation and final performance for the first time. More specifically, this study focuses on two staged performance from the development stage (development performance) and deployment stage (deployment performance) of the service innovation process. The development stage has two dual objectives: efficiency (time/cost) and effectiveness (functionality/experience), the development performance has two dimensions (Carbonell et al., 2009) (see Figure 1).
Theoretical development and hypotheses

**Modes of Service Innovation**
In this study, we employ Voss and Zomerdijk’s (2007) typology because it clearly distinguishes service innovations occurred in different levels and domains of an organization which is most applicable to our research design. Service product innovation involves the introduction of new service products, which could be one of the following: new to the market, new to the providing firm, new to customers, service product line extensions, bundling or unbundling of existing service products, modifications or repositioning of an existing service product (Voss and Zomerdijk, 2007; Wang et al., 2015). Process innovation focuses on changes in the internal organizational processes to increase firms’ efficiency and effectiveness to produce and deliver products or services (Piening and Salge, 2015). Service process innovation primarily takes place in the operational areas of the service system, including significant changes in the way of information exchange or interface between the service provider and its customers, and the back-office processes or internal organizational structure that can increase the efficiency to develop and deliver innovative services (Zomerdijk and Voss, 2011). A business model outlines the technologies and features in a firm’s product/service, the architecture of revenues, costs and profits associated with the firm developing it, and the mechanism of how the firm delivers the value of the product/service to customers (Teece, 2010). Compared with product and process, the design of business model is more fundamental to a firm’s competitiveness since it not only defines a firm’s product and operation process, but also how to allocate a firm’s asset or resource to fulfill customer needs and convert payments received into profits (Teece, 2010). Thus, the innovation of business model involves both a significant or even complete change in the way firms earn their revenues and the corresponding product and organizational arrangements made to accompany with the change (Voss and Zomerdijk, 2007).

**A Staged Performance Perspective towards New Service Innovation**
Johnson et al. (2000) capture the basic shared steps in previous service innovation process literature and propose four general stages of service innovation: design, analysis, development and full launch. Every firm begins its new service development process from the design stage and puts a great effort to it. The aim of this stage is to generate an idea with the greatest potential and design corresponding strategies and objectives. Then, in the analysis stage, any idea that can eventually be commercialized into a service product is perceived to have potential in
profitability in these two stages according to the specific evaluation system of an organization.

The tasks at the development stage are to allocate resources to develop and test the functionality of the core service, associated delivery system, and marketing program; train operation and delivery personnel, and get internal and external feedbacks to refine the offering (Melton and Hartline, 2010). Naturally, the more resources and efforts put into the development process, the better the functionality or customer experience of the service. Thus, firms need to achieve a tradeoff between efficiency (cost/time) and effectiveness (functionality/experience) at this stage based on their own capability and market competitiveness. Similarly, proficiency in the deployment and launch stage increases the efficiency of adoption and delivery of the innovation both within the firm and outside to customers which are conducive to assess internal and external reactions (Wang, Voss, and Zhao, 2018).

Hypotheses
For incremental service product innovations in the case of improvements, modifications, repositioning, or line extensions, firms are familiar with the original service, its technology, design, pricing and marketing programs (de Brentani, 2001). This can significantly reduce the difficult, effort, and cycle time needed for the project in the development stage and facilitate firms to develop comparatively advantageous services in a timely manner (Song and Montoya-Weiss, 2001). By contrast, when undertaking service product innovations with dramatic departure from current services, more trial, time, resources, learning, breakthrough technology, employee training, internal synergy, and external partner collaborations are needed to solve design and develop problems (Wang et al., 2015).

By significantly changing the back-office processes and organizational structures supporting the front-end processes, process innovation increases the efficiency of inter-functional communication and coordination between different departments within the firm (Wang et al., 2015). Business model innovation is the most disruptive innovation in organizations and involves substantial or even complete changes in the way firms convert revenues into profits (Markides, 2006; Voss and Zomerdijk, 2007). Thus, business model innovation typically leads to a better performance on the functionality of a firm’s service, but may not do good on the cost and time efficiency of the service. Here, we predict:

H1a: Incremental service product innovation is positively associated with the efficiency dimension (cost/time) of development performance.

H1b: Radical service product innovation is negatively associated with the efficiency dimension (cost/time) of development performance.

H1c: Service process innovation is positively associated with the efficiency dimension (cost/time) of development performance.

H1d: Service business model innovation is negatively associated with the efficiency dimension (cost/time) of development performance.

Incremental service product innovations are typically improvements or modifications which gradually remedy service insufficiency, recover customer complaints, and repair technology bugs and ultimately contribute to a continuous slight improvement of the functionality/experience of the service product. On the contrary, radical service product innovations are typically supposed to either meet customers’ specific requirements that can’t be met previously due to technology or resource constraints or create a totally new type of
Through efficient customer communication enabled by process innovation, firms can also get valuable feedbacks about their defects in the after-sale service and service remedy policies of existing services and use these to increase customer service in future service development (Chen and Tsou, 2012). Regarding business model innovation, since it can thoroughly change both the service and the way customers consume the service, it will bring customers a novel service experience that they have never experienced before (Amit and Zott, 2001). Based on all this, we posit:

**H2a:** Incremental service product innovation is positively associated with the effectiveness dimension (functionality/experience) of development performance.

**H2b:** Radical service product innovation is positively associated with the effectiveness dimension (functionality/experience) of development performance.

**H2c:** Service process innovation is positively associated with the effectiveness dimension (functionality/experience) of development performance.

**H2d:** Service business model innovation is positively associated with the effectiveness dimension (functionality/experience) of development performance.

As the world economy becomes more service oriented, firms compete fiercely on new service offerings (Bitnet, Brown, and Meuter, 2000). If a firm can develop a new service faster and with less costs than competitors, it will have enough time and resources to transfer the service across all appropriate intrafirm departments and external lead customers in the deployment and launch stage. In a similar vein, when a new service has preeminent functionality, it must be designed and developed properly based on in-depth market research, superior organization resources, and state-of-the-art technologies (Song, Song, and Di Benedetto, 2009). Careful development of the value proposition ensures that the service can deliver value correctly to both internal and external target users (Crawford and Di Benedetto, 2006). It is easy for the service innovation both to be deployed and diffused inside the firm to synergetic supports from different departments and get feedbacks from external users to refine the new offering. As a result, we postulate:

**H3a:** The efficiency dimension (cost/time) of development performance is positively associated with deployment and launch performance.

**H3b:** The effectiveness dimension (functionality/experience) of development performance is positively associated with deployment and launch performance.

Better intrafirm deployment enables different departments within the firm have an adequate understanding of the service innovation, reducing the difficulties in justifying the necessity to allocate managerial resources and exert synergetic efforts to support the launch and after-launch activities of the new service (Wang, Voss, and Zhao, 2018). Externally, early delivery to lead and other potential customers provides the firm an opportunity to collect initial market reactions to the proposed service and make sufficient adjustments to ensure the service addresses customer needs correctly at full launch (Song, Song, and Di Benedetto, 2009). Early delivery to market and sufficient managerial support facilitate the firm to grab market share and achieve superior benefits ahead of competitors. Accurate service proposition and perfect after-sales service also improve customer satisfaction and loyalty toward the service provider.

Moreover, the more proficiently the intrafirm deployment and refining is undertaken, the better the value proposition of the new service will be (Wang, Voss, and Zhao, 2018).
Subsequently, superior value proposition of the new service increases the target market’s acceptance to the service and gradually locks customers in the service. Due to the high searching costs and switching costs for customers to switch to another service provider, the firm can charge a relatively high price for premier benefits which ultimately lead to a better financial performance. Moreover, comfortable service experience derived from the superior functionality of the service that cannot be provided by other service providers increases customers’ satisfaction and commitment to the certain provider as well. Thus, we suggest:

\[ H4a: \text{Deployment and launch performance is positively associated with financial performance.} \]

\[ H4b: \text{Deployment and launch performance is positively associated with non-financial performance.} \]

**Method**

To design the measurement items, we invited three operations management professors and one marketing professor, all of whom were actively involved in teaching and research in Chinese and Western universities. 60 managers of service innovation projects were invited to pilot-test the questionnaire, and face-to-face interviews were conducted with them. 1000 companies were randomly selected from the four first-tier cities in China, namely Beijing, Shanghai, Shenzhen, and Guangzhou. The sampling pool consisted of the service firms listed in the database of National Bureau of Statistics and headquartered in any of the four cities. In total, the data collection efforts resulted in usable responses of 200 service innovation project from 141 companies for a response rate of 14.1%.

We used the bootstrapping-based partial least squares (PLS) approach to structural equation modeling (SEM) to test the overall model and relevant hypotheses. PLS simultaneously assesses the quality of research constructs and the proposed relationships between constructs, and has been widely adopted in business research fields such as operations management, information systems, and marketing.

Results show that incremental service product innovation exerted a significant positive effect on development efficiency \((\beta = 0.196, p < 0.01)\). Radical service product innovation, service process innovation and service business model innovation exerted a nonsignificant positive effect on development efficiency respectively \((\beta = 0.088, p = 0.381; \beta = 0.111, p = 0.261; \beta = 0.139, p = 0.238)\). As such, \(H1a\) was supported while \(H1b, H1c, H1d\) were not supported.

Incremental service product innovation and service process innovation exerted a nonsignificant effect on development effectiveness respectively \((\beta = 0.075, p =0.345; \beta = 0.098, p =0.267)\). Radical service product innovation and service business model innovation exerted a significant positive effect on development effectiveness respectively \((\beta = 0.163, p < 0.10; \beta = 0.173, p < 0.05)\). As such, \(H2b\) and \(H2d\) were supported while \(H2a\) and \(H2c\) were not supported.

Further, both development efficiency and development effectiveness exerted a significant positive effect on deployment and launch performance \((\beta = 0.251, p < 0.001; \beta = 0.356, p < 0.001\) respectively). \(H3a\) and \(H3b\) were thus supported.

Finally, deployment and launch performance exerted significant positive effects on both financial performance and non-financial performance \((\beta = 0.569, p < 0.001; \beta = 0.441, p < 0.001\) respectively), supporting \(H4a\) and \(H4b\).
Conclusion and Discussion

In recent years, the service sector has become dominant in economy and service firms compete fiercely in new offerings (The World Bank Data, 2017). Given the growing popularity of new service innovation activities and the complex outcomes of service innovation, this study attempts to build a staged-performance model for service innovation. The main objectives of this study were to identify key staged performance indicators derived from the new service development process, tie them to modes of innovation and final performance (financial and non-financial), and explore the mediating effects of those staged performance indicators between modes of service innovation and final performance.

Theoretical implications

To start with, this study highlights the importance to see service innovation performance in a staged model. Our study, by providing a staged model with multiple performance indicators, points out the need to assess innovation performance from an overall staged perspective since service innovation performance not only contains different dimensions, but also presents in a sequential way. The empirical results of our results suggest that different modes of service innovation first impact development performance, then deployment and launch performance, and ultimately financial and non-financial performance.

Further, we enrich the extant research on service innovation by showing that different modes of innovation have different staged performance model. Although previous study has already pointed out that different types of innovation may be associated with different development patterns and performance outcomes, relevant framework concerning such associations is still lacking (e.g., Avlonitis et al., 2001). Our study, by providing non-significant empirical evidence, points out that process innovation cannot improve development performance directly. Lastly, service business model innovation was found to be significantly associated with effectiveness (functionality) but not with efficiency (cost/time) of development performance.

Third, this study also explored the mediation effects of development performance and deployment and launch performance between modes of service innovation and final performance. Regarding development performance, its efficiency (cost/time) dimension fully mediates the relationship between incremental service product innovation and deployment and launch performance. And its effectiveness (functionality/experience) dimension fully mediates the relationship between service business model innovation and deployment and launch performance. These results provide favorable evidence for the argument in existing literature about the importance of the proficiency in development stage of service innovation (e.g., Song, Song, and Benedetto, 2009), especially for incremental service product innovation and service business model innovation.

Managerial implications

First, managers frequently confront a question: whether a new service idea can bring benefits to a firm after launched to the market? The findings of this study suggest that they should evaluate service innovation performance in a staged way. For instance, a poor final financial performance or non-financial performance do not necessarily mean that the service idea does not meet market demands. It is likely due to the poor execution and performance in the
Second, managers should pay attention to the modes of service innovation when assessing the intermediary performance indicators in the staged model because different modes of service innovation impact these indicators differently. The most challenging job for managers is the performance evaluation of service process innovation due to its insignificant direct effects on both efficiency and effectiveness of development performance. A possible solution is to indirectly examine process innovation’s ability in helping firms to acquire, integrate, and disseminate knowledge and resources.

Finally, this study is the first to identify the mediating effects of development performance and deployment and launch performance between modes of service innovation and final performance. This inspires managers that for a better final performance (both financial and non-financial), resources and attentions should be made to achieve high-quality development activities and deployment and launch activities in service innovation since only through well development activities can service innovation ideas be deployed and launched to both internal users and external customers, and only through well execution of deployment and launch activities can efforts made into development activities be transferred into final financial and non-financial performance.

Limitations and Future Research
First, this study used data from IT-related service industries only. Therefore, the results found in this research are tentative and subjective to characteristics of IT services. Further replications efforts are needed to test the conceptual model and relevant hypotheses in other service settings, such as personal services, professional services, or tangible products related services to advance the literature. Likewise, the cross-sectional nature of the data may cause biased results. Longitudinal data, multiple informant data, or data from multiple sources are therefore required in future studies to verify the results of this study. Third, our sample is constrained to the Chinese firms. Thus, the generalization of the results in other areas beyond China should be made with caution.

Lastly, in the empirical analysis of this study, we captured modes of service innovation from 170 innovation projects from IT-related service industries and then explored the individual effect of each mode on different staged performance indicators. However, as suggested by existing literature, different modes of innovation can coexist in a same innovation project (Wang et al., 2015) and exert synergetic effects on innovation performance (Visnjic, Wiengarten, and Neely, 2016). Considering the sample size and the complexity of the conceptual model, we neither proposed nor tested the interaction effects of different modes of innovation this time.

Abstract

The organisational transition from products to engineering services requires manufacturers to enable various changes at the organisational and individual level. The purpose of this paper is to investigate the individual level of servitization starting from understanding different strategic stages of transition. Based on an initial theoretical review of the literature on servitization, service operations and organisational psychology, we propose a conceptual framework that details organisational transition stages and the employee-related aspects. Providing an employee perspective of the transition could facilitate the overall transition by enabling managers to identify those aspects that require their attention and develop suitable strategies.

Keywords: organisational transition, engineering services, employees.

Introduction

Many manufacturers face organizational transitions to becoming increasingly service-focused (Vandermerwe and Rada, 1988) and customer-focused (Ahamed et al., 2013). This organizational transition has often been described under the keyword servitization. Organizational transitions require attention to the organizational level changes and the individual employee-level changes (Rese and Maiwald 2013).

Current research provides extended insights into the organizational level of servitization as the company strategy (Rabetino et al., 2017) and the organisational culture (Nuutinen and Lappalainen, 2012). The “organisational transformation” (Bustinza et al., 2017) or the “service journey” (Martinez et al., 2017) has been discussed as a process of integrating products and services in the business model of the company rather than a specific transition from offering products to offering services (Peillon et al., 2015). In this way, manufacturers that started adding basic services to their business models, later on,
based on their resources, could enlarge their offerings with advanced services in a process of integrating basic and advanced services in the portfolio (Benedettini and Neely, 2018). For the purpose of this paper, we decided to label the servitization process as the “organisational transition from products to engineering services” because we are interested in exploring and explaining different characteristics of the process as well as enabling managers to identify and use what is relevant for their specific transition (Bustinza et al., 2017; Lütjen et al., 2017). The label “engineering services” is used to describe both basic and advanced services due to their industrial approach and their common use in the manufacturing sector (Steinmann et al., 2014).

What is missing in the current literature are explanations of the individual level of servitization, with a focus on the employees implication (Rese and Maiwald, 2013). For a service integration, relevant support from individual employees that are expected to engage in the process is one of the key points (Bel et al., 2018). For example, the selling of services depends on people in relevant positions and, having the focus on employees’ skills and motivations is another key point for the transition (Kanninen et al., 2017). Moreover, authors have called for research to investigate the individual aspects that lead people to a specific behaviour in different stages of servitization (Lenka et al., 2018). In order to further the research interested in the individual level of transition we investigate the following research question:

What are the employee-related aspects that need to be considered in different stages of the transition towards engineering services provision?

This research proposes a conceptual framework that is aimed at providing guidance for further empirical investigations. We present an initial literature review to develop this conceptual framework.

Research method
In order to investigate the relevant stages of the transition towards the servitization and the employee-related aspects specific for each stage, we conducted an unsystematic theoretical review that enabled us to combine insights from theoretical and empirical studies (Paré et al., 2015). Considering the organisational transition as being specific for each organisation, we investigated strategic stages that could be relevant for different manufacturers due to their general approach. Starting from investigating the servitization literature and understanding the specific of the transition stages we linked, in an iterative process, two of the stages of servitization identified by Vandermerwe and Rada (1988) with three of the most frequent strategic stages identified in a review conducted by Martinez et al. (2017). For providing the employee perspective, we investigated the case studies concerning the servitization process, empirical studies that researched the employees as the operational resource of the company and a theoretical paper that proposed an orientation towards the individual level of servitization. Based on the specific of the change, we linked those specific employee-related aspects to each stage. Furthermore, general aspects that support the transition as different types of commitment and the individual change experience have been investigated in empirical and theoretical papers.

In the following sections of the paper, the stages of transition identified in the literature are described and insights into the employee-related aspects are provided.
Organisational transitions towards engineering services

The integration of services into the company portfolio is a long term process that involves different stages (Peillon et al., 2015) and consists of different models of change (Martinez et al., 2017). Vandermerwe and Rada (1988) explained the companies’ patterns as starting with a focus on only one of the offerings, products or services, which is followed by integrating those offerings in a package, and finally offering packages of services that cover the customer needs.

Following these descriptions, research papers offered a large overview of transition stages. Martinez et al. (2017) reviewed several examples and defined the servitization as happening in strategic and operational steps. The authors concluded that most of the companies’ strategic stages started with adding services related to their products. In this stage, companies are introducing into their portfolio, operational services that usually help the customer process of installing and maintaining the products (Salonen, 2011). For some companies, the services related to products, as delivery, are not creating revenue due to the lack of value awareness (Reinartz and Ulaga, 2008). In order to, build an image as provider of both products and services, the company undergoes the second most discussed strategic stage identified by Martinez et al. (2017), the development of a service culture. For manufacturers, this stage implies changing the mindset of stakeholders from offering products to providing solutions as a result of a long-term process of including the service values alongside to their core values (Gebauer et al., 2006). The following stage concerns the preparation of the product-services that should be included into the company’s portfolio (Martinez et al., 2017). The main focus here is on understanding the customer activities and needs (Lim et al., 2012) and could be similar to the last stage explained by Vandermerwe and Rada (1988). The last strategic stage describes the process of testing the design of the services (Martinez et al., 2017) and is not described in this paper as is more related to the service than the organisational transition. The operational level of transition includes mainly aspects related to internal level of the company as employees (Martinez et al., 2017).

Based on these investigations, the organisational transition of servitization can be conceptualised in three stages as depicted in Figure 1.

![Figure 1 - Strategic stages of the organisational transition towards servitization](image)

The first stage focuses on offering engineering services as a distinct business opportunity. In the process of adding engineering services to the main offerings of the company, the specific of the company - customer interaction shifts from “product provision – payment received” to developing continuous engagement around the service provision. The specific of the engineering services within this stage is related to the core product (Gebauer et al., 2006) hence the relationship between company and customers requires a low level of interaction (Salonen, 2011). In order to provide this type of engineering services, organisational capabilities that support the mutual engagement are required (Oliva and Kallenberg, 2003; Davies, 2004). This often involves the creation of a new service department including own performance metrics, local service culture and separate value stream with employees who specialise on the provision of engineering services and (Oliva and Kallenberg, 2003). The process of evaluating the company’s
offerings requires new performance metrics suitable for both products and services (Martinez et al., 2010) and performance indicators for employees (Gebauer et al., 2006).

The second stage focuses on building a service culture. Evaluating the organisational culture provides evidence for the overall image of the company (Nuutinen and Lappalainen, 2012) and the specific view of manufacturers as product providers is one of the main challenges in the transition process (Martinez et al., 2010; Dubruc et al., 2014). This includes internal standardisation and optimisation of service-related processes, including service provision, service development and sales. The aim is to have a standardised service portfolio that reflects organisational standards and image.

The third stage focuses on building a customer culture where customer needs are the basis for the provided and new service offerings (Marques et al., 2013). This requires manufacturers to restructure their value stream around the provided customer value rather than internal capabilities and processes (Martinez et al., 2017). Long-term and deep customer relationships are required to access the information needed for this purpose (Kreye et al., 2015).

**Employee-related aspects in the service transition**

The employee related aspects distil down to aspects that are specific to the transition stage, i.e. which one of the three transition stages described above the organisation is in, and general aspects that apply to any organisational change or transition. This section describes these elements in two separate sub-sections.

*Transition-stage specific employee aspects*

In the first transition stage (offering engineering services), the differences between production and service provision affect the employee-related aspects. The quality of services helps companies to build their external image as a trustworthy service company (Oliva and Kallenberg, 2003). As far as the employees are concerned, having the necessary knowledge and the required skills, among other aspects, helps their individual readiness for organisational change (Hanpachern et al., 1998). Baines et al. (2013) noted six sets of skills relevant for employees involved in advanced services, which cover activities related to the customer interaction or the technical aspects, depending on their role. These skills include employees’ soft skills and improve the way services are delivered (Antioco et al., 2008). In addition to having the necessary skills for services, employees need an appropriate motivation that supports the service provision (Kreye, 2016). This implies that, with the new requirement, rewards systems should support the service provision and motivate people involvement.

In the second transition stage (building a service culture) where the service strategy is integrated within the wider organisation, a wider circle of employees is affected by the organisational transition. This includes employees that affect the service value stream including otherwise product-focused departments such as planning, IT, logistics and marketing departments. Employees in these areas are expected to adapt their mindset to services as one of the offerings of the company (Martinez et al., 2010). Difficulties arise because the required mindset is related to the role of the employee and being involved in the product-related unit of the organization could hinder the collaboration with employees that are involved in the services (Rese and Maiwald, 2013). Organisational identity consisting of sharing the same purpose and standards as well as the shared identity with the subunit expressed as feeling a collective effort and responsibilities (van Dick et al., 2018) is an aspect that should be considered in this stage. Organisational identity may still consist of a product-focused mind-set and integrating a service-related identity can cause resistance and tensions (Huy, 1999).
In the third transition stage (establishing a customer focus), front-line employees are the starting point for organisational innovation of the service business and are, thus, not only an operant resource (Kreye, 2016; Martinez et al., 2017), but also a creative resource (Laperche and Picard, 2013). This means that front-line employees such as sales staff and service engineers have to not only adjust their behaviour according to the individual customer (Bowen and Ford, 2002), but also function as a source of information and inspiration for internal service innovation activities. This requires internal information processing to identify new value potential through tracking and understanding changing customer requirements as well as translating these into offerings. The type of relationship between customer and employees, could constitute the premise for increasing employees motivation through feedback from the customer (He et al., 2015).

General aspects involved in the transition
General aspects involved in organisational transformations are commitment and experience with changes, either influencing people support or resistance towards the change.

In general, commitment is explained as a force “experienced as a mind-set (i.e., a frame of mind or psychological state that compels an individual toward a course of action)” (Meyer and Herscovitch, 2001, p.303). Meyer and Allen (1991) model of organisational commitment explained three dimensions of commitment based on their specific triggers. This model includes, the affective commitment of individuals presented as the emotional investment and willingness to be part of the organisation, the continuance commitment associated to the cost felt by people for the turnover behaviour and the normative commitment driven by rewards in advance or investments that lead to the feeling of duty. Herscovitch and Meyer (2002) found out that the supportive behaviour towards the change could be explained by people organisational commitment towards the change rather than by their general commitment to the organisation. The authors explain that people’s emotional implication in the change process (affective commitment), their sense of duty and responsibility towards the change (normative commitment) the lack of choice and the pressure associated with resistance (continuance commitment) determines them to approve the transformation. However, only the first two dimensions influence people effort in supporting the changes, implying that not having an alternative will not make them supportive.

Furthermore, people experience in terms of their expectations and openness to change. The negative valence of personal experience related to changes in the organisation can cause doubt about the organisational success to implement change due to the inability of managers (organisational cynicism) and a diminished level of openness to change (Bordia et al., 2011). In other words, previous failures of organisational changes influence employees’ opinion about the management capabilities and motivations for change. Bordia et al., (2011) concluded that, this lack of trust in the change efforts, increases to the negative feelings and diminishes the willingness to support the process of change. In addition to the negative personal experience, people assumptions could influence their behaviour. Ford et al. (2002) noted different types of conversations about changes that shape people expectation and lead to different type of resistance. In this context, authors explained that the background conversation about the company traditional way of succeeding (complacent background) increases people expectations to success in the same way and not interfere with the routine. As far as the conversation about the failures of previous changes are concerned, attributing this lack of success to internal (resigned background) or external aspects (cynical background) leads to specific negative expectation about the people or company resources for succeeding (resigned
background) or about the possibility of anyone to succeed with this change (cynical background). As a result, people resistance is driven by the specific nature of each employee’s background.

**The proposed conceptual framework**

Based on the above considerations, we propose a conceptual framework of the employee-related aspects of the organisational transition towards engineering services in three stages: offering engineering services, building a service culture and establishing a customer focus. For each stage, we propose employee-related aspects that could facilitate the understanding of the individual level of servitization. Figure 2 summarises the proposed framework with concepts explained above.

**Figure 2 - The conceptual framework of the organisational transition towards servitization**

**Conclusion and further directions**

The aim of this paper was to identify those employee-related aspects relevant in the manufacturers’ transition towards providing services. In order to enable the research of those specific aspects, we proposed the following research question: *What are the employee-related aspects that need to be considered depending on the stage of the transition towards engineering services provision?* Theoretical and empirical papers provided us insights and concepts that facilitate the development of a conceptual framework of the employees’ side of the organisational transition towards the services provision.

The proposed conceptual framework represents a starting point for investigating the individual level of servitization in a structured process. Due to the theoretical approach,
the employee-related aspects could be considered only as preliminary outcomes that need further investigation. Further research consists on exploring the requirements from different types of stages of the transition and their impact on the employees’ level. Understanding individual aspects that influence people behaviour during the transition offers the possibility to predict and overcome internal resistances with specific strategies.

Abstract

This study theoretically articulates and empirically tests a model of the role played by advanced services (ADS) in supporting a business strategy based on product and service differentiation, taking into consideration the complexity of the business environment. Based on survey data from 931 manufacturers, we find that: i) environmental complexity has a positive impact on strategic focus on product and service differentiation; ii) strategic focus on product and service differentiation, but not environmental complexity, have a positive impact on ADS; iii) ADS have a positive impact on service differentiation advantage, but not product differentiation advantage.

Keywords: servitization, advanced services, competitive advantage.

Introduction

Manufacturing firms increasingly realize the strategic importance of service in achieving competitive advantage based on differentiation (Baines et al., 2017). Despite this, our understanding of the strategic and competitive role played by servitization is still incomplete (Bustinza et al., 2015). A telling manifestation of this is that research on the impacts of servitization on firm performance remains inconclusive, with several studies having revealed that these impacts are more complex and fine-grained than originally envisaged (Kastalli and van Looy, 2013; Eggert et al., 2014; Forkmann et al., 2017; Sousa and da Silveira, 2017). Specifically, we lack a more comprehensive theoretical articulation of how servitization can support a differentiation strategy in manufacturing firms. Ascertaining whether and under which conditions servitization supports differentiation advantage is essential for justifying such strategies’ effectiveness (Sousa and da Silveira, 2018; Voss et al, 2016).

To address this research gap, our study theoretically articulates and empirically tests a model of the role played by servitization in supporting a business strategy based on product and service differentiation. In doing so, we focus on the offering of Advanced Services (ADS), because the potential for differentiation lies with this type of services, rather than with Basic Services (Sousa and da Silveira, 2018).
Theoretical background
Advanced services and differentiation
ADS support the customer’s actions in relation to the product and the adaptation of the product use to the customer’s unique needs, usage situations, and behaviors (Eggert at al., 2014; Smith et al., 2014). Examples include training in using the product, product upgrades (to fit customer needs), consulting, and product rental. ADS are relational-oriented, involve significant co-creation of value with customers (influencing and sometimes managing their processes of value creation), intense interactions with the customers, and are often complex and customized (Sousa and da Silveira, 2017).

Differentiation in the marketplace can be achieved by a distinctive product and/or service offering (Porter, 1980). Hence, competing based on differentiation involves emphasizing the competitive priorities of product and service differentiation; differentiation advantage is achieved by excelling in the corresponding performance dimensions relative to the competition.

We develop a theoretical model to examine the role of ADS in supporting a business strategy based on product and service differentiation (Figure 1). The model integrates the two theoretical lenses that are most commonly employed in the servitization literature to understand its competitive role: market forces and capabilities (Eloranta and Turunen, 2015).

The market forces lens is rooted on Porter’s (1980) paradigm of competitive market forces, which advocates that service offerings need to fit the firm’s external environment and competitive strategy. In this context, servitization is often portrayed as a means to achieve differentiation in complex environments (Neu and Brown, 2005). The literature supports a two-pronged effect of external environment on servitization: a direct effect, by which service offerings need to be aligned with the environment (Gebauer, 2008); and an indirect (mediated) effect through competitive strategy, by which certain environments favor a differentiation strategy, which in turn can be adequately supported by servitization (Matthyssens and Vandenbempt, 2008). Based on this literature, we posit that ADS are appropriate to support differentiation strategies in complex environments.

The capabilities lens focuses on the resource-based view of the firm (Barney, 1991). It advocates that service offerings are associated with the development of valuable and difficult to imitate resources and capabilities that create competitive advantage (Ulaga and Reinartz, 2011). Based on the processes of value co-creation between manufacturers and customers during service encounters (Payne et al., 2008), we posit that ADS lead to differentiation advantage through the development of deep customer knowledge as a capability.

Research hypotheses
Market forces and advanced services
To examine the market forces perspective, we draw on the seminal dimensions of organizational task environment of Dess and Beard (1984), adapted to the study of servitization by Neu and Brown (2005): munificence (tame-hostile), complexity (simple-complex) and dynamism (stable-dynamic).

Munificence pertains to the availability of resources that allow an organization to survive and grow. In the servitization literature, the provision of services is seen as a way for firms to create additional value in highly competitive environments (Baines et al., 2017). ADS support this goal, since their high-value, differentiated nature leads to increased revenue and profitability (Eggert et al., 2014; Sousa and da Silveira, 2017).

Complexity pertains to the heterogeneity and range of factors that affect an organization’s activities. In the servitization literature, this dimension is related to market
complexity, involving the existence of different customer segments with different needs and a variety of contextual use scenarios (Neu and Brown, 2005). Such markets provide more opportunities to adopt differentiation strategies, as well as to offer new, customized services (ADS) targeting customer needs that are often not met by existing market offers (Neu and Brown, 2005).

![Figure 1. Theoretical model.](image)

**Dynamism** refers to the degree and nature of change in factors that are relevant to an organization’s activities. In servitization, this dimension is most often associated with the degree of technological change (Neu and Brown, 2005). Environments with a high degree of technological change provide opportunities for differentiation strategies (Ward and Duray, 2000). In addition, they are associated with high levels of technology-based product innovation. Such products lend themselves to value-added service provision (ADS) to help customers exploit the full potential of the innovations (Visnjic et al., 2016).

Neu and Brown (2005) propose that these three dimensions give rise to “complex markets”, driving servitization initiatives. Thus, we aggregate munificence, complexity and dynamism under a single construct of “environmental complexity”. Overall, the above arguments point to complex environments having both an indirect (mediated) effect on ADS through strategic focus on differentiation, but also a direct effect that goes beyond business strategy. Thus:

H1a/H1b. Environmental complexity is positively associated with strategic focus on product/service differentiation.

H2. Environmental complexity is positively associated with the offering of ADS.

Manufacturers compete based on differentiation by building non-price-based value offerings, comprising differentiated products and services (Matthyssens and Vandenbempt, 2008; Kastalli and van Looy, 2013). The customized, often complex nature of ADS is a core element of differentiated customer solutions (Sousa and da Silveira, 2017; Eggert et al., 2014). Thus:

H3a/H3b. Strategic focus on product/service differentiation is positively associated with the offering of ADS.
The servitization literature highlights customer knowledge as a key capability (e.g., Gebauer et al., 2011). In order for this knowledge to be a sustainable source of advantage, it should not be based solely on hard data such as customer satisfaction measures but should incorporate a deep understanding of customer experiences and processes (Payne et al., 2008), becoming a valuable and difficult to imitate capability. We argue that ADS lead to deep customer knowledge and differentiation advantage, as follows.

ADS involve understanding how customers use products in their specific context (e.g., equipment use physical environment) (Smith et al., 2014). This provides valuable information for designing new products or modifying/upgrading existing products to fit unique customer needs and use contexts (product differentiation advantage) (Visnjic et al., 2017). It also allows for the provision of higher quality service (e.g., customer support, customer training) by considering the product’s specific use context (service differentiation advantage) and allowing the manufacturer to actively influence customer processes (Payne et al., 2008). Thus:

H4a/H4b. The offering of ADS is positively associated with product/service differentiation advantage.

Following strategic management theories, strategic focus on differentiation leads to suitable resource allocation and configuration policies that promote differentiation advantage (Porter, 1980). This logic applies to service offers (e.g., Neu and Brown, 2005), as well as to goods offers (e.g., Hill, 1989). Thus:

H5a/H5b Strategic focus on product/service differentiation is positively associated with product/service differentiation advantage.

Our research model includes two relationships (H3b, H4b) which have been empirically examined using the same dataset by Szász and Seer (2018) as part of a model looking only at the service business of manufacturing firms. Our study re-examines these relationships in a broader, more comprehensive model, adding key constructs related to environmental complexity and the product business (product differentiation focus, product differentiation advantage).

Methods

Data and measures
We tested our model with data from the 2013/2014 International Manufacturing Strategy Survey (IMSS-VI). The following information about the survey was available from the network (IMSS, 2015) and appeared in previous IMSS studies. The survey was carried out in 22 countries by local researchers. It assessed the strategies, practices, and performances of manufacturing business units from ISIC sectors 25-30, which includes manufacturers of fabricated metal products, instruments, equipment, and machinery. The researchers initially contacted 7167 units and received 931 complete responses (13%).

The model included four sets of variables, namely environmental complexity, product and service differentiation focus, ADS, and product and service differentiation advantage. Based on the theoretical background, we developed environmental complexity as formative and the remaining variables as reflective (Diamantopoulos and Siguaw, 2006).

Environmental complexity was given by three formative indicators measuring the munificence, market complexity and dynamism faced by business units (Dess and Beard, 1984; Neu and Brown, 2005). Respondents were asked, "how do you perceive the
following characteristics of the environment in which your business unit operates?" Responses were given on five-point scales for "competitive rivalry within industry" ("Very low" = 1, "Very high" = 5) (munificence), "market span" ("Few segments" = 1, "Many segments" = 5) (market complexity), and "rate of technological change" ("Very low" = 1, "Very high" = 5) (dynamism), (IMSS, 2015). The scale was successfully validated through a MIMIC model (Diamantopoulos and Winklhofer, 2001; Diamantopoulos and Siguaw, 2006). The reflective indicators measured the perceived threats (i) that new players could enter the market ("market entry") and (ii) that products made by the business unit were replaceable ("products will become substituted").

Focus on product and service differentiation were operationalized by "order-winner" (Hill, 2000) indicators at the business unit level. Respondents were asked to "consider the importance of the following attributes to win orders from your major customers". Responses were given in a five-point scale of "importance in the last three years" with endpoints "Not important" (1) and "Very important" (5) (IMSS, 2015). The indicators were product customization (modification), product range (mix), frequent new products (changeover) and innovative products (changeover).

Focus on service differentiation indicators included product support (including after sales and technical) and customer service (including training, information, and help-desk) (IMSS, 2015). They matched closely the two most commonly found strategic types ("after-sales service provider" and "customer support service provider") in Gebauer's (2008) services configurations framework.

ADS was operationalized as in Sousa and da Silveira (2017), who also used indicators from IMSS-VI. The scale measured the extent of offering of ADS ("advanced services"), namely, rental/lease of products, product upgrades, help desk, user training, and consultancy (IMSS, 2015). Answers were given on a five-point scale with endpoints "None" (1) and "High (5).

Product and service differentiation advantage were measured by performance relative to main competitors. Respondents were asked, "How does your current performance compare with that of your main competitor(s)". Responses were given on a five-point scale with endpoints "much lower" (1) and "much higher" (5) (IMSS, 2015). Both scales should be symmetric in content with the product and service differentiation "focus" scales. Thus, service differentiation advantage included the two indicators of product assistance and customer service quality, and product differentiation advantage had three indicators including mix flexibility (ability to provide a wide product range), customization ability and new product introduction ability.

All models controlled for the ln-transformed number of employees in the business unit.

Measurement validation
Table 1 presents the means, standard deviations, and case numbers of all observed indicators. The maximum variance inflation factor was 2.22, indicating that multicollinearity was not problematic.

We carried out analyses in R version 3.4.3 (R Core Team, 2017) using Rstudio desktop version 1.1.419 (RStudio Team, 2015) in a GNU/Linux system. We tested measurement and structural equation models with the lavaan package (Rosseel, 2012) using maximum likelihood estimates. We tested the unidimensionality, validity, and reliability of scales with confirmatory factor analysis (CFA) of the complete measurement model. Initial fit statistics were satisfactory ($\chi^2$/df = 3.587, CFI = 0.929, NFI = 0.905, TLI = 0.906, RMSEA = 0.058 [0.052; 0.065]) but some standardized loadings $\lambda$ were low. We refined the model by dropping three indicators including product customization (product differentiation
focus), rental/lease of products (ADS) and mix flexibility (product differentiation advantage).

The refined model had satisfactory fit ($\chi^2/df = 2.412$, CFI = 0.971, NFI = 0.953, TLI = 0.958, RMSEA = 0.043 [0.035; 0.051]) (Bagozzi and Yi, 1988). Convergent validity was supported as $\lambda$ values were significant ($p < 0.001$) and average variance extracted (AVE) values were near to or greater than 0.50 (Fornell and Larcker, 1981; Bagozzi and Yi, 1988). The product differentiation advantage scale was somewhat below the convergence threshold (AVE = 0.49). However, we maintained that scale because overall model fit was satisfactory, and it had good conceptual symmetry with the product differentiation focus scale. Scales reliability was supported as all composite reliability (CR) values were greater than 0.60 (Bagozzi and Yi, 1988).

Discriminant validity is supported when pairwise correlations between latent variables are lower than the squared root of their respective AVEs (Fornell and Larcker, 1981). This was observed in all cases except in the correlation between service differentiation advantage and product differentiation advantage. So, we carried a nested models comparison test (Anderson and Gerbing, 1988). The constrained model had significantly worse fit than the constrained model ($\chi^2$ difference = 47.06, df = 1, $p < 0.001$), which is evidence to discriminant validity (Anderson and Gerbing, 1988).

**Results**

We developed a structural model to test hypotheses H1 to H5. Table 2 presents the path estimates and overall model fit. Fit statistics were all satisfactory (Bagozzi and Yi, 1988). Environmental complexity was positively associated with product differentiation and service differentiation focus, supporting H1a and H1b. However, it was not significantly related with ADS ($p = 0.056$), failing to provide support to H2. Both product differentiation and service differentiation focus were positively associated with ADS, supporting H3a and H3b. The differentiation focus variables also related positively with their performance advantage correspondents, supporting H5a and H5b. Finally, ADS was positively associated with service differentiation advantage but not with product differentiation advantage ($p = 0.076$), supporting H4b but not H4a.

**Discussion**

Concerning market forces, we found that complex market environments lead to the adoption of business strategies based on product and service differentiation (H1a, H1b) and these in turn drive the offering of ADS (H3a, H3b). However, our results raise doubts as to the direct influence of environmental complexity on ADS (H2). The absence of such direct effect would suggest that these traits only indirectly affect servitization, via the mediating effect of business strategy. Thus, the offering of ADS seems to by primarily driven by business strategy, confirming that ADS indeed have a key strategic nature and are integral to the manufacturing firm’s business model (Sousa and da Silveira 2017).

As anticipated, strategic focus on product/service differentiation per se led to increased product/service differentiation advantage (H5a, H5b). This reinforces the need for a clear strategic orientation towards differentiation of the product and service functions in the manufacturing firm. In examining the market forces view, we found that the offering of ADS is significantly influenced by contextual conditions, namely business strategy and (indirectly) environmental complexity. This encourages a more widespread usage of contingency approaches in the study of servitization (Forkmann et al., 2017).

Our study also supports the capabilities view, according to which service offerings are associated with the development of valuable capabilities that provide competitive advantage. We found that ADS have a positive impact on competitive advantage via
service differentiation (H4b), even after accounting for the positive effects of strategic focus on service differentiation (e.g., via suitable resource allocation and configuration). In addition, after accounting for the positive effects of strategic focus on product differentiation, there was no evidence that the offering of ADS affected product differentiation advantage (H4a).

A possible explanation for these results may be that servitization effects on product and service advantage work through different organizational mechanisms and time scales. Because of the intangible nature of services, customer knowledge accrued via ADS can be quickly absorbed by the service provision function in the manufacturing firm and used to improve services and achieve service differentiation advantage. However, for product differentiation advantage, customer knowledge needs to be fed back to the design, engineering and manufacturing functions to redesign products and manufacturing processes. This process takes longer and may be affected by organizational context traits, such as the degree of cross-functional collaboration and knowledge integrating mechanisms among the firm’s service and manufacturing functions (Schaarschmidt et al., 2018). So, the relationship between ADS and product differentiation advantage may be more complex.

Conclusions
Theoretical contributions
Our study advances the theoretical understanding of the competitive role of ADS, by integrating the market forces and capabilities perspectives on servitization and addressing both the product and service businesses inside the manufacturing firm. We complement prior research which has primarily addressed either product- or service-related outcomes, but rarely both simultaneously (Shaarschmidt et al., 2018). The study answers calls for developing stronger and more holistic theoretical foundations for ADS (Baines et al., 2017), increased understanding of the contextual conditions that influence the adoption of servitization (Baines et al., 2017; Forkmann et al., 2017), as well as to perform theory validation in the servitization field employing large scale empirical studies (Kowalkowski et al., 2017).

Managerial implications
Firms operating in complex environments could be tempted to offer ADS in a reactive response to the environment. Our study highlights the need for manufacturing firms to consider servitization as a strategic move integrated in an overall differentiation strategy – involving an explicit focus on product and service differentiation – rather than a piecemeal program. While the offering of ADS generates service differentiation advantage, it does not seem to have an impact on product-differentiation advantage. This allays managerial concerns that servitization could disrupt strategic focus in the manufacturing function and hurt product differentiation advantage (Josephson et al., 2016). Thus, managers pursuing product and service differentiation strategies should strive to incorporate ADS in their core corporate offerings. In doing so, they are able acquire a deep understanding of customer experiences and processes that can become a source of differentiation advantage.

Limitations and future research
We were not able to measure the deep customer knowledge capability. This was because of the complex and tacit nature of this construct, as well as because of limitations of our data. Future studies should develop scales to measure this construct and incorporate it in appropriate research models.
Our findings suggest future research avenues. Although we found that both product and service differentiation focus drive the offering of ADS, the impact of ADS on product and service differentiation advantage is distinct. This reinforces the need for servitization research to jointly address the product and service businesses in the manufacturing firm, as well as their interplay. Thus, future research should examine the role of integration mechanisms inside the firm (Schaarschmidt et al., 2018). Future studies should also examine the detailed mechanisms by which ADS affect product and service differentiation advantage. Of interest would be to conduct longitudinal case studies looking at the dynamics between customers and servitized manufacturers and the processes by which deep customer knowledge accrued by the offering of ADS is co-created, absorbed and leveraged by the manufacturer over time to produce differentiation advantage.

Abstract
The attention of practitioner and research on the concept digital twin is constantly growing: many companies have already in their offer a so-called digital twin and literature have seen in the recent years a strong increase of contributions on the topic, nevertheless, none of them ever stated if it is the same thing to which the professionals are referring to. For this reason, the purpose of this paper is to understand whether literature and practitioners are aligned about the digital twin paradigm, eventually identifying which are the differences and so define what are the possible developments for future research.

Keywords: Digital twin, servitization, literature review

Introduction
Worldwide, the new national development strategies for the industry – such as Industrie 4.0 in Germany, Industria 4.0 in Italia, Made in China 2025 in China and Smart Manufacturing in the USA – have the common goal of smart manufacturing (Kang et al., 2016), an emerging form of production integrating manufacturing assets of today and tomorrow with sensors, computing platforms, communication technology, control, simulation, data intensive modelling and predictive engineering (Kusiak, 2018). Based on that, an intensive and articulated application of networked information-based technologies throughout the manufacturing and supply chain enterprise is needed (Davis et al., 2012). Such technologies, such as sensors, cloud computing, augmented/virtual reality, additive manufacturing, machine learning, artificial intelligence, robots etc. produce, share and use big amounts of data that manufacturing companies and organizations need to transform in useful informations with the help of gaining richer and deeper insights and getting an advantage over the competition (Sagiroglu and Sinanc, 2013). One way to seize such opportunities is the concept of digital twin.

The concept of digital twin is born in order to add value and efficiency of both the data collected from the physical manufacturing sites and the data generated or existing in these deployed information systems (Cheng et al., 2018). It has found increasing attention by both industry and academic as the number of applications, on one hand, and contributions, on the other, has strongly
increased in the recent years: in the industry, numerous companies offer a so-called digital twin to their customers; in the literature, the number of contributions on the topic has greatly increased since 2017 (as the following literature review demonstrates). To this high number of contributions correspond a similarly high variety of definitions and interpretations of digital twin, depending on the type of industry involved and the field in which it is implemented (Tao, Sui, et al., 2018).

Considering such a high number of applications, it is evident that the possibilities in business terms need to be addressed, not just from a technical point of view, but also from a business model point of view, in particular the integration of the digital twin and service represents a promising research direction which should be addressed in future paradigms (Tao, 2018): servitization, the concept that refers to the transformation in which manufacturers are increasingly offering services that are directly coupled to their products (Baines and W. Lightfoot, 2013), is a topic for which there is a growing interest among academia, business and government because it is thought that a move towards servitization is a mean to create additional value adding capabilities for traditional manufacturers (Baines et al., 2009).

There is the need for studies in such direction but in order to seize such opportunities, it is fundamental that literature and practitioners are aligned about the digital twin concept; this is the reason why this paper aims to answer the following research question (RQ): are the practitioners and the literature aligned about the concept of digital twin?

In order to give an answer to this question, the definitions of digital twins that can be distinctly obtained analyzing the literature and the results coming off the combination of a survey with the interviews done with the practitioners, are compare.

The paper is structured as follow: first the method and results of the analysis of the literature review made on the Scopus database are presented, to which the genesis of the concept and its definition are deduced; then the results of a systematic combining of the results of the survey made on a sample of about 60 professionals, with in-depth interviews carried out on 15% of the same sample and therefore, are presented with its correspondent definition. Then the findings are discussed and so conclusions are made, The paper finishes with the definition of possible future works and the limitations of the research are pointed out.

**Literature review**

**Approach**

A literature review was conducted on the Scopus database searching for the “digital twin” term in the keywords: it resulted in 255 results of different types (articles, conference papers, etc.), distributed from 1993 (Koren et al., 1993) to March 2019 (Figure 1) and mainly focused in subject areas of computer science and engineering.

Based on a cross-referenced analysis of the results, 4 more papers have been added to the selection and included to point out the following definition of digital twin, for a total of 259 papers.

The analysis and the selection of the papers that have been considered the most relevant for the purpose to address the RQ, have been done reading in order the title, abstract and finally the entire paper; then, the selected ones (21 in total) have been used to obtain a general and common definition of digital twin.
Evolution of the digital twin concept
A first intuitive digital twin concept was introduced for the NASA’s Apollo project in the late 1960s, when NASA created two identical space vehicles where the ones left on earth was called “the twin” and was used to mirror the condition of the space vehicle that performed the mission, so a prototype that mirrored the real operating condition for the simulation of real-time behaviour; the NASA then evolved its concept of digital twin as an integrated multiphysics, multiscale simulation of a vehicle or system that uses the best available physicals models, sensor updates, fleet history, etc., to mirror the life of its corresponding flying twin (Glaessgen and Stargel, 2012). By the way, it is generally accepted (Cheng et al., 2018; Glaessgen and Stargel, 2012; Haag and Anderl, 2018; Padovano et al., 2018; Tao, Cheng, et al., 2018; Tao, Sui, et al., 2018; Zheng et al., 2018a, 2019) that the concept of digital twin was firstly presented by Grieves in a conference about PLM in 2003 as made of three parts, i.e. physical product in real space, virtual product in virtual space and the connection of data and information that ties two spaces together (Grieves, 2014). From Grieves, the concept of digital twin evolved in the years: until 2014, the different definitions given referred to the aeronautical field, with the digital twin concept that maintains the characteristic bi-part composition (i.e. virtual and physical) and integration (i.e. with data) but the concept of simulation is introduced (Glaessgen and Stargel, 2012; Hochhalter et al., 2014; Reifsnider and Majumdar, 2013); then, with the introduction of the Industrie 4.0 plan in Germany (Rosen et al., 2015), the concept of digital twin becomes broader, moving from products to processes (Rosen et al., 2015); from real-time representation to optimization and prediction (Tao and Zhang, 2017; Zhuang et al., 2018); from simulation to real-time and continuous evolution (Haag and Anderl, 2018; Tao, Cheng, et al., 2018; Tao, Sui, et al., 2018; Tao and Zhang, 2017).

The definition of digital twin from the literature
Based on the results of the research, literature defines the digital twin as a way to combine (Tao and Zhang, 2017), integrate and realize the interaction (Cheng et al., 2018; Shubenkova et al., 2018) between physical and virtual worlds. It can have different granularity since the physical object can be a system (Tao and Zhang, 2017) or a sub-system (Glaessgen and Stargel, 2012; Zhuang et al., 2018) and can be a product (Grieves, 2014) or a process (Rosen et al., 2015). The integration and interaction between physical and virtual worlds means that there is a bi-directional connection between the two parts: on one direction, various types of data are collected from the physical world and elaborated in the virtual world (Cheng et al., 2018; Shubenkova et al., 2018;
Zhuang et al., 2018). The connection is in real-time and enables the co-evolution of the virtual part with its physical twin (Haag and Anderl, 2018; Tao, Cheng, et al., 2018), since it is not only the representation of the current and past status of the physical part but of all its entire lifecycle (Cheng et al., 2018; Tao, Cheng, et al., 2018). In addition to this, the digital twin is not only a tool to manage, control and monitor the physical object but also to support the decisional making process as it can perform optimization and predictions of its future status (Cheng et al., 2018; Shubenkova et al., 2018).

**Digital twin possible uses**

The research gave also several results in term of possible uses of the digital twin as a base or enabler for different purposes: in (Rosen et al., 2015), the authors consider the digital twin as a key enabler for the autonomous systems, i.e. intelligent machines that execute high-level tasks without detailed programming and without human control; for (Zhuang et al., 2018), the digital twin provides a new solution to data management, acting as a single data source throughout the product lifecycle: first, the manufacturing connected resources generate real-time data; then, the data are real-time processed in order to guide the managers to dynamically optimize the production activity plans; finally, the newly production activity plan is fed back to the physical assembly shop-floor and guides the production second round.

In terms of service proposition, for (Padovano et al., 2018), the digital twin can be used as a based service oriented application for a 4.0 knowledge navigation in the smart factory (a KaaS, Knowledge as a Service model), as an holistic software platform that works as a service-oriented knowledge-aware expert system that offers a full set of services (diagnostics and condition monitoring service, prognostics and decision support service,...) designed as a separately-maintained and deployed apps accessible over standard internet protocols; (Tao, Cheng, et al., 2018) specify nine categories of services that can be develop thanks to the digital twin: service of real-time state monitoring, service of energy consumption analysis and forecast, service of user management and behavior analysis, service of user operation guide, service of intelligent optimization and update, service of product failure analysis and prediction, service of product maintenance strategy, service of product virtual maintenance, service of product virtual operation.

**Practitioners analysis**

**Approach**

In order to extract a general definition of digital twin from the practitioner perspective, the following approach was applied: a survey to different company managers and practitioners have been launched based on three core questions (what is a digital twin, what could be its purposes and which are its potential benefits); then, a semi-structured interviews to provide deeper insights into the digital twin; finally, a systematic combining of the results to provide a framework that describes the expectations of the community of the digital twin and to link the digital twin back to the literature.

Based on the research question detailed before, this was considered to be the most effective approach to gain insights from practitioners as it was conceived that the data (both ranking and open questions were used) from the survey results would help to show the gap between theory and practice with digital twins. This is confirmed by (Forza, 2002), who states that surveys are an effective tool to poll a population, which was from our own lists plus a self-selecting population from social media. The screening of the results was undertaken to ensure that industrial inputs were assessed.

The use of semi-structured interview is often used to provide deeper insights than from simple surveys, their applicability has been confirmed by (Barriball et al., 1994). The interview script -
focused on questions of the survey plus one open question - was built up based on the initial analysis of the survey results and made to 15% of the survey respondents.

We adopted systematic combining, in line with (Dubois and Gadde, 2002), in order to elaborate the framework that is presented in Table 1. In doing this, we moved back and forth between the empirical data and the extant literature, following a nonlinear analysis process (Eisenhardt, 1989): the open answers collected with the survey were transcribed, and enriched with the information coming from the interviews; we analysed the data qualitatively and the complexity was reduced through successive categorization of primary data (Bryman, 2004), in particular the content analysis was conducted by using ad hoc codes (manifestation of the findings recovered from the literature, around the conceptual definition of what a digital twin is, why a digital twin exist, how and what a digital twin does) that were converted into more meaningful “in vivo” codes, that were foundational to the development of the first-order categories; then, we moved back and forth to examine, compare, group, and find in-depth relationships among first-order categories and codes; doing this way, we reduced first-order categories to the most salient categories; finally, we established the 2nd order themes, that constitutes the pillars of the working definition of the digital twin.

During the mentioned stages we always referred to the literature to verify the explicative power of the working definition of the digital twin, to check for missing concepts, contradictions, and to improve the overall quality and internal consistency. We extensively used memos and affinity diagrams. We also shared the findings between the paper’s authors that initially had worked independently. Any discrepancy was analysed until we mutually agreed upon general and common definition of digital twin.

Results
Based on the 53 answers of the survey and the 9 interviews conducted, the results of the approach previously explained are shown in Table 1.

</table>
The definition of digital twin given by the practitioners

Summarizing the results previously showed, we can say that for the practitioners a digital twin is a virtual model of a real system or process, that can have different granularity; it can collect – even in real time and thanks to I4.0 techniques and technologies (i.e. VR, AR, 3D modeling, cloud, ML, IoT, numerical methods (CFD, FEA), etc.) - field data of different kinds coming from the object it represents, in order to integrate them and show the object status during its entire lifecycle (e.g. the contextual or environmental conditions, the operational conditions, the service activity) in a more meaningful way; the data are used not only to represent the status of the object but also to predict and optimize – thanks to simulation and scenario analysis (what-if?) that are feed by real data (data driven analysis) coming from Industrial Internet platforms, that integrate applications, resources and skills coming from different fields and actors of the ecosystem – the decision-making process. A digital twin can also send data to the real object, to control and change its current status.

Discussion

With the support of Table 2, we discuss the differences between the literature and practitioner definition of digital twin.

Starting from what is a digital twin, literature does not specify which kind of element (i.e. model, object, etc.) it is, and uses a more general term (“way”), instead practitioners specify that it is a model of a product or process with different granularity (system, sub-system); as previously described within the results of the literature review, in different use-cases and other papers we found instead a direct reference to simulation and/or modeling of products and/or processes.

In terms of what the digital twin does, it is commonly recognized that it realizes the interaction and integration between physical and virtual world in a real-time manner, along all of the lifecycle of the physical part, by a bidirectional flow of data: the data coming from the physical object are first collected in the virtual world; then, they are elaborated in order to predict and optimize its behaviour and to define a plan (Zhuang et al., 2018) that finally guides the user or the the virtual part on how to act on the physical part. The main difference to highlight is that if the practitioners intend the digital twin as a model/simulation of the reality and so something that simulates it, literature explicitly states that both worlds co-evolve together, just like they would be two “twins”.

2787
About how the digital twin does that, even if in the definition of the literature there is not an explicit reference to how the interaction and integration between the two worlds is done – also because, we assume, of the more general definition of what is a digital twin (a “way”) –, we found many different use-cases in literature that refer to the same technologies and techniques specified by the practitioners.

Conclusions

Based on the previous discussion of the results, we can conclude that literature and practitioners seem to be generally aligned on the digital twin paradigm; nevertheless, even if the practitioners are aware of the possibility to develop customized, punctual and fast services based on the actual status of product/process thanks to the digital twin, literature rather neglect – considering the total 255 results of the literature review – its plausible key role in the service strategy of product-based companies, claiming only that it can enable the development of new and smart product-service solutions (Tao, Cheng, et al., 2018; Zheng et al., 2018b) or making manufacturing as on-demand cloud services (Lu and Xu, 2019; Padovano et al., 2018). In particular, (Tao, Cheng, et al., 2018) specify nine categories of services that can be provided to product users and manufacturers but still state as a possible future work the development of smart service analysis method based on digital.

Considering that servitization is a data-intensive process and effective approaches should be adopted to exploit data for new revenue stream in manufacturing companies (Opresnik and Taisch, 2015); that massive user/product generated data serves as the key for value creation, while effective data analytics tools enable its success (Rymaszewska et al., 2017); that adopting a platform approach with modular architecture is very effective for overcoming the servitization paradox (Cenamor et al., 2017), as the general definition of digital twin highlights how much effective it should be to bring the data into action, we can conclude that apart the obvious need for future research works on relevant industrial applications (Negri et al., 2017; Tao, Cheng, et al., 2018) to develop the how-to part of the definition (considering also what has been done so far from a regulatory aspect), particular attention should be given to investigate how the digital twin enables the service growth of manufacturing firms and to demonstrate how much they would benefit from them.

The limitations of this research can be found both in the literature and practitioners analysis: the literature review was done based only on the Scopus database and does not consider papers that could use different terms of digital twin (i.e. digital shadow); instead, the survey and the interviews could be conducted in a more structured way (i.e. carefully planning the selection of the respondents) and it lacks of a deep analysis of the documents, magazine articles, etc. where is the explained the digital twin concept for manufacturing – but not only – companies.

Abstract
This study investigates the effect of service transition within traditional manufacturing companies on the job satisfaction of two functional groups of workers: salespeople and front-line service (FLS) employees. Although there is a growing body of work on the implications of service transition strategies for manufacturers performance, yet only limited attention has been given to how employees perceive of, and react to, such an important strategic redirection. We examine the effect of service infusion on the overall job satisfaction of sales staff and FLS personnel using data from an employee ratings company, with results showing differential effects.

Keywords: service operations, servitization, job satisfaction

Introduction
Over the last decade increasing attention has been devoted to manufacturing firms transitioning towards services – a phenomenon that is commonly known as ‘servitization’ (Baines et al., 2009; Vandermerwe & Rada, 1988). It entails manufacturing companies seeking to enhance their product portfolio by offering services and combining their products with services to create new offerings (Vandermerwe & Rada, 1988). Implementing a servitization strategy does not necessarily guarantee better performance (Gebauer et al., 2005). Recent studies suggest that significant initial investment is required (Visnjic Kastalli & Van Looy, 2013), that organizations need to reach a ‘critical mass’ for profitability from services (Fang et al., 2008), and that adding services does not linearly increase performance (Fang et al., 2008; Suarez et al., 2013; Visnjic et al., 2016). Although this is highly relevant, there is a need to take a step back and examine the implications of the transition upon the job satisfaction of employees. This aspect to date has been neglected in the extant literature. This is surprising as the performance of a firm will be in large part contingent on employee job satisfaction. So, whilst we have witnessed an ever-burgeoning literature on servitization, scant attention has been provided to how
service provision is actually impacting those that need to deliver it and their job satisfaction.

In this paper, we examine the service transition and its implications upon employees. In particular, there is a need to examine the implications of a transition towards services upon frontline staff (FLS) that are responsible for day-to-day service related activities, and, in most cases, at the coalface with the customer. Of interest are also sales employees who traditionally in manufacturing firms are responsible for the sale of products, with the sale of support services that help with the functioning of the product (Gebauer et al., 2010). Changing the business strategy towards services entails changes to the ‘dominant mindset’, which means changes to the psychological contract (Rousseau, 1995). Routines and practices for selling products tend to have become embedded and are difficult to adjust, especially given sales are incentivized in a way that potentially privileges product sales. Change is difficult. Hence, asking sales to now promote and sell services, which in the past may have given away for free (Witell & Löfgren, 2013), is no simple task; such changes rarely play out smoothly.

Most studies tend to rely on primary datasets based on surveys administered to evaluate employee satisfaction. In recent times, with the onslaught of new platforms to voice their views (via ratings and/or qualitative responses), employees - and former employees - freely provide their input when it comes to job satisfaction (Conway, forthcoming; Stamolampros et al., forthcoming; Huang et al., 2015). Such data offers potentially novel insights that would not have been captured via in-company surveys. In this study, we draw upon a novel dataset of online ratings provided by current and former employees to the job listings website, Glassdoor Inc., to examine the impact of service transition on employee job satisfaction. In so doing, we aim to address the following research question:

1. What is the impact of service transition on employee job satisfaction?
   i. What is the impact of service transition on salespeople’s job satisfaction?
   ii. What is the impact of service transition on frontline service employee job satisfaction?

We thus contribute to the servitization discussion by, firstly, providing evidence of the impact of service transition on employee job satisfaction and, secondly, by identifying and discussing the differential effect of service infusion on sales and FLS personnel.

The remainder of the paper is structured as follows: next, the theoretical background is presented, followed by our hypothesis development. After which we present our research methodology, followed by the results of the study. Lastly, we discuss our findings provide some tentative concluding thoughts.

**Theoretical background and hypotheses development**

Job satisfaction is a heavily researched domain by organizational scholars. It is argued that job satisfaction is influenced by numerous factors (Lawler 1973; Ilies et al., 2009; Judge et al., 2017). Numerous studies have been undertaken with different theoretical underpinnings when it comes to job satisfaction. There exist a plethora of definitions, models and theories that attempt to explain job satisfaction. One of the most commonly used definitions in organizational research defines job satisfaction as “a pleasurable or positive emotional state resulting from the appraisal of one’s job or job experiences’ (Locke, 1976, p. 1304). We will discuss some of the most prominent theories and models briefly below.

Arguably one of the best-known studies that explains job satisfaction being an outcome of the difference between expected and perceived rewards received in one’s place of work
(Lawler, 1973). In other words, it is rewards that meet expectations that drive job satisfaction, whereas rewards that do not meet expectations lead to dissatisfaction.

Hackman and Oldham (1976) proposed their job characteristics model. In this, they argue that core job characteristics seen as inherent in all jobs include skill variety, task identity, task significance, autonomy, and feedback which motivate employees towards desirable outcomes. When employees are able to use their many skills (i.e. skill variety) in order to complete a particular product (or service) (i.e. task significance), an employee will be able to attribute meaning and value to their work. When individuals have freedom (i.e. autonomy) to determine when and how they work, then they have a sense of responsibility and of being accountable for what they are trying to achieve because they have control of their job. When other organizational members – be they senior managers, supervisors, fellow employees, team members – provide input (i.e. feedback) on the (in)effectiveness it enables employees to improve. The model of Hackman and Oldham (1976) proposes that the strength of these relationships is moderated by an individual’s desire to derive satisfaction and personal growth and development, known as ‘growth needs strength’ (see also McClelland, 1987).

Herzberg (1966) proposed the two-factor theory to understanding the causes of individuals’ satisfaction. In this theory, job satisfaction and dissatisfaction are not considered to be two polar opposites on a single dimension nor an outcome of the same factors. Different factors thus are said to account for satisfaction and dissatisfaction. Job satisfaction is said to be an outcome of drivers known as motivators that result from the conditions of the job itself. Examples of motivators include things such as responsibility, advancement growth and recognition. The drivers of dissatisfaction are known as hygiene factors and are needed to ensure workers are content with their work.

Other notable work includes Karasek’s (1979) three-dimension demand-control-support (JDCS) model that explains the stress an employee encounters at work, emphasizing the situational predictors of job satisfaction (Karasek, 1979; Karasek and Theorell, 1990). In more recent times, Judge et al. (2001a; 2001b; 2017) consider the following to be important features of job satisfaction: promotions, pay, supervision, recognition, working conditions, the organization, management and coworkers.

Overall, it is fair to say there is no clear agreement as to what accounts for job satisfaction. Although there are some common drivers for job satisfaction, there are also different drivers and factors identified in the extant literature. This shows that there are a number of ways of understanding job satisfaction.

Next, we discuss service transition and its implication for job satisfaction for sales staff and FLS employees.

Service transition and job satisfaction
An extensive body of research claims that manufacturers are increasingly transitioning towards services and solutions as part of their offerings (Neu and Brown, 2005; Fang et al. 2008; Kowalkowski et al., 2012; Wise and Baumgartner, 1999; Storbacka, 2011). For example, the construction equipment company Caterpillar has increasingly infused services into its product offering - such as spare parts support, maintenance, “negative downtime” concept where customer only learns of an issue with equipment once it has been repaired – to meet customer needs. To date, much of the literature has focused on the strategic aspects of transitioning to service (Gebauer et al., 2010; Josephson et a., 2016; Patel et al., 2019), design considerations for firms (Foote et al., 2001; Davies et al., 2006; Raja et al., 2018), and financial performance (Eggert et al., 2014; Fang et al., 2008; Visnjic and van Looy, 2013; Visnjic et al. 2016; Visnjic et al., 2019).
Although the transition to services is an area that is receiving increasing attention, the pursuit of a service strategy and the implications this has upon employees has largely been neglected. It goes without saying that service transition is likely to have implications on the role of staff inside organizations. For example, salespeople who are accustomed to selling products will also be expected to promote and sell services. Although this may seem straightforward, it is anything but. Changing the routines that sales staff become accustomed to, measured upon are fraught with difficulties. In some cases, this has led to some arguing that firms are better off creating new service organizations with sales staff purely dedicated to selling service, or at least so that they are service-savvy (Reinartz and Ulaga, 2008; Ulaga and Loveland, 2014). Similarly, delivering service requires customer-facing FLS personnel. For many companies, they may already possess a field service workforce, though infusing greater service will mean expanding the demands that are placed upon the staff. In other cases, it will be a case or recruiting anew FLS personnel to meet customer needs and realize the service strategy. Of particular interest here is what such changes mean for employees in terms of their roles and resultant effect on job satisfaction for sales and FLS personnel.

We therefore examine the following hypothesis:

**Hypothesis 1:** As the level of service infusion increases, there will be a decrease in the job satisfaction of the non-customer facing employees

**Hypothesis 2:** There will be a U-shaped relationship between the level of service infusion and the satisfaction of salespeople

**Hypothesis 2:** There will be a U-shaped relationship between the level of service infusion and the satisfaction of salespeople

**Methodology**

**Sample and data collection**

The focus of this study is on manufacturing firms with primary 3-digit North American Industry Classification System (NAICS) codes between 333 and 336. These include manufacturers of machinery (333), computer and electronic products (334), electrical equipment, appliances and components (335) and transportation equipment (336). These are the industries in which servitization has been most prevalent according to the literature, seemingly due the properties of the manufactured products (relatively long-life and complex). The strict focus on manufacturing industries that are clearly conducive to servitization excludes companies that are practically unlikely to sell product-service offerings due to the nature of their products (e.g. paper product manufacturers), while it indirectly controls for industry-level factors that could confound the relationship between the extent of servitization and satisfaction with one’s employer.

Following prior research (e.g. Fang et al. 2008; Visnjic et al. 2019), as a proxy for the level of service transition of a manufacturer at any point in time, we compute their ‘service ratio’ (Fang et al. 2008). This is the proportion of a manufacturer’s total revenues in a year that comes from service activities. To obtain the required data, we use COMPUSTAT Business Segments because it provides time series of firm revenues from different business operating segments. For any given firm, the definition of the operating segments and the allocation of revenues between them is self-reported by the management team. Despite this disadvantage, this is the most common (and possibly, only) way to track a firm’s service transition over time. From the description of the operating segments and their associated NAICS code, we categorize them into service and nonservice, following the procedures specified in Visnjic et al. (2019). For a given firm in a given
year, the service ratio is the quotient of the division of the sales revenues from all service business segments by the total revenues.

To obtain measures of an employee’s satisfaction with their employer, we match our dataset with data supplied by Glassdoor, a job search engine and review website. We specifically utilize the ‘overall satisfaction’ rating, as well as satisfaction with four employment aspects: ‘compensation and benefits’, ‘career opportunities’, ‘work-life balance’ and ‘senior leadership’. All ratings range from 1 to 5, and we extract only those that come from employees (both former and current) of the manufacturers in our sample. Employee reviews begin in 2008, so this comprises the first period in our timeframe. We use the aggregate role categories, as specified by Glassdoor, to identify sales and front-line service employees, with all the rest being classified as ‘all other’ non-customer facing employees. Accordingly, roles such as ‘sales representative’ and ‘field sales manager’ are classified as salespeople, while ‘customer service’ and ‘field services’ are classified as front-line service employees.

Several variables that could affect both the extent of servitization of the company and the satisfaction of its employees, are included in the models as controls. These include firm size (total sales and number of employees), profitability (ROA), R&D expenditure, overall performance (Tobin’s Q), as well as industry (primary 3-digit NAICS code) and a linear time trend. Crucially, some manufacturers have begun their servitization ‘journey’ long before 2008, while others start reporting revenues from services only after 2008. We control for this using a dummy variable, as one could expect that the accumulated experience of providing product-service offerings (prior to the year we first start observing) may have helped senior management teams to implement policies and measures to address issues faced by their sales and service employees.

Analysis

As our dependent variables are naturally ordinal, the appropriate econometric models are the ordered logit and ordered probit. In the five models (one for overall satisfaction and one for each of the four separate aspects), the minimum number of observations (i.e. employee ratings) is 39822 (from 586 firms), and the maximum 41301 (from 595 firms). The 3-level categorical variable of job function enters our models as a set of two dummy variables, with the ‘all other’ category being the reference level. Crucially, to test our hypotheses, we interact these two dummies with the service ratio (and its quadratic term).

Results

Table 1 contains the main results of this work. The dependent variables in the five presented models are the ordinal scales of overall satisfaction (model 1) and the four separate aspects captured by Glassdoor: employee satisfaction with their compensation and benefits; the senior leadership in the organization; the career opportunities provided; and their work-life balance (models 2-5).

Clustered (by firm) standard errors in parentheses
* p < 0.1, ** p < 0.05, *** p < 0.01
The results can be summarized as follows:

- As service infusion increases, non-customer facing employees become increasingly unlikely to report a higher level of satisfaction with their compensation and benefits. There is no statistically significant effect of service infusion on the likelihood of higher overall satisfaction (or any other aspect).

- Compared to non-customer facing employees (the reference level), the likelihood that salespeople will report a higher level of overall satisfaction (and satisfaction with any other employment aspect) exhibits a (steeper) U-shaped relationship as service infusion increases. This is illustrated graphically in Figure 1, which presents the predicted probabilities of reporting a ‘5’ (the highest level) for the different aspects of employee satisfaction when the service ratio increases by 10% at a time. An interesting additional finding is that salespeople seem to be more likely to feel very satisfied when their employer is a pure product provider (service ratio = 0%) or fully ‘servitized’; namely, when the firm is 100% focused in either of side of the product-service continuum.

- The form of the relationship between service infusion employee satisfaction FLS personnel with their employer is not significantly different compared to the base-level. However, they remain the most unlikely to report higher levels of satisfaction as service transition progresses (Figure 1) and seem to feel less satisfied with all aspects related to their employment. In addition, one can notice that for a fully servitized firm (service ratio = 100%), the predicted probability that a sales person will report a high level of satisfaction with any aspect of employment is about double compared to a FLS employee.

![Figure 1 – Marginal effects of service infusion](image-url)
Discussion and contribution

This study contributes to the emerging body of work examining the implications of service transition upon employees. Specifically, this work has implications for the design of sales and FLS roles, and how to manage these individuals during service transition. The results suggest a differential effect of service transition for sales and FLS personnel. It is noteworthy that for the sales personnel role, the firms have managed to, over time, address the initial drop in satisfaction. In contrast, the situation for FLS personnel roles is bleaker; especially when it comes to ‘compensation and benefits’ the results indicate that these employees are increasingly dissatisfied, with little sign of recovery. As such, we raise important questions for addressing the job satisfaction levels of all staff, but specifically those in FLS positions. We argue that low job satisfaction may explain the high propensity for those firms transitioning to services to experience difficulties or, in some cases, bankruptcy (cf. Benedettini et al. 2015).

Abstract

Digital transformation of the manufacturing industry has been one of the dominant topics in recent years. Prior research investigated the impact of servitization on firm performance in terms of growth and stability. However, the moderating role of digital solutions was neglected. The aim of this study is to evaluate digital solutions in manufacturing firms and their impact on firm performance. Our analysis used a Serbian and Lithuanian dataset of 143 manufacturing firms from the European Manufacturing Survey conducted in 2018. The empirical results revealed that in manufacturing firms, product-related services, along with digital solutions, can significantly increase share of revenue.

Keywords: Servitization, Digital solutions, Social Network Analysis

Introduction

Servitization, the transformation of product-oriented companies towards service-oriented businesses, has flourished in recent years (Marjanovic, Lalic, Majstorovic, Medic, Prester and Palcic, 2018). The servitization trend was first mentioned by Vandermerwe and Rada (1988) to depict the relationship between product, service, knowledge, support and self-service, in order to offer fuller market packages and create added value for customers. An early study showed that the relationship between servitization and product innovation should be a central concern of the manufacturer both in the short and in the long run.
(Visnjic, Wiengarten and Neely, 2016). Product–service system (PSS) represents a tie between tangible products and intangible services designed and combined so that they are jointly capable of fulfilling specific customer needs (Tukker, 2004). PSS provides more specific PSS types, one of which is product-related service (Tukker, 2004). This type of provider not only sells a product, but also offers services that are needed during the use phase of the product (Tukker, 2004). A prior study makes recommendations for service-oriented manufacturing firms: "the adoption of an integrated product-service business model as a way of creating reciprocal spill overs between products and services" (Visnjic Kastalli and Van Looy, 2013, p.178). Moreover, evidence from other authors shows that servitization has a positive impact on the creation of added value in manufacturing firms (Eggert et al., 2014). The adoption of a gradual strategic change by manufacturers moving to product-related services and to customer support represents a growing trend in aspiring to offer an “integrated solutions” business by manufacturing firms (Baines, Lightfoot and Benedettini, 2009). To improve the business model, manufacturing firms are in constant struggle for application of digital solutions. Two thirds of manufacturing firms worldwide say that digital solutions in manufacturing are one of their highest priorities (Behrendt et al., 2018). The high complexity of production, services and external drivers clearly present the challenges of digital transformation (Liere-Netheler, Packmohr and Vogelsang, 2018). The share of a company’s sales that comes from exports seems to be another driver of service digitalization which provides transformation from PPS to digital PPS (Lerch and Gotsch, 2015). There is a real need for research on manufacturing transformation when a firm chooses to move from its traditional manufacturing focus towards servitization (Benedettini, Neely and Swink, 2015). Furthermore, the role of digital solutions in transformation of manufacturing is not sufficiently investigated (Ardolino et al., 2018). This paper investigates and offers an understanding of the impact of product-related services and digital solutions on the performance of manufacturing firms.

The remainder of the paper is structured as follows: Section 2 presents the literature review and describes the proposed model that has been used in this paper. In Section 3, we present data and research methodology. Section 4 provides the research results and discussion. Finally, Section 5 shows the conclusion of this paper with identified limitations of the study and suggestions for further research.

**Literature review**

The process of creating value by adding services to product offerings is known as servitization (Vandermerwe and Rada, 1988). Increasingly, durable goods manufacturers choose to innovate their offerings by providing services to accompany their existing products throughout the life cycle (Visnjic Kastalli and Van Looy, 2013). A prior research provides the evidence base underpinning servitization adoption. This research shows that diversification impacts between revenues from products and revenue from services are typically split 50/50 and enables overall business growth (Baines and Shi, 2015). In developed countries there is a considerable debate about the terminology, ideas and concepts which describe and differentiate products and services in manufacturing firms (Baines, Lightfoot and Benedettini, 2009). In the PSS communities, the core theme addresses potential commercial benefits to a manufacturer that provides service with or instead of a physical product (Baines, Lightfoot and Benedettini, 2009). Furthermore, another study shows that product-related services have a positive impact on a company’s turnover (Lalic et al., 2018; Marjanovic, Lalic, Majstorovic, Medic, Prester and Palcic, 2018). Moreover, some of the observed types of product-related services show the highest positive impact on the turnover of companies when directly invoiced (i.e. maintenance
and repair; design, consulting, project planning; software development; revamping and modernization and end of life services) and indirectly invoiced (i.e. maintenance and repair and design, consulting, project planning) (Lalic et al., 2018; Marjanovic, Lalic, Majstorovic, Medic, Prester and Palcic, 2018). It could be argued that round the world, high-quality product-related services are significantly related to customer satisfaction and loyalty (Zahringer et al., 2011).

The field of digital servitization is differentiated from mainstream servitization in different aspects: the marginal cost of digital services is lower than with traditional services; traditional services are usually complementary to a product offering, while digital services are often substituted for traditional products, and finally, digital technologies open new business opportunities, especially the application of information technology in the manufacturing sector (Vendrell-herrero et al., 2017). Furthermore, a study from the German Manufacturing Survey in 2012 shows that digitalization is positively associated with manufacturing companies' share of turnover with new products (Kroll, Horvat and Jäger, 2018). Lerch and Gotsch argue that as the final step of the transition to a services focus, digitalized PSSs move firms beyond traditional service offerings in their high degree of automation and in their ability to act independently and forecast product-service requirements and failure modes (Lerch and Gotsch, 2015). Cambridge Service Alliance identified top five service technologies and all of them are digital services: predictive analysis, remote communications, consumption monitoring, and two aspects of mobile communication platforms (Dinges et al., 2018). Moreover, these digital services are in line with digital solutions which were identified by the European Manufacturing Survey (EMS)(Fraunhofer Institute, 2018). Prior research has pointed out the importance of digital solutions; thus, this represents a fruitful area for further examination. To shed more light on this important area of production research, the authors investigate which digital solutions have a dominant place in manufacturing firms.

The product-related services and digital solutions presented in the model (Figure 1) were identified based on exploratory interviews with practitioners and group discussions with experts in the field. All EMS consortium members were involved in the process of identification, which resulted in a universal list of digital solutions (e.g web-based services for customized product configuration or product design, web-based offers for product utilization, mobile devices for diagnosis, repair or consultancy, digital (remote) monitoring of operating status, data-based services based on big data analysis). Based on the literature review of digital solutions in manufacturing, the following research question was posed:

- **RQ1**: Which digital solution has a dominant place in manufacturing firms?

Previous research has already demonstrated the move from product-related services to digital services through phases: manufacturer, IT-based services, pure digital services and digitalized PSSs (Lerch and Gotsch, 2015). Digitalized PSSs incorporate digital solutions as a novel component besides the product-related service in the PSS, creating intelligent, independent operating systems (Lerch and Gotsch, 2015). Moreover, Carlos Gonçalves dos Reis et al. (2018) argued that managers should adapt their business strategy to the digital reality by integrating new technologies in their business models, if they want to have better results on the market. Furthermore, researchers presented drivers for digital transformation in two groups, namely: organizational (e.g. process improvement, workplace improvement, vertical integration, management support, horizontal integration and cost reduction) and external (e.g. customer demands, supply chain, innovation push,
market pressure and laws/government) (Liere-Netheler, Packmohr and Vogelsang, 2018). From this point of view, it is possible to pose the following research question.

- **RQ2: How do product-related services, along with a digital solution, affect firm performance?**

To address RQ1 and RQ2, the following model is proposed in Figure 1.

![Proposed research model](image)

**Figure 1 – Proposed research model**

**Data and methodology**

The survey was conducted under the international project EMS which was coordinated by Fraunhofer ISI Institute from Germany. The dataset used in this paper was built from 2018 data collection. Manufacturing companies (NACE Rev 2 codes from 10 to 33) having at least 20 employees in Serbia and Lithuania were considered, taking into account 143 responses in total. Each survey was carried out based on a proportionally size- and industry-based stratified random sample. Cochran’s (1977) method was used as the sampling technique. Moreover, the data collection procedure was in line with Dillman’s (1977) method. The comparison of data regarding firm size distribution between Serbian and Lithuanian subsamples, and those of other EMS countries (e.g. Croatia, Germany, Slovakia, Slovenia) shows no significant size bias. Table 1 and Table 2 show that both samples of EMS have reasonable representation for all firm sizes and fair coverage of all manufacturing industries.

Social Network Analysis (SNA) was used for data analysis. SNA method is widely used in the social sciences (Wasserman and Faust, 1994). Moreover, SNA is used in economics, marketing, and industrial engineering (Wasserman and Faust, 1994). According to (Goes et al., 2017; Leng and Jiang, 2018; Li, Jiang and Zuo, 2018; Omar, Minoufekr and Plapper, 2018), SNA should be used as a research method in the manufacturing context. Early studies applied SNA in Industry 4.0 (Omar, Minoufekr and Plapper, 2018), creation of personalized manufacturing service (Zhang et al., 2013), rural manufacturing (Molano, Polo and López, 2015), etc. This paper applies two-mode networks in manufacturing. One group of nodes represents firms, and the other group of nodes represents services (i.e. product-related services and digital solutions). An earlier research has proposed eigenvector centrality, which computes the importance or dominance of a node in the network (Wasserman and Faust, 1994). For example, if firm 1 (F1) is connected with resource 1 (R1) and firm 2 (F2) is connected with resource 1, then F1 and F2 are connected. Two-mode data offer some interesting possibilities for gaining insights into macro-micro or node-structure relations (de Laat et al., 2007; Rakic et al., 2018). With two-mode data, researchers can examine how macro-structures (e.g. manufacturing sector) affect interactions between product-related services and digital solutions. In this paper, a dataset of firm by firm ties was created, measuring the strength of the tie between each pair of firms by the frequency of use of the same resources. The digital solution which has the highest eigenvector centrality is the dominant node in the network, and it was included in the regression model. To identify a relevant effect of product-related services on firm performance (i.e. share of revenue), we tested two node-level regression models: (1) with the application of the dominant digital solution and (2) without the application of the dominant digital solution. The regression model is presented in Figure 1. Both research questions were analysed using UCINET (Borgatti, Everett and Freeman, 2002) to examine the data and generate the graph.
Results and discussion
The results of the present study will be analysed as follows: RQ1 based on Figure 2 and Table 3, and RQ2 based on the regression model. For RQ1 (Which digital solution has a dominant place in manufacturing firms?), the use of digital solutions in manufacturing firms was evaluated based on the data analysis. In order to answer RQ1, digital solutions are ranked based on eigenvector centrality in the network. Figure 2 depicts the network between firms and services. In Figure 2, red circles represent firms, and blue squares represent services.

![Figure 2 - Graph illustrating network between manufacturing firms and services (product-related service and digital solutions)](image)

Table 3 shows the results of eigenvector centrality between digital solutions in the two-mode networks. A very common and a very useful approach to two-mode data is to convert it into two one-mode datasets, and examine relations within each mode separately (Hanneman and Riddle, 2005). The authors applied this approach to discuss the results and they evaluated the relations between digital solutions which are presented in Table 3.

<table>
<thead>
<tr>

Web-based services for customized product configuration or product design have the highest rank because they have the highest eigenvector centrality (0.643). Furthermore, this digital solution was included in the regression model so that the authors could investigate the moderating role of the digital solution on firm performance. For RQ2 (How do product-related services, along with a digital solution, affect firm
two regression models were tested. In the model that estimates the effect of product-related services on firm performance without the application of digital solutions, it is shown that the impact is significant and positive. Introduction of the best ranked digital solution (i.e. web-based services for customized product configuration or product design) into the model increases the positive effect on firm performance, providing support to RQ2. The $R^2$ changes from 0.22 (without application of digital solution; $B = .473, p < .001$) to 0.25 (with the application of digital solution; $B = .496, p < .001$). In terms of profitability, our findings support the earlier research, which presented a positive effect of product-related service on firm performance (Gebauer et al., 2008; Lalic et al., 2018; Marjanovic, Lalic, Majstorovic, Medic, Prester and Palcic, 2018). Moreover, at the same time, we presented that the moderating role of digital solutions increases the positive effect on firm performance.

**Conclusion**

This paper evaluates the use of digital solutions in manufacturing firms. Furthermore, it contributes to the existing literature by presenting the position of digital solutions in manufacturing firms. The research was conducted under the international project EMS. The dataset used in this paper was built from 2018 data collection. The results showed that web-based services for customized product configuration or product design are the best-ranked digital solution. Moreover, the results for the model with the application of web-based services for customized product configuration or product design show a higher positive effect on the share of revenue than the model without it. It could be concluded that manufacturing firms, in order to achieve better performance, need to integrate business processes with digital solutions.

This approach could be helpful to managers of manufacturing firms. With this information, managers can better shape the package for their customers when offering products. Furthermore, they could put emphasis on things that add value to firm performance. Production managers could introduce corrective actions in order to increase the effectiveness of production, develop strategies to address problems, provide better services for their customers, and create a more efficient business.

This research is limited only to the impact of one digital solution on the manufacturing firms’ performance. There are other digital solutions which are important for manufacturing firms that could be included in future research. Also, this research considers only a dataset from Lithuania and Serbia. Future research should take into consideration different challenges in measuring the impact of other digital solutions provided by manufacturing firms from different countries.

Abstract

A challenge for manufacturers is the constant pursuit of improving their economic efficiency and profitability. With the increase in the use of ICT, Internet of Things and Big Data, the integration of products and services is reshaping the business models. This paper aims to investigate the main factors to advance with the integration of products and services in Mercedes-Benz and other business units of Daimler Group. The findings suggest that several interviewees mentioned the necessity of technical improvement of current products to meet the needs of the market, confirming the internal culture focused on product.

Keywords: PSS, Servitization, Business Model, Operations Strategy.

Introduction

In recent years, several factors have led to changes in customer-business relationships, from the growth of the world population and the consequent increase in consumption and demand to new consumer behavior and lifestyle (KÖLSCH et al., 2017). With globalization, new competitors unexpectedly emerged threatening traditional businesses’ profitability and economic efficiency. In pursuit of profitability or even for the sake of survival and maintenance of their business, we note the growth of the integration of products and services, especially in globally active companies (Reim et al., 2015).

Neely (2008) has compared data between 2004 and 2007 of a sample of more than twelve thousand companies in several countries. The author reveals that the percentage of companies with services in the descriptive memorial of its social name in the United States is 59% while in Finland it was (53%). Singapore (49%), Malaysia (46%) and the Netherlands (40%) were also highlighted with large percentages of services in the total number of businesses. More recently, Santamaria et al. (2011) reported that one out of five companies surveyed reported introducing integration of PSS products and services. In China, this percentage increased from 1% in 2002 to almost 20% in 2011 (Neely et al., 2011).
In addition, with the increase in the use of IT services, Big Data, IoT and the consequent development of smart products, it is expected to reach the level around 212 billion of product until the end of 2020 (Manyika et al., 2013; Seregni et al., 2016). Therefore, a new strategy is increasingly being considered by organisations. There is an opportunity to take advantage of the concepts of the industry 4.0, IoT, and sustainability to meet the new reality of the consumer market (Al-Fuqaha et al., 2015).

The benefits to compete by introducing advanced services include revenue growth and greater economic profitability (Eggert et al, 2014), improved product innovation, quick response to customers, creating new possibilities for revenue (Baines and Lightfoot, 2013), increase customer loyalty (Saccani et al, 2016) and support to exceed barriers toward the competitive advantage (Oliva; Kallenberg, 2003). However, how to provide such services has challenged many companies (Baines et al., 2017).

One of the biggest challenges to change the business model of a typical manufacturing company towards servitization is how to transform the organization for this purpose. What is known is its business model must be adapted or transformed (Weeks; Plessis, 2011).

The literature has shown that the fundamental concepts of servitization are well established on contrast to the necessary practices to promote this change (Baines et al., 2017). Thus, understand how the companies move from a product-oriented for a result-oriented perspective through a PSS business model is still an open topic.

This paper aims to answer the question on how and to what extent product and services are being integrated in an automotive company. A case study in the Daimler group was developed with predominant focus on the Brazilian truck unit of Mercedes-Benz.

**New PSS Business Model Development**

Reim et al. (2015) defined business model as being the design or architecture of the mechanisms of creation, capture, and supply of value. They conducted a systematic literature review of 67 articles to understand how companies adopt and implement PSS, using the former classification from Tukker (2004): product-oriented (PO), use-oriented (UO) and result-oriented (RO). By analyzing the content of the articles, it was found that scholars tend to discuss PSS business models and implications for implementation using five distinct sets of tactics: contracts, marketing, work network, product and service design and sustainability strategy.

Contracts refer to how rights and duties are distributed between supplier and customer. A PSS contract must be developed addressing all aspects of the service provided very clearly, involving the obligations, any failures and all legal considerations involved. These contracts have a complexity far beyond the simple sale of a product and the terms and agreements must be adapted according to the negotiated context of PSS (Reim et al., 2015).

The second set of tactics describes how PSS providers interact, communicate and use customer and market insights to implement their business model in PSS. The extent of customer interaction increases when the company shifts to a service-oriented business model. Communicating the value of the service with transparency and unambiguity, as well as showing how it differentiates from the competitors and seeking to gain a new segment of customers. Finally, use the customer and market insights, considering the collection of product data or service in use through interaction with them.

The third set of tactics describes how PSS providers use their networks and relationships with partners to ensure that the PSS business model is successfully implemented. This strategy refers not only to whom to make partnerships, but also to
what type of partnership, shaping the sharing and coordination of the activities (Reim et al., 2015).

Product and service design tactics describe how PSS providers structure their products and services to meet the needs of customers and thus achieve success in implementing the PSS business model. To meet the new design requirements of products and services, it is needed to give emphasis on the alignment of the physical characteristics of the product with the characteristics of the service offered and vice versa (Reim et al., 2015). A closer and long-term relationship requires a product and service design perfectly adapted to the needs of the customer.

Most of the studies show that PSS implementation results in sustainability benefits and avoid rebound effects. PSS business model may facilitate the extension of product life cycle, collection of end-of-life products, as well as remanufacturing, recycling, as appropriate disposal of parts and components.

The tactics presented by Reim et al. (2015) although involve several aspects for the implementation of a new business model. However, they leave out the human aspect approach. In this sense, Weeks and Plessis (2011) emphasized the importance of organizational culture and human resources policies in the implementation of PSS. They observed that organizational culture and shared business values, from executives to the employees, demonstrate the importance of unique identity, common understanding and shared company-wide attitude in the development of a new business model. Other characteristics such as individual autonomy and support in decision making, risk tolerance, high performance to the form of conflict management are determinants for the implementation of the new PSS business model (Weeks; Plessis, 2011).

Similarly, in a systematic review of literature, Brax and Visintin (2017) found eight stages to move forward a PSS model: production, business analysis, solution design, supply network design, implementation, operation, support and disposal, not necessarily all of them being used sequentially. In addition, these stages, also three value elements are identified: financing of the capital good investment, system ownership and payment model. System ownership and payment model are considered as revenue models elements, while financing is considered a supplementary value element.

Ulaga (2013) argues the need of a transition planning to a PSS business model. The involvement of the company's board of directors is crucial. Many companies due to the complexity of the change, decided to split the business and creating separated business unit, or even create a new company to quickly develop the new PSS business model (Ulaga, 2013; Baines et al., 2017).

Reinartz and Ulaga (2008) highlight the need to develop ways of service charging (pay-for-use, pay-per-hour). In the customer service, the back-office processes should be monitored and the processes not necessary should be eliminated. Instead, create an experienced sales force services for the complex services solutions requires long sales cycles and decisions are made by high-ranking customers, which demand experienced and prepared team for such negotiations.

Foote et al. (2001) state that in terms of reorganization it will be important to hire trained and specialized technicians in working with ICT as well as in performing new services such as consultant and customer training. Moreover, it is needed a definition of an organizational structure to meet this new demand (Baines et al., 2017).

An analysis of the economic feasibility, considering the servitization paradox and the U-Curve effect may be necessary, since the investments for such implementation may have their return in a period such that the levels of risk can hinder this process (Eggert et al., 2014; Kwak; Kim, 2016). Regardless of complex economic analysis, companies
should recognize the importance of integrating services as a proactive and conscious strategy that enables its growth and increase profitability (Kwak; Kim, 2016).

The studies have reinforced the importance of the current organizational structure and the adaptations needed for the implementation of PSS, in addition to the human management and internal behaviors of the company. Individual autonomy, structure, support, identity, performance, conflict tolerance and risk tolerance. These characteristics of the organizational culture and its attributes, added to the internal behaviors, are also determinants for the implementation of the new business model PSS (Weeks; Plessis, 2011).

Gebauer et al. (2005) argue the main aspects concerning to the organizational culture were the necessary motivation of the managers and the opposition behavior limiting the business model change.

Methodology
Changes in strategy and business model, especially those regarding the inclusion of services into products can be very complex to be understood. Thus, conventional data gathered techniques, in which respondents complete questionnaires remote does not seem enough to secure and generate practical insights (Baines; Shi, 2015). Based on the characteristics of the subject, this study can be considered qualitative empirical research involving a single case. The case study seeks to show a reality that is not enough known not trying to establish cause-and-effect relations (Yin, 2017). Therefore, this research is characterized as ‘exploratory’ in the specific context of a Brazilian subsidiary of a multinational car manufacturer located in Sao Paulo.

Despite its limited use for theory-testing, case study research has been used in the field of operations management to test complex issues such as business strategy implementation (Voss et al., 2002, Yin, 2017).

Respondents and data sources
One of the most important aspects in the definition of the respondent is the level of knowledge about the subject being investigated (Baines; Shi, 2015). In order to reduce this vulnerability and the risk of repetitive responses in this study, due to the company's internal culture, it was decided to expand the research not only by focusing on Mercedes-Benz but also on other Daimler companies. The research was therefore extended to companies Daimler AG (Germany), Detroit Diesel Corporation (DDC), Daimler Trucks North America (DTNA), Mitsubishi Fuso Truck and Bus Corporation (Japan) and Daimler India Commercial Vehicles - DICV (India).

The respondent’s profile was firstly a person is part of the organization of one of the companies of the Daimler group, be it in the supply or consumption of services, be personally involved in the provision of services or related activities, have knowledge and experience in the function, and preferably have some authority on the subject. In addition, to avoid the risk of inhibitory factor by the function performed by the respondents, only those with executive positions of different levels of hierarchy (sequentially in ascending hierarchical order, Managers, Senior Managers, Director, COO and CFO) and of several areas of responsibility: Operations, Sales, After Sales, Human Resources, Quality, Controlling, Industrial Planning, Purchasing and Information Systems IT.

Furthermore, the research also count on a participant observation since one of the researcher has been working for 35 years in the Daimler Group, currently at the Global Procurement department of the Brazilian subsidiary of Mercedes Benz but already had in
the Cost and Value Engineering, Truck Product Planning, Product Cost Calculation & Investment Analysis departments.

Participant observation is commonly linked with the data collection phase, but it cannot be resumed on this. The participant observation can be defined as an observation process of a community or social group where the researcher has a role in this unit of analysis in order to share experiences (Bernard, 2017). According to Jorgesen (2015), the researcher interacts with people in everyday life while collecting information. It is a single method for investigating the richness, complexity, even conflictual and diverse experiences and thoughts.

Results

Current PSS context in the company

Prior to officially interviews get started, some meetings with the sales department of Mercedes-Benz were carried out and it was realized that to some extent a PSS model is currently been in deployed since a newly data equipment has been offered, called Fleetboard. This equipment is one of the most advanced telematics systems, that uses the computer integration facilities with the resources of the internet and mobile network with the intelligent processing of truck data. For the carrier and those responsible for fleet management, it provides important data on the use of their vehicles. For example, an analysis of driving by the driver (driving style), checking habits and vices in the steering wheel, or monitoring of routes with verification of stopped time and in movement. The diagnosis allows an evaluation of the operation of the engine and equipment in general, including digital map, geographical position, check driving conditions in different types and different road conditions and prognostics maintenance, based on forecasting and use.

The Fleetboard is currently offered only as a product supporting the management of the fleet. However, there is a way to obtain all information pertaining to the use of the product, from the availability on the Internet, of a source of data that must be stored and analyzed and can become an important source of information for an adding value. The question is: how data can be exploited and made available and how to add value and increase the profitability of the company with the use of this data?

In this paper, the sale of data will not be our focus since the proposal is to use these data to generate a form of different product sales embedded services, advancing with the use of IoT and Big Data.

Insights from interviews

To facilitate the organization of the data obtained in the research including both, the interviews and documents, it was elaborated some figures summarizing the main aspects related to each constructs and dimensions as well as the actions of PSS. The changes in the business model was discussed as an open topic regarding the importance of the PSS business model for the company, the integration of services to the truck product and the business vision for the company’s future business model.

All respondents agreed on the need for a change to improve the company’s profitability, but it is interesting to note that several of them mentioned the necessity of technical improvement of current products to meet the needs of the market, confirming the internal culture focused on product (PO), according to Tukker’ typology (2004).

Specifically on the topic of integration of services to trucks, the respondents agreed that it should improve profitability, but they advocate the integration of lower grade. The director supports the truck rentals, sales manager cited the sale of maintenance services and sales senior manager the extended warranty and driver training sold jointly to the
product. On the other hand, the respondents agreed that the integration of product services should be a matter of survival, which reinforces the findings of Reim et al. (2015).

Most of the respondents considered very difficult for the company to reach the new business model due to cultural issues. However, these cultural issues should be managed by the company executives, corroborating with the findings of Weeks and Plessis (2011). Training of employees is also vital, particularly technical staff such as product engineers, as the company is totally dedicated to the development of new products instead of service-oriented solutions.

Fourteen respondents stated that creating a business unit separate from the current company to foster the development of the new PSS business model may be the most viable alternative, reinforcing the studies of Ulaga (2013) and Baines et al. (2017) which argue that the only way to speed up and facilitate the development of the new business model for PSS.

Four respondents also cited the use of startups and one cited the company's current project, called Leadership 2020, which uses ideas incubators, especially for the lower investment needed.

We evaluated several currently sorts of contracts, from those related to the purchase of material to those referring to purchases of machines and equipment. Our findings suggest that no partnership was observed. People from procurement area presented the parts and tools contracts used in the company and reinforced that they are always related to the supply of a physical product and not services. In the case of services, the scope is usually defined as the payment with a fixed amount according to a worksheet accompanying the tasks, as highlighted by purchase director, with a form of turnkey payment, that is, full payment when the task is executed and final delivery.

Long-term contracts cover a maximum of 5 years, but most of the contracts analyzed has 1 year as duration. According to Baines and Shi (2015), companies with a PSS model must have long-term contracts and managed risks. All the contracts examined were standardized and any change should be approved through the legal department, having developed an internal system for this purpose.

The contracts are managed and monitored by the contract manager and no risk management instruments have been observed. Controlling director clarified that it will be used investment analysis spreadsheets on the acquisition of capital goods, given by the controlling department of the company, being considered viable the investments that generate returns in a maximum of two years. This is in line with one of the important aspects cited by Brax and Visintin (2017) for the implementation of a new PSS business model.

According to the experience of companies with PSS business model, we tried to understand some services that the company already provides, but by the current PO business characteristic are not charged. People form sales and strategy have argued that the sales area has a software to calculate the Total Cost of ownership (TCO) as recommended by Roda and Garetti (2014). This software is used by technical sales assistants to suggest, according to the customer needs, the most viable products from the point of view of total cost. We found that this same worksheet is used by the post-sales staff as a guidance tool for large fleet owners to optimize costs and this service is offered but not charged (Reinartz and Ulaga, 2008).

The interaction-relationship of the sales staff with the dealers of trucks is very close, including using sales performance indicators and basis for comparison of them and, even, for the best awards. People from strategic area reinforced that, however, there is small interaction with final customers, for example, with logistics companies that are large
consumers of trucks. With this, the development and preparation of the employees do not focus on serving the public directly, but only to the dealers.

The company uses the concept of indicators of the balanced-score card, with annual definition of goals, being cascaded and monitored monthly. The business strategy area, directly linked to the CEO, is responsible for the control and monthly reporting of the results of the indicators. The main performance indicator used by the company is return on sales (ROS), not only by the Brazilian subsidiary but by all Daimler group.

It was also noticed a difficulty in reflecting on possible future clients in the PSS model, due to the culture of products and the current relationship through dealers.

In general, the managers understand that this topic is a huge challenge, because the company does not present a culture of partnerships and networking.

According to interviews with the controlling area, Mercedes-Benz has never used the concept, for example, of open-book, open structure and shared costs with its business partners. Neither it has any kind of sharing of internal information since it is characterized as confidential information, which makes it difficult to use the PSS business model as discussed by Foote et al. (2001).

Respondents generally considered that a large majority of internal processes being bureaucratic and non-agile, especially due to the rigid compliance rules, with regulatory standards followed by all the employees. According to the procurement manager, this directly influences even the training and skills required for purchasing personnel who end up following the standards and do not develop in commercial and non-technical aspects for a business partnership. In managers’ views, it should be developed the new business model PSS in a separated organization, or it could be a business unit or even a startup. Human resources director considers that several factors make it difficult to change the business model for PSS, but in particular by the very closed corporate culture also in the upgrade process, not based on partnerships and trust, essential as pointed by Baines and Shi (2015), but in rigid contracts and communication in the majority of official character, through letters and controlled emails.

Some previous attempts of internal changes were carried out without agility and were very difficult to involve all the executives, probably because the size of the company and problems related to internal communication or even motivational reasons. It has also been pointed out that the several years of crisis and the constant reduction of personnel generate a certain pessimism and lack of motivation in the case of need for change.

The product development department appears to be focused on the technology of new products, with little customization. Customization is carried out especially by companies that complement the trucks with items to meet the specific use of the products. Most of the product developments are carried out in the headquarter, which in turns bring low flexibility and would be a major disadvantage for the implementation of the PSS business model (Baines et al., 2007).

We tried to deep in the characteristics and information provided by the Fleetboard with the sales area. They mentioned the difficulty in use it as a new service.

Regarding the concepts of Big Data, people from IT area cited the implementation of the concepts of industry 4.0 in production but regarding the use of Big Data in products is still outside the current reality of the company in Brazil.

Managers have shown great concern with sustainability. Chief of operations mentioned the sustainability in the production processes by reusing material such as waste, burrs, lost parts used in production. In relation to sustainable products, the use of alternative materials, such as the development of trucks using coconut fiber instead of foams.
Mercedes-Benz has developed an area for motor reconditioning and resale of used products, but without yet worrying about the final disposal of the end-of-life product. The company controls the conservation of environment and natural resources of their direct and indirect suppliers, including having an annual award for the different actions on the environment.

Organizational and human management was stressed as a crucial issue by all respondents. A common agreement was regarding the need to hire qualified personnel for the new PSS business. A sample of this was that few respondents demonstrated knowledge of PSS and constantly returned to product focus. Specially, Mercedes-Benz Chief Operating Officer believes it is complicated to achieve full executive motivation and an awareness of the need for change. The respondents also considered that internal motivational campaigns would not have positive effects nowadays because of the negative market situation and ongoing staff reductions leading to a non-positive climate to a campaign of this type.

Another finding is that interviewees of the quality department did not agree that the personal of this area should to add a capacity of services. Likewise, the services director considered that both the technical training and the psychological profile of the staff are focused on technology and new products, not services. However, senior manager of DICV stated that since the company is relatively new, the staff personal was prior recruited prioritizing qualifications for the service area.

**Conclusion**

Transforming a product-oriented organization to compete through services is a challenge for practitioners. So it is for researchers to understand and facilitate the transformation towards service-orientation. In general, the academic research is fragmented and no frameworks explains how to the shift towards the integration of products and services. Thus, this is inevitably a barrier to the adoption of servitization (Baines et al., 2017).

Our findings indicate that PSS consider manufacturing companies as a service provider, instead of being considered as customers. Many manufacturing companies are now customers of advanced services, through partnerships and the acquisition of complex manufacturing technologies such as machining, extrusion, forging and casting. This topic raises questions about the relevance of manufacturing servicing and requires further studies.

For reasons of scope definition, this paper focused on the strategic and behavioral actions of change of the PSS business model in a manufacturing company. Internal issues of logistics or production processes were not taken into account. This is certainly an area that should be considered for future research.

A limitation of this paper is that it is based on a single segment (loads) and a specific product (trucks). However, it was minimized using multiple respondents from various companies of the Daimler group from different countries and with access to different sources and internal documentation. Moreover, expanding the research to other Daimler companies reduced the risk concerning the repetitive responses in the Brazilian subsidiary.

In terms of managerial implications, Mercedes-Benz should use the information provided by Fleetboard to infer the use of product data and change the current business model, to supply not only a truck, but a complete transport solution, adding new services to the currently product.

To take advantage of Big Data can, for example, with accurate information conductivity style's designated driver, the company should propose exchanges drivers to
more appropriate routes or more appropriate costs (for the driver who can have good savings fuel and consumption in general, the same must be placed in routes of great consumption). Another possibility is, from the data of duration and movement in a certain route, the causes of loss of time and efficiency can be determined. From that alternative routes (that bring better yield) can be proposed or an integrated mesh of transport of load can be redesigned. With tele-diagnosis data, a predictive maintenance can be proposed, or even negotiated with a supplier. For example, tire wear and tear information directly to producers, following the model of the Michelin implanted concept.

It is also possible to provide service training, whether it is for drivers, fleet operators or even the maintenance companies. Also propose the sale of a powertrain (engine, transmission and drive axle) suitable for general use of the product, in order to generate a total cost optimized for fleet owners, through better efficiency and adequate consumption, form pay-per-use. Or a partnership with a specialized company in logistics and transport, offering not only a truck but a complete integrated transport solution that meets the needs of the customer.

Abstract

Product-service systems (PSS) are presented in various sectors, yet most of the theoretical framework of servitization is based on manufacturing firms. The primary sector diverges from manufacturing in many aspects, despite highly representative economically, introduces particularities intrinsic to the primary activities. Thus, this article performs a critical analysis of the main model of PSS transition process, Oliva and Kallenberg’s model (2003), and propose a comprehensive framework validated through an exploratory analysis in coffee production’s suppliers. The findings provide evidence that servitization differs from the manufacturing PSS transition, and serve as a guide for provisioning of services at the primary sector.

Keywords: Product-Service Systems, Servitization, Primary Sector.

Introduction

Vandermerwe & Rada (1988) evidence of the importance of supply a bundle of goods and services to customers, showing that this was a recurring practice in organisations seeking superior performance. However, although widespread, diversification by services would not per se guarantee this result (Brax, 2005; Hou and Neely, 2013). For this purpose, the innovation movement with services should be progressive, from a restructuring of the business model, migrating from product orientation to service orientation (Kastalli and Van Looy, 2013). In this process, called Servitization, products and services would find the necessary structure for the formation of a single intricate unit, a product-service system (PSS) (Mont, 2002).

Several authors (Dimache and Roche, 2013; Reim et al., 2015) advocate that the transition from a product-centric firm to a "servitized" enterprise can be envisaged in a continuum of PSS supply possibilities. In this continuum would be several combinations of PSS from the less advanced (with greater appeal for products and services as coadjutants), to those more advanced (with greater importance of the services, including with the possibility to suppress the possession of the physical product by the client).
However, for this offer to occur, an intrinsic service issue cannot be neglected: the need for a more in-depth relationship, since the value created emerges precisely from the interactions between customers and sellers, which boosts earnings for both (Gronroos, 2015).

In the primary sector, the inter-firm trade model prevails, or business-to-business (b2b), whose relational aspects and network structures are superior, allowing the creation of closer ties, of longer duration, and with greater intensity for the expected return (Ford, 1980; Saccani et al., 2014). Also, there is concern about the performance of the business on both sides of the negotiation (Cannon & Perreault, 1988), which enhances the environment for the most exclusive and innovative service offerings (Bastl et al., 2012).

Despite this favourable profile for servitization, we find a gap in studies that contemplate this type of transaction. For the author, this gap would mainly come from the lack of available data and the lack of knowledge and mastery of the theme by the researchers. This reflects a significant number of research papers in servitization that is based mainly: a) in cases of companies operating in the business-to-consumer type of market; b) in case studies dealing with particular sectors; and c) studies encompassing a group of manufacturing firms. As a result, the main advances and frameworks on the subject follow the particularities of direct contact with the final consumer in the delivery of the service.

The present article brings a critical re-reading and adaptation of the servitization model by Oliva & Kallenberg (2003) to encompass the characteristics peculiar to services in the primary sector and the lack of understanding in the literature of servitization beyond manufacturing.

**Methodological aspects**

In order to attend the goal of this article, the first step was a qualitative work, with the literature review subdivided into two complementary phases: a) search of the main works on the measurement of servitization in manufacturing; and the second, b) search for studies on the subject for the interfirm sector. In these stages, the main databases of journals accessed were EBSCO, Jstor, Emerald, Elsevier (Science Direct), Web of Science and Google Scholar.

As a result of this qualitative research, the article “Managing the transition from products to services” from Olivia & Kallenberg (2003) was recognized as one of the most significant impact in the literature about servitization, having been cited as a reference by at least 800 articles since its publication (data from Emerald Insight, 2017). Thus, we chose to use the framework proposed by the authors as the initial parameter of classification of the services identified in the evaluated companies, aiming to verify the applicability of the conceptual framework for the interfirm sector.

Subsequently, we make a critical analysis of this model, with the proposal of a new conceptual framework (Convergent Typology) aggregating the proposals of classification of the services considering its complexity, orientation, and the possibilities of supply. In this direction, the text proposes a new more comprehensive framework based on the literature review of the theme (Baines and W. Lightfoot, 2013; Dimache and Roche, 2013; Gebauer, 2008; Mathieu, 2001; Parida et al., 2014; Reim et al., 2015; Saccani et al., 2014; Ulaga and Reinartz, 2011).

The second part was to validate the new model through an exploratory analysis of the intensity and occurrence of supply of PSS in seven firms: four companies that supply agricultural machinery and implements with a recognized investment in the portfolio of services (Identified as A1, A2, A3 and A4); and three companies that supply agricultural inputs which offer differentiated services to customers (Identified as B1, B2 and B3).
The focus on primary sector firms is based on two main factors: a) academic research that encompasses the development of services for the interfirm sector, and b) high potential for servitization in primary sector firms. Neely (2013) states that companies of farm machinery and implements (in particular the production of grains) can be considered as one of the most servitized in the world. In general, in the primary sector, the servitization strategy has been used as an exit to solve intrinsic issues, such as product technologies become increasingly mature making it more difficult to achieve technological superiority through the actual product, and, with it, the difficulty of standing out in the competitive market. Thus, we can see a demand for studies that contemplate this transition of products for services also in this market.

We chose to research companies that work in coffee production because of its cultural and economic importance for the country (Brazil is considered the world's largest producer and exporter of coffee, commercializing 30% of the volume of grain sold in the international market, according to data from the Ministry of Agriculture, Livestock and Supply.

The data collection took place in two relevant coffee production areas in Brazil, representing together almost a third part of the total production of the country and a large number of specialised suppliers. The interviews were conducted with the managers responsible for the service area in each of the companies and had an average duration of half an hour. During the collection of data with the questionnaire, the collection of printed data also took place: event folders, field work day worksheets, user manuals, technical delivery procedures, sale catalogues, among others accessed through electronic means in the institutional sites. Additionally, as a way to ensure the understanding of the types of services available to clients, interviews were also conducted with Technical experts and managers from three Cooperative of Coffee Growers (COOCAFÉ, EXPOCACER and ACARPA).

**The conceptual framework of reference**

Oliva & Kallenberg (2003) evaluated 11 manufacturing companies in the process of servitization to describe how the process of organisational transition occurs for the provision of services. The authors use the concept of a product's installed base (IB) as a parameter of the measurement of services offered jointly to existing assets. Thus, the product's installed base (IB) "is the total number of products currently under use", and in this context, IB “is the range of product-services or process related services required by an end-user over the useful life of a product in order to run it effectively in the context of its operating process”.

This transitional process would consist of a four-step evolution: 1) Consolidate the product-service systems, combining the offer of services with the supply of goods to the end user; 2) Enter the market for the provision of installed base services, which implies identifying a profit opportunity with the services and creating the necessary structures and processes to exploit it commercially; 3) Expand the service offered through two transformations - a) migrating focus from transactional to relational; and b) changing the focus of the value proposition solely based on the effectiveness of the product for its effectiveness and efficiency in the process for the end user; and 4) Assume the operations of the end user, entering the field of operational services (no company surveyed had reached this level). The services fall into four categories: basic installed base services, maintenance services, professional services and operational services.

Thus, walking on the continuum for more advanced supply, the assets would become supporting elements of the offer, making their possession less important, and the impact
of services increasingly prevails on the results of the supplying organisation. In short, in the transition model proposed by Oliva & Kallenberg (2003) has some assumptions:

- Although not considered mandatory, the maintenance services were identified as necessary for the company to be prepared structurally for the evolution of service;
- Basic services (IB) are product oriented, with the identification of basic services directed to the process of the end user not being adequate;
- The most advanced services are called operational, process-oriented. Both descriptions of the service assume that the moment of the offer of the service is after the purchase, that is when one already has some level of relationship in progress with the client;
- The most successful companies in the provision of services are those that maintain specific organisational separation for the operation with products and services.

The Convergent Model: A new proposal to re-read the reference framework

As evidenced, Oliva & Kallenberg (2003) identified four types of service, limited to two types of orientation: to the product and end-user (Figure 1). However, more recent studies to measure servitization (Dimache & Roche, 2013; Reim, Parida & Örtqvist, 2015; Gebauer, 2008; Saccani, Visintin & Rapaccini, 2014) classify services in PSS into three forms of orientation, which are superimposed on the model by Oliva & Kallenberg (2003). It occurs that, each of these three forms of orientation has specific characteristics, with its separation being necessary to compose the continuum of PSS: a) services oriented to the physical product; b) services oriented to the use of this service; and c) service oriented to the results of the service. Saccani et al. (2014) did a complete bibliographic review of the PSS offerings summarising how services can be categorised not only between their orientation towards product or use but also to results. The authors identify the characteristics related to the recipient of the PSS such as their intensity of relationship and level of customisation. In this sense, as the PSS changes from product-oriented to use-oriented and subsequently to result-oriented, the level of customisation becomes greater, and the need and intensity of the relationship increases. Besides, Reim et al. (2015) identified that results-oriented services are those that demand greater responsibility and attention from suppliers because they are the riskiest. This is evidenced by the high possibility of customisation, the innovation required in the processes, the need for constant communication and interaction based on trust, and the high formalisation of activities. The counterpart of this initial cost would be the highest returns to the business, promoting the joint creation of value and being able to reach the competitive advantage more easily (Vandermerwe & Rada, 1988; Reim et al., 2015).

This interaction should, therefore, be based on greater trust among those involved, increasing the necessary degree of contact with the client and the focus on the joint creation of solutions. With this, and for greater freedom to provide the result, the PSS supplier can offer greater possibilities of customisation, with more significant opportunities for innovation and greater flexibility in both the production of the PSS and the established routine. Despite the advantages, it poses a higher risk to the PSS, if an internal restructuring does not support the path through the PSS continuum, the chance of failure before reaching this orientation is high (Reim et al., 2015).

In addition to the result orientation, which would represent the most advanced services in the continuum, there would still be two types covered by Oliva & Kallenberg (2003): the most basic, or least advanced, characterised as well-oriented; and the intermediate, denominated due to its use-orientation. In the first type, services are directly related to the good offered, requiring less interaction with the user and/or involvement of the provider
and lower investments. Consequently, it has a lower risk of execution and little or no possibility of customisation. In the second type, there are those services rendered for the use of that good, involving the user more directly, and becoming less tangible.

Given this differentiation, we sought to verify the compatibility of the reference framework cited with the reality of the primary sector in particular four main points:

- Oliva & Kallenberg (2003) argue that the evolution of service supply would be required to reach higher levels of servitization. Given that the more service-oriented companies need to compose a range of comprehensive services, it is expected that the most service-oriented firms will be those with a more significant number of linked services. Therefore, it is expected that the company will first offer basic installed based services or maintenance services, and subsequently, began offering professional and operational services;
- Basic services would only be those focused on products, and it is not appropriate to identify basic services for the end-user process. Therefore, it is expected that all services falling within this category will be product-orientated;
- The most advanced services are termed as operational, process-oriented. Both descriptions of the service assume that the moment of the offer of the service is after the purchase, that is when they already have some level of relationship in progress with the client. Thus, it is expected that the most advanced services will be identified in the post-sale;
- The most service-oriented firms are expected to show an organisational separation between operations for integrated products and services (PSS).

All the assumptions are based on the classification of the service as a starting point for the identification of the service level. The new Convergent Typology is represented in Figure 1, which brings a comparative representation between the classification of services in both typologies.

![Figure 1 - Comparative representation between the reference framework and the new proposal.](image)

In the new classification we have the dimension of the importance of services and the need for product ownership, as evidenced by Saccani, et al. (2014), among other authors who classify services through their orientation (Dimache & Roche, 2013; Reim et al., 2015; Mont, 2002; Gebauer, 2008). Thus, for services classified as product-oriented (basic and maintenance), the importance of services would be lower, with a greater need for ownership of the product, which is the main purpose of support. Three key points should be highlighted in this new classification:
The division of services considered as basic (IB), between product-oriented and use-oriented. This was a demand evidenced by the theory and confirmed in the data collection, since the effort necessary to supply use-oriented services is greater, although they are considered basic. As such, basic use-oriented services are more advanced than product-oriented services but less advanced than services identified as user-oriented professionals.

The professional services were subdivided according to their orientation, which may be less advanced (use-oriented), or result-oriented. This differentiation was also corroborated by the research findings since the efforts for sale (still in pre-purchase) signalled the assistance of consultancies, experiments, and advice with a focus on the performance of purchased products and how to improve production management.

Services considered as operational, contrary to what is signalled by Oliva & Kallenberg (2003), were reclassified as result-oriented (for the authors, these were user-oriented services and with high a demand of relationship). This new categorisation reinforces the great need of relationship evidenced by the authors, keeping the service receiver as a process manager and with a high possibility of customisation.

The new table shows nuances of the evolution of the servitization in a given company, stratifying levels of evolution that were previously not perceived in the classifications surveyed. Also, it is perceived that there is no need to overlap less advanced services so that more advanced services can be offered. Therefore, we seek to identify the main services with this format mentioned in the literature, not limited to those in manufacturing. Thus, we recognize during literature review 24 types of service identified in the companies in the process of servitization (code and type of service): (S1) Maintenance (various); (S2) Deliveries and logistics; (S3) Troubleshooting and problems-solving; (S4) Training/ seminars/lectures; (S5) Consulting, auditing and customer service; (S6) Inspection/ Monitoring / Diagnosis; (S7) Replacement management; (S8) Customer support; (S9) Updates and Upgrades; (S10) Documentation / information material; (S11) Help Desk; (S12) R&D; (S13) Installation / Commissioning; (S14) Demonstration; (S15) Supply of utility items/ consumption items; (S16) Technical assistance; (S17) Recruitment of staff; (S18) Revenues; (S19) Warranties; (S20) Lease of goods; (S21) Orders; (S22) Cost-benefit calculation; (S23) Analysis of manufacturability and viability of goods; (S24) Client Process Operation.

In addition, Figure 2 shows the representation of the services found in firms served by the framework of reference and the new Convergent Typology.

**Presentation and discussion of results to validate the new model**

The initial analysis starts with the identification of the types of services found in the sample, characterising them according to the classifications proposed in the reference framework - Oliva & Kallenberg (2003). It was to be expected that most services would be concentrated on those basic products, but product-oriented. This is because, according to Parida et al. (2014), for manufacturing, this is the main frame, whose services are based mostly on maintenance services. For the primary sector, this is most relevant, because, in a commercial interfirm relationship, the aspects related to the product are usually overcome by those related to the relationship between the parties (Bastl et al., 2012).
We can verify that the differentiation between service supply was identified for the companies of the two surveyed sectors. Industry A offered 12 basic services (product-oriented), while only one service of this type was identified by industry B (deliveries and logistics). On the other hand, basic services, but use-oriented are proportionally more used by companies in Industry B, which is justified given the intrinsic characteristics of the goods traded (low differentiation, low technological input, single use). This differentiation can be seen in other well-oriented services, such as maintenance, which was found only in industry A.

Professional services could be found in companies of both industry A and industry B, practically in the same proportion. These services, which are not directly related to the product marketed, but to customer service through the sale, shows that both companies can offer it, being able to be an even more significant differential for those of industry B, given their limited offer possibilities. Although no company presented results-oriented services (according to the reference classification), we can verify that company A2 was the one that presented the most significant amount of services (15) and a larger number of more advanced offerings and can be classified as the most servitized in the evaluation. The most advanced services fall into the category of professional services since no services of the “operational” types were identified. In the last ranking, however, there is company B2 that has a lower number of more complex supplies, being also between the last two in quantity of services made available to the client.

The company categorised as more servitized (A2) was also the one with a more significant amount of services; however, it can not be said that the number of services offered is decisive for a higher service level. This is confirmed by evaluating the B2, B3, and A4 service supplies. As shown in Figure 3, companies B2 and B3 have the same amount of services offered (5); however, company B1 offers two professional services, while the others offer only one. Thus, it is possible to highlight at least three points that are discordant to the framework created by Oliva & Kallenberg (2003):

- The findings show that the provision of less advanced services in the PSS continuum is not a necessary condition for the firm to be more servitized. That is, the company can offer more advanced services without necessarily offering also less advanced services. This is evident when observing that all the companies
surveyed offered at least one professional service, including B2 and B3, which did not offer maintenance services.

- The number of services, per se, is not a determining factor for servitization. What adds greater weight is the number of services in more advanced categories, including a necessary separation between the services considered basic by their orientation (whether by product or by use). For the authors, this distinction does not exist, since all services considered to be basic would necessarily be product-oriented. However, in the practice of the companies surveyed, we can verify that there are two types of basic services: those product-oriented (services that support the commercialised item) and use-oriented (services that support the use of the commercialised item).

- Another relevant issue concerns the fact that there were no services that fit into the classification of result-oriented services (as can be seen in Figure 3). In using the criteria by Oliva & Kallenberg (2003) would be only those focused on the transaction with the client and the process management. That is, assume that the services in question are valid for the post-purchase and that consulting, training and other services would not be in this category. However, the findings of this research show that, specifically for the field of agricultural inputs, this categorisation does not contemplate the reality of the sector. The results of this research showed that some of the services categorised by Oliva & Kallenberg (2003), as professionals and use-oriented, are result-oriented services to the result of the business being able to occur, including in steps before purchase. Thus, these services would be at another point on the PSS continuum, more to the right, that is, they would be more advanced. In the companies surveyed these services were found in the three companies in the field of agricultural inputs (B1, B2, and B3).

The possibilities of supplying services serve as a guide for managers to highlight opportunities that were not contemplated. In addition, we can see that some services are not offered due to the incompatibility of the commercialised product. The classification proposed by Oliva & Kallenberg (2003) allows to identify that the majority of the services offered by servitized firms are characterized as basic, that is, they are still on the left side of the PSS supply continuum, indicating that ownership of the item is still very relevant, contributing to a relative importance of goods significantly higher than the importance given to services. According to the authors, the organisations that only maintain services that fall into this category are more likely to face problems to have the expected return with servitization.

Although there is a greater possibility of offering services at the time of purchase, the types of services supplied are considered as basic, that is to say, as those services additional to the supply of goods, characterised by a low level of customisation and value perceived by the customer. The only two services characterized as operational, that is, those in which there is the greater relative importance of services and which are located to the right in the continuum of PSS are in pre-purchase possibilities, as a way to assist the operation of the customer's processes and in the improvement and updating of the items. It should be emphasised that there be a concentration of services of a higher degree of servitization for when improvement and update are performed on the items, with two services known as professionals, R&D and Consulting, auditing and customer advice for business, in addition to the service listed as operational.
In this analysis, two companies of agricultural inputs (B1 and B3) proved to be more serviceable than machines and implements (A1 and A3), by offering professional services that are use-oriented. This verification contradicts the profile found for manufacturing firms, according to the classification by Oliva & Kallenberg (2003), insofar as for Industry B companies, they are not based on maintenance services (pointed by the authors of the reference framework as relevant for more advanced firms in the servitization process).

**Conclusion**

The present study brings contributions to the theoretical framework involving the service and its form of measurement in the PSS continuum. Therefore, we propose the Convergent Typology between two approaches of classification of services with distinct and complementary approaches, namely: a model based on the complexity of the PSS supply, starting with the model by Oliva & Kallenberg (2003). This new typology has allowed the classification of services into more categories within a continuum that varies between basic service-oriented good and operational service-oriented result.

The field research findings reinforce the inconsistency of the framework proposed by Oliva & Kallenberg (2003) to classify the identified services, making it necessary to adapt them to the reality of the interfirm sector. This issue was evidenced in four aspects: a) when reclassifying the services and identifying the most service-oriented company; b) when dividing services from the basic type into product-oriented and use-oriented; c) when going from the professional services division into use-oriented and result-oriented; and d) when it is perceived that it is not necessary to offer less advanced services, in order for one to be, necessarily, more servitized (including the number of services was not relevant for the companies evaluated).

Thus, in addition to the theoretical discussion provided by the new typology of services classification and the identification of the supply through opportunities in the pre-sale moments, sales and after-sales, it can be seen that most of the service offerings are concentrated as basic, which also occurs for manufacturing companies (Parida et al., 2014). However, we realise that there is a higher incidence in those considered as use-oriented. The latter requires the supplier to be more prepared, especially concerning the customer, being more complex than the basic services oriented to the product. We did not identify a service considered as more complex, neither (operational results-oriented services). In addition to the higher supply of basic services mentioned above for

---

![Diagram of service classification](image-url)
companies that supply agricultural machinery, equipment and implements, the possibilities of offering services and the way in which the deal with the customer exists resemble the manufacture since it allows the provision of product-oriented services. These, such as maintenance services, are gaining strategic importance and differentiation for customer choice in becoming loyal. However, the differentiation between service offerings concerning those identified in manufacturing is undeniable, especially in the field of agricultural inputs. We expect this new framework to be a driver for the manager to invest in services that bring a higher return, given the existing structure.

The primary objective of the research was to foster the discussion about the servitization in a format and sector not explored in the literature of the area. We recommend the replication of the new framework to other sectors in the interfirm sector and manufacturing so that the results can be compared directly.

A Grounded Theory Analysis of Complex Service Networks

Chara Makri (cam221@cam.ac.uk)  University of Cambridge

Andy Neely  University of Cambridge

Abstract
This study explores the complexities faced by organisations operating in service networks, using grounded theory. In total, 68 interviews were conducted with experts employed in servitized manufacturers from various sectors. This led to the development of the ‘CAGE’ framework and revealed safety as a recurring theme from the discussions. Overall, this study contributes to knowledge by examining, the complexities of service networks, complexities that can impact service provision both from an operational and a safety perspective, and the manner in which servitized manufacturers can manage them. Thus, in addition to the academic contribution, the results also have significant practical implications.

Keywords: Servitization, Complex Service Networks, Safety

Introduction
Rapid economic growth during the Golden Age of Industrialisation, led to a shift in demand from quantity to the quality of “manufacturing consumption” (Versen and Wren, 1998, p. 510). This situation, combined with rapid technological advancements (Ostrom et al., 2010), increased automation and decreased cost of manufactured goods (Johnston, 1994), has resulted in the rapid development of the service sector (Memedovic & Lapadre, 2009; Ostrom et al., 2010). As a result, the world is becoming dominated by services (Memedovic and Lapadre, 2009) with developed economies generating more than 70% of their Gross Domestic Product (GDP) from the service sector (Johnston, 1994; Ostrom et al., 2010).

This shift towards providing more services, also called “tertiarization” (Memedovic and Lapadre, 2009), or for manufacturers specifically, the “servitization of manufacturing” (Vandermerwe and Rada, 1988), requires significant organisational changes, and involves the creation of new capabilities and processes in order to support the relational nature of services (e.g., Oliva and Kallenberg, 2003; Gebauer et al., 2005; Baines et al., 2009a). According to (McKinsey, 2012, p. 103), successful organisations of the future will also need to be able to work in large networks effectively, in order to build new knowledge and capabilities and “sell products and services to diverse customer bases”. Due to the complexity of these networks, and the costs of gathering information, this can be rather challenging; the information is dispersed across various different locations and parties, and thus, an individual or an organisation can only hold partial or misinterpreted information (Pidgeon and O’Leary, 2000).

For organisations to operate successfully in networks and perform every day operations, each organisation will also need to have a clear understanding of where their
accountabilities lie throughout the whole lifecycle of a product and/or a service (Fielder et al., 2014). Fuse (2013) identifies this process as Through-Life Accountability (TLA) and defines it as “…the duty to inform, justify and accept the consequences of decisions and actions taken during the entire lifecycle of assets and associated services. Critically it involves understanding the boundaries of and responsibilities for safe and consistent outcome delivery over an extended service contract involving multiple organisations”. However, this is far from straightforward, since the complexity of service networks does not always allow control of all the elements involved (Fielder et al., 2014). While the understanding of TLA is important for organisations operating in complex service networks, more research is needed from the academic community in order to understand more about the different dimensions of accountability, and the risks that a lack of its understanding may entail (Fielder et al., 2014).

When considering manufacturers who diversify into services, the challenges of operating in service networks can be even greater. For example, it has been argued that by taking over the customers’ operations, servitized manufacturers have to deal with greater responsibilities than before, and for long periods of time, and assume risks that were previously the concern of the customer (Oliva and Kallenberg, 2003; Tukker, 2004; Neely, 2008; Nordin et al., 2011). In order to be able to produce their products and function in today’s global supply chains, despite the challenges, manufacturers also have to depend on a large number of service providers (McKinsey, 2012). However, the extant literature tends to focus on the positive consequences of servitization and disregard any relevant risks (Nordin et al., 2011; Benedettini et al., 2015; Durugbo and Erkoyuncu, 2016). Thus, more research is needed in order to understand what the implications for these organisations working together are (Ostrom et al., 2010; Valtakoski, 2017).

**Theoretical Background**

Due to the nascent nature of this research, the literature review includes a range of different research fields. There are three main streams of literature that are relevant to this research: TLA, accountability and servitization of manufacturing.

*Through-Life Accountability*

The concept of TLA was first introduced by Fuse (2013). In their follow up study, Fielder et al. (2014) emphasise the importance of TLA by describing the HMNB (Her Majesty’s Naval Base) Portsmouth business model, an example from BAE Systems Maritime Services, where the company has a contract to maintain maritime vessels. As part of their role, BAE has also been tasked not only to maintain it, but also to run the Naval Base. This includes providing catering, accommodation and social facilities for many employees including sailors. Since BAE do not have the expertise in all of these areas (e.g., catering) they outsource parts of the contract to external contractors, but the company is still responsible in case the agreed standards are not met by any of the partners.

A thorough understanding of TLA, therefore, provides servitised organisations with better control over their networks. What is more, such an understanding can shield them against potential risks. Interestingly, however, relevant academic research on TLA is sparse at best. For example, when using “Through-Life Accountability” as the search term in online research databases (e.g., Scopus® and ScienceDirect®) returned zero results. This motivated an expanded search of the term “accountability” separately.

Two distinct streams were identified in this literature. In the first, authors argue that accountability has different forms and attempt to identify them. In more detail, accountability is differentiated between individualising (internal or personal) and socialising (external or structural) forms (e.g., Roberts, 1991; Sinclair, 1995). According
to these studies, accountability can be further broken down into hierarchical and professional forms, as part of the personal accountabilities, and into legal, public and political forms, as part of the external accountabilities.

For organisations, firms and the society as a whole to secure their prosperity, they need to find a balance between the different forms of accountability and align the pursuit of their economic goals with a wider “ethical discourse” (Shearer, 2002, p. 570). However, finding the balance between the different forms of accountability can only be achieved under ideal conditions (e.g., Sinclair, 1995). This leads to the second stream of the literature, in which researchers argue that the multiple forms of accountability can lead to conflicting situations – a Multiple Accountabilities Disorder (MAD) (Koppell, 2005) or an “accountability bias” (Behn, 2001, p. 12) – since actors and organisations may be accountable for more than one dimension (e.g., Sinclair, 1995).

The complex meaning of accountability and its multiple forms, therefore, can lead to conflicting situations, since actors are often required to give account to a variety of different stakeholders against a broad range of criteria. Thus, it is far from straightforward for organisations to understand and deal with their accountabilities, especially in the case of servitized manufacturers where the product may be provided by one organisation and the support services by a large network of partners. However, while numerous studies discuss the complexity of accountability, there is a paucity of research on the guidance or tools that can be used by organisations for identifying and managing accountabilities.

Servitization

Nowadays, the provision of services is a key aspect of a manufacturer’s business. An increasing number of – previously – traditional manufacturing organisations in developed economies will need to adopt this strategy in order to remain competitive in the current globalised economic environments (e.g. Mont, 2002; Neely, 2008).

Despite the various benefits of servitization, as several authors point out (e.g., Oliva and Kallenberg, 2003; Martinez et al., 2010), the transition to services involves significant challenges that render the success of the servitization strategy far from being certain. Indeed, the review of the literature of servitization reveals that there are a number of different risks/challenges related to the servitization of manufacturing. These include: operational risks (e.g., Nordin et al., 2011; Durugbo and Erkoyuncu, 2016); risks for specific functions of the organisation (e.g., Erkoyuncu et al., 2013); risks for customers (Holmbom et al., 2014); a transfer of risk from the customer to the manufacturer (e.g., Tukker, 2004); challenges in successfully diversifying into a service provider (e.g., Mont, 2002; Martinez et al., 2010); challenges in successfully delivering value to the customer (e.g., Neely, 2008; Holmbom et al., 2014); cultural challenges and challenges related to the complexity of service networks (e.g., Neely, 2008; Martinez et al., 2010; Holmbom et al., 2014; Durugbo and Erkoyuncu, 2016) and financial risks (e.g., Neely, 2008; Visnjic and Looy, 2013; Benedettini et al., 2015).

In fact, according to evidence provided in a number of empirical studies (e.g., Neely, 2008; Visnjic and Looy, 2013; Benedettini et al., 2015), it seems that manufacturers are not generally able to achieve the financial benefits of servitization that they might have expected, a finding that is widely known as the “service paradox” (Gebauer et al., 2005, p. 14). Due to the “service paradox”, however, most studies focus on the impact of these on the delivery of the service to the customer, or on the failure of manufacturers to create value and/or profit from service provision, rather than the challenges of a fully and successfully servitized organisation. What is more, relevant studies, examine these issues either in dyadic or triadic relationships (e.g., Raddats et al., 2017; Finne and Holmström, 2013, respectively) within service networks. However, operating in today’s highly dynamic service environments requires a broader understanding of the interactions.
between the different actors (Li et al., 2017), and is more complex than simply understanding interactions between dyadic relationships (Banoun et al., 2016).

While identifying and understanding any potential risks and challenges that arise when operating in complex service networks is important for servitized manufacturers, extant research is limited and unstructured. All the identified challenges, however, have a common element: in order to successfully deliver the service to the customers, manufacturers need to form, operate in, and manage large and complex networks of partners and customers. To achieve this, the use of effective communication and information exchange is important, but not always easy. Indeed, a number of studies highlight the importance of being able to operate in networks and build close relationships with suppliers and customers. A number of studies also recognise these as a challenge. The required capabilities needed in order to be able to create, manage and operate these networks (as identified in the relevant literature) are: establishing and managing networks (e.g., Baines and Lightfoot, 2013); building and maintaining relationships with suppliers and customers (e.g., Baines and Lightfoot, 2013; Kreye, 2017); effective communication and information sharing (e.g., Baines et al., 2009b; Raddats et al., 2017) and sharing intentions and aligning goals (e.g., Jacobsson and Roth, 2014).

However, there is currently limited research regarding the challenges and risks involved after these networks are formed. For example, what are the specific elements that make managing these networks challenging? Why is this challenging? What type of information does the organisation need to ensure is shared? Put differently, what are the common sources of complexities in service networks that arise from the involvement of multiple organisations?

Research Design and Methodology
This study is addressing a nascent research problem (Edmondson and McManus, 2007), that is, a topic for which there is no previous theory within the context of complex services that could be used to support its methodology. Thus, it is an exploratory study that aims to “seek new insights” and “assess phenomena in new light” (Saunders et al., 2009, p. 139). For exploratory studies that aim to build theory, Glaser (1998), recommends the use of Grounded Theory (GT) as it has the ability to introduce new concepts, as these emerge directly from the data without forcing any leads.

Data Collection and Analysis
The sampling process for this study involved theoretical sampling and the recruitment of organisations and participants that are experts in the subject matter, or directly involved in the research problem (e.g., Glaser, 1998; Edmondson and McManus, 2007; Saunders et al., 2009) and both primary and secondary data can be used to address the research problem of a study (Glaser, 1998).

Due to the grounded nature of this study, it should be noted that, while the paper follows a more traditional structure where data and findings follow the initial theoretical overview, it is important to keep in mind that the actual process was far less linear. The research process, therefore, is presented in two different phases. Phase 1 represents the initial review of the literature that motivated this research, the narrative literature review of accountability and the systematic literature review of servitization. Phase 1 also represents the preliminary study conducted in order to narrow down the scope of the research. The analysis from Phase 1 has resulted in the creation of the CAGE framework that can help organisations identify the common sources of complexities within a service network. Phase 2 represents the main data collection and analysis stage of this study that collected data from three different ServManufacturerPro sites. The purpose of Phase 2
was to validate the CAGE framework that emerged from the analysis of Phase 1. An overview of the data is presented in Table 1.

As GT requires, data analysis for this research begun soon after the first data were available by looking at the interview transcripts for emerging themes, and constantly comparing them and updating them (Glaser, 1998). Although the NVivo® software was used to assist initial coding, the process was supplemented by what Glaser (1998, p. 184) calls “memoing” in order to ensure that the relationship between the categories was identified for theory to be generated. The final framework is presented in the following section and summarised in Figure 1.

**Results - The Cage Framework**

**Competencies**

Manufacturers need to consider the competency of employees along with the assessment and training that partners provide for them, as competent people are required for the successful and safe delivery of the service. What is more, employees need to be continually assessed and developed in order to have a clear understanding of their accountabilities. Furthermore, even if all accountabilities are clearly explained and presented in the service contract, they will need to be reviewed constantly and understood on a case by case basis. This requires genuine knowledge and employees who are not hiding behind their organisation, but are willing to take on personal accountabilities. Last but not least, the technology and systems available within every partner organisation need to be considered. While some interviewees linked complex technology with increased risk, it was also recognised that technology can be used as a tool to clarify accountabilities, drive behaviours, and improve everyday communication, and, as a result, maintain a high level of safety. Therefore, further than individual competencies, the training provided to employees, and their continuous assessment, along with the technology and systems available are of key importance.

**Attitudes**

Organisations will also need to consider the individual people involved within their service network, as their personal attitudes and values can affect the way everyday processes are performed. Servitized manufacturers not only need to understand these, but also find a way to drive the right behaviours. This would require a better understanding of the personal cultures of the individuals involved. While this is not an issue unique to large networks, more differences are expected to arise within complex service networks. These differences could arise from an individual’s country of origin, religious beliefs and professional background. Therefore, it is important for servitized manufacturers to be able to distinguish between these different attitudes and behaviours in order to be able to deal
with them efficiently and promote a safe and just culture across the whole service network. The next theme related with this characteristic highlights the importance of a joint and aligned incentives’ system across the whole network. Incentives drive behaviours and need to be linked with a just culture or they can bring the opposite results. What is more, safety targets are harder to measure, and, as a result, “the safety message tends to get watered-down, because it is not what pays people’s wages.” This brings back the issue of finding the right balance between cost and safety, and the last theme that highlights the constant tensions between commercial and operational functions of organisations. For instance, as one of the interviewees points out, product-based organisations have far less things to consider compared to service-based organisations, since the latter need to consider the support of a product for the next 10 to 20 years. Even the shift from maintenance contracts to through-life support contracts can lead to changes in culture. In maintenance contracts the supplier benefits from replacing as many parts as possible, whereas in through-life support contracts the service provider prefers to re-use as many parts as possible. Similarly, even differences between departments need to be considered. Therefore, organisations need to understand the individuals’ attitudes; the tensions between commercial and operations; and the incentives that exist within the service network, since these drive behaviours.

**Governance**

Another common concern is related to a general lack of control to take proper actions. According to the interviewees’ responses, a lot of these issues can arise from the large number of parties involved in service networks, and depends on which entity has the right to govern or take decisions at each point in time. To this end, it is important to have clear governance with well-defined accountabilities, and a unified incident reporting system that promotes a culture of continuous learning. Two main themes were identified: procedures and regulations and structures and hierarchies. The first theme refers to the procedures that exist within the partners. According to the interviewees, procedures determine the way things are done and also drive behaviours. The second one refers to the general structures and hierarchies that exist within the network. In more detail, organisations should seek partners who have designated safety managers and safety management systems independent from commercial departments. This is critically important, since safety managers need to be able to put the delivery of a project on hold if they think something is not right. As mentioned previously, the categories presented here are closely linked. The tension between commercial and operations for instance, explains why safety managers should be independent to the commercial managers in order to be able to take proper actions when required.

**Environment**

Servitized manufacturers need to clearly understand the environment in which their partners and customers operate in. This involves understanding more about the sector and relevant legislation. While the environment is not something that can be affected, it provides crucial information for setting up the processes and communication paths between the partners. In more detail, each sector can have different approaches to safety and acceptable levels of risk. For example, the acceptable level of risk in military environments is different than civil ones. As one of the interviewees explains, in the former case, “the trade of safety versus performance is absolutely part of the trading space, because it is a weapon.” Finally, legislation is important as it determines the acceptable levels of risk (per country or per sector), the requirements for both safety management and incident reporting systems and any ISO and HSE requirements.
Conclusion and Implications

The analysis of the preliminary study revealed four main sources of complexities: competencies, attitudes, governance, and the environment in which the partners operate, all of which are also closely interrelated. However, the main purpose of this preliminary study was not only to understand more about the common sources of complexities in service networks, but also to identify the main concern of the participants and proceed to the next round of data collection with a more focused approach and generate theory (e.g., Glaser, 1998). Despite the various challenges that the participants identified, a common issue was present in all four dimensions.

For instance, one of the main concerns in the competencies dimension was related to having both competent people and systems, so as to ensure that the whole network can sustain a high level of safety. Considering the second dimension, attitudes, one of the main concerns was related to having a unified incentives system and specifically one that does not compromise safety. One of the main concerns in the governance dimension was to have a clear separation between safety managers and operation managers. This would ensure that the organisation will not compromise safety in order to secure revenues. Finally, with regards to the fourth dimension, environment, the main concern was that the different environments that partners operate in can have an effect on acceptable levels of risk, and therefore, safety. Thus, it is clear that across the different themes and participants, potential safety risks seem to be a common concern.

In order to further support this finding, the researcher run a frequency word search in the transcripts with the help of the NVivo® software. In more detail, the frequency query looked into the forty most mentioned words in the transcripts, excluding any words with less than three characters. From the initial list of forty words, twenty-three words, such as ‘yes’, ‘got’, ‘example’, or ‘back’, among others, were excluded, since they offered no further insights. The researcher then looked into the remaining seventeen words in order to verify or refute the previous finding. The detailed list of the final seventeen words is presented in Table 2.

Not surprisingly, the most frequently used word was accountability. This finding supports the previous argument that most of the challenges identified were related to a confusion of accountabilities or conflicting accountabilities. Even after excluding any references, where the word was used as part of the main theme of the interviews, that is, “through-life accountability” or “accountability through-life”, the word was still mentioned 648 times (or 856 times including the word “accountable”), a lot more than the next most frequently used word, “service”. The frequent use of the latter was also to be expected since the discussions were related to complex services. Two more of the most frequently used words were “people” and “organisation” showing that service networks are dynamic and largely depend on the people and organisations involved. The fourth most mentioned word was “contract”, most often used referring to a service contract. The sixth most mentioned word was the word “safety”. What is more, “safety” was mentioned by 91% of the respondents, supporting the argument that safety was a common concern between the majority of the participants.

Contributions and Implications

The main contribution of this study is in the field of servitization. More specifically, this study addresses an under-researched part of servitization: the sources of complexities associated with service networks characterising service provision, and the impact that these complex service networks can have on safety.

This research addresses an important issue for practitioners. With services becoming increasingly important, organisations need to be able to work in large networks effectively. The research revealed the common sources of complexities within a service network that organisations need to be aware of. Servitized manufacturers first need to address these elements within their own organisations. Then, identify any misalignments within the service network and address them externally as well. By identifying any misalignments within their service networks, organisations can identify the specific areas that need improvement. The framework, therefore, can be used in a number of different ways by servitized manufacturers, such as for understanding complexities/risks within their networks, for planning purposes or for selecting suppliers/customers and for audit/mentoring purposes.

It is also found that complex service networks can expose the organisation to increased risks that can impact safety. The dimensions of the CAGE framework can help the organisation understand the areas that need to be improved. The recommended framework represents a novel approach for managing complex service networks, and also demonstrates that the different risks must not be treated as stand-alone or static elements but rather as a holistic framework. Managing complex service networks is an ongoing process that involves multiple organisations and people.
Limitations and suggestions for further research

As an exploratory research, this study presents a number of limitations that serve as promising avenues for future research. Particularly, although the selected methodology was justified, the research was qualitative and exploratory and therefore, does not provide statistical but only theoretical generalisation (Yin, 2003). Furthermore, the study focuses on 68 interviews from experts in the service field, and from a small number of different organisations. Using a sample from additional sectors might provide new insights. What is more, since the majority of the interviews involved participants from the main ‘contractor’, further research could focus on involving a larger sample of participants from the customer of these contracts and sub-suppliers of the service network. To this end, further research from a series of quantitative studies, such as anonymous surveys, that can include a large number of both organisations and participants and various sectors, can help weigh, assess and rank the different dimensions in terms of importance and criticality. The main purpose of this study was to examine the sources of complexities within a service network. But most importantly, since the findings from the preliminary study show that despite the various challenges that organisations operating in complex service networks face, a recurring theme revolved around how these can potentially impact safety, future research should focus more on understanding the impact that these complex service networks can have on safety.

Servitization in the renewable energy supply chain
– Explorative analysis in the Finnish energy sector

Saara A. Brax (saara.brax@lut.fi)
School of Business and Management, LUT University

Jukka Hallikas
School of Business and Management, LUT University

Abstract

This explorative study investigates the actors and services in the renewable energy supply chain in Finland. A data set of 86 companies is developed, consisting of 1116 documents describing the service portfolio of the companies and their business activities. These are analysed to characterize the companies and examine the scope of their service activities. Specialized services and actors are identified for each type of renewable energy, and further research avenues for servitization scholars are proposed.

Keywords: Servitization, Renewable energy, Supply networks

Introduction

The adoption of renewable energy (RE) production technologies increases the number of actors and geographical decentralization in the energy supply network. Large installations are developed by energy companies especially for wind power, but the number of small, distributed installations also increases. The growth of distributed renewable energy forms depends on new actors taking the role of producer in the RE supply. These actors can be local ‘prosumers’ and energy production may not be their core activity (Child et al., 2017). Renewable and carbon-free energy necessitates the use of energy reserves, smart grids and local micro-grids to balancing of the production and consumption (Camarinha-Matos, 2016). These developments introduce market needs for advanced and supporting industrial services in the energy sector supply chain.

This research project explores services supporting and enabling renewable energy supply chains (RESC, for short) in the Finnish energy sector. The research aims to identify and categorize actors and service activities associated with the different forms of energy production in the RESC. The study uses the structural meta-model of servitization (Brax & Visintin 2017) to compare the service activities and map the range of services across the life-cycle of the renewable energy product-service systems.

Research methods

Explorative and theory building mode is used due to the novelty of the research topic. As explorative research requires boundaries to control the amount of data, the current analysis focuses on the Finnish energy sector which was selected as the case market for several reasons. Finnish industries are known to have high levels of servitization, and...
several OEMs providing technology products and services for energy production are located in Finland. Furthermore, the regulations for operations and safety are strict, the renewable energy sector is growing, and trading surplus energy to the grid has become available to small-scale producers relatively recently.

The study aimed at forming a representative dataset of companies operating in the renewable energy supply chain in Finland. While the electricity producers, distributors and trade companies are easily identifiable from business information databases, industry classifications are less specific in identifying suppliers to renewable energy production. Therefore, the strategy to identify companies combines online searches on various websites and company lists based on industry classifications from statistical database (Amadeus from Bureau van Dijk).

The final sample of the current analysis, 86 firms, was searched as follows. Amadeus database was searched for active companies in focal industries. NAICS industry codes were used as selection criteria as, in comparison to NACE, NAICS enables a more fine-tuned sorting of industry activities in the sub-industry level. The researchers first identified the focal subindustries:

- 221111 - Hydroelectric Power Generation
- 221114 - Solar Electric Power Generation
- 221115 - Wind Electric Power Generation
- 221116 - Geothermal Electric Power Generation
- 221117 - Biomass Electric Power Generation
- 221118 - Other Electric Power Generation
- 237130 - Power and Communication Line and Related Structures Construction
- 237990 - Other Heavy and Civil Engineering Construction
- 238210 - Electrical Contractors and Other Wiring Installation Contractors
- 333611 - Turbine and Turbine Generator Set Units Manufacturing
- 334413 - Semiconductor and Related Device Manufacturing
- 335311 - Power, Distribution, and Specialty Transformer Manufacturing
- 423690 - Other Electronic Parts and Equipment Merchant Wholesalers
- 926130 - Regulation and Administration of Communications, Electric, Gas, and Other Utilities.

This search identified 5419 active firms in Finland (out of 447 916 firms in the database globally). Next, to scope the search on companies operating in the renewable energy supply chain, a set of textual search terms were used in three descriptive fields (trade description, national activity labels, and overview), to identify any of the following terms: "hydro", "solar", "wind", "geothermal", "biomass", "alternative energy", and "ocean wave". The list of search terms was developed based on an examination of the descriptions of the NAICS codes in the abovementioned industries. This search resulted in a list of 337 companies in Finland (out of the global 32 951 such companies in the database). Statistics and background information for the companies in these lists was downloaded from Amadeus.

The list of 337 companies was manually examined and implemented in the data collection process which resulted in the final sample consisting of 86 companies. For each of the 337 companies, the researcher first examined the company records in the Amadeus database, to determine whether it was an independent company or a subsidiary. Next, the researcher examined whether the company had a website that describes their business activities and offerings. Then, the researcher downloaded the descriptive web pages, recorded them and saved as PDF files. The researcher sought information about the firm’s business, products and services, and about the company itself. The highest amount of
documents was 128 for Fortum Oyj which is also the largest company in the sample, and 46 documents for the next one, Prokon Oy. Excluding Fortum as an outlier, the sample has 11.6 documents per firm on average. Companies without a website were excluded from the data in the preliminary analysis which is reported in this study. Companies without websites appeared to be typically either 1) very small and temporary developers for wind park permissions, as described below, 2) privately owned small wind turbine installations, or 3) active water plants producing electricity to institutional customers.

The data was collected in the level of independent, operating companies. For subsidiaries, the researcher thus identified their parent company. If the company had several companies as owners, none of them to the extent of a parent company (i.e., owning shares exceeding 50%), the firm was considered independent. The global ultimate owner indicated by the database was used, if it was a company, not a private person or a municipality. For giant multinational companies the direct foreign parent of the Finnish subsidiary was used. These steps were necessary as the energy sector is highly networked, apparently more so than in manufacturing companies. This is because the companies producing or consuming large quantities of energy secure the supply by distributing production and ownership to several forms of energy production, on multiple locations, and in several companies. In this industry, all production units are typically subsidiaries, not branches. Thus, smallest firms are the size of a single windmill. Moreover, since the process to gain permissions for a wind park is risky and challenging, small private startups exist only to develop permissions for a specific location, and sell the plans to larger firms if they succeed in the process, thus being somewhat temporary arrangements in the supply chain.

The data was then thematically analyzed using the meta-model of servitization (Brax & Visintin, 2017) as a reference structure, using the Atlas.TI software for coding. Due to the complicated procedures in the sampling stage, the data collection was much more laborious than expected. Thus the current paper reports preliminary findings from this data set.

Findings

The preliminary findings indicate that advanced services are provided for wind energy installations and hydropower plants across their lifecycle, and for solar power installations in the early phases of the lifecycle. The service profile for different forms of RE vary; solar energy requires very little maintenance, whereas windmills require regular highly specialized maintenance. Wind farms is a growth market, whereas the hydropower market (about 250 plants) is not likely to grow.

Finnish RE technology providers are OEMs that provide services for the entire lifecycle of the installations. These include VEO, Moventas and Naps Solar. VEO provides installations combining multiple renewable energy sources (thermal, wind, hydro) and hybrid-engine power. In addition to providing gearboxes and basic maintenance services, Moventas provides refurbishing services with preowned gearboxes. In addition to OEMs, some project integrators are found in the market. For instance, SavoSolar develops photovoltaic power plants and exports them. Specialized firms provide technical consultancy and inspection over the life-cycle of windmills, and legal services for new wind farm projects. Services are provided especially in the planning phase, and some companies such as JBE Services provide continuous monitoring, maintenance and dismantling services. Companies with Finnish origin serving the wind farms include JBE Services, Moventas and Suomen Hyötytuuli, a company owned by major Finnish city energy companies that operates several offshore wind farms. Maintpartner operates and maintains six hydropower plants for UPM, a large
paper mill company. Naps Solar combines business intelligence with solar power systems, providing turnkey on-grid photovoltaic systems, remote monitoring and maintenance, consulting and ‘solar power as a service’. Nocart provides integrated product-service-systems for power plants combining multiple technologies to produce renewable energy, including biogas, thermal, solar, wind and hydropower.

The data set includes two particularly innovative startups. The technology provider Wello is a startup OEM developing and manufacturing boat-like small power plants to generate electricity from waves. The other interesting startup is Soletair. This firm develops carbon recycling processes based on air-capture technologies. In the Soletair concept, carbon is captured from air to be combined with hydrogen to produce hydrocarbons that can replace fossil based hydrocarbons and, when made into long-lasting products, form artificial carbon sinks. As the name of the company suggests, the carbon recycling processes are operated using solar energy.

Foreign RE companies with customer base in Finland belong to the OEM category, including Vestas, Siemens Gamesa, The Switch, Nordex, Rexel and Areva Solar. Areva Solar provides solar panel installations based on a product-focused business model. Rexel combines photovoltaic systems with industrial data centers and smart home solutions, including lighting, vehicle charging and data cabling. Vestas has provided over 350 wind turbines to Finnish wind farms and provides maintenance and operations services to them, as well a fleet optimization and, partnering with Utopus Insights, digitalization for renewable energy assets.

In addition to OEMs, a growing number of foreign investor-developers develop, build and own wind parks in Finland: ABO Wind, CPC Germania, Enefit, Entelios, Etha Wind, Intercon Energy, OX2, Sauria, Svevind, Vindin, and WPD. These companies typically enter the market by buying projects from small entrepreneurs who initiate the project and sell the plans if permissions are granted.

In contrast, Finnish developer companies carry out the risky planning and permission process themselves, and also offer development services for private investors and land owners. These companies are Allwinds, Hyötytuuli, Ilmatar, Lestijärvi Windpower, Lumituuli, Lähituuli, Puhuri, Rajakirsi, Smart Windpower, Suomen Merituuli, Suomen Tuulivoima, Services provided by these companies fall into two main categories, these consist of project management services focusing on the development and building of wind parks, or cover the entire lifecycle of the wind park from initial business screening to demolition. Because many of these companies are relatively young in the Finnish market, in-depth comparisons of their economic success are not worthwhile at the moment. Acquiring of permissions for wind parks is risky and can be extended due to complaints and appeals, and the proceedings required by authorities – these are assessed individually for each case.

**Conclusion and discussion**

Servitization scholars in the operations management community can contribute to sustainability in the energy sector by focusing on the service operations that support the renewable energy supply chain. The exploratory study indicates that Finnish technology companies exhibit advanced capabilities in servitization especially in the area of wind power and mixed power systems, and successfully export their services.

Service requirements for solar power are less complex and therefore represent the product-centric end of the servitization meta-model. However, the data shows that companies that develop and operate large installations can develop successful business models in the solar power sector as well. The competitive elements in such succeeding
business models are in the service aspects of an end-to-end solution, as price competition for the solar power panels is tough, and the panels in the market are substitutable.

Servitization research has mostly focused on OEMs in various technology intensive manufacturing industries, without particular interest on the renewable energy supply chain. The current analysis shows that the renewable energy supply chain is an important area for servitization scholars to explore further as the supply of renewable energy is critically dependent on several types of services. Since activities in the renewable energy production are rapidly increasing, as fossil-based energy production and peat are replaced with more sustainable energy forms, development of the services in these supply chains can contribute to improved efficiency and green sustainability.

In addition, servitization research in the past has focused on the transition of industrial companies towards more service-dominant business models. The energy sector is facing a transition as established companies are changing their power plants and production facilities to enable the use of renewable sources of energy. In addition, this disruption requires advancing digitalization across the RE supply chain, as other forms of biofuels need to be readily available and used to balance the fluctuation in wind and solar power.

The current study is a brief outlook on the developing renewable energy supply chain in the Finnish market and thus is a subject to major limitations. In its current form, the sample is neither fully representative nor random. This is because not all companies provide information about their offerings online - this is especially common for small companies, as well as for companies that are specialized contractors for other firms and do not market their services. The aim is to develop a dataset representative of the large and midsize companies in the market. Large and midsize companies extensively document their service portfolio in the publicly available material. The collected data allows a detailed analysis of the business activities of the firms in the sample. Further and more detailed analysis are to be carried out, aiming at quantitative analysis across the different types of services.

Abstract

This paper aims at smoothing the servitization process for capital asset OEMs. To such purpose, the paper provides a map that links a wide range of services with the maintenance technologies which capacitate the manufacturers to deliver the service in a cost-effective way. The process of shifting towards a business model of servitized maintenance is supported by considering the characteristics of operations management to take into account in this new scenario. The consideration of the operational aspects is proposed by means of Technology Roadmap tool with a new extra layer considering structural and infrastructural operational characteristics.

Keywords: Servitization, Maintenance technologies, Operations characteristics

Introduction, motivation and related works

Original Equipment Manufacturers (OEMs) have been challenged by the increasing presence in the market of new producers able to offer acceptable quality standards at a low-cost labour base (Baines, et al., 2007). This change of paradigm has encouraged their transition from selling products to selling services, seeking high returns and additional growth opportunities (Kohtamäki, et al., 2018). The transition process, known as servitization, transforms the strategic and operational business logic from product-oriented to service-oriented by placing increasing emphasis on customers and relationships (Baines, et al., 2009a; Rabetino, et al., 2017). In this context, the offer based
in the pure product is shifting towards an offer in which the product and the services are bundled to provide higher value to the user (Lightfoot, et al., 2013; Baines & Lightfoot, 2013). The conjoint offer of product and services is known as Product-Service-System (PSS) and it is of special interest for the scope of the paper - in spite of the several streams of their study (Kohtamäki, et al., 2018) - the body of research that understand them as technical services to be included in the life-cycle of the OEMs’ installed base of capital assets (e.g. Aurich, et al., 2004; Nordin & Kowalkowski, 2010).

The adoption of PSS is expected to bring additional value not only for the asset manufacturer but for the customers as well (Cohen & Whang, 1997). Therefore, the conjoint offer of services and knowledge-intensive products may stand as a competitive advantage (Baines, et al., 2007; Banks, 2003). However, the technical complexities regarding the asset make the definition and implementation of PSS rather challenging (Teixeira, et al., 2012). In such context, the asset management discipline stands as a key pillar to capacitate the transition from a product-based offer to PSS whilst properly addressing the assets’ technical challenges. As a matter of fact, most of the PSS offers found in the literature for capital assets include a considerable amount of maintenance related services (Gaiardelli, et al., 2014), and maintenance management has been considered a fundamental process of asset management indeed (Hastings, 2010; Crespo, et al., 2009). Therefore, if OEMs are willing to offer maintenance services for their installed base, one way to do so is by using their technological competences (Gremyr, et al., 2010; Exner, et al., 2017).

The benefits of the synergy among PSS and operational excellence has already been stated (e.g. Exner, et al., 2017; Goncalves & Kokkolaras, 2017). The idea considering the servitization of maintenance is not new in the literature (Lee, et al., 2014a) and it is expected to bring benefits in terms of service quality, downtimes reduction, product reliability or trustworthy relationships among others (Mourtzis, et al., 2017; Exner, et al., 2017; Gaiardelli, et al., 2014). However, manufacturers usually face technical challenges associated with the management of the PSS and the absorption of risks related to the service. In spite of the extensive research existent for both, maintenance management and servitization, to the best of authors’ knowledge, it is difficult to find information regarding the technological capacitation requisites in order to offer certain maintenance-related PSS ensuring the profitability of the business.

Hence, this paper aims at smoothing the servitization process of OEMs willing to offer maintenance-related services for their installed base. To such aim, the PSS classifications proposed by Gaiardelli et al. (Gaiardelli, et al., 2014) and by Rabetino et al. (Rabetino, et al., 2015) are adapted. In the research, the classification is made according to three main types of PSS: (i) Product-oriented, (ii) Use-oriented and (iii) Result-oriented (Tukker, 2004).

- **Product-oriented**: the owner of the product is the customer and the business model is still focused on the product. The manufacturer provides additional services included in the sale (Aurich, et al., 2010).
- **Use-oriented**: the ownership of the product remains in the manufacturer and the business model is to sell its use, therefore it is the manufacturer the responsible of the services (Aurich, et al., 2010; Kang & Wimmer, 2008).
- **Result-oriented**: the business model shift to a scenario in which it is the outcome or capability of the product what it is sold. The manufacturer owns the product and the customer pays its performance (Tukker, 2004).

The work here presented relates the services with the maintenance technologies to develop if the services were to be implemented in the PSS portfolio of the OEMs. Here the term *technology* is defined as “the knowledge for solving technical problems”
Accordingly, the maintenance technologies are also conceived regarding whether they enable the transaction of the asset or the relationship with the customer, a perspective also found in the literature (Rabetino, et al., 2015). The linkage between the services and key-resource maintenance technologies is considered within the wide context of asset management. Hence, other fundamental aspects of asset management are considered as supporting processes for achieving servitization whilst thriving at maintenance.

Among the fundamental aspects of asset management, special emphasis is made on the operations strategy of the OEMs in order to implement the maintenance-related services. Applying traditional operations concepts to the management of service operations may limit the success of the service implementation (Davis & Heineke, 2004), given that service operations tend to focus more on relationship development whereas product centred operations tend to be more transactional-oriented (Baines, et al., 2009b). According to Baines et al. (Baines, et al., 2009a), the different operations strategy aspects are classified as structural or infrastructural. Besides, it is essential that the operations are considered from a product-centric services perspective.

In order to provide with a comprehensive and practical approach to consider all the aspects related to maintenance and asset management, a roadmap template is proposed as a tool intended to facilitate the implementation of the maintenance-related services and their associated technologies. Technology Roadmap (TRM) has position itself as one of the most well-known methods for aligning strategy and management of technology (Phaal, et al., 2004; Lee & Park, 2005; Amadi-Echendu, et al., 2011). Its popularity is due to the capability of providing a graphic representation to explore and communicate relationships among markets, products/services and technologies over time (Geum, et al., 2013). Although there are many variations for the representation of a TRM, it usually includes a connected multilayer perspective with a time-oriented distribution (Probert, et al., 2003; Wells, et al., 2004). In Table 1, the layers considered by Carvalho et al. (Carvalho, et al., 2013) are presented. In the literature a variety of roadmaps applications can be found but, given the introduced shift to servitization, the research direction should be headed to the co-evolutionary and integrative planning of PSS (Geum, et al., 2011). The proposal here presented, links the services associated with the installed base of OEMs with the maintenance technologies needed for proper service delivery. The literature has shown that roadmaps are a useful tool not only for the implementation of PSS (Geum, et al., 2011; Geum & Park, 2010) but for achieving maintenance excellence (Mostafa, et al., 2015; Hauge & Mercier, 2003).

Research methodology
The research here presented is the output of the interplay between two literature reviews regarding (i) servitization and PSS definition and (ii) maintenance within asset management discipline. The linkage among these two topics is what will contribute to the servitization of maintenance and it is based on the extensive literature review and the authors’ experience with industrial applications.

On the one hand, the PSS offerings have been adapted from the research conducted by Gaiardelli et al. (Gaiardelli, et al., 2014) in which the offering is classified according to the dimensions defined by Tukker (Tukker, 2004) and explained in the previous section. The selected PSS offerings have been represented in blue circles codified by a reference number, the correspondence among the codification number and PSS can be seen in Table 2.

</table>

On the other hand, the research conducted for the different maintenance technologies and their relationship with the several PSS offerings can be seen in Table 3. In the table, each one of the technologies is briefly explained from the service-related perspective, given the scope of the paper. Besides, for the readers interested in further information, key references on each technology are presented also in Table 3. The maintenance technologies have been arranged according to whether they enable the transaction of the asset or they tend to promote a relationship with the customer. The potential of advanced maintenance technologies as enablers of service-oriented business model has been stated in the literature (Arnaiz, et al., 2016) and the transactional-relational perspective can be seen in previously mentioned related works (Gaiardelli, et al., 2014; Rabetino, et al., 2015).

**Contribution. Services and maintenance technologies map**

According to the research supported by the related works and the authors’ experience in several industrial applications, the map of Figure 1 has been created. In the figure, the different services to offer in order to achieve the servitization of maintenance are mapped with the several maintenance technologies which play a key role in maintenance management excellence.
In the map of the figure, the y-axis for the services has been defined according to the characteristics stated in previous sections: product, use, and result oriented. However, the maintenance technologies have been sorted attending to their potential to make more appealing the pure purchase of the asset (transactions enablers) or their potential to foster loyalty and a long-term relationship with the customer.

As it can be seen in the map, by scaling up the top part, where the services are located, the OEMs achieve the servitization of maintenance and their offers based on PSS become more attractive for the customers. Besides, if whilst scaling up in the services offer, they increasingly adopt the maintenance technologies, not only do they reap the benefits of a more attractive offer, but increase the margins of the offer as well by achieving excellence in maintenance.

Nevertheless, the implementation of the services and the adoption of maintenance technologies aiming at servitization and excellence of maintenance it is not an easy task. A systematic approach is a must to consider the implementation of the targeted service.
and the adoption of the technology needed to deliver the service in an efficient and sustainable way. This paper provides a proposition of a roadmap as a tool to ensure that the services and associated technologies, which can be identified in the map in figure 1, are properly considered within the perspective of operations management and thus, ensuring they are cost effective.

The classification of the operations characteristics into structural and infrastructural has been adopted from the literature research, more precisely the operations characteristics proposed in the paper are the product-centric servitized operations deeply explained in (Baines, et al., 2009a). The aspects covered by both types of operations characteristics are:

- **Structural characteristics of operations.** Include the specific technologies needed in the operations, it is necessary to consider if they are the same for delivering the services. The contemplated aspects regard capacity and facilities needs in case the demand is changing when the services are deployed. Also the positioning in the supply chain in terms of vertical integration and partnerships. Finally, it is also considered here that the planning and control should have the focus on fulfilling the objectives defined by the service contract.

- **Infrastructural characteristics of operations.** It is considered the capacitation of human resources in terms of high product knowledge and relationship development. The quality assurance is controlled according to customer satisfaction assessment and the performance and availability of the product. The portfolio of PSS offers needs to be defined and the launch of new offers should be co-created with the customer and build quality relationships. It is also considered the nature of relationships with the suppliers, they should focus on integration to achieve cost-effective supplies for the PSS.

The consideration of operation management in the roadmap is integrated by means of adding a supporting layer to two bottom layers of the generalized TRM architecture previously described in Table 1. In this supporting layer, the operational aspects are decomposed into two categories according to the previously presented classification of structural and infrastructural aspects from a servitization point of view. A graphical representation of the new TRM proposal which integrates the operations layer can be seen in figure 2. By integrating this extra layer in the roadmap the considerations regarding the operational aspects are taken into account therefore further ensuring the proper implementation and profitability of the services to-be-delivered.

![Figure 2 – Proposal of roadmap with operations layer](image)

If the OEMs are willing to deploy certain services by using the proposed roadmap, the design of the two bottom layers is facilitated with the proposal of the services and maintenance technologies map of figure 1. Besides, in order to fully achieve the business
and market goals, the changes in the operations management are considered with the new supporting layer. With this comprehensive proposal, the maintenance technologies, the services, and the operational needs are aligned to the strategic objectives and it is presented in a time-oriented distribution.

**Concluding remarks**
This paper proposes a research work in the servitization of maintenance for capital assets OEMs. The approach presented comprehensively considers the servitization process within the asset management discipline, especially in terms of its relationship with operations management. It is explored within a roadmap proposal for implementing the services and developing the proper technological capabilities whilst taking into account the characteristics of servitized operations. However, in spite of the novelty of the presented approach, further research is encouraged to explore the wide applications and implications of the ideas here presented. The authors identify future research lines that cover the development of how the operations should be adapted if the OEMs thrive for the servitization of maintenance. Besides the applicability of the research here presented is also worth of validation and test via case studies given the increasing interests of OEMs in profiting from maintenance as a service.

The literature shows that there is an increasing number of capital assets OEMs willing to undergo the servitization process seeking recurrent income through servitized maintenance. Therefore the maintenance technologies and services map here presented has the potential of easing their transition, not only in technology capacitation but in operational readiness to support the deployment of maintenance services.

Janet Godsell
Warwick Manufacturing Group, University of Warwick, Coventry, CV4 7AL, UK

Abstract

The core rationale of supply chain management envisages an integrated supply chain as key to enhanced performance. However, this “end-to-end” approach has not been fully realized. The aim of this paper is to provide a comprehensive review and analysis of factors influencing integration in the supply chain. This is achieved through an exhaustive systematic literature review. From the analysis of 74 articles, a three-path influencing factors model is identified at internal, supplier and customer scopes. Subsequently, influencing factors are categorized into enablers, inhibitors, and dual according to behavioural patterns. The proposed framework provides an all-encompassing overview of factors influencing integration.

Keywords: supply chain integration, enablers, inhibitors

Introduction

Integration is the underlying perquisite to effective supply chain management (SCM). Hence, the study of supply chain integration (SCI) is central to SCM. Approaches to SCI suggest an emphasis in collaboration, coordination and integration in the flow of materials, services, processes and information through the entire SC with the ultimate objective of achieving an end-to-end supply chain (Chang et al. 2016; Childerhouse and Towill, 2003; Flynn et al. 2010). Despite the large number of publications exploring SCI, very few firms have yet materialized the seamless supply chain (Towill, 1997). In this view, the industrial challenge of planning integration processes among SC partners is still a major source of poor performance (Richey et al. 2009). Thus, there is a need to identify a novel approach for improving performance across the entire SC beyond the realm of the individual firm.

The present paper focus on the first part of this challenge. Accordingly, the purpose of this paper is to investigate and explain both, sources of poor integration and opportunities to enhance SCI. The aim of this paper is to identify the corresponding roles of different influencing factors in enabling and/or inhibiting SCI. This is achieved through an exhaustive and inclusive systematic literature review (SLR).

Methodology
This paper adopted a five-step improve methodology prescribed by Denyer and Tranfield (2009) to systematically reviewing papers in the field of SCI. This methodology encompasses the five-steps of question formulation, location of studies, selection and evaluation, analysis-synthesis, and report of results. The present research design aims to provide rigor and transparency while minimizing bias. In addition, it benefits from enabling replicability.

Formulation of over-arching research question followed a process of setting the scope of the study, identifying emerging literature and further discussions with members of the review panel. The review question is derived as:

- What are the factors that influence the performance of SCI?

The over-arching question suggested the following sub-research questions:

- What are the sources that lead to poor integration?
- What are the sources that provide an opportunity to improve integration?

Two types of keywords relating to the concept of supply chain and integration were used in developing search strings with Boolean operators. Construct search strings are shown in Table 1:

In order to allow access to all relevant literature search strings were applied across four databases: Emerald, ScienceDirect, Scopus and Web of Science. These were screened for title and abstract publications in English language, including academic journals, chapters of edited books, and reports published between 2000 and 2018. From initial search, 23,940 papers were retrieved. Following elimination of duplicates, title and abstract of remaining papers were screened against inclusion and exclusion criteria.

Subsequently, the remaining papers were read in full. In order to identify most relevant publications studies were evaluated against a set of specific quality criteria based on subject matter and quality assessment. These included papers providing a comprehensive understanding of the research are of SCI. Then, studies that contributed to the increasing knowledge of factors influencing the performance of SCI were selected. As a result, 66 papers from the original search were identified as relevant for this research. In addition, 8 publications were included from cross-referencing that were not originally identified in the primary search. In all, 74 papers were analyzed for descriptive and thematic findings. Full selection process is detailed in Figure 1:

![Figure 1: Selection process for relevant papers](image-url)
Descriptive Findings
The 74 papers selected for review are descriptively analysed in this section in respect of year of publication, research methodology, journal, field of study and industry. The aim of the descriptive analysis is to identify the research trends in the field of SCI.

Figure 2 indicates a gradual interest over the years, with a dramatic increase between 2009 and 2017. During this time 55 papers were published, which amounts to 75% of papers included in this study. A surge in recent publications clearly indicates an increased interest of academics in SCI within the operations management field.

Accordingly, 88% of studies were empirical of which 57 (87%) employed survey and fewer 8 (12%) a case-study method. This confirms the advance mature stage of SCI field, emphasizing a high degree of theoretical development through validation.

The studies selected for this review were exclusively published in academic journals. Once again, this illustrates the mature stage of this area of research. Likewise, most papers were published in operations management and technology journals (82%), operations research & management science (7%), information management (7%), marketing (1%) and social sciences (1%). This indicates the predominance of studies in operations and technology with little interest from other fields of research.

Finally, the presence of industry sectors is fairly represented across SCI studies. Manufacturing/Machinery (23%), consumer products (19%) and electrical/electronic are predominantly the most discussed industries.

Thematic Findings
This section identify and explain a three-path influencing factors model at three different scopes including internal, supplier and customer.

Types of influencing factors to SCI
Factors are classified as inhibiting, enabling and dual. Inhibiting factors have an exclusive inhibiting influence to a particular scope. Enabling factors have an exclusive enabling influence to a given scope. In contrast, dual factors may act as both enablers and inhibitors at any scope.

At internal scope financial and risk are classified as inhibiting factors. Technology, human intervention, communication, alignment, culture, uncertainty, strategy and
organizational are dual factors, while commitment is a single inhibiting factor. At supplier scope, financial is classified as single inhibiting factor. Correspondingly, technology, human intervention, communication, alignment, culture, uncertainty, strategy, organizational, trust, commitment and risk are dual factors. Dependence and power are single enabling factors. In addition, financial and risk are inhibiting factors to customer integration. Technology, human intervention, communication, alignment, culture, uncertainty, strategy, organizational, trust and commitment are categorized as dual factors. In contrast, dependence and power are classified as enabling factors. The following section identifies influencing factors across different scopes. Figure 3 depicts SCI influencing factors model.

**Influencing factors: inhibiting forms**

**Common across all scopes (internal, supplier and customer)**
Influencing factors inhibiting integrative practices across all dimensions include lack of access to high-class technology (Leuschner et al. 2013); lack of a supporting platform/and or practices for technology (Cousins and Menguc 2006); management resistance to change(Bernon et al.,2013; Frohlich, 2002); lack of management support to assist SCI practices (Zhao et al. 2015); management minimizing sharing of sensible strategic information (Trkman et al. 2007; Wang et al., 2014) ; management lack of understanding of SCI; poor SCI- Issue fit Strategic Alignment (Flynn et al. 2016); lack of communication (Forslund and Jonsson, 2009; Pagell, 2004); low levels of environmental uncertainty (Wong et al., 2011); high levels of market, demand and supply uncertainty (Childerhouse and Towill, 2003; Lu et al. 2018); financial and supply risk (Leuschner et al. 2013; Zhao et al. 2013); independent functionality (Richey et al. 2009); lack of technical and business skills, and fragmented planning system (Frohlich, 2002); poor strategic alignment (Flynn et al. 2016); time constrains (Alfalla-Luque et al. 2013); lack of external perspective (Richey et al. 2009); and increased cost associated with acquisition of supporting infrastructure for SCI (Terjesen et al. 2012)

**Specific to external scope (supplier and customer)**
Influencing factors specific to the external scope include continued use of low performance logistic tools that are outdated and/or incompatible and management “know-best” decision-making (Forslund and Jonsson, 2009); Management hindering integration practices to avoid personal risk (Villena et al., 2009); lack of trust (Revilla and Knoppen, 2015); absence/poor commitment (Yuen, 2016); partners lack of alignment (Das et al., 2006); deviation from the “optimum level” of integration (Swierczek, 2014); restricted share of knowledge or information sharing (Zhu e al., 2018); formal communication channels encouraging transmission but not proximity (Alfalla-Luque et al., 2013); SC partners organizational culture differences (Trkman et al., 2007); lack of governance structure to handle integration (Cousins and Menguc, 2006); centralised hierarchical structures that minimize employees involvement (Flynn et al., 2016); poor understanding of SCI (Leuschner et al., 2013); complexity of processes and materials requirements (Lockström et al., 2010); use of indiscriminate integration practices (Das et al., 2006; Gimenez et al., 2012); shared resources (Van Donk and Van Der Vaart, 2005); excessive intensity of SCI (Swierczek, 2014); and cost focused firms (Van Der Vaart and Van Donk, 2004)

**Specific to internal scope**
Influencing factors specific to the internal scope include employee use of soft skills to avoid undesirable jobs (Wang et al., 2014); poor functional, departmental and systems
alignment; poor quality of information hierarchical cultures that promote distance and remove power (Pagell, 2004); internal politics that are not inclusive of SCM practices (Zsidisin et al., 2015); and organizational resistance to change (Gimenez and Ventura, 2005).

Specific to supplier scope
Inhibiting forms include management cultural differences and a lack of cultural understanding (Lockström et al., 2010); and poor quality of information (Alfalla-Luque et al., 2013)

Specific to customer scope
Influencing factors specific to customer scope include instrumental commitment (Zhao et al., 2008); hierarchical cultures (Cao et al., 2015); high levels of demand risk (Zhao et al., 2013); and partners use of coercive power in the relationship (Zhao et al., 2008).

Influencing factors: enabling forms
Common across all scopes (internal, supplier and customer)
Influencing factors enabling integrative practices across all dimensions include logistic tools (Alfalla-Luque et al., 2013); processes supporting its functioning (Arun et al., 2006); top management support (Zhao et al., 2015); human capital (Huo et al., 2016); high levels of communication (Bernon et al., 2013); supporting communication structure (Kim and Narasimhan, 2002); information and knowledge sharing, and knowledge capability supporting structure (Prajogo, and Olhager, 2012; Richey et al., 2009; Turkulainen et al., 2017); commitment to the relationship and identification with the firms’ norms and values (Huo et al., 2016); alignment of SCI to the type of performance indicator aimed to improve and alignment of enabler and degree of SCI (Wong et al., 2011); development and group cultures (Cao et al., 2015); high environmental uncertainty (Terjesen et al., 2012); an external strategic orientation (Yunus and Tadisina, 2016); pursuit of both internal and external integration jointly as they beneficially influence one another (Gimenez and Ventura, 2005); strategic processes and practices that support SCI (Terjesen et al., 2012); closer location to the customer order decoupling point (CODP) (Van Donk and Van Doorne, 2016); supporting management and information and processing infrastructure (Srinivasan and Swink, 2015); and use of common platforms (Ralston et al., 2015).

Specific to external scope (supplier and customer)
Enabling forms of factors specific to the external scope include the use of inter-personal relationships (Wang et al., 2016); information integration (Prajogo, and Olhager, 2012); equal levels of dependence among SC partners (Zhang and Huo, 2013); trust (Chang et al., 2016); a reliable and genuine interest in the relationship (Vijayasarathy, 2010); desire to move from traditional to strategic collaboration (Yuen, 2016); open-minded and honesty (Zhang and Huo, 2013); appropriate use of power (Wang et al., 2016); partners alignment (Li et al., 2009); externally focused culture (Yunus and Tadisina, 2016); high Specification and volume uncertainty (Van Donk and Van Der Vaart, 2005); internal integration approach as key to achieve further integration (Gu et al., 2017); an evolutionary process approach to integration (II-SI-CI) (Chen, 2016); strategic collaborative practices (Frohlich, 2002); information integration strategy (Prajogo, and Olhager, 2012); pursuit of coordinative practices (Wiengarten and Longoni, 2015); a simplification approach (Childerhouse and Towill, 2003); use of intangible/inimitable resources (Xu et al., 2014); a low “proactive” strategic orientation (Stonebraker and Liao,
2004); an “inside-out” removal of integration obstacles strategy (Frohlich, 2002); a socialization strategy (Cousins and Menguc, 2006); a continuous improvement approach to integration “not a one-time thing” (Trkman et al., 2007); joint influence of both interpersonal relationships and inter-organizational relationships (Wang et al., 2016); and a long-term relationship approach (Yuen, 2016).

**Specific to internal scope**
Enabling forms of factors at the internal scope include an open communication climate (Zsidisin et al., 2015); real time cross-functional communication that is informal (Arun et al., 2006); employee commitment (Alfalla-Luque et al, 2015); goal alignment (Turkulainen et al., 2017a); inter-departmental alignment (Alfalla-Luque et al., 2013); cultures that promote collaboration (Pagell, 2004); an innovative orientation (Lii and Kuo, 2016); the “optimal timing” of Integration efforts must precede the practice intended to improve or being applied at a nascent stage (Narasimhan and Das, 2001); flatter/ decentralized organizational structures (Flynn et al., 2016); and inter-functional and Inter-departmental integration (Moyano-Fuentes et al., 2016).

**Specific to supplier scope**
Enabling forms specific at supplier scope include alignment of SCI efforts-environment (He et al., 2017); collectivism Culture (Chang et al., 2016); risk management practices (Villena et al., 2009); technological uncertainty (Huang et al., 2014); joint decision-making (He et al., 2017); and imitation of peers (Turkulainen et al., 2017b).

**Specific to customer scope**
Specific enabling forms at customer scope include high quality and consistent information (Chavez et al., 2015); and planning systems integration (Bernon et al., 2013).
Conclusion
This paper investigates factors that influence realization of SCI. From the analysis of 74 papers a three-path influencing factors model is identified at internal, supplier and customer scopes. Subsequently, influencing factors are classified as enabling, inhibiting, and dual according to behavioural patterns. The main outcome of this study is the establishment of a framework that explains the relationship between influencing factors and integration at specific scope levels. Hence, influencing factors to SCI act at scope level, with all three scopes influenced differently resulting in factors variation across scopes. This illustrates the complexity to understand SCI in practice and to achieve realization of the seamless SC. This framework should be used as a foundation to develop hypothesis and further empirical work.

Supply Chain Management
Supply Chain Finance: a decision framework for inventory and equipment-based solutions

Abstract  
This paper aims at investigating a new stream of Supply Chain Finance literature called Asset-Based Lending that encompasses 3 inventory-based and 4 equipment-based financing solutions. The objective is to create a decision framework that could help in the choice of implementing a specific solution, given the objectives of a firm and the contingent factors that push companies in adopting it. The research was carried out adopting a case study methodology, in particular 25 embedded case studies by interviewing 15 solution providers. Results show which are the most relevant objectives and contingent factors that influence the adoption of ABL solutions.

Keywords: Supply Chain Finance; Asset-Based Lending

Introduction  
Supply Chain Finance (SCF) is a mix of models, solutions, and services aiming to both optimise the financial performance and control working capital within a supply chain, exploiting a deep knowledge of supply chain relations and dynamics. (Gelsomino et al., 2016). The SCF solutions investigated in literature mainly focus on trade receivables and payables, more seldom inventories, while some authors suggest to include also the financing of fixed-assets within the scope of SCF (Caniato et al., 2019). Generally, the focus is on financing and cost optimisation of working capital within the supply chain, but also the management of fixed assets covers an important role in the evaluation of firms’ performances (Gomm, 2010). For these reasons, some authors are extending the SCF vision to the domain of assets and an important stream of literature, called Asset-Based Lending (ABL), is emerging (Berger & Udell, 2006; Buzacott & Zhang, 2004; Hofmann, 2009; Cornaggia et al., 2013). Asset-Based Lending includes all those solutions in which a physical asset is the collateral of the financing agreement. (Osservatorio Supply Chain Finance, 2018). Unlike traditional loans, that tend to focus first on the amount of cash to be lent and then on finding an appropriate collateral, ABL focuses first on the valuation of the asset as a collateral, followed by the cash flow definition. Thus, the amount of credit offered is strictly linked to the value of the asset being pledged. In the area of ABL, first of all two main streams of literature are identified on the basis of the collateral taken into consideration, namely inventory (Buzacott & Zhang, 2004; Hofmann, 2009; Chen & Cai, 2011) or fixed assets (Adams & Clarke, 1996; Berger & Udell, 2006). Including both
inventory and equipment financing solutions from a Supply Chain Finance perspective is quite innovative for Asset-Based Lending, since most of the studies focus only on one of the two. Besides, complete decision models guiding firms in the choice of the most suitable ABL solution are still missing.

From the analysis of the extant literature two relevant gaps can be pinpointed: i) The first gap is the absence of a holistic perspective on ABL concept, especially with respect to the definition we assume. Many authors address ABL solutions separately focusing either on equipment-based (Berger and Udell, 2004) or inventory-based solutions (Buzacott and Zhang, 2004); those who deal with ABL in a broader sense, anyway include in the assets used as securities for the financing only current assets, namely inventory and receivables, neglecting noncurrent physical assets, and they tackle ABL just from a financial perspective. No one has elaborated yet a study presenting ABL as the set of solutions in which the collateral of the financing can be either inventory or equipment. ii) The second gap concerns instead the lack of an organic view about which could be the factors leading a firm to select an ABL solution in terms of both objectives driving the choice and contingent factors that may influence the decision for an ABL solution. Indeed, literature provides some insights in this regard, presenting some possible variables that could be relevant in the adoption process (e.g. Hofmann, 2009; Pföhl and Gomm, 2009); however, there is no clear understanding on how these variables are and how they affect the selection process. Therefore, understanding this point can be helpful for managers who need to orient themselves in the ABL solutions landscape to select the most suitable solution for their firms and their supply chains.

This paper aims at filling these two gaps using the contingency theory as theoretical lens. In order to operationalize this goal, we formulate 3 research questions and propose a comprehensive research framework.

**Research questions and Research Framework**

**Objectives**

The first step in selecting an ABL solution is the objective definition. (Martin & Hofmann, 2015) In order to configure the best solution, companies need to specify these objectives and rank them on the basis of their relevance. Thus, objectives identification triggers the decisional process driving firms to adopt an ABL solution in terms of aims and purposes. The main objectives leading a firm to adopt an ABL solution have been clustered into firm-focused and supply chain-focused objectives. The first ones are objectives leading a firm to adopt an ABL solution mainly for its own interest, while the second ones are those triggering the adoption of an ABL solution to gain a positive outcome for the whole supply chain or at least a part of it. Three firm-focused objectives have been identified and considered: i) Liquidity increase, referring to the need of liquidity firms may have for several reasons (e.g. to sustain a project). From academic literature and secondary sources clearly emerges that increasing liquidity is what leads firms to look for a “pure ABL” solution. Specifically, firms ask for a credit line using inventory or equipment as collateral to generate liquidity and take advantage of the utilisation of their current/non-current assets (Merrill Lynch, 2014); ii) Flexibility, referring to the possibility to use an asset without owning it and to repossess the asset more easily at the end of the contract and reallocate the capacity at a lower cost. Flexibility is one of the objectives leading to the adoption of leasing, especially of Operative Leasing, since it allows the lessee to recover some flexibility when making its managerial decision (Bourjade et al., 2017); iii) Asset derecognition: removal of an asset or liability (or a portion thereof) from an entity's balance sheet. For instance, currently Operative Leasing allows firms to derecognize the leased goods that, consequently, do not appear in the balance sheet of the lessee but stay in the hands of the lessor. In addition, three
supplementary objectives have been identified: i) Reduction of supply chain disruption risk, i.e. reduction of the risk of failure or bankruptcy of one or more players of the supply chain, with a subsequent effect on the other members (e.g. shortage of supply) (Wuttke, 2013; Gelsomino et al., 2016; Martin and Hofmann, 2015); ii) Reduction of supply chain cost of capital, i.e. the reduction of overall financial cost sustained by different actors of supply chain for financing their net operating working capital or fixed assets (Randall, 2009; Hofmann, 2009; Martin and Hofmann, 2015); iii) Minimization of supply chain cost of adoption, referring to the cost to adopt the considered solution. Since the objectives of adopting an ABL solution seemed to be an important decisional variable, the first research question is:

RQ1) What are the objectives for which a company selects an ABL solution?

Contingent Factors
Contingent factors that can affect the adoption of an ABL solution once defined the primary objectives. Literature gives insights into what contingent factors are, what variables they are influenced by and which type of effect they have on solutions. In particular, 5 relevant contingent factors were identified: i) Balance sheet composition: the structure of the assets of a company. It depends on the amount of current assets, which include inventory, non-current assets, composed by machinery, equipment, intellectual property and their relative weight in the balance sheet. A firm tends to choose a solution employing either current assets or non-current ones according to its balance sheet composition; ii) Loan-to-value (LTV) ratio: the ratio between the amount of granted loan and the liquidation value of the borrowing base (Song, 2016). The borrowing base is the combination of the assets the borrower uses to secure the ABL loan and their value (book value) (Buzacott and Zhang, 2004); iii) The marketability of underlying assets, i.e. the easiness of reselling goods in the market in case the borrower fails in fulfilling its obligations, is crucial in choosing solutions in which the financier retains ownership of the asset, such as Operative Leasing, rather than solutions in which the customer owns the asset, such as Financial Leasing (Gavazza, 2010); iv) Visibility: the degree of visibility along the supply chain, i.e. the amount of information that a player in the supply chain possesses about other players (Pfohl and Gomm, 2009). In a condition of low visibility the absence of information induces providers not to offer any solution (Pfohl and Gomm, 2009); Legal system: it concerns the strength of the lending infrastructure for what concerns movable assets; in particular, it refers to the existence of laws safeguarding lenders for asset repossesssion (strength of contract enforcement laws) (Berger and Udell, 2006; Calomiris et al., 2017).

In extant literature, contingent factors seem to play an important role in the solution’s decision as they may act as moderating variable. Hence, the second research question is:

RQ2) What are the main contingent factors that influence the choice of an ABL solution?

Solutions
Studying the extant literature, a common framework that help to identify all ABL solutions does not exist. Moreover, there is not a model that links objectives and contingent factors to the decision of a specific ABL solution. After a deep investigation, the ABL solutions that have been taken into account are classified into two categories: Inventory-based and Equipment-based solutions. The first category refers to those solutions that have Inventory as object of financing, while solutions belonging in the second group are triggered by the value of company’s equipment. In Table 1 the considered solutions are reported with their definitions.
Hence, the third research questions that came out was:
RQ3) How do objectives and contingent factors influence the choice of an ABL solution?

To answer these research questions, a preliminary framework developed on the basis of a literature was developed (see Figure 1).
The model aims to shed light on the potentialities of ABL solutions focusing on:
- The objectives of a firm in choosing an Asset-Based Lending solution;
- The contingent factors that push a company in adopting an ABL solution;
- The specific solution that has been chosen on the basis of the two previous variables.

**Methodology**

Due to the exploratory nature of the topic, case study methodology was chosen. In particular multiple embedded case studies were selected: interviews with different providers have been conducted to collect relevant data which were subsequently analysed and compared with a solution-oriented perspective. The adopted unit of analysis is the solution and each provider was interviewed for each ABL solution offered. The final sample includes 15 providers with 25 final case studies, combination of provider and solution *(Table 2)*. Although the framework is meant to be a decision model to help customer firms in the selection of the most suitable solution, interviews have been made with providers of ABL solutions both in Italy and abroad. The focus was on providers in order to leverage the experience they gained by offering the same solution to many clients, thus having the possibility to collect their perspective about commonalities and differences among different users. A semi-structured interview protocol was developed; interviews were conducted face-to-face by at least two researchers and recorded upon permission.

</table>

The decision of interviewing different providers for the same solution gave the possibility to conduct a multiple case study, in which first was carried out a within-case analysis, where each of the cases were analysed as a stand-alone entity, and then a cross-case analysis to compare answers about the same solution from different informants in different firms. For each solution all the relevant interviews have been compared across the considered variables to understand which factors were considered the most relevant by the informants (cross-case analysis). However, with the purpose not to limit the scope to the variables already taken into consideration by thee literature, an investigation has been made to find new variables from the interviews through an inductive coding approach: starting from the transcripts, it was looked for “in vivo” codes or constructed new ones, then comparing such codes among different interviews and trying to find common patterns to turn into more aggregate concepts, with the purpose of identifying new variables. Finally, data were triangulated with secondary sources, such as reports and providers’ website. At the end of the data analysis, new variables emerged from the interviews through an inductive coding approach.
approach and a final framework was created.

**Preliminary Results**
The cross-case analysis allowed to answer the research questions and to start get some preliminary results. First of all, the framework was revised in order to identify which are both objectives and contingent factors relevant for the choice. This step allowed to eliminate some variables (e.g., Balance sheet composition and Loan-to-value (LTV) ratio) and to add new ones (e.g., Tax Shield). In *Figure 2* the revised framework.

*Figure 2: the revised framework*

![Revised Framework Diagram]

The first outcome of the interviews is the detection of new variables that were added to the revised framework: tax shield and inventory cost reduction (included in minimization of supply chain cost of adoption) are two new objectives which emerged to be strongly relevant respectively for OL, FL and for IFCM. Instead, tax shield is not mentioned as an objective leading the adoption of SLB(OL) and SLB(FL). Among contingent factors, economic and financial situation of the firm was added since it affects mainly leasing solutions. Other relevant added factors were the combination of physical assets and receivables, that has an impact only on ABL solutions where the collateral is mainly the mean of financing (IFTM, IFDM, EBL), and technology obsolescence, that only affects Leasing solutions (OL and FL). It emerged also that digitalisation has an impact on all the solutions, hence it was added among the contingent factors in the revised framework.

Then, objectives (see *Table 3*) and contingent factors (see *Table 4*) relevant for each specific solution were identified.
Starting from the initial framework, some variables that were thought to influence the decision of implementing an ABL solution, actually do not: reduction of supply chain disruption risk and reduction of supply chain working capital emerge to be weak objectives sought through the adoption of none of the considered Asset-Based Lending solution. In the same way, balance sheet composition was a relevant variable only in Equipment-Based Lending. Instead, three variables emerged as strongly influencing the choice of adoption: the marketability of the collateral, the financial and economic situation of the firm and the objective of liquidity increase. For example, the marketability of the collateral linked to the objective of ABL adoption may address the choice of the company towards one specific solution. Most of the solutions under scrutiny need a high marketability of the collateral asset to be implemented. However, some solutions are available even if the marketability

of the collateral good is low (IFCM, SLB(FL), FL). On the other hand, while Inventory-Based solutions have the only purpose to access further funding sources, the landscape of Equipment-Based ones is more nuanced, since there are solutions that allow a preservation of cash flow (FL and OL), others that grant access to additional liquidity (EBL) and others both (SLB(OL), SLB(FL)). Moreover, for some solutions the lending is not only based on the marketability of the good, but the lender takes into consideration also the financial and economic situation of the firm. Indeed, from the case studies, it emerges that the assessment of the good is more relevant compared to that of the firm for what concerns “pure” ABL solutions (IFTM, IFDM, EBL), confirming what already stated in literature. However, for the other solutions this does not hold true and the assessment of the financial and economic soundness of the client acquires importance. The only solution that potentially does not have high requirements both in terms of marketability of the goods and financial and economic situation of the firm is IFCM.

Relevance
In terms of theoretical contribution, the paper extends the concept of Supply Chain Finance to the set of ABL solutions. The results obtained make it possible to fill the gaps in the literature that were highlighted during the definition of the research questions: the creation of a framework that includes holistically the solutions of Asset-Based Lending, both those based on inventories and those based on equipment, and the main relevant variables that have an influence in the process of adoption is useful to have clear what is the starting perspective when considering this category of solutions in view of future developments. An academic literature review and the analysis of the interviews have allowed to identify the main criteria for the adoption of each specific solution, exploring also new factors such as the legal frame in which ABL solutions are offered. On the other hand, from a managerial perspective, the paper provides a decision-making tool for managers who are considering the adoption of ABL as it is supporting the choice of the most suitable solution, given the firm’s objectives and its contingent situation. The findings also have value for solutions’ providers: financial providers can understand how to adapt their solution offerings based on their customers’ objectives and characteristics and how to manage the adoption process in the most efficient and effective way possible, considering all relevant aspects, so as to propose a low-risk solution that is winning for all parties involved. Future research could use more quantitative methods to define the relative importance of variables (e.g. survey) as the results were built in a qualitative way, considering variables that are relevant and comparable, on the basis of information received. Moreover, given the nowadays dynamic context, characterized by strong innovation (especially technological), solutions are in continuous evolution. Future research should therefore monitor the evolution of the analysed paradigms, performing a continuous assessment of the model, in order to have a constantly updated classification of solutions.

Abstract
This study aims to explore the information integration practices adopted by small and medium sized enterprises (SMEs) (borrowers), and their impact on the supply chain finance (SCF) decisions of a core firm of a supply chain (lender) and SMEs’ financial performance. This study conducts a case study of a supply chain in Chinese smartphone industry. A mixed method design is used. We find that information system integration is positively associated with SCF and financial performance whereas social interaction is negatively associated with SCF and does not significantly affect financial performance. In addition, SCF is positively associated with financial performance.

Keywords: supply chain finance, mixed method research, information integration

Introduction
Supply chain finance (SCF) is the inter-organizational optimization of financing and involves the integration of financial with information and physical flows in supply chains in order to decrease the cost of capital. Small and medium sized enterprises (SMEs) in supply chains usually lack financial resources to support operations (e.g. purchasing of raw materials and large scale production) and growth (e.g. investment in research and development and commercialization of new product designs) (Xu et al., 2018). Meanwhile, a supply chain’s core firm’s operational decisions can be severely constrained by its suppliers’ financial resources (Wuttke et al., 2016). Cash constrained SMEs may increase supply chain risks and negatively influence supply chain efficiencies. To improve working capital and optimise supply chain processes, a core firm of a supply chain is motivated to offer SCF to alleviate its supplier’s financial distress through the collaboration with financial institutions and technology providers (Gelsomino et al,
The core firm may also benefit from exploiting the differences in the cost of capital between different supply chain members and from the reduced risk of bankruptcy throughout the supply chain (Bals, 2018).

Although SCF is challenging existing business models and supply chain management, and is receiving growing attention in research, there is a lack of empirical analyses addressing SCF implementation and the empirical evidence on its effects is still fragmented. For example, Gelsomino et al. (2016) review SCF research and find that only around 20% of the studies use empirical methods. They also highlight there is a lack of practical guidance on the adoption of SCF and point out that the impact of SCF on financial performance has generally been neglected in the literature. Xu et al. (2018) conduct a bibliometric analysis of SCF studies and find that the majority of SCF research uses analytical models to investigate the issues related to trade credit and operational decisions. They also call for more empirical evidence on the management of SCF. Researchers further argue that the adoption process of SCF is complex and information integration plays a critical role in the success of SCF. Enabled by the information systems and internal-organizational processes, the connectivity and information flows of supply chains can be significantly improved, leading to lower information asymmetry between a core firm (SCF lender) and SMEs (SCF borrowers). Although researchers argue that information integration allows SMEs to access financial resources which can improve their performance, how SMEs can create processes to successfully collaborate with a core firm in a supply chain to reduce information asymmetry is largely ignored in the literature.

Credit rationing provides a useful perspective to explore SMEs’ information integration with a core firm and the implementation of SCF. Credit rationing occurs when a core firm supplies a smaller loan size than that demanded by SMEs. A core firm must use a variety of screening devices and mechanisms to identify the SMEs who are more likely to repay SCF loans. SMEs and a core firm may have differential access to information about a project’s risk. The uncertainties of SMEs’ ability or willingness to repay SCF loans may also lead to moral hazard and adverse selection. Therefore, when information asymmetry between SMEs and a core firm is high, the core firm tends to implement more credit rationing by reducing SCF loans. As a result, SMEs must develop strategies and systems to integrate with a core firm which can improve the transparency of the information flows and reduce the core firm’s uncertainties and risks.

The objective of this study is to empirically investigate the impacts of information integration on SCF and financial performance. We aim to answer two research questions. First, what are the information integration practices SMEs can adopt to integrate with a core firm of a supply chain? Second, how does information integration affect SCF and financial performance? The findings can provide empirical evidence on how SMEs can successfully integrate with a supply chain to obtain financial resources. The study also enhances current understandings of SCF implementation and the mechanisms through which information integration between a lender and borrowers affect the lender’s SCF decisions and the borrowers’ financial performance. In addition, the findings can provide guidelines to SMEs’ on how to alleviate a core firm’s credit rationing and benefit from implementing SCF.

Research methods
This study adopts a case study approach and uses a mixed method design. This choice is motivated by the research objectives and the lack of empirical evidence on SCF. The mixed method design links qualitative and quantitative data which allows us to provide analytic texture of SCF and strengthen the analytical findings. Specifically, we combine the inductive theory-building and natural experiment methods of case studies (Welch et
First, we conduct an explorative case study which uses an inductive logic and aims to propose associations between constructs and variables and develop testable hypotheses which large-scale quantitative testing is based on. Qualitative data is collected from both the core firm and SMEs of the supply chain and is used for theory building and contextualization (Welch et al., 2011). Second, we conduct a confirmatory case study based on deductive logic. Quantitative data are collected from SMEs and the core firm at both project and firm level to test the hypotheses, leading to the modification and extension of the theory. Finally, a follow-up interview is carried out with the senior managers of the core firm to discuss analytical results of quantitative data. Therefore, this study combines theory-building and theory-testing approaches of case study which allows us to capture the richness of empirical context and generate internally valid explanation (Ridder, 2017). Qualitative data can help the quantitative side of the study by aiding in conceptual development and instrumentation, and also by validating, interpreting and clarifying the quantitative findings. Collecting qualitative and quantitative data from a core firm and SMEs of the supply chain enables us to yield data from multiple sources (i.e. both lender and borrower) for triangulation and derive solid research results based on theoretical and analytical generalization.

**Explorative case study**

A supply chain in the Chinese smartphone industry was chosen because it can offer insights into SCF and allows the researchers to provide detailed description and analysis to gain a better understanding of how information integration affects SCF. Specifically, the core firm of the supply chain (CJ) offers SCF to supply chain members who are cash-constrained SMEs since 2009. CJ is acknowledged as one of the most successful SCF providers in the great bay region of China. For example, it has gained the “AA” rating of enterprises recognized by the Chinese customs and the “Direct Passage” status awarded by Shenzhen tax bureau. CJ has also developed a thorough process and information system to collaborate with SMEs and support their supply chain management. Therefore, the case offers opportunities to open a black box of the relationships between information integration and SCF.

The research team interviewed ten senior managers in CJ, including president, director and vice director of information system department, director and vice director of risk control department, director of financial department, two business managers and two operations managers, and nine managers in the members of the supply chain who are SMEs, including four general managers and one finance manager from four smartphone designers, one vice general manager and two product managers from two smartphone manufacturers, and one marketing director from a raw material supplier. Each interview lasted approximately 2 to 3 hours and was conducted in Chinese.

As SCF offered by CJ is different from bank loans, communications and interactions between CJ and SMEs’ employees play a critical role in facilitating the SMEs to understand their obligations and CJ’s internal standards and regulations, especially how CJ controls SCF risks and manages supply chain operations. The SMEs also rely on social interactions to share information and collaborate with CJ to reduce information asymmetry. For example, managers in the SMEs all mentioned that their employees keep close contact with CJ to ensure that they can get support in the purchasing, production and delivery processes which are jointly managed by CJ. They actively share information about market environment and process improvement suggestions through social interactions. Through frequent social interactions, CJ and SMEs can also align business processes and coordinate decision making. Therefore, social interactions help CJ accumulate knowledge about SMEs and their operations.
Moreover, CJ has spent a great deal of efforts and resources in information technology architecture and has developed an E-SCM with a myriad of software systems. CJ’s directors explained that CJ had installed a SAP ERP system as the backbone of the information technology infrastructure. It has purchased an IBM Si integrated data centre and developed a B2B web-based database to interact with supply chain members which allows them to use the system through an Internet portal. The CJ’s president commented that the system enables faster communication, shorter lead time, lower transaction costs, lower pipeline inventory and more effective planning and coordination in supply chains. However, CJ’s managers noticed that E-SCM cannot realize its full potential because some SMEs do not have a compatible information technology infrastructure and the information system integration between CJ and them is weak. Therefore, CJ encouraged the SMEs who do not have an adequate information system to use E-SCM directly to acquire, share and analyse data or to develop a compatible information system that can be easily connected to the E-SCM. CJ’s directors also emphasized the SMEs can improve the quality, quantity and speed of the information sharing through using E-SCM. The operational and financial information exchanged on E-SCM forms a foundation for the collaboration between SMEs and CJ on supply chain management which reduces information asymmetry and risks for the SCF loans. CJ’s president further commented that the degree of information system integration has become a key criterion for CJ to make SCF decisions. Therefore, the case evidence reveals that information integration between SMEs and CJ relies on both social interaction and information system integration.

Social interactions allow employees in CJ and SMEs to develop a common expectation of their roles and responsibilities in SCF. They also facilitate the exchange of tacit knowledge such as organizational culture and technical knowhow. As explained by CJ’s directors, social interactions help them identify and collaborate with the SMEs with compatible culture, goals and strategies, which build a foundation for developing trust and long-term relationships. CJ’s managers also emphasized that such relationships can avoid SMEs’ opportunistic behaviours and deal with the problem of moral hazard. In addition, CJ can accumulate more knowledge of SMEs’ capabilities and operational processes, which decrease uncertainties and help CJ better evaluate SCF projects. Thus, social interactions reduce information asymmetry about SCF projects and motivate SMEs and CJ to coordinate business decisions and strategies. As CJ’s perceived SCF risks are reduced, it will alleviate credit rationing. Therefore, we propose the following hypothesis.

**H1. Social interaction between a core firm and an SME is positively associated with SCF received by the SME.**

As commented by CJ’s president, E-SCM allows CJ to link different stakeholders such as designers, raw material providers, manufacturers, and logistics service providers together. He believed that the integration between SMEs’ information systems and E-SCM plays a critical role in the success of SCF projects and hence CJ uses the degree of information system integration as a key criterion in evaluating the risks of SCF projects. Supported by highly integrated information systems, CJ can timely and accurately acquire operational information including procurement, production, logistics, and settlement, from SEMs which improves the transparency of the SMEs’ operations and allows CJ to monitor and control the financial flows in real time to ensure the repayment of SCF loans. In addition, the large amount of structured data stored in E-SCM about past projects helps CJ develop a better understanding of SMEs’ capabilities on profiting from different SCF projects and the risks associated with the projects. Information system integration thus can reduce the information asymmetry and uncertainties of SCF projects, which promote CJ to alleviate credit rationing. Therefore, we propose the following hypothesis.
H2. Information system integration between a core firm and an SME is positively associated with SCF received by the SME.

Both CJ and SMEs agreed that social interactions help them coordinate supply chain processes which can improve operational efficiency and financial performance. The case evidence reveals that social interactions help CJ and SMEs collaborate on supply chain management. For example, the communications with SMEs’ employees help CJ grasp technical specifications and requirements of SMEs’ products and processes. This is very important for improving supply chain performance as CJ is actively involved in the SMEs’ operations. In addition, social interactions provide a channel for SMEs to provide improvement suggestions, increasing supply chain processes. They also help SMEs understand CJ’s procedures and rules better, which can reduce miscommunications and misunderstandings during cooperation. Thus, SMEs can reduce costs and improve flexibility by creating a seamless and smooth physical flow, which increase financial performance. Therefore, we propose the following hypothesis.

H3. Social interaction between a core firm and an SME is positively associated with the SME’s financial performance.

The case evidence also reveals that information system integration plays an important role in improving SMEs’ operational efficiency and financial performance. The interconnected information systems allow CJ to obtain real time operational and market information from SMEs and their customers which help CJ reduce operational costs, product defects, and lead-times. CJ also motivates SMEs to use its E-SCM system to interact with customers and manage financial flows which can avoid miscommunications and greatly improve SMEs’ cash-to-cash cycle. As SCF projects are co-managed with CJ, information system integration enables SMEs to obtain speedy and high quality information in respect to purchase and delivery of raw material, production and delivery of finished goods, and settlement and repayment, which allow SMEs to improve operational scheduling and strategic planning, ultimately increasing financial performance. Therefore, we propose the following hypothesis.

H4. Information system integration between a core firm and an SME is positively associated with the SME’s financial performance.

CJ’s president commented that the SCF offered by CJ can improve SMEs’ financial performance for two reasons. First, SCF allows SMEs to expand their businesses by capturing more marking opportunities and serving more customers even if they have limited financial resources. As highlighted by the SMEs, it is impossible for them to conduct and profit from some projects without the SCF loans offered by CJ. Second, SCF greatly reduces SMEs’ financial costs and the cash-to-cash cycle. With the loans from CJ, SMEs do not need to pay a high interest rate to banks or financial institutions for cash. In addition, they can invest capital in upgrading equipment, improving human resources and developing new products and processes instead of occupying all cash into daily operations. In this way, SMEs can improve their operational capabilities, resilience for supply chain risks, and responsiveness for market changes, increasing financial performance. Therefore, we propose the following hypothesis.

H5. SCF is positively associated with an SME’s financial performance.

Confirmatory case study
Quantitative data were collected from CJ and SMEs to test the hypotheses. Specifically, transactional data about SCF projects were collected from CJ and survey data about information integration were collected from SMEs. After consulting with CJ about the data availability, we decided to focus on the SCF projects financing SMEs’ raw material purchasing. There were 39 SCF clients who were SMEs and successfully obtained SCF
loans from CJ. After contacting the SMEs, 33 were willing to participate in this research and allowed CJ to share their project data with us. Then, through the collaboration with CJ, we have identified and collected data of 207 SCF projects from E-SCM system. Both firm (e.g. number of employees and interest rate) and project level data (e.g. SCF loan, sales, total purchase amount, payment terms and service fee) were collected. A questionnaire has been designed based on existing literature and the exploratory case study to collect information related to information integration from the SMEs.

Information integration was measured in the questionnaire using a seven-point Likert scale to capture the perceptions of the respondents. Specifically, social interaction was measured by four items concerning the interactions between CJ’s and SMEs’ employees through which they share improvement suggestions, rules and procedures, and information about business processes and requirements. Information system integration was measured by four items about the interconnectedness between CJ’s and SMEs’ information systems and the practices of sharing information and managing business processing by using information systems. The respondents were asked to assess the degree of agreement of the statements (1= “totally disagree”; 7= “totally agree”). The data about SCF and financial performance were extracted from CJ’s database. SCF was calculated by the proportion of SCF in total purchasing cost of raw materials in a project. SMEs’ financial performance was measured by the cash-on-cash return of a project, which is calculated by the ratio of total cash income over total cash investment. The measures were developed in consulting with CJ and SMEs. During the interviews, CJ and SMEs both mentioned that SCF loan is used to finance part of the raw materials purchasing. CJ also explained that the credit rationing will consider SMEs’ financial needs and risks, and the SCF invested in a project is largely influenced by the overall raw material procurement costs which is related to project size. The amount of SCF cannot accurately reflect CJ’s credit rationing decisions because a large amount of SCF may be caused by high procurement cost of a large scale project and is a result of high credit rationing. Therefore, we use the ratio of SCF loan over the total purchasing cost to control the influences of project size. A high ratio indicates that CJ is willing to finance a large proportion of the raw material purchasing costs, which reflects that CJ believes the risk of the project is low and applies lower level of credit rationing. As highlighted in the interviews, SCF borrowers are all cash-constrained SMEs and the main reason for using SCF is to improve cash flow. The managers in SMEs also emphasized cash flow management and viewed speeding up turnover of their working capital and cash return generated from projects as key performance indicators of SCF. Cash-on-cash return captures cash income earned on the cash invested, which reflects the effect of SCF in alleviating SMEs’ cash constraint. We also included firm size, which was measured by the number of employees and interest rate as control variables for SCF and financial performance. Moreover, we controlled the effects of uncertainty of purchase and uncertainty of receivables on SCF. We also controlled the duration of a project, which is calculated by the days between an SME starts to cooperate with CJ and CJ collects the principal and interest of an SCF loan from customer payment, on financial performance.

We first conduct the psychometric tests of the two constructs (i.e. social interaction and information system integration). An exploratory factor analysis was conducted. The results indicate that the items have strong loading on their corresponding constructs. We use the composite reliability and Cronbach’s α to evaluate reliability. The results show that the composite reliability values are 0.94 and 0.93, and the Cronbach’s α values are 0.91 and 0.90, showing that the reliability of the constructs is acceptable. Average variance extracted (AVE) is used to test the convergent and discriminant validity. The AVE values are 0.80 and 0.76, indicating that the convergent validity is acceptable.
comparison of the correlations and square roots of the AVEs indicates adequate
discriminant validity for the constructs. We then conducted the multicollinearity test. The
results reveal that the smallest tolerance is 0.768 and the largest variance expansion factor
is 1.302, indicating that multicollinearity is not a serious problem.

We use the multilevel structural equation modelling with robust maximum likelihood
method and MPLUS software to test the hypotheses because we proposed a two-level
model with data collected from both firm and project level. The unidimensional parcels
of the two multi-item constructs, which are calculated using principal component scores,
are used in data analysis. The model fit index are as follows: Chi-Square/df = 1.15, p =
0.327, comparative fit index = 0.991, Tucker-Lewis index = 0.958, root mean square error
of approximation = 0.029, standardized root mean square residual (SRMR) (value for
within) = 0.015, and SRMR (value for between) = 0.014, which are better than
corresponding threshold values. The findings show that the $R^2$ for SCF is 32.9%.
Information system integration is positively associated with SCF ($b=0.305$, $p<0.05$),
whereas social interaction is negatively associated with SCF ($b=-0.284$, $p<0.05$).
Therefore, $H2$ is supported whereas $H1$ is not. The results also show that interest rate
($b=0.138$, $p<0.01$) and uncertainty of purchase ($b=0.212$, $p<0.01$) are positively
associated with SCF whereas uncertainty of receivables ($b=-0.188$, $p<0.05$) is negatively
associated with SCF. Firm size does not significantly affect SCF. We find that $R^2$ for
financial performance is 27.4%. Information system integration ($b=0.413$, $p<0.05$) and
SCF ($b=0.212$, $p<0.01$) are positively associated with financial performance whereas the
impact of social interaction is not significant. Therefore, $H4$ and $H5$ are supported
whereas $H3$ is not. Moreover, we find that the impacts of project duration, interest rate
and firm size on financial performance are not significant.

Discussion

This study contributes to literature in three ways. First, the findings contribute to SCF
literature by providing empirical evidence on the implementation of SCF (Gelsomino et
al., 2016, Xu et al., 2018). This study adopts a mixed method design and both qualitative
and quantitative data have been collected from SCF lenders and borrowers. The design
includes both explorative and confirmative case studies, which allow us to triangulate the
evidence to verify and generalize the findings. Moreover, the multilevel statistical
analysis can provide insights into the impacts of firm level practices on SCF projects. The
case study thus allows contextualization of credit rationing in SCF and provides a holistic
picture on how to reduce information asymmetry through the collaboration of different
stakeholders. As a result, the case study offers a balanced view of information integration
and credit rationing from both a core firm’s and SMEs’ perspectives. In addition, this
study provides empirical evidence on how the information integration between a lender
and a borrower affects credit rationing. The case study also sheds light on the impacts of
SCF on supply chain management. The findings thus extend current understandings on
how a supply chain can successfully implement SCF.

Second, this study empirically identifies two kinds of information integration
practices and examines their individual effects in SCF credit rationing, enhancing existing
knowledge on the integration and coordination of information and financial flows in
supply chains (Bals, 2018). The findings reveal that SMEs use both social interaction and
information system integration to integrate information with a core firm, providing
insights on how a core firm makes credit rationing and SCF decisions and how an SME
can create processes and systems to avoid credit rationing. The statistical analysis further
discovers that information system integration can reduce credit rationing, whereas there
is a gap on the perception and reality of the impacts of social interaction on SCF. The
finding that social interaction increases credit rationing enhances current knowledge on the effectiveness of relationship lending in SCF and the special characteristic of SCF comparing with bank lending, revealing that social interaction and information system integration play different roles in affecting a lender’s SCF decisions. In addition, the result highlights the importance of information system integration in reducing information asymmetry and supporting SCF. The findings also contribute to supply chain integration literature by linking information integration with SCF and enriching current understandings of the benefits of information integration.

Third, this study contributes to the supply chain management literature by enhancing current understandings on the impacts of SCF and information integration on management of cash flow and by highlighting the importance of joint management of information, financial and physical flows in a supply chain (Wuttke et al., 2016). The findings reveal that information system integration and SCF are positively associated with cash-on-cash return, which enhances existing knowledge on how SMEs can alleviate cash constraint. In addition, the result improves current understandings on the performance outcomes of SCF (Wuttke et al., 2016). By linking information integration with financial performance, this study finds that social interaction and information system integration plays different roles in affecting cash flows in a supply chain. Although existing empirical evidence reveals that social interaction can improve operational and marketing performance based on survey data, this study finds that social interaction does not affect the cash flow by combining survey and objective data. The finding thus contributes to the supply chain integration literature by providing insights into the performance outcomes of information integration.

The findings can provide guidelines for both a core firm and SMEs of a supply chain to successfully adopt SCF and benefit from its application. We suggest a core firm of a supply chain offer SCF to SMEs because it is a very effective method to improve the cash flow of the supply chain and reduce financial risks. A core firm should establish close relationships to get loans from banks and other financial institutions. It should also select and offer SCF to the SMEs who have compatible culture and high market and technological capabilities but lack physical assets for collateral and have weak cash flows and hence encountering difficulties to get loans from traditional channels. The study suggests a core firm apply credit rationing based on the degree of information asymmetry and manages and controls risks of SCF by actively participating in SMEs’ supply chain operations, such as purchasing, production, delivery and payment processes to monitor and control the physical, information and financial flows. In addition, we suggest a core firm implement a digitalization strategy to integrate information, financial and physical flows to form a closed-loop system and invest to develop an integrated and advanced information system to manage SCF and the supply chain. For example, a myriad of software systems, such as ERP, CRM, and AI, and an Internet platform to promote fully automated transaction exchanges and enable different stakeholders, such as SMEs, customers, and government agencies who have different information systems to communicate and share information. Moreover, a core firm should motivate SMEs to integrate and use the information system and digitalize their processes. Furthermore, a core firm should be aware that although social interaction with SMEs facilitates the exchange and transfer of knowledge, it may lead to more credit rationing.

We suggest cash-constrained SMEs who have low credit rating and cannot get loan from banks to apply SCF from core firms of their supply chains to improve their cash-to-cash return. The SMEs should understand that SCF could be used to finance raw material purchasing which enables the SMEs to expand businesses and grow with limited financial resources. SMEs should be aware that the SCF requires them to closely cooperate with a
core firm on supply chain management. To demonstrate commitment and improve transparency, they must allow a core firm to participate in and manage some of their operations. Therefore, SMEs must develop inter-organizational processes to integrate the physical and information flows with a core firm and develop long-term and collaborative relationships in supply chains. In addition, SMEs should understand that reducing the information asymmetry on a project can alleviate a core firm’s credit rationing and allows them to get more credits. We suggest that SMEs adopt information integration with a core firm when applying for SCF. They can also rely on information system integration and the digitalization of operations to improve financial performance. For example, SMEs could integrate their information systems with a core firm’s information system and exchange information and knowledge and collaborate with the core firm on supply chain and business process management using the system. However, SMEs should be warned that although social interactions with a core firm, such as the communications and interactions between employees, may improve supply chain operations, they may reduce the SCF obtained from a core firm and do not significantly affect their financial performance.

Conclusion
This study conducts a case study of a supply chain in the smartphone industry in China. We adopt a mixed method design and collect qualitative and quantitative data from both a core firm (SCF lender) and SMEs (SCF borrowers) to empirically investigate the relationships among SMEs’ information integration practices, a core firm’s SCF decision and the SMEs’ financial performance. Based on the credit rationing and sociotechnical systems theories, we first conduct an explorative case study using qualitative data. We have identified that SMEs and CJ can integrate information via social interaction and information system integration. A framework has been developed which proposes that social interaction and information system integration positively influence SCF and financial performance, and SCF improves financial performance. We then conduct a confirmatory case study using quantitative data. A multilevel structural equation modelling analysis based on survey and second-hand data reveal that information system integration is positively associated with both SCF and financial performance and SCF enhances financial performance. However, social interaction is negatively associated with SCF and does not significantly affect financial performance.

This study has three main limitations which open avenue for future research. Frist, the findings of the study are based on a case study of a supply chain in the smartphone industry in China. The implementation and effectiveness of SCF might be influenced by the industrial and institutional environments. Future studies could verify and generalize the findings in other contexts. Second, this study focuses on information integration. Researchers argue that the integration of financial, information and physical flows and collaboration in supply chains are critical for SCF. Future research could extend this study by investigating the impacts of business process and strategy integration on SCF. Third, this study focuses on the interactions and collaboration between SMEs and a core firm. During the case study, the CJ’s managers mentioned that its long-term objective is to develop a platform on which different stakeholders, such as SMEs, customers, banks, and government agencies, can collaborate with each other to create an ecosystem. Future research could adopt a longitudinal design to explore the establishment of and transition to ecosystem and how the ecosystem affects SCF and the performance of supply chain members.

Abstract

This paper explores how companies in automotive manufacturing supply chains can successfully upscale and respond quickly to market demand. Specifically, we look at the capabilities across the supply chain and we examine the impact of supply chain architecture on upscaling. We use multiple case study method and we draw data from 3 manufacturers and 2 tier-1 suppliers. The findings provide insights of the upscaling process, the challenges and the capabilities needed across the supply chain. Moreover, results show how different sets of capabilities are combined with different supply chain architectures which in turn, leads to different upscaling performance.

Keywords: Supply chain upscaling, Capabilities, Supply chain architecture

Introduction

In periods of growth the demand for existing or new products increases and supply chains need to be ready to upscale in order to achieve a quick time-to-market and time-to-volume, meet the demand and increase the revenues (SMMT, 2018). In the UK, automotive manufacturing experienced continuous growth until 2018 and there is a well-expressed need for government support and investments, especially in a post-Brexit environment where more indigenous/UK-centric supply chains are needed (HM Government, 2018). In addition, new technologies and mobility trends (e.g. autonomous driving, electrification, digitalisation) put enormous pressures on manufacturers to develop new products and supply chains to seize these opportunities in the market (APC, 2016). For example, demand for electric vehicles is constantly rising (SMMT, 2018), new registrations of plug-in cars in the UK increased from 3,500 in 2013 to more than 195,000 by the end of January 2019 (Lilly, 2019) and EV manufacturers (e.g. Tesla) face a number of challenges with regards to upscaling their supply chain (McKevitt and Patrick, 2017).

Previous research has shown how to strategically plan for a ramp-up with the use of lean and integrated approaches to support decision-making, and how important the investments into R&D and production capabilities are (Becker et al., 2017; Christensen and Rymaszewska, 2016). Researchers have also looked at the importance of knowledge management and how it can inform the upscaling process (e.g. spillover learning, copy-exactly strategy) (Terwiesch and Xu, 2004). From a supply chain point of view, only a
few researchers have investigated the ramp-up and they have highlighted the need for collaboration, flexibility and responsiveness (Kalaitzi et al., 2019; Li et al., 2014). But the literature is scant on the capabilities that manufacturers and suppliers should have in order to be ready to upscale and also on the role of supply chain architecture in upscaling.

In light of the gap in the extant literature, this research aims to explore how companies in automotive manufacturing supply chains can successfully upscale and respond quickly to market demand. In particular, we answer the following two research questions:

- What is the right mix of capabilities that companies should have in order to succeed in upscaling?
- Does supply chain architecture affect upscaling and how?

We anchor our research on dynamic capabilities theory in order to capture the dynamic nature of automotive manufacturing and guide the capabilities assessment process for a successful upscaling (i.e. quick time-to-market and time-to-volume) (Teece, 2007). Based on prior research and dynamic capabilities theory, we develop a conceptual framework proposing that the capabilities internally –into the organisation– and externally –across the supply chain– impact the upscaling performance and also that supply chain architecture impacts the upscaling performance.

We begin our paper by reviewing the literature on upscaling and dynamic capabilities theory. We then present the research methodology followed by the findings. Finally, we conclude by discussing both research and managerial implications.

**Literature review and theoretical background**

A well-established stream of literature that examines the upscaling or ramp-up phase uses the definition given by Terwiesch and Xu (2004) who defined the ramp-up as ‘the period of time during which a manufacturing process is scaled up from a small laboratory-like environment to high-volume production’ (Christensen and Rymaszewska, 2016; von Gleich et al., 2012; Surbier et al., 2014) and that is because upscaling has been mainly approached as an internal challenge and not as a supply chain challenge. At the conceptual level, it is also unclear when this phase begins, which functions of the company are involved and what processes are taking place for managing the supply chain.

More specifically, a considerable body of literature exists on how companies should plan internally for production ramp-up, what strategies to adopt and what capabilities to acquire. A number of authors have recognised that for a successful strategic ramp-up, an integrated approach among different decisions (e.g. production volumes, transportation volumes, capacity) is more beneficial than a sequential approach (Becker et al., 2017; Ball et al., 2011) and the application of lean practices in strategic decisions can help companies to acquire competitive capabilities and achieve a faster time-to-volume (Christensen and Rymaszewska, 2016). Also, Juerging and Milling (2005) who examined the copy-exactly and process change strategies, suggested that the more innovative the product is, the more beneficial a copy-exactly strategy is. For a faster time-to-market and ramp-up time, researchers suggested investments in product development capabilities, development of global R&D networks (Carrillo and Franzia, 2006, Kuenmerle, 1997) and allow time for “learning before doing” (Terwiesch and Xu, 2004).

However, there is limited knowledge about the supply chain implications of upscaling and the capabilities across the supply chain needed in order companies to succeed in upscaling. Nugroho (2010) and van Echtelt et al. (2008) looked at the supply chain relationships during upscaling and they supported that long-term collaboration between the buyer and the suppliers yields great benefits (e.g. supply flexibility, shorten ramp-up). Likewise, Kalaitzi et al. (2019) who explored the dependencies in supply chains during production ramp-ups suggested a relational approach in inter-company relationships and
Li et al. (2014) supported that a collaborative network of the focal firm and its suppliers can contribute to a rapid production ramp-up. Moreover, Johansson (2011) provided some empirical insights into the ramp-up process and concluded that integration of customers and suppliers, use of outsourcing strategy, collaboration, responsiveness to changes and flexibility across the supply chain can act as enablers to a more quickly ramp-up process.

In our study we use the theory of dynamic capabilities to guide the capabilities assessment process and help us come up with a set of capabilities that companies should have to succeed in upscaling. These capabilities can be ordinary or dynamic. Ordinary (or operational) capabilities are the sets of learned processes and activities that every company in the same industry can learn about them (Kleiner, 2013). Dynamic capabilities are idiosyncratic and unique because they are related to companies’ history and path over the years (Helfat et al., 2007). Teece (2007) highlighted that the most critical capabilities an enterprise should have in order to build and sustain a competitive advantage are the ability to sense and shape opportunities, the ability to seize opportunities and the ability to manage threats and reconfiguration. These capabilities can help managers to get the future right by preparing existing resources for the future (Kleiner, 2013).

Dynamic capabilities is the most appropriate theory to use in order to capture the dynamic nature of automotive manufacturing (e.g. product lifecycle compression, needs continuously change) (Becker et al., 2017) and the dynamic nature of the upscaling where high risks and low initial level of knowledge exist (Surbier et al., 2014). Also, it is a well-suited theory to help us come up with a set of capabilities that companies should have in order to succeed in upscaling since an effective upscaling is an important factor in gaining competitive advantage (Akkermans et al., 2019). Moreover, dynamic capabilities theory has been widely considered to look into capabilities at the supply chain level enhancing its applicability to this study (Mitrega et al., 2017; Lee and Rha, 2016).

The architecture of the supply chain is another factor that has been linked to the upscaling performance measures (e.g. time-to-market, time-to-volume, quality and cost) but not directly addressed within the upscaling context (Fine, 1998). A supply chain that exhibits close geographic, organisational, cultural and electronic proximity among its parties is characterised as integral supply chain. In that case, the degree of outsourcing is low and the processes are highly synchronised. Close collaboration and a great deal of interactions and efforts is required to yield results and it is not very flexible, but it has the potential for high performance (Nepal et al., 2012; Park, 2014; Ülkü and Schmidt, 2011). A supply chain that exhibits low geographic, organisational, cultural and/or electronic proximity among its parties is characterised as modular supply chain. Of course, modular supply chain architectures do not have low proximity in all the elements described otherwise it would be hard to survive let alone to be advantageous (Fine, 1998). In that case, the degree of outsourcing is high and the suppliers have responsibilities over the final product which create risk sharing opportunities (Nepal et al., 2012; Park, 2014). Modularisation is characterised by a mix-and-match of capabilities allowing for cost reduction opportunities, increased quality and increased product variety (Doran et al., 2007). The rational for designing integral supply chains is usually based on performance while for modular supply chains is usually based on time-to-market and cost considerations (Fine et al., 2005). Ülkü and Schmidt (2011) suggested that when the development capability difference between the firm and its supplier is large then a more integral architecture is preferable.

The empirical study that follows draw from our synthesis of prior literature on upscaling and from the theory of dynamic capabilities. Figure 1 presents our conceptual framework which proposes that capabilities in the supply chain impact the upscaling performance and also the architecture of the supply chain impacts the upscaling
performance. The capabilities have been collected from the literature on upscaling and dynamic capabilities and these can be ordinary or dynamic. We also explore if there is any relationship between the factors capabilities and supply chain architecture.

**Figure 1 – Conceptual framework**

**Research methodology**

We focused on the automotive manufacturing sector to investigate the upscaling as it is a highly competitive and dynamic sector with frequent ramp-ups because of continuous market changes and technological advancements (SMMT, 2018; APC, 2016). The rational to select a single sector was the different ramp-up drivers (e.g. product lifecycle, frequency of ramp-up, product complexity, industrial set-up) between different industries (von Gleich et al., 2012). So, the focus on automotive manufacturing provides a rich setting for our research and offers the potential for important insights into the capabilities needed and the impact of supply chain architecture on upscaling.

**Multiple case studies and unit of analysis**

The case study research was opted as the most appropriate method to conduct exploratory research (Yin, 2014). Multiple case studies were used to offer a deep understanding of the upscaling process and to produce robust results to reveal the case companies’ capabilities and supply chain architecture that allowed them to succeed (Huq et al., 2016). Moreover, multiple case studies enhance the reliability of findings and reduce researcher bias as they offer the opportunity to compare and contrast different cases improving the external validity (Busse et al., 2017). The criteria for selecting the case studies were to be automotive manufacturers and suppliers, start-ups and well-established companies with research and design activities and manufacturing capabilities and to produce products of high volume and variety. Firms’ capabilities, supply chain architecture and upscaling performance were investigated. So, the unit of analysis, i.e. case, is the firm with each having a clear supply chain role (i.e. manufacturer or supplier).

**Data collection and analysis**

We collected data from 5 case studies: 3 manufacturers and 2 tier-1 suppliers and the data collection process took place from May 2018 to February 2019. The main sources of data were semi-structured interviews mainly because of their strength to focus on the research topics allowing at the same time explanations and personal views. A semi-structured interview protocol was used and the interviews designed to last about 1 hour, allowing for enough time to gather the data and respecting the informants’ availability. The
exploration began with some rational and direction from the conceptual framework. A total of 17 face-to-face semi-structured interviews were conducted with directors, supply chain, purchasing, logistics and production managers (Table 1). The interviews were recorded unless participants objected. We supplemented the interviews with five factory site visits, internal reports and multiple sources of secondary data to support interview data and also protect against researcher bias. Also, two secondments took place within the supply chain departments of two suppliers in order to gain rich insights on how to get the supply chain ready for production ramp-up and get hand-on experience.

Transcripts together with comprehensive notes were produced and unclear issues were clarified in follow-up emails. The analysis was performed using a combination of within and cross-case analysis (Wilhelm and Sydow, 2018). In the within-case analysis, we sought to understand what upscaling is, how they manage it and get their supply chain ready for production ramp-up by assessing their capabilities and their supply chain architecture. In the cross-case analysis, we sought to identify commonalities and differences in the upscaling process between the 5 cases; manufactures and suppliers.

Moreover, to ensure methodological rigour, we used and met the criteria of internal validity (e.g. we draw on different literatures; ramp-up, dynamic capabilities, supply chain architecture), external validity (e.g. we used multiple case studies and collected data from multiple sources), construct validity (e.g. we presented the analysis to experienced academics and industrial experts) and reliability (e.g. we developed and used an interview guide) based on the recommendations of Garver (2019) and Selviaridis et al. (2016).

**Findings**

*Within-case analysis*

Auto_1 is a start-up automotive manufacturer specialising in the design and development of electric vehicles and is considered a highly technological and innovative company both in terms of product design and business strategy. In the upscaling phase, the company determines the resources needed, the associating costs, the people and the skills needed. The upscaling phase starts at the R&D stage and successful upscaling means reaching the production target and having the market ready.

Auto_2 is a well-established multinational automotive manufacturer. The company classes upscaling as a new product development which starts when a contract to build a vehicle is agreed. The supply chain team is instantly getting involved with sourcing to influence the suppliers or influence the selection of the suppliers. The SCM of Auto_2 reported that “suppliers should match the company’s capabilities otherwise they’re limiting the company’s ability to perform to their best of their capability”. Successful upscaling means that all of the targets for each of the different functions are met.
Auto_3 is also a well-established multinational automotive manufacturer which views upscaling as the introduction of a new product or modification of an existing one. The supply chain and purchasing team gets involved as soon as the engineering team pass them the project specification and a successful upscaling means on time deliveries, correct product specifications and be on budget.

Auto_4 is a start-up tier-1 supplier of electric parts for the automotive sector. For the company upscaling is the whole preparation for ramping-up and the process for getting the company fit, getting the product fit and the getting the suppliers fit. Upscaling starts at the proof of concept stage and the successful upscaling means achieving the volume in time, in budget and in quality.

Auto_5 is a well-established global tier-1 supplier of electric parts for the automotive sector. The company classes upscaling as a new product introduction and successful upscaling means delivering to the customer on time without additional costs.

Table 2 briefly presents the case studies’ capabilities and supply chain architectures.

Table 2 – Brief within-case analysis and quotations
Cross-case analysis

Our cross-case analysis indicated that both manufacturers and suppliers consider upscaling as a supply chain challenge and not solely as an internal challenge. The start-ups, Auto_1 and Auto_4 give most of their attention on planning internally for upscale by determining resources, costs and investments needed and they face a number of challenges with regards to building a supply chain able to support their future capacities, increase their credibility and develop trust (“at the moment, there is a lot of begging involved where the supplier has all the power, … but those relationships have to change” SCM, Auto_1). On the other hand, the well-established companies, Auto_2, Auto_3 and Auto_5 class the upscaling as new product introduction where they either use their existing supply chain or add some new suppliers but in both cases they need to go through the process of assessing the readiness of their supply chain and making sure that they are able to upscale and support their volumes. All of the interviewees agreed that supply chain and purchasing functions should get involved in the upscaling project as early as possible, before even the proof of concept stage in order to design for manufacture (“there is no use in designing something that cannot be manufacturing, so critical suppliers are instantly on board” HP, Auto_3), plan and determine costs and investments needed.

Our research shows that manufacturers and suppliers have developed dynamic R&D capabilities as they are trying to generate innovation by exploiting external resources (e.g. suppliers, customers, market) to respond to the changing market condition (“most of the flexibility is that we are talking about product flexibility and volume flexibility and will depend on what the market wants more” CTO, Auto_4). Also, we observed manufacturing capabilities with companies highlighting the importance of designing for manufacturing and dynamic managerial capabilities with managers being able to sense forthcoming changes and being proactive to avoid delays in the process or managers recognising the importance of spillover learning (“we do things to speed up the process, we are aware of the changes that are coming so we go to the suppliers ask them about lead times, cost etc.” HP, Auto_3, “we transfer the knowledge from one project to another” SCM, Auto_3, “push much earlier for information than expected time” LPM, Auto_5). Moreover, some of the companies had developed relational capabilities as a result of the good relationship with their supply chain partners, the information exchange, the regular communication and the development of trust. In particular, Auto_2, Auto_3 and Auto_5 had developed strong relational capabilities with their suppliers and customers resulting in increased flexibility, time savings and even cost reductions (“always involve the suppliers at the very outset, it will save a massive amount of time” HP, Auto_3, “we tend to be more in a partnership relationship rather than customer-supplier relationship, … we both have on target, to be successful” LPM, Auto_5). In Auto_2, we also observed strong supplier development capabilities where the company has a separate department assigned to prepare the suppliers to meet production demand (“at the moment we have many suppliers who are struggling to build and support our volumes, so many different suppliers, lots of different telephone conferences, lots of different visits from my team and try to understand how we can improve them” SCM, Auto_2, “good planning and preparation of the supplier from us means that we can reduce costs” SCM, Auto_2).

Regarding the supply chain architecture we categorised the cases into two groups. Auto_1 and Auto_4 presented characteristics of an integral supply chain as they have low degree of outsourcing, low dependency levels, full control over their product design and quality for different reasons and no close relationships or partnerships with their suppliers. This architecture have given them the potential for high performance and quick time-to-volume, but not high products variety (“when you’re doing most in-house you’re...
in control but it’s costly and you cannot have a lot of projects, different projects, you cannot make everything in-house” (HP, Auto_3). On the other hand, Auto_2, Auto_3 and Auto_5 presented characteristics of a modular supply chain as they have high degree of outsourcing and they have developed trust with their suppliers, strategic alliances and partnerships. This architecture have given them the advantages to produce products of high variety, share risks and increase their flexibility. Moreover, it is interesting to note that the cases with characteristics of an integral supply chain (Auto_1, Auto_4) have highly invested in developing core capabilities in-house while the cases with characteristics of a modular supply chain (Auto_2, Auto_3, Auto_5) have significantly invested in developing capabilities across their supply chain and they present a mix-and-match of capabilities.

Discussion and conclusions
Our research shows that dynamic R&D, manufacturing and managerial capabilities, should be coupled with strong relational and supplier development capabilities in order to carry out a successful upscaling. This is in line with the findings by Trebilcock (2016) and Thiedell (2012) who have showed that limited capabilities across the supply chain, unable suppliers and poor infrastructure make it hard for manufacturing companies to meet the demand. We also confirm previous findings in the literature about the importance of R&D capabilities, learning activities (Carrillo and Franza, 2006; Terwiesch and Xu, 2004) and supply chain collaboration (Kalaitzi et al., 2019; Li et al., 2014) and we demonstrate how different sets of capabilities are combined with different supply chain architectures which in turn, leads to different upscaling performance. Finally, our findings highlight dynamics in upscaling (e.g. market dynamics) and the importance of adapting to changes (e.g. design or volume changes) through increased flexibility across the supply chain.

Theoretical implications
This research increases our understanding of the upscaling process and adds further empirical evidence to the body of literature. In particular, we clarify the concept of supply chain upscaling and we consider implications for the supply chains during production ramp-up by demonstrating how the case study companies prepare and get ready their supply chain for upscaling. By drawing on the dynamic capabilities theory, we go beyond a structured way of investigating the upscaling and we identify and propose specific capabilities to allow companies in manufacturing supply chains to carry out a successful upscaling. Applying a dynamics perspective has also shifted our attention to the importance of adapting to changes (e.g. design or volume changes) through increased flexibility across the supply chain. Finally, our study not only contributes to the upscaling and supply chain management literature but also to dynamic capabilities theory by identifying dynamic capabilities in manufacturing supply chains that help companies to achieve a quick time-to-market and time-to-volume. Previous research in strategic management literature have explored and proposed specific dynamic capabilities to allow firms to successfully adapt to changing environments and gain a competitive advantage (Mitrega et al., 2017; Lee and Rha, 2016) but not in the context of upscaling.

Managerial implications
This research addresses a real industry need for strengthening and growing supply chains and our findings provide several implications for managers of automotive manufacturers. First, we propose specific capabilities to facilitate the upscaling process in dynamic environments. Second, we show how managers should match capabilities with the
architecture of their supply chain to achieve the desired upscaling performance. For example, we show that companies that deploy an outsourcing strategy have extended their upscaling to their suppliers and they should focus on developing supply chain related capabilities, support and guide their suppliers and strengthen the relationships with them. So, much of the responsibility for the success of upscaling lie with the supply chain and purchasing teams to manage the supply base. Also, at the very practical and operational level both manufacturers and suppliers should consider implementing shared platforms to facilitate transparency and information sharing especially when there are changes.

Limitations and future research
Notwithstanding the novel context of this study, the research is not without its limitations. First, the empirical data were collected only from the automotive manufacturing sector and that limits the generalisation of the results. Aerospace or high-tech manufacturing sectors which have been discussed in the literature with regards to upscaling may produce different results because the ramp-up drivers (e.g. product lifecycle, frequency of ramp-up) differ significantly. Second, more cases are needed to explore upscaling. This is an ongoing research so in the future more case studies will be included to build on these insights. And third, our research is positioned in periods of growth but there are also times of recession. So, there are promising directions for further research to explore how companies should manage the dynamics of upscale and downscale in automotive manufacturing sector following the work of Akkermans et al. (2019) in digital services.

Exploring the effects of the agile, adaptable and aligned supply chain on performance: the mediating role of collaboration

Abstract

This paper analyzes the mediating role of supply chain collaboration (SCC) in improving performance (SC efficiency and SC responsiveness) from the Triple-A SC variables (agility, adaptability and alignment). PLS-SEM has been used in a sample of 277 Spanish companies (more than 50 employees). The results show that there is a direct effect of SCC on both SC efficiency and responsiveness. The mediating role of SCC has been found in the relationship between SC agility and SC alignment, and both performance constructs. SC adaptability has no significant direct effect on collaboration and collaboration does not mediate its relationship with performance.

Keywords: Triple-A, Performance, Collaboration

Introduction and purpose

Managing the supply chain (SC) effectively has become critical for firms’ growth and survival. Several authors highlight that supply chain integration (SCI) is the core component of SC (Kim, 2009). SCI implies “collaborative inter- and intra-organisational management on the strategic, tactical and operational levels of activities (and their corresponding materials, funds and information flows) that, starting with raw materials suppliers, add value to the product to satisfy the needs of the final customer at the lowest cost and the greatest speed” (Alfalla-Luque et al., 2013, pp. 2).

Previous research agrees that a higher level of SCI positively influences performance (e.g., Kim, 2009; Zhao et al., 2013), although there are some other studies that do not confirm this (e.g., Swink et al., 2007; Alfalla-Luque et al., 2015). Thus, results are inconclusive (Jin et al., 2013; Chang et al., 2016) and more empirical research is needed on this topic (Leuschner et al., 2013).

There is also a consensus in the prior research that customer and supplier collaboration (external collaboration or SCC) is a key factor and even an antecedent of SCI (e.g. Flynn et al., 2010; Alfalla-Luque et al., 2013; Tsanos et al., 2014; Liao et al., 2017). Previous studies confirms the impact of SCC on performance (Soosay and
Hyland, 2015; Ralston et al., 2017) but mixed results have been found (e.g., Anderson and Jap, 2005; Villena et al., 2011; Fawcett et al., 2015). Consequently, there has been a recent call for a better understanding of mediating routes by which SCI affects performance to gain a comprehensive knowledge of the phenomenon from an academic and management point of view (e.g., Chang et al., 2016; Ataseven and Nair, 2017; Niranjan et al., 2018).

SCC has been considered a crucial mediator between several SC dimensions and performance (Baihaqi and Sohal, 2013; Wu et al., 2014; Hui et al., 2015; Kim et al., 2017; Salam, 2017; Levi-Bliech et al., 2018). Therefore, the lack of consensus in stating that the relationship between SCI and performance is positive perhaps may be due to that SCI can be a transversal element in the SC management and, consequently, act as a mediator for the achievement of performance/competitive advantages (CAs) from business strategies and practices (Vanichchinchai, 2012; Alfalla-Luque et al., 2015). One of the most prominent strategies and practices has been proposed by Lee (2004), who states that a successful SC must be agile, adaptable, and aligned (Triple-A SC). There are some calls in recent literature for more attention and research efforts on these variables (Dubey et al., 2015; Li et al., 2015; Alfalla Luque et al., 2018; Feizabadi et al., 2019), but so far there are few research studies that have analyzed antecedents, consequences or moderated/mediated factors of the three variables together in the same framework. This research analyzes the mediation role of SCC in the relationship between Triple-A SC variables and performance. In this regard, the literature has considered Triple-A SC to be an antecedent of SC performance (i.e. Whitten et al., 2012) but has not explored the possible mediating influence of SCI determinants such as collaboration. Therefore, this study focuses on analyzing the mediating role of SCC in improving performance from the Triple-A SC.

Theoretical background and hypotheses

SCC and SC performance

SCC is defined as “a partnership process where two or more autonomous firms work closely to plan and execute SC operations toward common goals and mutual benefits” (Cao and Zhang, 2011, pp. 166). Consequently, SCC is based on mutual trust and goals, shared reward and risk, and joint decisions seeking a win-win relationship between partners that achieve more benefits than if they were to act independently (Cao et al., 2010). Coordinating efforts with SC partners enables responsiveness to real-time demand changes and competitor strategies (Kahn et al., 2006).

The ultimate goal of an effective SCC capability is to achieve differential performance and, ultimately, create and sustain a competitive advantage (CA) for SC partners (Cao and Zhang, 2011; Hui et al., 2015). Growing research interest confirms the impact of SCC on performance (Soosay and Hyland, 2015; Ralston et al., 2017). Among the main traditional operational benefits of SCC that should be noted are: cost reductions; enhanced quality and inventory management; shorter cycle times; delivery improvements; higher flexibility and adaptability to cope with uncertainty and variability; responsiveness; and enhanced customer service levels (e.g., Hui et al., 2015; Kim et al., 2017; Ralston et al., 2017).

Although there is a broad consensus in the prior research that a higher degree of SCC leads to superior performance and CA, it is important to highlight that mixed results have been found (e.g., Anderson and Jap, 2005; Villena et al., 2011; Fawcett et al., 2015). These mixed findings reveal the complexity of the SCC-performance relationship and further investigation is needed (Liao et al., 2017). In order to contribute
to the previous research, the following hypotheses are proposed:

- **H1**: SCC is positively related to SC efficiency.
- **H2**: SCC is positively related to SC responsiveness.

**SC agility, SCC and SC performance**

SC agility is the ability to rapidly detect and respond to short-term changes in real demand and supply in order to generate or maintain a CA (Alfalla-Luque et al., 2018). SC agility is identified as a key element of competitiveness and directly impacts on producing and delivering products in a timely and cost effective manner (Swafford et al., 2006). SC agility is essential for inventory reduction and the ability of firms to respond to final demand more quickly, adapt to market variations more efficiently, and integrate with customers and suppliers more effectively (Mason et al., 2002). Firms have responded to dynamic and volatile markets by developing an agile SC, which implies the capability of interpreting and responding to real demand (Scholten et al., 2010).

Scarce studies include all the Triple-A SC dimensions in the same framework and analyze the individual impact of each on performance/CA (Dubey et al., 2015; Dubey and Gunasekaran, 2016; Attia, 2016; Dubey et al., 2018; Alfalla-Luque et al., 2018). In this regard, SC agility has been demonstrated to have a positive impact on organizational performance (Khan and Pillania, 2008; Attia, 2016), logistics and human performance (Dubey et al., 2015), humanitarian SC performance (Dubey et al., 2015; Dubey and Gunasekaran, 2016), CA (Dubey et al., 2018), flexibility CA, and financial CA (Alfalla-Luque et al., 2018). However, the findings of some studies have been mixed. Thus, Alfalla-Luque et al. (2018) have not confirmed a positive impact on cost CA, quality CA and delivery CA.

Taking the previous research into account, new empirical evidence of the relationship between the Triple-A SC and performance is required. Hence, the following hypotheses are formulated:

- **H3**: SC agility is positively related to SC efficiency.
- **H4**: SC agility is positively related to SC responsiveness.

SCC plays a key role between several SC dimensions and performance. For example, Baihaqi and Sohal (2013) propose that information sharing across the SC is crucial but insufficient on its own to bring significant performance improvements. These authors confirm that collaboration with SC partners fully mediates the relationship between information sharing across the SC and organizational performance. In the same vein, Wu et al. (2014) test relationships between several SC drivers or antecedents (trust, commitment, reciprocity, and power), information sharing and SCC, and SC operational and financial performance and highlight that a successful SC could not be achieved without the mediating role of information sharing and SCC. In addition, SCC is shown to play a much greater mediating role in achieving SC performance than information sharing. However, no studies have been found analyzing the mediating effect of SCC between SC agility and performance. Consequently, the following hypotheses will be tested:

- **H5**: SCC has a mediating effect between SC agility and SC efficiency.
- **H6**: SCC has a mediating effect between SC agility and SC responsiveness.

**SC adaptability, SCC and SC performance**

SC adaptability can be defined as the ability to adapt strategies, products and/or technologies to structural market changes (Alfalla-Luque et al., 2018). The complex and
turbulent market environment requires an adaptable SC to increase the possibilities of survival and this has become a key prerequisite for achieving a sustainable CA. Scarce research has been found about adaptability in the SC context (i.e. Ivanov, 2010; Eckstein et al., 2015; Schoenherr and Swink, 2015).

Focusing on the papers that consider the three Triple-A SC variables in the same framework and analyze the individual impact of each on performance/CA, a positive impact of SC adaptability has been confirmed on organizational performance (Khan and Pillania, 2008; Attia, 2016), logistics performance (Dubey et al., 2015), humanitarian SC performance (Dubey and Gunasekaran, 2016) and cost CA, quality CA, delivery CA, flexibility CA and financial CA (Alfalla-Luque et al., 2018). Nonetheless, Dubey et al. (2015) did not confirm a positive impact on human performance. Based on previous mixed findings, the following hypotheses are formulated:

**H7**: SC adaptability is positively related to SC efficiency.

**H8**: SC adaptability is positively related to SC responsiveness.

As in the case of SC agility, the mediating effect of SCC in the relationship between SC adaptability and performance has not been analyzed in previous research. This research contributes to the literature testing the following hypotheses:

**H9**: SCC has a mediating effect between SC adaptability and SC efficiency.

**H10**: SCC has a mediating effect between SC adaptability and SC responsiveness.

**SC alignment, SCC and SC performance**

SC alignment is the ability to share information, responsibilities, and incentives with SC members to coordinate activities and processes (Alfalla-Luque et al., 2018). SC alignment implies strategic coordination between partners (Flynn et al., 2010) and pursues the consistency of all SC members’ interests (Lee, 2004). The SC should be managed to meet the demands of product/market speed and complexity through the coordination of operations (Kehoe et al., 2007).

SC alignment has been determined to have a positive impact on organizational performance (Khan and Pillania, 2008; Attia, 2016), logistics performance (Dubey et al., 2015), human performance (Dubey et al., 2015) and cost CA, quality CA, delivery CA, and financial CA (Alfalla-Luque et al., 2018). A positive impact on humanitarian SC performance (Dubey and Gunasekaran, 2016) and flexibility CA (Alfalla-Luque et al., 2018) has not been confirmed, however. Consequently, the Triple-A SC dimensions show different impacts on different performance/CA measures, and the results are inconclusive. The following hypotheses are proposed:

**H11**: SC alignment is positively related to SC efficiency.

**H12**: SC alignment is positively related to SC responsiveness.

Finally, the mediating effect of SCC in the relationship SC adaptability – Performance will be analyzed through the following hypothesis.

**H13**: SCC has a mediating effect between SC adaptability and SC efficiency.

**H14**: SCC has a mediating effect between SC adaptability and SC responsiveness.

Considering all the above, this study contributes to the previous literature analysing the relationship between SCC and performance, specifically regarding SC efficiency (H1) and SC responsiveness (H2). Specifically, this study analyzes the mediating role of SCC in improving performance from SC agility, SC adaptability and SC alignment. This research analyze the individual effect of each Triple-A SC variable on performance (H3, H4, H7, H8, H11, H12) and the mediating effect of SCC (H5, H6, H9, H10, H13, H14). The proposed research framework is shown in Figure 1.
**Methodology**

To provide empirical evidence of the different proposed research hypotheses, a population of 2,650 Spanish manufacturing firms (with a minimum of 50 employees) was established as the object of study. 277 companies (10.5%) responded to the survey (confidence level of 95% for \( p = q = 0.5 \)) from January to July 2018. No evidence of response bias was found in a comparison of respondents and non-respondents. The first forty responses and the last forty responses were compared and no significant differences (\( \alpha = 0.05 \)) were found for any of the variables, which confirms that there was no late response bias. In short, the data and analysis confirm that the sample used in the study was randomly obtained and that it statistically represents the population.

SC agility, SC adaptability, and SC alignment scales have been adapted from previous research on this topic (Tachizawa and Gimenez, 2010; Arana-Solares et al., 2011; Qi et al., 2011; Gligor et al., 2013; Marin-Garcia et al., 2018). SCC has been measured through a simple scale focused not on the object or content of collaboration (activities, information, resources, etc.), but on the scope of collaboration (Barrat, 2004). SC efficiency measurement have been adapted from Liu et al. (2009) and Danese et al. (2012), and SC responsiveness from Reichhart and Holweg (2007) and Bortolotti et al. (2015). All the constructs were modeled as reflective with 3 to 6 indicators measured on a five-point scale.

The research model was tested using PLS-SEM with SmartPLS 3. This variance-based multivariate statistical technique is being increasingly used in many disciplines, including SCM. Model evaluation was carried out in two stages: a) assessment of the measurement model, and b) assessment of the structural model. The path weighting approach was used to estimate model coefficients and statistical significance was tested by bootstrapping with 5,000 subsamples.

**Results**

*Measurement model*

The research model includes six constructs. For the evaluation of the measurement model, reliability of these constructs (through the composite reliability index), convergent validity (by AVE, Average Variance Explained) and discriminant validity (with the Fornell-Larcker criterion) were verified.

As can be seen in Table 1, the constructs’ composite reliability varies between 0.80 and 0.90, which is above the 0.7 minimum required to confirm their reliability. Convergent validity is also fulfilled, given that AVE is higher than 0.5 in all cases.
Table 1 – Reliability and convergent validity of latent variables

<table>
<thead>
<tr>
<th>Latent variable</th>
<th># items</th>
<th>Loadings</th>
<th>Composite Reliability</th>
<th>AVE</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>SC Efficiency</td>
<td>3</td>
<td>.681 – .845</td>
<td>.800</td>
<td>.573</td>
</tr>
<tr>
<td>SC Responsiveness</td>
<td>5</td>
<td>.664 – .845</td>
<td>.891</td>
<td>.622</td>
</tr>
</tbody>
</table>

Finally, discriminant validity is also demonstrated by the fact that all between-construct correlations are below the square root of the constructs’ AVEs (Fornell-Larcker). In view of these results, we can conclude that the model is reliable and valid, so the structural model can be analyzed.

**Structural model**

Regarding the structural model, Figure 2 shows the results of the direct effects estimations (path coefficients and p-values in brackets). The results show that there is a direct effect of external collaboration on both SC efficiency and responsiveness, so H1 and H2 are supported.

In addition, some differences have been found in the analysis of the relationship between each Triple-A SC and the performance measures. SC agility has a positive and significant impact on SC efficiency and responsiveness (H3 and H4 confirmed), but neither SC adaptability nor SC alignment has confirmed these effects (H7, H8, H11 and H12 not supported).

Figure 2 – Main results of the model

Table 2 shows the indirect effects in the model. The mediating role of SCC has been found in the relationship between SC agility (H5, H6) and SC alignment (H9, H10), and both performance constructs. SC adaptability has no significant direct effect on collaboration and collaboration does not mediate the relationship with performance (H13 and H14 not supported).

Conclusions

The literature has considered Triple-A SC to be an antecedent of SC performance (i.e. Whitten et al., 2012) but has not explored the possible mediating influence of SCI determinants such as collaboration. By assessing the mediating effects of collaboration, the results of this study contribute to the SCM literature by answering the call for a better understanding of the interaction between SCI and performance (e.g., Chang et al., 2016; Ataseven and Nair, 2017; Niranjan et al., 2018) and, specifically, represent a clear step forward in the knowledge of Triple-A SC-performance relationship. This is especially appropriate and useful when mixed findings as to the relationship between SCI and performance have been detected in prior research, in general, and in the area of the Triple-A SC, in particular.

One of the main novelties of this study is that it goes one step further in the Triple-A SC by finding that the direct impact of each Triple-A SC variable on performance is different. Only the direct effect of the SC agility is significantly positive on efficiency and responsiveness. This finding is in line with a previous research (Khan and Pillania, 2008; Attia, 2016). Therefore, SCC acts a mediating variable in the relationship SC agility-performance and SC alignment-performance.

These results represent a novel contribution to our knowledge of the impact of a Triple-A SC on performance/CA and demonstrate the importance of SCC especially. It is important to remark that very few empirical studies have analyzed in the same framework the impact of Triple-A SC variables on performance (Dubey et al., 2015; Dubey and Gunasekaran, 2016; Attia, 2016; Dubey et al., 2018) and only one, their impact on CA (Alfalla-Luque et al., 2018).

Several managerial implications can be drawn from this study. OM and SC managers should be aware that their efforts to improve the implementation level of the Triple-A SC should be accompanied by advances in SCC intensity with partners. SCC has demonstrated its direct impact on performance and its mediating effect with SC agility and alignment.

Future research may find further evidence of the relationship between the Triple-A SC and performance, and the role of mediating variables such as SCC. This will enable progress to be made in the development of Triple-A SC theory through testing the hypotheses in different countries and samples.

This study is not free of limitations that could be the basis for future research. The aim of the analysis is exploratory in nature and data are cross-sectional and collected from only one country. In spite of this, one of the study’s main strengths is worth stating: This is one of the few empirical studies on Triple-A SC that analyzes a broad, multisector (14 different sectors) sample and uses a relatively large sample (277 companies). A logical extension of this study is to replicate the research framework in other geographical settings and to conduct longitudinal studies to analyze interactions and interdependencies among Triple-A SC dimensions and CA, and track changes over...
time (Li et al., 2015; Alfalla-Luque et al., 2018).

In addition, the analyzed mediating effects are consistent with prior SC research; however, there are many other SC aspects that could play crucial mediating, and even moderating roles in the relationship between the Triple-A SC and CA. Among the factors that could be suggested are type of industry, firm size, environmental dynamism, uncertainty, SC structure and complexity, position in the SC, competitive intensity, product characteristics and time. This would extend the research and allow new insights to be gained.

Abstract

Purpose: To identify the factors of traceability that impact digital supply chain evolution and to provide a framework for successful digital transformation in such context
Methodology: A case study on the implementation of new traceability regulation in the distribution network of pharmaceuticals in Europe.
Findings: Provide an in-depth analysis, from a Supply Chain lifecycle perspective, of the contingent variables (enablers, barriers) and expected benefits of traceability implementation.
Relevance/contribution: Likely to be the first study providing empirical evidence on the digital transformation process of a whole sector through a Supply Chain lifecycle evolution perspective.

Keywords: Digital Transformation, Supply Chain Lifecycle, Traceability.

Introduction
Falsification of medicines has been on the rise since more than a decade. European Union (EU) statistics report a sharp (threefold), increase of falsified medicines seized at borders starting from 2006 (2.7M articles). The World Health Organization (WHO) estimates a market share of up to 1% for falsified medicines in industrialized countries, while the European Commission (EC) has estimated that approximately 1.5 million falsified packs make it as far as the legal Supply Chain (SC) (European Commission, 2015).

Besides the socio-economic costs of related illness (estimated at almost €1 billion a year in the EU), falsified medicines also represent a significant damage for the players of the pharma SC, through increased costs for recalls, loss of product trust and damage of company image. This also impacts the broader European economy, since protecting the competitiveness of the pharmaceutical sector is critical in meeting the Europe 2020
targets on qualified employment, Gross Domestic Product (GDP) and Research & Development expenditure. (European Commission, 2015)

In February 2016, a delegated regulation, known as EU Falsified Medicines Directive (FMD) was released by the EU commission to implement traceability in the SC of pharmaceuticals within three years (by 2019). This new EU regulation requires the implementation of the first traceability system for medicines across all the EU and the European Economic Area (EEA), and it is based on the authentication model of traceability through serialization (Greenberg, 2014).

The implementation of such a system impacts the whole Pharma sector, since it is the shared accountability of all the SC stakeholders: Pharmaceutical Companies, Generic manufacturers, Parallel traders, Wholesalers and Pharmacies (Retail and Hospital), who have the shared accountability over the new system (European Commission, 2016/161).

The FMD traceability system is also a major investment in the digitalization of the pharmaceutical chain in Europe since, before EU FMD, there was no pan-European system available and traceability systems where not even present in many countries or, if they were, they were not interoperable with each other (European Commission, 2015).

A total of 155,000 SC players will need to legally comply with the regulation and thus connect and operate in a new and single traceability system, where every single pack of medicine will have a serial number stored and a chain of events recorded through its lifecycle (European Commission, 2016/161, EMVO, 2019), making EU FMD one of the largest and most comprehensive product traceability implementations in an industry sector.

When looking at the academic literature on traceability, while different studies can be identified addressing traceability in SC (Greenberg, 2014, Rotunno et al., 2014, Oldland et al., 2015, Simoens, 2009, Engelseth, 2009, Banterle, Stranieri, 2008), few take into consideration a whole sector or move beyond a single player’s perspective.

By illustrating the implementation of traceability in a whole sector and from a multi-stakeholder perspective, this paper wants to propose an understanding of traceability as a factor of SC lifecycle evolution (MacCarthy et al., 2016), and it aims to provide the first empirical evidence on the contingent factors and the expected benefits of digital SC transformation of such kind.

The SC lifecycle can be thought, similar to a product lifecycle, to comprise the different stages of emergence, growth, maturity and decline of a supply chain, this shifts the focus from the management of existing supply chains (at whatever stage they might be) to understanding the overall patterns of supply chains (MacCarthy et al., 2016).

Theoretical Background

Contingency Theory

Since the aim of this paper is to study the impact of a new regulation, in the frame of which the SC of pharmaceuticals needs to operate, and that the pharmaceutical supply chain is regarded as a highly regulated SC that takes its shape from the regulatory environment in which it operates (Greenberg, 2014, MacCarthy et al., 2016), our research will be guided by contingency theory (CT).

We provide a brief outline of CT and the reason why we believe it provides a good fit with this research, before moving on with the more specific theoretical background of our study.

CT stipulates that organizational performance is driven by the fit with the environment, enabled through a high level of integration in the organization itself (Lawrence, Lorsch, 1967).
From a CT perspective, the evolving Operations Management (OM) practices that organizations take, from time to time, are their response to the contextual variables, while their fit to the context is one of the pillars of performance (Sousa, Voss, 2008).

CT is one of the most enduring theories used in OM, while Supply Chain Management (SCM) is the most frequent topic of study in OM (Walker et al., 2015).

The relevance in taking a CT view in SCM is also highlighted by (Kembro, Selviaridis & Näslund, 2014), they have recognized an increased use of CT “acknowledging that there is no universal solution how to approach information sharing in a supply chain”. They also suggest that the appropriate level of information sharing is determined by the supply chain context and call for more sophisticated ways to use contingency theory through in-depth case studies.

CT is thus a well-grounded theoretical underpinning in both OM and specifically in SCM and its continued use is advised for research on SC collaboration and information sharing.

Virtual and Digital SC
Since a key element of traceability is the flow of information along the SC (Engelseth, 2009), we find useful to briefly mention some of the key research on SC digitalization from the outset of the internet era, as these can still provide important elements into our study of traceability from a SC lifecycle perspective.

The concept of virtual SC was articulated in the early internet era, during the development of e-commerce, to identify a network of firms that temporarily come together, enabled by the Internet, on an opportunistic bases to exploit fast changing business opportunities (Strader, Lin & Shaw, 1998).

A virtual SC has its own lifecycle going through the four phases of firms’ identification, SC formation, SC operation and, ultimately, SC termination; with important enablers for a successful lifecycle being the level of SC integration, activity coordination, IT infrastructure and information sharing (Strader, Lin & Shaw, 1998).

The need for adopting a virtual SC is driven by a change in the overall business logic, which is challenged by underlying contingent factors such as shortened time to market, blurring of organizational boundaries, increased knowledge intensity and IT-based competition (El Sawy et al., 1999). Virtual SC also lead to the development of new capabilities to create value out of the knowledge in IT systems but require the integration of the IT strategy into the overall company strategy (El Sawy et al., 1999).

Key success factors for virtual SC have been identified in development of strategic alliances with partners, internet-based IT, process re-engineering and visibility in supply chain, with information sharing as the driving force of the SC (Gunasekaran, Ngai, 2004).

Taking stock of the previous virtual SC literature, (Swierczek, Kisperska-Moron, 2016) identify, through a quantitative study, the key attributes of manufacturers in virtual SC as being their level of IT investment, shorter planning horizons and higher levels of inventory of a wide range of standardized products; while also recognize as key enablers the ability of these companies in blurring the organizational boundaries, establishing partnership along the SC (even with competitors) and holding a strong customer orientation and superior product value.

Summarizing the key findings of the virtual SC literature, we can say that the virtual evolution of SC was triggered by some of the early trends of SC globalization, such as time pressures, boundary blurring and the advent of the knowledge economy, and it relied on some consistent enabling factors such as the level of IT infrastructure, the level of SC partnering, the level of information sharing permitting SC visibility. The development of Virtual SC has also led to the development of specific SC characteristics such as broad
standardized product ranges, increase in customer orientation and service and continued investments in IT, together with the development of new capabilities relying on an intensification of the use of data and information.

As the use of internet-enabled technologies became more established and widespread, the distinction between virtual and non-virtual SC blurred, as most companies adopted internet technology at different levels. We will call this new phase with the general term digital SC.

While the benefits of internet-enabled SC are now established, the reasons behind different levels of performance is further investigated.

Concerning the enablers in digital SC performance, some are similar to those identified in the earlier Virtual SC literature, like supplier synergy, IT infrastructure, information intensity, and executive’s IT knowledge, however some new elements regarding the need of formal governance structures, IT systems interoperability and IT investment propensity start to emerge as key antecedents for the achievement of higher levels of benefits (Ranganathan, Teo & Dhaliwal, 2011).

The influence of broader contextual variables such as the level of Supply Chain Integration (SCI) and the level of collaboration of national cultures is also established as a moderator of SC performance (Davis et al., 2014).

It is recognized that information and knowledge management (KM) is not a “one size fits all” capability and that the achievement of higher organization performance requires the careful selection of a KM construct that fits with the organization’s needs (performance criteria and dimensions of SC agility), so as to leverage the human capabilities within the organization (Raisinghani, Meade, 2005).

More recently, as the amount of data circulating in SC grows, research on the use of information (Big Data) is intensifying. The intensified use of data is expected to bring both opportunities, such us greater SC visibility and operations efficiency as well as challenges through a potential lack of IT capabilities and infrastructure and concerns over cyber-security, making the case for good SC integration and collaboration together with effective governance even more important (Kache, Seuring, 2017).

We can conclude that, with the evolution of digital SC the focus has shifted to understanding the different levels of performance in SC. New enablers (Governance, SCI) and blockers (Cybersecurity, IT capability) have emerged with information usage and KM seen as a key competitive capability.

**SC traceability**

As mentioned at the beginning, product traceability is a key trait of digital SC since the coordination and integration of different flows of information along a supply network is one of the foundations to enable the tracing of goods (Engelseth, 2009).

Following (Engelseth, 2009) further, traceability is more complex than just the technical integration of information. It first relies on the capability of interwinding such technical aspects of information connectivity with the organizational capabilities of SCI, that integrate the different forms of knowledge available in the network. The level of network integration also needs to be at a high level, to be capable at accurately capture, process and analyse data and make the resulting information available in a timely manner and according to customer needs.

The high level of change in network integration required by traceability and the impact it has on the stakeholders of a supply chain, requires further changes also to the governance and the coordination agreements of the network, making system management more standardized and centralized as well as calling for new specific agreements for vertical coordination (Banterle, Stranieri, 2008).
Different authors have studied the application of traceability in the pharmaceutical supply chain or in a health care setting from different perspectives. (Rotunno et al., 2014) have summarized the requirement on pharmaceutical traceability and analysed the impact of traceability on different aspects of the pharmaceutical production systems. They argue that traceability can both improve private companies’ competitive advantage while delivering social benefits in terms of patient safety and quality of life. (Greenberg, 2014) presents the main responses from regulators to the concern of pharmaceutical counterfeiting through traceability, identifying two key models for traceability: the authentication model, which is a product serialization and end-point verification model, and the track-and-trace model where each product is authenticated in each node of the supply chain. She then moves into identifying several benefits, beyond compliance, that can arise from traceability systems, such as supply chain visibility, reverse logistics, pharmacovigilance, reimbursement of drugs and personalized medicines. (Simoens, 2009) has analysed the drug authentication system in Belgium to develop a threshold of product defects (recalled or expired products) that would make the implementation of similar traceability solutions cost effective in a country. (Oldland et al., 2015) have studied the benefits on dispensing error rates by introducing a bar code verification system for drugs in an academic hospital. Their empirical findings support the need to interwind technical and organizational integration in traceability as the rate of errors have decreased only after the introduction of staff training alongside bar code scanning.

While these studies in the pharmaceutical/health-care setting confirm the ongoing interest for traceability in SC and reinforce the role traceability plays in digital SC, they are either more theoretical in nature or focus on only one specific actor, or player, in the supply chain.

Summarizing our review so far, we can affirm that the introduction of product traceability in a supply network is a complex undertaking, that can have profound effects on the development of the SC as its implementation is increasingly required at the level of a whole sector (European Commission, 2016/161, Rotunno et al., 2014).

Further research is thus needed to understand the impact that traceability has on the evolution of digital SC, so we propose to take a SC lifecycle view on traceability in addressing the following RQs:

- RQ1: What are the most relevant contingent variables and how do they impact the digital transformation process?
- RQ2: Which benefits (or dis-benefits) is such a digital transformation and the greater availability of data expected to create?

We use an in-depth case study to answer our RQs

**Research framework and study methodology**

Summarizing the review of the literature, a theoretical framework was developed in light of the SC lifecycle model (MacCarthy et al., 2016) to understand which contingent variable are most relevant during successful digital transformation and in which areas are the benefits to be expected (Figure 1). (MacCarthy et al., 2016) identify six key factors that impact SC lifecycle evolution: technology and innovation, economics, markets and competition, policy and regulation, procurement and sourcing, SC strategies and re-engineering. They also postulate that a different subset of the factors will be at play in different lifecycle phases and that the industry sector will influence the pattern of emergence and evolution of the factors themselves.

We have thus identified two key factors that have influenced the evolution of digital SC: technology and innovation, SC strategy and re-engineering; these act across two SC lifecycle phases: establishment and growth. In addition, we have included the policy and
regulation factor as directly influencing the other two factors, since it is the EU FMD regulation itself that has mandated both the requirements for IT implementation and for specific governance structures as well as shaping the overall implementation of traceability in the pharmaceutical sector (European Commission, 2016/161).

This framework was used to develop the case study protocol and guided our enquiry during the case study.

The case study was carried out on the pharmaceutical distribution chain in three European countries. In a pharmaceutical distribution chain, products are shipped from pharmaceutical manufacturing sites into a distribution center serving the country or a group of countries. Products are then sold to the relevant in-country full-line wholesalers who then sell products onwards to pharmacies and sometimes to hospitals. For certain products, distribution centers might ship directly to hospitals or pharmacies.

The study is set up as a case study on multiple countries with the distribution network implementing FMD being the unit of analysis.

To select the countries for the study, out of the thirty-two countries in scope for EU FMD, different strategies where combined. The countries should have been in an advanced stage of EU FMD implementation with key supply chain stakeholders ensuring adequate support in carrying out the study. A senior expert at EU level recommended countries to involve (reputational selection) based on interest for research and access to data. The researchers have then made the selection of the three countries, out of six eligible countries, based on preliminary discussions with leading EU FMD stakeholders from these countries and ensuring a good mix in country sizes, geographies and environments.

Data collection was performed following a case study protocol developed from the theoretical framework. Data on the key elements of the framework were gathered through documentation (slides, reports) and semi-structured interviews. The relevant documentation was gathered from different sources, publicly available data was searched, company documents were collected during and after the interviews and the researchers
had also EU FMD specific documents available as part of one of the researcher’s practitioner role in the pharma industry.

A total of nineteen semi-structured interviews where run across the three countries and interviewees represent most of the supply chain in scope for the study in each country. All interviewees held senior roles in their organization with several years of professional experience in the sector/industry.

**Findings**
To date, the interviews and data gathering in all three countries has taken place and for one country we have conducted the transcribing, text coding and preliminary analysis. We will thus provide, with this working paper, a brief preliminary extract on this single case. This is meant to provide an illustrative example of the flow in the case study, in the most general and high-level terms. We aim to develop the work into a full paper once we have finalized the full analysis on all three country cases.

**Description of the context**
The country of study is a smaller country in the north of Europe with a specialized SC for pharmaceuticals, the key players in the network were included in our study (Figure 2).

![Figure 2 – Distribution network](image)

Almost all large pharmaceutical companies have a presence in the country, they are the owners of the medicinal product and are responsible for the supply of the medicines into the country from a global network of manufacturing sites, so we regard them as the starting point in the supply chain in the country. Within this case, we have interviewed one major global company and the Trade Association of Pharmaceutical Companies.

The next tier involved in the chain are third party logistics providers (3PL). In this country the major 3PLs are vertically integrated with the full-line wholesaler business and this segment of the SC is also highly concentrated, with two companies holding 90% of the market share. Both companies have been interviewed in our study.
The last tier of the SC is represented by pharmacies and hospitals, which are the ones who dispense products directly to the patients. There are around 100 hospitals (including public and private) and around 1,800 pharmacies operating in the country. For the development of the case we have interviewed two major hospitals, one public and one private, located in the capital city and that attract patients from all over the country, being leading hospitals. For pharmacies, considering their high number and dispersion, we have interviewed for our study their national association, who is also the organization involved in the implementation of FMD on behalf of all the pharmacies in the country. For pharmacies is also worth noting that one of the two integrated wholesalers is also vertically integrated with a retail pharmacy chain, this has provided an additional perspective on pharmacies besides the association’s.

Finally, the EU FMD regulation has mandated the establishment of a specific organization that is responsible for the implementation and running of the traceability system in the country, namely National Medicines Verification Organization (NMVO). We have included and interviewed this organization as well into our study.

**Description of the case companies**

Each organization interviewed was studied in detail as part of the case study, we provide below an example of a case company description.

Wholesaler B is an integrated health system provider of services and supplies. It has two fundamental branches of work; the first is in the manufacturing area, offering solutions for product manufacturers, the second is in the retail area in which it distributes products to community pharmacies, so that they can provide a better and more profitable service.

Wholesaler B was established in 1994 from the merger of a wholesaling group and a distributor. Its main headquarters are in the capital city, with approximately 400 employees and reported revenues of approximately €1,296M (for year 2016).

The main objective of the company is the creation of services and innovation for pharmacies and manufacturers, to make a difference in the pharmaceutical industry. The strategy to achieve this objective rests on two key pillars: implementation of technologies and implementation of innovation. In this way, Wholesaler B seeks to add value for the patient, and for those involved in medicines distribution, in terms of costs, product accessibility and service quality.

Wholesaler B vision can be summarized as working with pharmacies and manufacturers to improve patients’ health by ensuring compliance in terms of times and costs of service to ultimately generate value for their partners and win the confidence of the consumers.

**Case analysis**

The evidence collected from the field research is analysed following the framework presented, to derive meaning from the collected materials and ultimately provide a synthesis in answering the two RQs. We offer an extract of such an analysis, in respect to Knowledge Management, below.

The different participants recognise the value of information but at different levels, with integrated wholesalers offering a good overview on the enabling factors and potential uses of KM (Table 1).

In terms of commercial benefits, the improvement in access to information seems key. Although some participants have already good access to SC information through agreements, the current process is tedious and resource intensive and information sharing is hindered by non-compatible information systems.
This led to highlight the important aspect of standardization of data and technological systems, to enable visibility along the chain.

Some of the benefits that emerged, pertaining the implementation of the regulation, are: i) improvements in the information management allowing the advancement of control mechanisms in the SC, ii) information precision increasing patients’ safety, iii) improvement in performance measures, increasing transparency throughout the chain.

Table 1 – Key KM factors for wholesalers

<table>
<thead>
<tr>
<th>Knowledge Management</th>

</thead>
<tbody>
<tr>
<td><strong>Role of data:</strong></td>
</tr>
<tr>
<td>• There is no complete exploitation of the recorded data; it could be beneficial for the overall business with each client; business as pharmacy chains are very interested in data because it allows them to know the trends in their market.</td>
</tr>
<tr>
<td>• The information is useful to not waste unnecessary resources and products coming downstream the chain to customers. There are some opportunities for the manufacturers in the commercial field.</td>
</tr>
<tr>
<td>• Data is useful to know performance, what products pharmacies are selling, it can give a perspective, considering the recent changes in which pharmacies are more financially controlled, if their business model is right, if they need to reduce pricing, among others.</td>
</tr>
<tr>
<td>• Problems could arise if important decisions are made based on poor data or partial data, it is difficult to have the whole picture.</td>
</tr>
<tr>
<td>• At operational level, FMD is good in terms of the batch data - which is a major cost. Operationally it is good for the process of returns and recalls, safer for the patient and gives more certainty for the companies recalling a product.</td>
</tr>
<tr>
<td>• It is a focus for the next years, to interpret better and deeper the data to give customers the possibility to improve.</td>
</tr>
<tr>
<td>• Specific agreements with each client (manufacturer or customer) for data management and privacy - providing full information of the product chain.</td>
</tr>
<tr>
<td>• For the manufacturers is good if the implementation reaches the stage in which they share their needs to the wholesalers and then they receive the information back from pharmacies, so they have the whole picture of their market; today that is not possible, the trace is lost at some points</td>
</tr>
<tr>
<td>• From the perspective of the supply chain there is much more information - particularly to plan better the replenishment from manufacturers and to customers, knowing what is physically and potentially in every place</td>
</tr>
</tbody>
</table>

| **Patient information:** |
| • Pharmacies can construct profiles of their clients also. |

**Discussion and Conclusions**

Is beyond the scope of this working paper to discuss the findings of the study and develop the conclusions, since a full analysis of the case is still pending and the findings in this working paper serve as a mere illustration of the structure.

We however believe that this is the first empirical study to explore a SC lifecycle evolution of a sector. It also aims to be a comprehensive study on the impact of SC regulations on a whole industry sector across multiple countries and stakeholders.

Abstract
Collaboration in micro and small enterprises is often perceived as highly desirable, considering the limitations imposed on these enterprises due to their size and resources. However, the focus of academic and practitioner literature is on collaboration experiences amongst Small and Medium enterprises (SMEs). Adopting mixed method approaches of secondary research and a focus group, this research investigates the pre-conditions and motivations of the collaborative experience in SMEs. The study suggests that motivation to collaborate can be attributed to organisational, operational, marketing, knowledge transfer, and social factors. Furthermore, factors including organisational, strategic and resource-related are regarded as pre-conditions of collaboration.

Keywords: Collaboration, microbrewery, operations management

Introduction
Collaboration in micro and small enterprises (SMEs) has always been encouraged due to their restricted resources as a result of their size, skills and financial constraints. While these enterprises play an important role in the economic development of countries, usually they receive only scant attention with most studies focused on SMEs. This paper aims at contributing to filling the above gap by investigating the motivations and pre-conditions to instigate successful collaborations in SMEs. According to Business Statistics (2018), there were 5.4 million micro businesses with 0-9 employees, which adds to 96% of all businesses in the UK. Micro businesses account
for 33% of employment and 21% of turnover of the whole UK economy. Around 4% is small businesses while less than 1% is medium. In 2017, there were approximately 6,700 SMEs in the UK food and drink sector with turnover of around £18 billion and 120,000 employees. But most published research focuses largely on the food industry and less research is evident on the drinks industry, although both sectors are strategic for UK economic growth.

Relatively little work has been published on the collaboration in micro and small drink enterprises, including the microbrewery industry. While research and practitioner literature in the brewery industry focuses on major companies and their supply chain, they omit the increasingly growing number of entrepreneurial new enterprises over the last decade. These new enterprises brew their own beers at a micro scale level, offering differentiated products that have gradually shaped the microbrewing movement (Cabras and Bamforth, 2016). Although consumers’ beer preferences have changed and the microbrewery industry has become the center of media attention, there is a dearth of academic research on this industry (Karampela and Waehning, 2017).

Historical context has been discussed in previous research such as Cabras and Bamforth (2015). However, there is a lack of understanding on how micro-firms perform within their local networks and how they can survive in the competitive environment (Flanagan et al. 2017, Granata et al. 2018, Karampela and Waehning, 2017). One way to survive is to collaborate. Small breweries work in a collaborative/competitive environment, which is characterised by exchange of knowledge, information, and mutual support that facilitates creativity and innovation in both processes and recipes. However, literature is poor in portraying a clear description of what the motivations are for microbreweries to collaborate, what the preconditions are for such a collaboration and how this collaboration can work in practice (Flanagan et al., 2017).

Therefore, this research aims to fill these gaps by investigating the following research questions:
RQ1: What are the motivations for craft breweries to collaborate?
RQ2: What are the pre-conditions for craft breweries to collaborate?

This paper contributes to current knowledge on collaboration specifically in micro and small businesses by first illustrating the motivation factors for such collaboration. Furthermore, what pre-conditions need to be fulfilled beforehand? This information was realised through both analysis of secondary data and a focus group, with different stakeholders as attendees who present different viewpoints necessary to structure a comprehensive framework for collaboration in SMEs.

The paper is organised as follows: The literature review section includes discussion on horizontal collaboration with a focus on collaboration in micro and small enterprises, including the microbrewery industry, followed by synthesis of literature on motivations and pre-conditions to collaborate. Thereafter, we discuss methodology: secondary data analysis as the first phase; and the focus group as the second phase. In the next section, the results of secondary data analysis and focus group are reported. Finally, we make conclusions for each of the research questions. In conclusion, limitations and avenues for future research are discussed.

**Literature review**

The literature review conducted in this section is organised as follows: first, the relevant studies in the field of horizontal collaboration are reviewed and discussed; then, collaboration in SMEs, including the microbrewery industry, is specifically investigated.
Horizontal Collaboration
Collaboration is a strong strategy that facilitates the achievement of a vision which might not be possible for the entities working independently (Alonso and Bressan, 2017). Supply chain collaboration refers to “no less than two autonomous firms working together across their boundaries for the fulfillment of a shared goal” (Un and Kim, 2018). Collaboration is crucial to support long-term partnership and facilitate participating stakeholders to share their assets (materials, labour, infrastructures, facilities and equipment, and machines) and capabilities (technology, business processes, policy and legislation, and finance). Hence, uncertainties can be reduced, risks and costs can be shared, and finally, customers are served in the right time, right quantity, and right quality without disregarding the interests of other stakeholders (Dania et al., 2016).

In this study, we focus on horizontal collaboration, which is defined as “concerted practices among companies operating at the same level(s) in the value system” (European Union, 2001). These companies can be competitors or unrelated members of supply chains, such as suppliers, manufacturers and retailers that share information facilities and resources to reduce costs or improve services (Perez-Bernabeu et al., 2015). Such collaboration allows involved companies to achieve better performance than those who are working on their own (Pomponi et al., 2015). Reciprocal trust is crucial in successful collaboration (Wilhelm, 2011). Therefore, paying close attention to the initial stages of relationship development is very important (Pomponi et al., 2015). Thus, selection of collaborative partners and management of the negotiation phase are critical (Audy et al., 2012).

Horizontal collaboration has a more crucial role for SMEs. They have more limitations in terms of resources; therefore, there is more need to develop collaborative networks in order to benefit from complementary core competencies and sharing of joint resources. In this way, they can become stronger and achieve cost and risk reductions, and better access to information (Vlachos and Gutnik, 2016). However, considerable research gaps remain in exploring collaboration from different perspectives: the development of university and industry relationships; implementation of e-collaboration among SMEs; and collaboration in emerging industries, as in the case of the growing craft brewing industry (Alonso et al., 2018).

Craft brewery industry means independent, traditional and small breweries tend to work together to help the industry as a whole, rather than competing with each other (Berning and McCullough, 2017). This cohesion could build and maintain human capital or lead to collaborative brewing efforts, which can result in a variety of products. Micro and small breweries tend to be defined as craft breweries (Cabras, 2018). Two common classifications regarding the definition of microbrewery that exist in the literature follow the number of employees and production threshold. First, microbrewery is defined as a business with fewer than 10 people, while a small brewery employs between 11 and 49 people. Second, a microbrewery is defined as a small-scale brewery operating under the UK Progressive Beer Duty threshold of 5000 hectolitres annually (Danson et al., 2015). The growth and performance of craft beer sector can be influenced by four different contexts: institutional context (legislation and regulation in different countries); business context, which is the effect of market and industry; spatial context (place matters significantly to microbrewing) and social context (closeness to consumers and related issues). The social context is where brewers share crucial resources and collaborate in different areas (Drakopoulou Dodd et al., 2018).

This research focuses on the social aspect, which includes collaboration in the microbrewery industry. We have conducted our literature review in two parts: first, we look at motivations and then the preconditions. We look at the agri-food industry,
specifically the drink sector, as there is limited available literature on the brewery industry. Table 1 presents the motivations of collaboration.

There are some pre-conditions for collaboration. Trust is an important element. Therefore, firms first look at those whose working philosophies are the same and who have a comparable business reputation (Hanna and Walsh, 2008). Table 2 lists preconditions of collaboration.

1- Alonso and Bressan (2017), 2- Granata et al. (2017), 3- Hanna and Walsh (2008), 4- Fearne et al. (2001), 5- Moutaoukil et al. (2012), 6- Dania et al. (2016), 7- Pérez-Bernabeu et al. (2014)

It can be concluded from the literature review that, first, there are few academic papers looking into motivations and pre-conditions of the collaboration in micro and small businesses, specifically in the drink industry. This highlights the research gaps and calls for more research on collaboration in micro and small businesses, specifically the drink sector.
industry as an important industry in the UK. Second, it can be concluded that “combining strengths to achieve competitive advantage” is the most important motivation for collaboration in the industry. Furthermore, “trust” is a crucial pre-condition for collaboration. To have a clear portrait of motivations and pre-conditions of collaboration in micro and small businesses, we further investigate the industrial reports, followed by a focus group with different stakeholders.

Methodology
A very limited number of academic papers investigate collaboration in the craft brewery industry. Therefore, we decided to review industrial reports on this issue as part of our research methodology. The review focuses on industrial reports, including cases from Spain, France, New Zealand, Australia and the United States. Then, to gain in-depth knowledge to understand motivations and pre-conditions for collaboration, we conducted a focus group with different stakeholders. Therefore, the research methodology adopted in the first phase was secondary data analysis of practitioner literature, followed by a focus group of three hours.

In designing the focus group, there are two important factors: group size and composition. A manageable group size for focus group is between six and ten persons. We sent our invitations to 44 microbreweries who had websites among 110 microbreweries in Wales and five industrial partners, including consultancy companies and trade associations. All industrial partners replied to emails and three confirmed their attendance. Among breweries, just one email confirmation was received. The rest were followed up three weeks later by phone. Ten confirmed that they would attend. However, only five managed to attend the session. Thus a total of eight participants including three trade associations attended the session. This enabled the capture of different perspectives that shaped a complete and overarching understanding of collaboration in the microbrewery industry. In terms of composition of the group, there is a need for a mix of interests and expertise so the purpose of the research can be reflected properly. The focus group was designed in an unstructured approach i.e. raising a few questions so that free discussions between participants can be started. This approach is more popular within exploratory studies (Sanchez Rodrigues et al., 2010). The focus group was held in South West Wales in July 2018. It included two sessions of one hour and a half. The sessions were facilitated by authors of the paper who have knowledge in this research area and experience of conducting focus groups. The focus group was recorded with the permission of participants for transcription and summary for the analysis later.

Findings
Findings emerging from secondary data analysis
Different collaborative models are reported in the industrial reports concerning the microbrewery industry.

Collaborative partnership can have different motivations. Reports from 2013 presented a collaboration in which Beavertown, a microbrewery based in East London, collaborated with Jameson, which is an Irish whisky distillery, for St Patrick’s Day product offerings. Both partners shared similar ethos and ideology that shaped their collaborative process. They developed an imperial stout aged in rare Jameson casks (World top brewery, 2013). Many brewers, such as Titus Bentley, brewer at Fort Collins’s Horse & Dragon Brewing Co., believe that it is an opportunity to learn new techniques and improve their processes. He states that working with brewers whose processes and procedures are different from his broadens his horizon significantly (The Brew Enthusiast, 2016). Collaboration for most brewers is an opportunity to learn new brewing techniques, to see different brewery set ups, and experience different styles and ingredients. Another motivation is exposing
their brands to new drinkers, especially in foreign markets. It can also simply be for fun. Many brewers see collaboration as an opportunity to hang out with friends and relax as community, which is very important in the craft beer industry. Also, for many, collaboration is a desire to promote craft beer as artisanal, experimental and celebratory (Sammartino, 2015). “I prefer to be a travelling artist collaborating at someone else’s facility so I can see how things are done outside our environment”. Each collaboration is a chance to explore other breweries, invest in new friendships, and make others aware of the brands (Arthur, 2013).

Collaboration needs different pre-conditions. One is mutual respect, which was highlighted by Green Flash brew master, Chuck Silva, who explains the evolution of his relation with St. Feuillien brew master Alexis Briol as allowing them “as international counterparts to find common grounds”. They believe that they are always eager to learn from each other. They even have opposite specialities and approaches but could collaborate successfully for three years for three different products (Johnson, 2015). Justin Tilatto, head of sales and marketing at Boulder’s Twisted Pine Brewing Company believes having a good relationship with those they know results in good collaboration, whereas with strangers it is almost impossible. He believes that trust and tolerance lead to good collaboration (The Brew Enthusiast, 2016). Brewers rarely collaborate with those they don’t know. Good reputation of the partner is important for shaping the collaboration (Sammartino, 2015). “There isn’t a published set of rules for collaborating on beers, but there are a few things I consider before agreeing to make bedfellows with another brewery. First and foremost, I believe with conviction there needs to be a legitimate reason for collaborating. Without this, you have no story, and interest in the project will be tepid at best.” (Arthur, 2013).

Findings from focus group
In the focus group, participants were asked to comment on why they collaborate (Motivations). One of the motivations stated by the breweries was being Welsh language oriented: “…he’s a Welsh-language brewery, so we have a lot of synergy. Like I said, there aren’t a lot of people out there marketing themselves in the Welsh language, which we do, to a certain extent, not as much, perhaps, as this other guy ... So, it makes sense for us to work together, to gain greater access to the market surrounding, which tends to be fairly stitched up by specific bigger ones, they do the bars and stuff and other events as well. And they have recently got into bed quite heavily with another big name to command better prices on beer, which means that we are further excluded from what ought to be a natural market for us. So, it’s a way of trying to get closer.”

They also considered collaboration as a strategy to get closer for stronger voice: “It makes sense for us to work together, to gain greater access to the market surrounding, which tends to be fairly stitched up by specific bigger ones, they do the bars and stuff and other events as well. And they have recently got into bed quite heavily with another big name to command better prices on beer, which means that we are further excluded from what ought to be a natural market for us. So, it’s a way of trying to get closer.”

Another motivation was entering new areas: “We’ve done sort of collaborative partnership ... we go to spaces that they’d rather not go to”.

An important pre-condition is the element of trust mentioned by different stakeholders during discussions in the focus group “I think the premise of collaboration is trust; there has to be an element of trust.”

Furthermore, knowing the partner was a stated pre-condition for collaboration. One of the participants stated that he shared his excel based accounting system with another partner because he knows him quite well: “One of the ones I work with..., so I know him quite
well and so I'm going to basically do a little cut-down version of mine that he can pick up, because he’s like... “I haven’t got a clue about accounting, I haven’t got a clue about Excel, so I’ll use that.”

Having surplus capacity was also mentioned as a pre-condition for collaboration “...running a lorry is expensive, running a lorry half-full is even ... you know, astronomical really, so where there’s surplus capacity, definitely [collaboration is helpful].”

Discussion and conclusion
Knowledge on the specificities of micro firms is still partial and fragmented (Grananta et al., 2018). Among all micro industries, craft brewing is still in its emerging stage (Alonso et al., 2018). This research aims to shed light on collaboration in the microbrewery industry as a strategy whereby these micro and small firms can overcome their limitations in terms of resources. One of the first steps is to investigate motivations and preconditions which are needed for collaboration. We began this research with a complete literature review on motivations and preconditions in the agri-food industry, as there was very limited research available on collaboration in micro and small industries, specifically the drinks industry. Because of this lack of academic research to respond to the research questions, we conducted extensive secondary data analysis in order to be able to fully respond to the two research questions. Furthermore, the focus group, with different stakeholders, could intensify our conclusion regarding motivations and preconditions for collaboration in micro and small businesses, specifically in the microbrewery industry.

We conclude from our secondary data analysis and focus group that microbreweries can collaborate with operational, organisational, marketing, knowledge transfer, and social motivations. These motivations are presented in Table 3.

</tbody>
</table>

While the specific hierarchical categorisation does not exist in literature, some of the items related to the main categories gained from the secondary data analysis and focus group are in line with what we have found in the literature. The main themes gained from
our focus group and secondary data analysis, “shared communal ethos of collaboration”, is in line with literature review (Drakopoulou Dodd et al., 2018). Furthermore, our finding of “knowledge transfer” theme is in line with the literature (Alonso and Bressan, 2017). “Combining strengths to achieve competitive advantage” was the most important motivation for collaboration in the literature review. This means that improving different performance outcomes, such as quality (Drakopoulou Dodd et al., 2018), sale (Granata et al., 2017) and technical performances (Hanna and Walsh, 2008), are more highlighted in the literature. However, our findings show that marketing issues, specifically brand issues, are the important motivation in both industry analysis and our focus group attendees’ viewpoints.

We conclude from our secondary data analysis and our focus group that organisational, strategic and resource-related pre-conditions are needed for collaboration. These pre-conditions are presented in Table 4.

Table 4- Pre-conditions for collaboration from the focus group and secondary data analysis

<table>

</tbody>
</table>

While the specific hierarchical categorisation for pre-conditions of collaboration does not exist in literature, some items related to the main categories gained from the secondary data analysis and focus group are in line with our literature findings.

Above all, “trust” is the most important pre-condition stated in almost all academic papers, including Alonso and Bressan (2017), Granata et al. (2017), Hanna and Walsh (2008), Moutaoukil et al. (2012) and Dania et al. (2016), highlighted by our attendees in the focus group, and our secondary data analysis. Furthermore, our findings in strategic pre-conditions, such as “similar mission”, are in line with literature considering common aims (Hanna and Walsh, 2008; Fearne et al., 2001) as important pre-conditions for collaboration. In addition, “surplus capacity” was highlighted as a resource-related pre-condition in our focus group, which is in line with Granata et al. (2017) stating personal resources as an important pre-condition for collaboration.

In conclusion, this study sheds light on collaboration in micro and small enterprises; specifically in the drink sector; thereby, contributing to the operations and supply chain management research.

In terms of managerial contribution, this research will raise awareness amongst managing directors of drinks companies on how collaboration in their operations and supply chains can improve the performance outcome of their company as well as the sector. As the first step, understanding of motivations and preconditions can prepare owners and managers in breweries to establish effective collaboration.

**Limitations and avenue for future research**

One of the obvious limitations is the issue of generalisability. As the data is taken from a sample of microbreweries in Wales, there is restricted generalisability to the wider food and drink sector across the UK. However, this research can be seen as a starting point to
investigate collaboration in micro and small businesses with specific focus on the drink sector as an important sector within the UK economy. As most research has concentrated on SMEs, there exists an obvious gap in terms of micro and small businesses.

Based on this scoping research, future research can investigate how microbreweries, and the drink sector in general, can collaborate in order to improve their performance outcomes. This also calls for designing research in both a qualitative and a quantitative way and gathering data both nationally and internationally for a more in-depth research into collaboration in micro and small businesses, specifically in the drink sector.

Abstract

This paper analyze the impact of team rewards (TR) on NPD success. In particular, we analyzed whether the use of TR affect the success of NPD team projects not only by accomplishing for their work as a team and the performance their perform but also considering the enhancement of the involvement of internal functions and external actors (suppliers and customers) in these projects. Using SEM we observed that TR do not produce a direct effect, but do it through the involvement of SC members in the early stages of NPD. Without involvement, it is not possible to obtain desired NPD success.

Keywords: New product development; Team Reward; Involvement; Supply Chain

Introduction

New product Development (NPD) is a critical concern for manufacturers in an increased global competition. Literature on NPD success has mainly been positioned in the domain of supply chain management (SCM) (Mazzola, Bruccoleri and Perrone; 2015). The most cited references in the field advocate for the involvement of suppliers and customers in NPD process (Flynn et al. 2010) and also to look for complementarities involving internal functions in a collaborative way to achieve NPD success (Homburg and Kuehnl, 2014).
Involving heterogeneous actors in NPD allows firms to enhance the value of knowledge-based resources (Cabrera and Cabrera, 2005). In this sense, evidences has shown that combination of broad and varied information and points of view is positively related to new product performance in terms of cost, time to market and quality (Mishra and Shah, 2009) and also with firm innovation capabilities, and firm performance (Petersen, Handfield and Ragtz, 2005). Nevertheless, some researchers also highlights the costs and challenges of collaborative competences in NPD among SC members (Fawcett et al, 2015), referring to what is known as the “dark side” of collaborative NPD process (Villena, Revilla and Choi, 2011).

As a result, the debate is open, and more research is needed to improve the understanding on how to involve a number of SC agents in the process of developing new products (bringing them closer and involving them), and how to design mechanisms to promote this process (Yang and Wagner, 2017). More specifically, researchers in the field have made a call to analyze organizational issues that promote SC relationship in order to overcome dark-side effects of involving external and internal sources of information and knowledge to achieve NPD success.

With this framework, the aim of this paper is to analyze the impact of team rewards (TR) on NPD success. In this context, an interesting question is whether the use of TR affect the success of NPD team projects not only by accomplishing for their work as a team and the performance their perform but also considering the enhancement of the involvement of internal functions and external actors (suppliers and customers) in these projects.

Overall this study makes three important contributions to the extant literature. First, this study advance in the study of TR on NPD success considering TR as a tool to work in-group involving different and distant actors in the process of NPD. This approach is aligned with the new trends in the field of R & D that recognizes the need for openness and integration of different sources of information and knowledge, providing a clear vision about the importance of adopting integrative strategies as the best way to achieve innovation performance (Crisquuolo et al., 2017). Second, the analysis consider different dimensions of NPD success distinguishing between time to market, technical issues and cost of manufacturing, usually considered in an aggregated way. Third, empirical evidence use an ample database including a more than three hundred of manufacturing
companies from fourteen countries, including developed and developing countries, and from three industry sectors, thus giving more relevance to the results found.

Theoretical background.

**Team Reward in New product Development Projects**

A reward system entails the use of the pay system to guide, control and affect the behaviors and efforts of individuals and sub-units toward the achievement of organization’s strategic goals (Gomez-Mejia and Balking, 1992). Total reward is defined as the combination of both the financial and non-financial rewards made to the employees and usually includes basic salary, variable pay, pension benefits, death-in-service benefits, long-term disability benefits, private medical insurance, vacation entitlement, and others (see Jiang et al., 2009).

The group-based incentive plans, such as profit sharing, gainsharing, and team-based reward, may provide an effective means of linking pay to performance in work settings where high-powered individual incentive plans are difficult to implement. Sarin and Mahajan (2001), based on the principles of the organizational control literature proposed to distinguish TR in process-based rewards and outcome-based rewards. Process-based rewards are tied to the accomplishments of procedures, behaviors and other means of achieving desired outcomes, while outcome-based rewards are defined as the degree to which team rewards are tied to the bottom-line profitability of the project. Process controls are exercised during the execution of a task while output controls are exercised after a task is completed. Researchers highlight the both types of rewards may have positive effects on team performance but depends on contingencies of projects.

**Team Rewards and NPD success**

Empirical evidences exploring the relationship between TR and NPD is scant and varied in terms of the measures of TR and performance measures used and mixed in terms of findings. Bonner et al. (2002) considered TR in three ways: financial rewards, internal promotion and recognitions for successful performance. They measure project performance in terms of adherence to budgets and costs, meeting schedule and ask managers to rate for product performance and team functioning performance. They find out no statistical significant relationship between TR and project performance, but all measures were treated in an aggregated way as additive indexes. Chang et al. (2007)
analyzed the effects of joint rewards on NPD performance. The authors distinguished five types of joint reward systems (reward allocation, process-based reward, outcome-based rewards, risk-free of participants, and over-reward incentives) as antecedents of NPD performance. In this case, performance refers to innovation performance in terms of sales, profits and market share, and comparing this measure with regard to competitors, and finally performance in term of the overall profitability. They find out that the overall joint reward system was positive and significantly related to NPD performance. However, only two types of overall reward systems were significant: reward allocation and risk-free to participants, but no significant effect was observed for process-based reward or outcome based rewards.

More recently, Carbonell and Rodriguez-Escudero (2016) analyzed the impact of both process control and process-based rewards (based on procedures and activities) on new product performance and job satisfaction. They find out mixed results since find out a negative association between process-based rewards and quality of new products, a positive association of rewards and the adherence to project schedule and not significant with project budget. The authors also looks for interaction between process control and process-based rewards, but results were not significant to explain project performance, but positive interaction between both tools to explain the quality of new products.

In this paper, we focus on “internal” NPD success measures, considering technical performance, time to market and manufacturing cost (Mishra and Shah, 2009). The adoption of TR is expected to be positively associated with NPD success. Rewarding all team members according with achieving project goals reinforce the perception of workplace justice, avoiding opportunistic behaviors and encouraging cross functional and interfirm collaboration. As a result, the application of TR it is expected that affect team project promoting to work hard to achieve NPD goals.

According with this arguments, we propose the following hypotheses:

\[ H_{1a}: \text{Team rewards positively impacts on technical performance.} \]
\[ H_{1b}: \text{Team rewards positively impacts on time to market.} \]
\[ H_{1c}: \text{Team rewards positively impacts on manufacturing cost.} \]

Team Rewards and the involvement of SC members on NPD
In this section we analyze the effects of adopting TR on the involvement of SC members in early stages of NPD. In particular, we consider bundles of practices in hand of the NPD team, both internal and external, aimed to involve SC members in providing valuable information and ensuring their effective participation in the decision-making process in the early stages of NPD. External involvement (EI) include practices fostering the coordination of decision making and the implication of suppliers and customers in providing valuable information. Internal involvement (II) of manufacturing function encompasses practices concerned with matching design requirements and process capabilities.

The resource based view-RBV (Barney, 1991) suggest that integrating heterogeneous interdependence and complementary source of knowledge is beneficial for all partners involved in NPD processes (Zhao et al., 2011). Related studies have suggested the benefits of adopting bundles of practices aimed to involve complementary sources of information from external and internal SC actors. However, involving internal and external SC members in NPD is a paramount, mainly due to knowledge sharing risk and the hidden cost of coordinate and support relationships with SC actors (Um, Ki-Hyun, and Sang-Man Kim, 2018), which sometimes generates socio-structural resistance by the different members implicated (Fawcett et al., 2015).

In addition, the social capital theory highlight the value of capital as those resources inherent in social relations which facilitate collective action. Related literature stated the positive effects of social capital among the supply chain, promoting cooperative behavior between members, sharing vision, trusting relations, and social ties and reducing the likelihood of conflicts. Nevertheless, some scholars find out the risks and potential negative consequences associated with social capital, which have been recently named as the dark side of social capital (Villena, Revilla and Choi (2011).

From a different perspective, the expectancy theoryconsiders the effort of employees as a function of the perceived value of a reward and the perceived effort-reward probability. As a result, NPD team members will strive more in the search of collaboration of the SC agents if the companies have established a reward system based on the achievement of the objectives of the project especially if these objectives are achievable.

According with this arguments, we propose the following hypothesis:

\[ H_2: \text{Team rewards positively impacts on involvement practices of SC agents} \]

**Involvement of SC members and NPD success.**
Evidences analyzing the process of NPD suggest the benefits of adopting involvement practices with all SC actors in early stages of NPD. Researchers highlight the absorptive capacity of team members, defined as the ability of companies to effectively acquire and exploit both external and internal knowledge to achieve innovation success, as one of the main reasons behind the success in NPD in manufacturing firms (Laursen and Salter, 2006). While firms learn from their external partners, they need to have the internal absorptive capacity to enhance their innovation performance. Hence, Daghfous (2004) highlight the importance of internal mechanisms to learn, to disseminate, and to exploit knowledge to enhance NPD performance.

Thus, practices aimed to involve SC actors are determinant to resolve manufacturing issues in early stages in order to achieve easy manufacturing and improving manufacturability. Johnson and Filippini (2009) comparing collaborative NPD practices such as CI, SI and II across the world on performance, stated that the use of internal involvement is more emphasized than external integration and this was translated into better product performance. In the same way, Ragatz et al. (1997) suggest that the effective integration of suppliers into NPD processes can yield benefits through reduced time to market an improved access to the application of technology). Similarly, involving customers in early stages allows NPD team to know customer assessments in early stages.

According with these arguments, we propose the following hypotheses:

\[ H_{3a}: \text{Involvement positively impacts on technical performance.} \]
\[ H_{3b}: \text{Involvement positively impacts on time to market.} \]
\[ H_{3c}: \text{Involvement positively impacts on manufacturing cost.} \]

Methodology
Sample

The data used for empirical analysis was collected from the fourth round of the High Performance Manufacturing Project (HPMP), a research project conducted by a team of researchers working in different universities all over the world. The survey was conducted during 2013-2015 in manufacturing plants operating in three industry sectors: machinery, electronics and automotive components (SIC codes: 35, 36 and 37, respectively) and located in different countries: China, Germany, Sweden, Japan, Korea, Spain, Italy, Israel, Brazil, Finland, Austria, Taiwan, United Kingdom and Vietnam). The final data set consists of 309 responses. In table 1 we can observe the profile of the sample for the different countries and for the three industries.

Measures
We used 16 items to measure supplier involvement, customer involvement and manufacturing involvement in the NPD process. The items included in the scales have been used by other researchers who have addressed the issue (Mishra and Shah, 2009). The annex shows all these items, to which respondents indicated their agreement/disagreement on a five-point Likert-type scale (from 1 = strongly disagree to 5 = strongly agree). The survey included also other questions related to the country where the companies are located and its activity sector.

We model involvement as a reflective second order construct to capture complementarities arising from the three first order constructs (suppliers, customer and manufacturing). This second order, involvement construct accounts for multi-lateral interactions and covariances among the first order constructs. The use of second order construct to represent complementarities among first order constructs has been well documented in existing studies (Shah and Ward, 2007).

NPD success is assessed using three commonly used items reflecting time-to-market, technical performance and unit manufacturing cost. NPD project managers were asked to rate the success of the product development project relative to the set goals and objectives on the three measures on a 5-point Likert-type scale (“How successful were the new products in terms of reaching their goals?”).

In order to check for common method variance we used Harmann’s single factor test (Podsakoff & Organ, 1986). This test was conducting using principal component analysis and loading all 20 items (variables of interest) on one factor. The 33.8 % variance explained by a single factor shows that the common method bias is not a major concern in this study (less than 50% cut-off point).

The methodology was developed in two stages. First, the validation of the assessment scale for involvement was settled. The second stage was the assessment of the hypothesized structural relationships of our model. The analysis was conducted using Structural Equation Modeling (SEM) techniques, also with EQS 3.0 software. The seminal works of Baron and Kenny (1986) and Zhao et al. (2010) have inspired the analysis of the mediation role of involvement. Results are summarized in Table 1.

*Table 1. Decomposition of the parameters of the research model.*

<table>
<thead>
<tr>
<th></th>

</tr>
</tbody>
</table>
Involvement □
Technical performance 0.574 (4.19) - 0.574 (4.19) (H2a Accepted)

Involvement □
Time to market 0.494 (3.73) - 0.494 (3.37) (H2b Accepted)

Involvement □
Manufacturing cost 0.453 (3.18) - 0.453 (3.18) (H2c Accepted)

Team Rewards □
Technical performance 0.202 (1.175) 0.352 (2.48) -0.150 (-1.810) (H3a Refused)

Team Rewards □
Time to market 0.279 (1.622) 0.303 (2.37) -0.024 (-0.267) (H3b Refused)

Team Rewards □
Manufacturing cost 0.284 (1.512) 0.278 (2.15) 0.006 (0.064) (H3c Refused)

Standardized parameter (t-value).

Findings confirm the first hypothesis that team rewards have a positive impact on involvement; the overall involvement construct is directly influenced by team rewards and the standardised coefficient is 0.614. First hypothesis is then confirmed. In its turn, involvement impact on positive and significantly on the three NPD success items considered, hence the hypotheses H2a, H2b and H2c are also confirmed. One the other hand, neither of the last three hypotheses (H3a, H3b and H3c) can be confirmed.

Conclusions
New product development (NPD) is critical for firm competitive (Brown and Eisenhardt 1995). Studies analyzing NPD success factors have neglected the study of how to involve SC members in early stages of NPD process through the use of motivational practices. The estimations results shed novel evidence. The main finding shows that TR positively affect NPD success in terms of cost, quality and TTM, but, surprisingly, this effect are throughout the involvement of SC members. For NPD projects, linking rewards to the output produced by the team (outcome-based rewards) has a positive influence on SC agents involvement and finally on the internal dimensions on NPD success. Regardless of the type of reward implemented, if team rewards are used to motivate the members of the NPD team, it will be easier to achieve the objectives regarding quality, unit manufacturing cost of products launched and, also, the time to market of new products. In sum, all the impacts of team rewards on NPD succeed are achieved through the mediation of involvement, which highlights the paramount importance of this construct (involvement). On other words, no effect of TR is achieved without the mediation of involvement.

Abstract

New formats of retail stores continue to emerge, in order to better meet the needs of consumers. In Brazil, the Cash & Carry format occupied a leading position due to the high growth in number of stores and billing volume. This research aimed to characterize the value chain of the Cash & Carry format in Brazil, in comparison to the traditional physical stores in search of the justification for this phenomenon. Through a documentary research, the ten largest retail chains of the country and their brands of physical stores and wholesale stores were analysed, in order to construct the presented models.

Keywords: Supply Chain Management; Cash & Carry; Value Chain

Introduction

Retail organizations are diverse and new forms continue to emerge so that consumers can now buy goods and services in a wide variety of stores (Da Conceição, 2018). The idea of cash & carry, better known as "Cash & Carry" in Brazil, came into being in Europe and was more developed in the United States from 1980 onwards. The idea came from the following understanding: having a store capable of bringing the desired product to small retailers or objective consumers, without offering any services but with a more robust mix of products (Napoleão, 2017).

According to Abad (2016) and Napoleão (2017), Brazilian families has preferred the "Cash & Carry" to the supermarket and hypermarket. This research aims to characterize the chain of values and the format Cash & Carry, demonstrating the main advantages obtained by this business model in comparison to the traditional physical retail that justify its recent rise and its impacts in the retail supply chain in Brazil. The contribution of the results obtained here derives from the example of this operation in an emerging country.
Literature Review

Chain of Values For an examination of the activities performed and the way they interact, for a broad approach and identification of the main process flows of the company, the chain of values can be introduced as a systematic tool for such an evaluation.

According to Porter (1990: 31): The value chain disaggregates a company into its strategically important activities so that it can understand cost behavior and existing and potential sources of differentiation. A company gains competitive advantage by performing these strategically important activities at a cheaper or better way than the competition.

The performance of the value chain represents a process of differentiation between companies and their processes and the establishment of competitive advantages. Figure 1 illustrates the value chain model proposed by Porter (1990).

![Value Chain Model, Porter (1990)]

Primary activities are those involved in the physical creation of the product and its sale and transfer to the buyer, as well as after-sales service. In any company, primary activities can be divided into five generic categories: (1) internal logistics: the activities associated with the receipt, storage and distribution of inputs in the product, such as material handling, warehousing, inventory control, fleet scheduling, vehicles and return to suppliers; (2) operations: the activities associated with the transformation of the inputs into the final product, such as working with machines, packaging, assembly, equipment maintenance, testing, printing and production operations; (3) external logistics: the activities associated with the collection, storage and physical distribution of the product to buyers, such as storage of finished products, material handling, delivery vehicle operations, order processing and programming; (4) marketing and sales: these are the activities associated with providing a means by which buyers can buy the product and induce them to do so, such as advertising, promotion, sales force, quotation, channel selection, channel relationships and pricing; and (5) technical assistance: these are activities associated with the provision of service to enhance or maintain the value of the product, such as installation, repair, training, parts supply and product adjustment.

Support activities can be divided into four generic categories. Like the primary activities, each category of support activities can be divided into a series of activities of
value that are distinct and specific to a particular company. The generic categories of support activities are:

(1) acquisition: refers to the function of purchasing inputs used in the company's value chain, not to the purchased inputs themselves. Inputs purchased include raw materials, supplies and other consumer items, as well as assets such as machinery, laboratory equipment, office equipment and buildings. Although these acquired inputs are commonly associated with primary activities, they are present in each value activity, including supporting activities;

(2) technology development: it consists of several activities that can be broadly grouped together in efforts to perfect the product and process. The development of technology related to the product and its characteristics can support the entire production chain;

(3) human resource management: consists of activities involved in the recruitment, hiring, training, development and compensation of all types of personnel. Human resource management affects competitive advantage in any company, through its role in determining qualifications and the cost of hiring and training; and

(4) company infrastructure: consists of a number of activities, including general management, planning, finance, accounting, legal, government affairs and quality management. Infrastructure, unlike other support activities, generally supports the entire production chain and not just individual activities.

Porter (1990) relates an advantage to value creation, that is, the competitive advantage arises from the value that a company can create for its buyers and that exceeds the cost of manufacturing the company and provides the difference between a firm's offer and that of others.

From the evolution of Supply Chain to Cash & Carry

When looking to analyse the dynamics and structure of the chain of supermarkets, it is necessary, at first, to understand some basic concepts that guide the actions of the products and services that are in networks. The need to understand the performance scenario is fundamental for assertive and optimized decision making throughout the chain.

By understanding the organizations and the ways that these are instituted, it becomes perceptible to understand the dynamics and structure of the business and therefore outline the strategies needed to gain competitiveness. The understanding of economic reality requires interpretations that are based on a systemic environment, which involves not only the parts, but the whole and their interrelations (Capra & Jakobsen, 2017).

Antonialli et al. (2016) infer that it is emphasized as the importance of studies on productive chains requires evaluations of both economic and technical operations throughout the stages of production and consumption of goods, ranging from (organizational, institutional, consumer) environments that permeate the production chain, essential for the construction of the competitive advantage of the chain (Antonialli et al, 2016).

Although dynamics is different from that of the Supermarket Supply Chain, these studies converge to the same point, being applied to all sectors, which are the structures of their respective chains (Zylbersztajn, 2005). By using the concepts of chains, production systems and coordinated subsystems, the expansion of volumes of empirical research volumes, both national and international, was evident from the 1980s to the present day. Whether in agro-industrial systems or in any other organization, they all employ the concept of continuous production steps, from the raw material to the finished product, in order to guide their analysis (Andrade, 2015).
The supply chain, according to the Supply Chain Council (2002), infers that "the supply chain covers all efforts involved in the production and delivery of an end product from the vendor supplier to the customer's customer" (Machline, 2011). Thus, typical transactions and the influence of institutional and organizational environments (which are defined as determinants of competitiveness) are common to all chains, regardless of the theoretical conceptualization (Zylbersztajn, 2000).

This relationship between supplier, producer and client creates and models the organizational and institutional environment, from which it is intrinsically linked to the cultural environment and the consumer environment, as shown in figure 1. Thus, the Supply Chain can be understood as the "main cell" in all production dynamics of products or services goods, since each chain link is affected, directly or indirectly, by any actions that affect one of its agents.

When we turn the perspective to retailing in the dynamism of information and interpersonal relations, new approaches emerge not only in the academic environment, but also in the commercial relations and the Cash & Carry is one of those results coming from the modifications in the organizational and institutional environments, as mentioned above.

Cash & Carry
According to Oliveira, Lima-Filho and Watanabe (2013), it is understood as Cash & Carry being the format of store known in Brazil for being a mixed operation of wholesale and retail, of which its actions are intended to serve preferentially, purchase (Silva, 2017).

In addition, it is important to note that the quality of the food service is not limited to the food service sector. According to Broud (2016) and Levy (2000), Cash & Carry is understood to be: The "Cash & Carry" is a phenomenon nowadays, mainly in Brazil, this model joins features of wholesale retail and aims to provide products with lower prices to the client to offer good services. This model does not have a refined structure, the design is low cost and its focus is on "pay and carry" (Broud, 2016; Levy, 2000).

Napoleão (2017) advocates that over the years, the development of this type of business has brought from new purchasing systems to adoption of new practices, such as the agglomeration of additional services added to the physical structure of the store, and in this way, it is possible offer not only cheaper products, but also, better quality services whose situation ends up adding more value to the enterprise.

Methodology
This work, in terms of its concept, is characterized as qualitative, through documentary analysis as scientific articles, as well as reports of specialized journals in the field, descriptive-exploratory. This infers that this type of research seeks to understand a reality that has not yet been studied, in which one can describe how the phenomena related to it occur (Gomes, 2006; Reis, 2018).

Pimentel (2001), shows us that studies based on documents as primordial material, be they bibliographic reviews or historiographical research, extract from them all the analysis, organize them and interpret them according to the objectives of the proposed research, giving them the specific treatment in order to corroborate with the object of study (Pimentel, 2001). Garcia Gutierrez (1984) apud Junior, Medeiros & Augusta (2017), reflects on documentary analysis as "all recognition and study that is made of a document, requiring an identification of the physical characteristics, which would be the form, and the intellectuals, the content". These elements corroborate the establishment of the best method to organize all the "information" expressed in the document (JUNIOR, Medeiros & Augusta, 2017).
It was applied in this work the analysis of documents such as scientific articles, books and reports in magazines or nationally recognized electronic sites that dealt with the theme of evolution and modification in the structures and dynamics of the retail chain and seek to understand what the current panorama of the transition traditional market of the hyper and supermarkets for the recent cards.

As a study delimitation, we opted to work on the analysis with the top 10 retail chains in Brazil's supermarket or hypermarket sector, according to the Brazilian Retail and Consumer Society (Sbvc, 2017). From the list obtained, company flags were tabulated in a spreadsheet and classified according to their size and sales format (small retail, super / hypermarkets, cash backs, etc.). In order to obtain a broad analysis specifically of the cash cards, the analysis of the discount cards that make up the Brazilian Association of Wholesale Carriers (Abaas, 2017) was included in the analysis. Below, the table 1 presents the flags chosen for the analysis.

From the choice of the sample, the electronic websites and news related to the respective flags were searched and the data obtained were classified in a spreadsheet, so that the specific characteristics of each company were allocated according to each activity of the value chain. Then, the data collected and classified were submitted to content analysis according to Bardin (1977), and the content analysis categorization was based on Porter's value chain proposal (1990).

Findings and Discussion
In analyzing the Brazilian retail supply chain over the last decades, it is notorious to realize that there has been a restructuring between distribution channels both among internal and external agents and, therefore, shaping the structure and dynamics of the latter. With this, several consumers have migrated their shopping environment, but mostly inserted in the super / hyper format for the retail and small retail formats.

This fact can be evidenced when it is observed that the largest retail groups operating in Brazil started to enter this market more intensively over the years, especially in the
infrastructure and locality models of their stores. To better elucidate this phenomenon, the section will be presented in three stages. The first presents the comparisons of traditional retail value chains versus the retail value chain. Subsequently, the traditional structure of the Brazilian retail chain is presented, followed by the characterization of the chain after the rise.

The retail versus retail chain of value - Traditional structure of the retail chain in Brazil

The Cash & Carry in Brazil, although recent, presents a highly dynamic and increasingly comprehensive structure. The distribution channels between the suppliers of inputs, products or services to the final customer, generate impacts at all levels of the chain. The more complex and long the relationships between the agents that feed the chain, the more financial and managerial resources will be needed, and this is the dynamics of the traditional retail model in Brazil, where the acquisition, inventory, distribution and sale management of products of the supermarkets, presents in its great majority, like an extensive and pushed system. Figure 1 summarizes the distribution channels of the products in the traditional retail markets in Brazil.

Retail Chain - Previous View

In this model, the product manufacturer presents itself not only as the one who produces a particular product, but also becomes a stockist (in this case, stockist would mean the manufacturer as being the maintainer of the products in its own physical structure for later distribution) and sometimes acts as a distributor to the wholesale or traditional retailer. The Wholesale in turn supplies the small retailers that make the products available to customers, replacing them from time to time. The same happens with traditional retail, where the products are stored at the disposal of the final customer. In this model, the interfaces between the links in the supply chain show an increase in the final cost of the product, since each agent must receive a value for transportation, inventory and / or resale of the products to final customers.

Losses, low optimization of inventory management and costs, is recurrent in this type of marketing. Sometimes this commonly used structure has certain barriers that raise costs throughout the chain, as explained above. Linked to this favor, chain coordination
becomes fragile because it has several links between agents, which, due to the complexity of coordination conditioned to the various factors, can generate countless losses due to the organizational environment that this chain is inserted.

In addition, the operational costs of the distribution operations mean that the products that reach the end of the chain have an additional level of intermediation and consequently an added value that ultimately increases the final price of the product to the final consumer.

*Current structure of the retail chain in Brazil*

At Cash & Carry sector, dynamics and coordination of the chain become leaner, with the optimization of the distribution and storage of products. In the meantime, it is worth stressing with the performance of the chain is more dynamic, both the product outputs and the search for these products by the end customer. This coordination of the chain reinforces the considerations of the Value Chain proposed by Porter (1990) and demonstrate the impacts that the operations both internal and external, modify the organizational and institutional environment of the retail chain as a whole.

Thus, stores denominated Cash & Carry become the link between the manufacturer and final consumer, presenting not only as a retail store, but also as a wholesale center and as a Distribution Center (CD - It would be inferred that it is a warehouse whose purpose is to manage the inventory of goods in the fixed distribution (Abralog, 2016; Do Nascimento et al., 2018).). This changes the whole structure of internal logistics, operations and supplier, vendor and consumer relations. In this sense, Cash & Carry is a protagonist in relation to the position in the supply chain, since it occupies in a concentrated and strategic way, a new location in the structure of the chain. Figure 2 demonstrates the Chain Supply Chain and its structural arrangement differentiated from the traditional chain.

**Retail Chain - Current View**

![Retail Chain - Current View](image)

*Figure 1 - Current structure of the retail chain in Brazil – By Authors*

Notorious is the concentration of the agents under a single player that are nets of Cash & Carry. These, in turn, have the following characteristics: 1) attacked; 2) Retail and 3)
Distribution Center for himself as well as the small and medium retailers of the surrounding region. This explains the growth of this type of commercialization in recent years in Brazil, since in addition to reducing the costs of maintenance, personnel and charges with CD’s, the cash cards provide a greater mix of products in a single structure and increase the capillarity of distribution of the products.

In addition to providing support to small retailers, the final consumer is also impacted by the quantity / price ratio, where more quantity, lower price than the cash cards provide and corroborates for the maintenance of small retail stores with quick purchases in small quantities and (which does not, on certain occasions, also exempt the consumer from purchasing small quantities in the card in certain situations or preferential).

This new arrangement solidifies the trend of the expansion of the Cash & Carry in Brazil, because it meets the assumptions of the Brazilian consumer (be it the final or internal consumer of the chain), which is the question of price. As the prices are better in the wholesale account, one can then refute, at first, that the card is a fad, but a new business model that emerges to consolidate over time.

**Delimitations and Suggestions**

This research was limited to a brief illustrative analysis of the structure and dynamics of the supply chain in Brazil, since the incipient studies are about this topic in depth and, thus, propose new perspectives and considerations about the Cash & Carry Brazilian. However, the limitation was only limited to some academic articles available and also focused on specialized magazines in Brazilian wholesale and retail.

As a suggestion for future research, it is the search for correlating international and national articles (if there is one) to understand the coordination of this chain and the economic, financial and social impacts that the attack provides to the region in which it is installed, such as employ ability, cost and inventory, logistic cost, among other determinants. Moreover, the authors of this work sought to demonstrate the Cash & Carry chain as a whole in its physical structure, but without neglecting or omitting, as shown in figures 2 and 3, the profound changes that online retailing causes and will cause in retail as a everything.

Thus, it is suggested that further studies are about what impacts online retailing can impact on the retail strategies, as well as, to understand the dynamics of Online Retail Supply Chain in the interfaces between supplier and buyer, restructuring the organizational and institutional environment of retail trade.

**Conclusions**

Cash & Carry, although widespread around the world for more than two decades, presents substantial growth in Brazil only from 2012 to the present day. However, the Brazilian retail sector is not in line with this expansion, since only large groups started to emerge for this new modality that is Cash & Carry. The perception of traditional retailers needs to be reviewed and, above all, studied and disseminated in their planning and management strategies so that there is no disappearance of traditional retails or even the bankruptcy of several of these, due to a strong and massive competition resulting from credit cards.

Since the Brazilian consumer is more closely linked to the prices of the products, the Cash & Carrys appear as an innovative and comprehensive business model, providing a more balanced inventory management between a push-pull management, since the latter occurs more strongly in the traditional retail. This leads to a reduction in the costs and concentration of the products in the own cards that not only replenish their stores in their gondolas, but also have their own stock at the same time, as well as serving as a CD for small retailers, that is, an anchor for other people in the chain.
This all leads to a reduction in costs and optimization of transactions across all interfaces, which today, is a matter of survival of most businesses. Thus, the exponential growth of Brazilian cash loans is more like a market trend than just fad or punctual actions of large corporations. The dynamics of the current relations are getting faster and faster and adapting to the new trends is and will be, in most cases, the threshold between the success or failure of the cash advance in Brazil.

Abstract

Nowadays, the rapid growth of e-commerce supply chains has created substantial environmental problems, such as excessive energy consumption of logistics, packaging waste etc. By means of a case study of an e-commerce supply chain for a food SME, this research focuses on the role of internal stakeholders and how the management mechanisms work from a vertical perspective. The study indicates that the awareness, motivation and capability of GSCM implementation diminish down the hierarchical ladder, while, the advantage of the e-commerce supply chain in GSCM implement is obvious.

Keywords: Green supply chain management, Management mechanism, E-commerce supply chain

Introduction

Nowadays, the rapid growth of e-commerce has created substantial environmental problems, such as excessive energy consumption of logistics, packaging overuse and waste in general (Mangiaracina et al., 2015). Companies have already adopted green supply chain management (GSCM) as a creative marketing tool to contribute to the awareness of social responsibility and the improvement of environmental quality. However, in countries such as China, the implementation of GSCM is still in its infant stage. To improve the environmental behaviour of companies, the Chinese government proposed to launch a nationwide policy for collaboration in e-commerce and reverse logistics. Up till now, however, the academic insights and practical implications and regulations to guide companies in the development towards greener e-commerce supply chains are lacking and urgently needed (Wang et al., 2018, Maditati et al., 2018).

Scattered research on environmental behaviour of companies shows that (a) industries were not equally environmentally sensitive (Wilmshurst and Frost, 2000), (b) different manufacturing industries reflected different levels of GSCM implementation and outcomes, and (c) the specific nature of each industry has to be taken into consideration (Zhu et al., 2017). Research findings show that the electrical/electronic
industry has relatively higher levels of GSCM implementation and achieves better performance outcomes than others such as power generating, chemical/petroleum, and automobile manufacturer types, because of more experience (electronic industry) and regulation pressure (power generating industry). However, although at present insights in GSCM research are to a certain extent available for manufacturing, service, construction, automobile, and electrical/electronic industries (Mitra and Datta, 2013, Lin et al., 2011, Balasubramanian and Shukla, 2017), to our knowledge, no study has been undertaken from the perspective of e-commerce (Somsuk and Laosirihongthong, 2017, Vijayvargy et al., 2017).

With the development of e-commerce on both B2B and B2C trading, the traditional supply chain service changed. Because of information transparency, the gathering and distribution of information has become more important and is gradually replacing the physical logistics. Moreover, supply chains are facing the challenge of effectiveness when the trading process is shortened and trading cost decreased sharply. Consequently, companies in various industries organise their supply chain management activities in different ways. The main question is whether the disparities between e-commerce and traditional supply chains will bring companies new opportunities or rather obstacles when implementing environmental activities and developing environmental behaviour. Why certain organisational and network structures are chosen and why certain initiatives are undertaken in e-commerce is often unclear (Asrawi et al., 2017).

GSCM can help to translate a company's environmental sustainability strategy into value-creating activities at the operational level (Longoni et al., 2014). On this premise, it becomes imperative for managers to understand the factors that drive the adoption of GSCM. Among the internal and external drivers of GSCM, managerial characteristic constraints contribute towards an organization's inner motivation and managerial commitment toward environmental sustainability (Dubey et al., 2015). Management mechanisms are illustrative for the intra-organizational sentiment to the adoption of GSCM. In this perspective, research provides evidence to suggest that employees' empowerment, involvement and incentive programs (such as a reward and appraisal systems) are strongly associated with successful adoption and implementation of GSCM practices (Hanna et al., 2000, Jabbour and de Sousa Jabbour, 2016). GSCM initiatives require that the vision and staff members from all hierarchical ranks are aligned. However, few studies discussed the impact of management mechanisms from a hierarchical perspective on GSCM practices (Agi, 2017, Dubey et al., 2015).

The lack of specific understanding, of the impact of management mechanisms on GSCM in e-commerce supply chain formed the motivation of this research, which aims to develop and validate a multi-dimensional GSCM framework for e-commerce supply chains. This study covers: a) identify the key supply chain practices and the management mechanism (in this paper, “management mechanism” refers to the intra-organizational management of stakeholders within a company), b) the practices at a specific e-commerce supply chain company, and c) discuss the potential capability of GSCM practices.

The specific objectives of this study on e-commerce supply chains are as follows: a) to describe the management mechanism; b) to identify the obstacles and possibilities for environmental behaviour adoption.

The remainder of the paper is structured as follows:

In Section 2, this study will provide a basic conceptual framework for the holistic investigation. The methodology of this study will be illustrated in Section 3, including a case study approach, data source and analysis, and sample selection. Next, findings and discussion will be explored in Section 4 and Section 5, respectively. Finally, conclusions and implications will be drawn in section 6.
Conceptual Development
To illustrate the management mechanism, this study’s focus is on the vertical perspective. In this respect, the difference between employees, middle management and top management is taken as a starting point. This study will focus on differences between hierarchical stakeholders with respect to “what is GSCM” (know), “why should I act” (want), and “how can I act” (achieve), i.e. awareness, motivation and capability (Figure 1). In addition to this, the analysis will focus on differences between traditional and e-commerce-supply chains as well as company-specific characteristics.

This research is embedded in the self-determination theory. This theory originates from psychology and includes elements of human motivation and personality. Crucial within the theory is the motivation behind choices while making abstraction of external influences. The theory links the behaviour of the individual with self-motivation and self-determination. Three key elements of the self-determination theory are further explored in this research: awareness, motivation and capability.

Self-determination theory (SDT) is a theory of human motivation and personality (Ryan and Deci, 2000b, Deci and Ryan, 2012). Based on SDT, the individual differences focus on concepts resulting from various stakeholders from a vertical perspective of management mechanism. According to the individual difference, we propose the individual difference of different hierarchical management levels (Ryan and Deci, 2000b). Intrinsic motivation will be explored from a progressive perspective. Firstly, this study proposed antecedent motivation as “awareness”, which illustrate the initial knowledge and attitude of environmental issues. Secondly, the conception of “motivation” here only refers to initiatives and drivers that contribute to their environmental behaviour improvement. Thirdly, the study proposed “capability”, to elaborate the link between motivation and performance.

Awareness
Awareness has been associated with autonomous functioning, and it is a crucial element in the existence of a self-determined process (Ryan and Deci, 2017). The sensitivity of environmental changes (e.g. the climate change, pollution etc.) varies in different individuals. The concept of awareness could be extremely useful to provide an antecedent understanding of the drivers’ effect. Previous research shows that lacking awareness environmental knowledge of is an important inhibitor of GSCM (Sarkis, 2014). However, it was only recently that the researchers incorporated the idea of GSCM in SDT analysis, especially from the antecedent perspective of motivation (Murphy, 2014).

Motivation
The motivation of GSCM refers to the impetus or inspiration to act environment-friendly behaviour (Ryan and Deci, 2000a, Haddock-Fraser and Tourelle, 2010). Self-Determination Theory (Deci & Ryan, 1985), generally distinguishes between different types of motivation based on the different reasons or goals that give rise to an action (Deci and Ryan, 2012). Intrinsic motivation refers to doing something because it is inherently interesting or enjoyable, this kind of motivation has emerged as an important driver for internal-stakeholders in GSCM (Rao, 2002). Previous research proposed three different types of motivations of firms for pursuing GSCM, i.e. legitimization, competitiveness and ecological responsibility (Vanpoucke et al., 2016).
**Capability**
Capabilities are “complex bundles of individual skills, assets and accumulated knowledge exercised through organisational processes, that enable firms to coordinate activities and make use of their resources” (Murphy, 2014). It is an essential link between motivation and performance to make sure the motivation can be transferred to practices effectively and efficiently. K.-C. Shang proposed that GSCM capability can be calculated by the sum of green purchasing, green materials management, green distribution, and reverse logistics for the whole company, which means the types of GSCM capability various according to different practices for different individuals (Shang et al., 2010). In this study, to compare the individuals from a vertical perspective, a comprehensive amount of capability among each hierarchical level will be tested.

![Figure 1- Framework of management mechanism analysis](image)

**Methodology**

*A case study approach*
This study adopts a case study approach to gain insights into the role of management mechanisms on internal stakeholders’ GSCM practices. We used a case-based methodology in this study for two reasons. First, a case study is believed to be a better approach of theory building where the relationships between important constructs are poorly understood. Second, the use of series of research-motivated case studies has been encouraged within the field of operations management as a means of providing a rich description of phenomena in a natural setting, based on first-hand observation and examination of numerous factors and nuances (Boyer and Swink, 2008).

Following Ketokivi and Choi (Ketokivi and Choi, 2014) three different methodological approaches to case research can be distinguished: theory generation, theory testing, and theory elaboration. Theory elaboration is not aimed at generating new theories or testing existing theories but aims at introducing new concepts, examine boundary conditions, or investigate relationships between concepts. This research follows the theory elaboration approach by extending the knowledge from the self-determination theory into the field of green supply chain management.

The research is based on an in-depth case study of a Chinese food supply chain service e-commerce platform company. The case is used to explore and describe the role of management mechanisms on internal stakeholders’ GSCM practices in e-commerce supply chain perspective.

**Sample selection**
The case selected for this research is for a number of reasons. Firstly, the case company is a typical e-commerce supply chain service-company. The company is a subsidiary company and is one of the supply chain service-companies on its parent company’s
electronic system. Secondly, the case company is a newly established Small to Medium-Sized Enterprise (SME). In China, with the rapid development of e-commerce, more creators realized the opportunity of e-commerce and established their own businesses. Different from focal companies, who have already obtained the environmental strategy and economic capability, SMEs are facing more challenges relating to social responsibility. Thirdly, the case company focus on the food supply chain from a B2B perspective. Next, to the well-known B2C e-commerce (electronic product, cosmetics and garment) activities, this new multi-industrial supply chain (Information industry, Logistics and Agriculture) is a popular and typical phenomenon in China at present.

Data sources and analysis

In 2019, 12 in-depth, semi-structured interviews and semi-structured surveys were conducted (see Table 1 for an overview). Next, to primary data collection, secondary data such as company material, industry reports and press clippings were used as a means of data triangulation in order to strengthen external validity. In order to increase construct validity, we deployed different techniques: multiple sources of evidence were used, interviews on different levels were conducted and key informants reviewed the case in depth (Gibbert et al., 2008).

Findings

Background of the case company

This study offers a more nuanced view of how e-commerce supply chain service-company is greening its supply chain. As a subsidiary company, the case is the largest supply chain service-provider of its parent company, which is also the company running the electronic platform. It relies on the e-commerce supply chain electronic system for B2B services. Its main customers are retailers (supermarkets), restaurants, entertainment-casinos, etc. (Figure 2)

The case company was established in July 2018 with 100 million RMB, which means it is only 9 months old and is still at an infant stage. There are approximately 160 employees in total, including managers. In the Chinese classification system, the company is considered as an SME at present. When it comes to the management structure, there are four independent executive departments, i.e. purchasing department, sale department, warehousing & logistics, and quality management. Furthermore, there are
also three supporting departments: the CEO office, the operations department and the financial department. All departments report directly to the CEO. Departments collaborate and support each other with both online and offline business in supply chain service. The management team of the case company participates in an active and democratic atmosphere. According to the interviewees, most of the participants spontaneously mentioned they feel free to provide their suggestions and opinions, and think their company has a higher level of democratic decision-making than other peer companies. “As an SME company, it is easier to communicate and collaborate flexibly” (No.2 Senior manager of operation department). Moreover, No.3 Consultant of law & Assistant of CEO mentioned that “With the growth and development of the whole company, the democracy and standardization may have a different combination proportion but proper balance as well”.

![Management Structure of the Case Company](image)

**Figure 2 - Management structure of the case company**

**Awareness, motivation and capability comparison from a vertical perspective**

To identify the management mechanism from a vertical perspective (top-down versus bottom-up), we compared the participants with different hierarchical management positions and their GSCM awareness, their environmental motivation, and their working implement capability to capture “to what degree do they know of GSCM”, “would they like to do” and “can they realize and achieve”. We established an evaluation system from the three perspectives above, in each perspective 5-6 progressive evaluation points are included (Scores vary from 1 to 5). The disparities among senior manager, middle manager and employee are shown as Figure 3.

The results show that the averages of senior management on all three indexes (awareness, motivation and capability) are highest than both middle and employee levels. According to the educational background and the knowledge of social and environmental concerns, it is easier to understand that top managers are more aware of GSCM. However, the difference between middle management and top management seems small. An interesting observation is that senior management obtains a higher level of capability to implement environmental activities. The capability to implement can be divided into different types depending on the position in the company. The work senior manager requires more consciousness consideration while the employee is supposed to obtain
higher degrees of standardized implementation capabilities. However, yet, the capability of lower staffs still remain at a relatively low level.

![Figure 3: Disparities of management mechanism from a vertical comparison of individuals](image)

**Discussion**

The underlying mechanism of how a company behaves is complex. GSCM practices are no exception to this rule. To illustrate how the management mechanisms work and what the role of different internal-stakeholders is, we give a number of examples of practices in relating to environmental behaviour, and misunderstanding and opportunities in GSCM.

*Top-down motivation in new energy cars plan*

In this specific environmental practice, most of the awareness and motivation is at the level of the senior management, while middle managers and employee present to be a more neutral role. There are three reasons for a senior manager to consider new energy cars. Firstly, it is easier to get licenses for the cars in Beijing compared with traditional cars. Secondly, new energy cars might be much cheaper when it comes to cost. Thirdly, based on its electronic system, e-commerce supply chain companies can insert their own electronic system on new energy cars for digital monitoring. However, barriers still exist for implementation of new energy cars plan, which needs the help and professional support from middle managers. First and foremost, new energy cars can’t replace traditional logistic transportation totally; not only because of the capability to deliver (amount and distance limited) but also because of functional weaknesses. The demand for temperature requirements for food logistics is not optimal, as a professional transportation needs normal temperature, 0-4 °C fresh and freezing function are all needed. However, new energy cars can only realize a normal temperature now. In addition, as the batteries of new energy cars need to be changed after 4-6 years, the further cost needs pre-tested. More financial forecasting and professional distribution design for the new routes are essential.
**Bottom obstacles in reusing and reducing package practices**

Sometimes, motivations of environmental initiatives diminish from top to bottom, and obstacles from motivation and capability of employees can become a relatively controversial power, which needs higher policy strategy and management regulation adjustments. After the last half-year operation, senior management found their low-value consumables usage is much too high. Because of the improper usage or package overuse of employees, there is still a certain improvement environmental behaviour by professional training, while recycled baskets can be used for the supply chain service company to cut the cost without any impact of the food quality as well. Senior managers tried to adopt two new practices: “reduce” and “reuse” by training and responsibility regulation relatively.

Based on less awareness of employee, it is not easy for them to recognize environmental behaviour themselves. For daily work, they prefer to choose convenient behaviour to meet the basic standard. However, the capability of the employee differed in the two practices above. Reduce the usage of package behaviour needs employee not only realize the problem but also needs professional guidance by training, as the profit rate of training is not clear, this plan is still in planning stage. On the contrary, the other plan for reuse the plastic baskets. They published a new regulation to confirm the responsibility of plastic baskets at each delivery worker/driver, i.e. if the plastic basket is lost, the worker/driver should pay himself. The results of this small step recovered and retrieved 80% of lost plastic baskets. As no further or difficult capability demand, this regulation achieved as soon as the employees’ awareness and motivation changed.

**GSCM practices are noticed and ignored**

There is a big misunderstanding or incorrect knowledge of one particular element of awareness on an individual level, which is the environmental behaviour derived from social responsibility. Moreover, in their opinion, the company won’t consider the environment issue until they have more economic support after they get through their infant stage. However, saving energy and recycling are considered in their daily management already, while GSCM is not in their mind. The original motivation comes from a financial consideration; a cost-cut for both energy saving and recycling behaviour. The operation department and CEO office recognized the cost of their daily energy usage and an optimization plan is considered. This kind of management greening derived from profit pursuing, which can be titled as internal motivation. On the contrary, there is also another kind of supply chain greening practices derived from the pressure of customers. The demand of the customers sits at the first position especially for such an SME company at an infant stage. As non-coercive requirements from government, they prefer to focus on the financial reasons, both income from customer demand and cost-cut from operational consideration. What’s more, GSCM practices are already implementing in different departments and their implement stages are varied.

**Linkage in relating traditional food security to new GSCM**

In China, “green food” is a crucial linkage in relating traditional food security to a new GSCM. However, it is still far from the aim of installing an environmental management system based on green food development. At present, Green food management required the practices and collaboration of quality management and marketing demand considerations. GSCM and environmental traceable systems can obtain the establishment more efficiently if it depends on and develops from “green food” management systems. Meanwhile, it is crucial to establish a tracking system for the products’ original region management based on green food managerial improvements. As an e-commerce supply
chain, the electronic system provides them with a more easy way to realize information transparency. However, there are still obstacles. Higher qualified and environment-friendly food leads to a higher price, because of the limited consumption ability of most customers in China, this “green food” demand finally performed weakly to green the supply chain now. In addition, even if the tracking system is a plan and a trend in the food industry already, at present, companies focus much more on the final quality of the food itself instead of what the product “experienced” before. In other word, further responsibility and non-coercive standard of their supplier still need a long run to realize.

**Conclusion**

Management mechanisms performed different roles in the e-commerce supply chain at different levels. This study illustrates how the management mechanisms contribute or limit the improvement of GSCM from a vertical perspective.

First, the awareness, motivation and capability of GSCM implementation all showed a top-down decreasing trend. The knowledge of GSCM is still lacking from all hierarchical levels of staff. However, there is still space for GSCM practice improvement, which can be realised by professional training.

Second, the advantage of the e-commerce supply chain in GSCM implement is obvious, even if the development is not standardized and lacks guidance now. The electronic system and its information transparency enable the company to realize more environmental collaboration with its suppliers and customers. Moreover, information technology and electronic system also contribute to the new energy logistics in e-commerce supply chains.

Third, at present, the management mechanism involved Green food management in both quality management and marketing demand consideration. In China, “green food” management is a crucial linkage in relating traditional food security to new GSCM. GSCM and the environmental traceable system can obtain a more efficient establishment if it depends on and develops from “green food” management system.

Abstract

The paper provides the attempt to combine 6 types of innovations offered by BCG in 2017 and supply chain strategies in modern knowledge economy where the role of information became crucial. Logistics providers create supply chains as owners and outsource all production, transportation and other physical processes keeping the position of “control towers” with efficient utilization of information. Two innovations models out of six are suitable for this supply chain models, they are “Expander” and “Fast follower” with main focus on agility based on information utilization.

Keywords: innovations types, supply chain, knowledge economy

6 types of innovations

The current management theory trends are oriented to digitalization, new business models, the transformation of paradigm and the word “innovation” is not on the cutting age last decade. Despite this fact we shouldn’t underestimate the role of innovations in any type of development, so we tried to combine the theoretical background of innovation management and the tendencies of switching management focus to the supply chain management. We agree with the position about growing role of supply chains comparing with the roles of discrete firms. Furthermore we share the opinion (Gassman, 2016) about the new way of competition based on different business models instead of product or process innovations.

The research done by Boston Consulting Group in 2017 offered the classification of innovations. These types of innovations are not something radically new but they used as examples modern companies and justify the actuality of the classification. They describe six types of innovation (BCG, 2017):

1. Creator
2. Solution builder
3. Leverager
4. Expander
5. Defender
6. Fast follower

The Creator model is the most visible: Apple, Tesla and Netflix. According to the BCG report, these companies are highly innovative, managed by a strong visionary leader, introducing disruptive (radically new) products to the market, which then become the industry standard.

A Solution builder is a company that implements improving innovations and actively listens to the needs of customers, creating niche solutions for different groups. An example would be the manufacturer of sports equipment Nike.

A Leverager is a model of a company that can be described with the slogan "we make our business better than anyone." The firms applying this model concentrate on continuous improvement of the basic version of the product. The best example is the automaker Toyota - the "cradle" of the concept of continuous improvement, although BCG gives other examples, such as the Spanish clothing manufacturer Zara.

A Expander is a type of company that takes away part of the market from existing players through radical innovations. At the same time, the company focuses on one or two “advanced” product features and is constantly experimenting, looking for new ways to better meet the needs of the market. Here we will name the company Amazon as a leader in this model. So the apply best in class technologies expanding their role in supply chain from storage to selling to distributing and sometimes production.

Defender is another type of model that uses innovation to counter expander and others. The model is found in capital-intensive industries with high research and development costs, examples being such giants as pharmaceutical Pfizer and insurance AIG. The key activity here will be constant monitoring of new disruptive innovations of competitors, protective measures, including mergers, acquisitions and cooperation agreements with the most promising rivals. Another key activity in the “defender” model is continuous improvement, as in the “leverager” model.

The Fast follower - the last of the six models - provides for tracking the actions of the advanced and most progressive competitors, as well as following their decisions with the first market evidence of their success. Due to this model, a fast follower saves costs, because the “pioneers” bear most of the risk and initial costs of bringing innovations to the market. In such organizations, the speed of implementing decisions is highly important; the ability to change quickly is more typical for “flat” organizational structure. That is how the financial leader JP Morgan Chase works, for example.

As we can see from the descriptions, BCG was focused only on individual firms, they didn’t estimate supply chains and partners of focal company. We add to this analysis of strategic aspects of supply chains of companies in order to combine and find connectivity of their types of innovations and supply chain characteristics. We believe that such combined analysis can give new insights to management theory and offer practical implementation. The theoretical hypothesis we formulated as following: companies with different types of innovations should use different supply chain strategies. Thus, there is a need to adapt management methods so that measures applied to one company, for example, innovation strategy, take into account potential factors of influence on other companies of this supply chain.

Supply chain strategies

When organizing supply chains, three basic types of strategies are used: effective, focused on minimizing costs and reducing losses; agile, flexible or manoeuvrable, focused on factors of unpredictability of demand and other external factors and tuned to
the ability to quickly respond to changes; hybrid, combining the advantages of both strategies, that is, preserving the necessary level of flexibility while minimizing costs.

From the description of supply chain strategies, it is obvious that hybrid strategy should prevail, but the complexity of this strategy is the decision on the ratio of an effectiveness and flexible. The literature identifies as the main difficulty of implementing this strategy the identification of the "point" of decoupling from an effective to a flexible strategy. This "point" is determined by analyzing information about the unpredictability of demand or directly by the occurrence of a particular order. Within one company there is no such a "point", rather it should be in the whole supply chain. It is also important who is the owner of the supply chain; it means which company has main influence on the operationalization of supply chain. Traditionally it is based on the specifics of goods and services served by particular supply chain. As two polar examples it is possible to allocate the supply chain formed by industrial companies, defining a common strategy for the supply chain based on the type of product and the supply chain, where the main requirement originates from the distribution network and retail.

Nowadays we can face more and more supply chains controlled by the retail as an owner. Big retail chains become the company which role in value creation for the final customer is the biggest as these chains are able to satisfy the demand quickly. Such chains serves as distributors, they control amount and price of product etc. We found the reason for this change in supply chains in logistics provider’s development.

In this regard, it is important to mention the classification of logistics providers, which appeared at the end of the last century due to the fact that the role of logistics operators has increased significantly. According to the "United Nations Convention on international multimodal transport" of 1980, logistics operators began to be included in contracts between the manufacturer and the destination of the goods as a third party with its rights and obligations.

**Role of logistics providers in innovations**

This classification identifies 4 types of logistics service providers for the set of functions for which they are responsible. Accordingly, the first level providers are manufacturing companies that are responsible for delivery by their own transport. So here we can imagine transportation task as just deliverance from point A to point B without any optimization schemes. The second level includes companies that have vehicles and are external logistics service providers. Typically such companies are called transportation companies and their main task is to optimize utilization of vehicles. At the third level of classification, consulting is added to the logistics functions, that is, logistics companies already partially assume management functions, including responsibility for the results of the logistics component of the company. The fourth-tier providers include operators that do not have any transport or other capacities, but are centers of competence. At the same time, such companies should not only have knowledge in the field of logistics operations, but should also be competent in market trends. As they create the supply chain based on their knowledge about the market they define supply chain strategy and innovativeness level. As we can see the level of innovativeness will influence the supply chain strategy and we can try to combine the BCG’s innovation classification with strategic aspects of supply chains.

The creator is a highly innovative company that influences the entire industry, both at the level of the products being developed, as well as technologies and operations. As an example of such a company that changed the principles of the automotive industry, could be Ford Motor Company. In-line production of cars has changed not only the
product itself, but also had a huge impact on the supply chain. With this level of innovation, the company does not yet have an existing market, it forms it, so it cannot wait for market signals to determine the demand. Such an innovative strategy leads to the choice of a push strategy to bring the product to the market, which allows to focus on an effective strategy.

Solution builder - a company looking for solutions based on market signals, its innovations are focused on meeting current customer needs and adaptation. The greatest priority for such an innovative model is flexibility, including flexibility in the supply chain. An example of such a company is Nike, which can customize its products to customer needs.

For the leverager - the main priority of this innovation strategy is a business model that allows capitalizing on market opportunities. That is, in this case, the supply chain itself is an innovative solution. Such companies as ZARA, Uber, Dell showed successes in the implementation of this innovation strategy. It is important to note that currently there are enough followers of these business models, which proves that the effect of a change in the supply chain can also give significant results and be innovative.

The expander - such an innovation strategy is characterized by the development of new areas or even industries due to the obtained successful experience and existing competitive advantage. An example is Amazon, which has changed the focus of its business from sales to technological sales services, in other words, to the process infrastructure. Using this logic not for one company, but for the supply chain, it can be assumed that the company - participant of the supply chain chooses vertical integration in order to gain the position of the "owner" of the supply chain.

Defender strategy of innovation characterizes resistance to innovation. Such a strategy is suitable for functional product industries, where an effective functional supply chain strategy is most applicable. A company choosing such a strategy is most at risk due to the lack of flexibility of both the product or service and the supply chain as a whole.

Fast follower companies prefer to copy the most successful practices, while gaining a competitive advantage due to the speed of reaction, which confirms the need for flexibility in the supply chain. The level of product innovativeness here could be quite low, but the level of competences in supply chain should be very high, over wise the followers couldn’t be fast.

Thus, from the strategies described above, three types of strategies that characterize the most radical innovations and three types of less innovative strategies can be distinguished (Table 1).

<table>
<thead>
<tr>
<th>Innovation level</th>
<th>Supply chain strategy</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Efficient</td>
</tr>
<tr>
<td></td>
<td>Creator</td>
</tr>
<tr>
<td>Low</td>
<td>Defender</td>
</tr>
</tbody>
</table>
Accordingly, the radical innovation strategies will include Creators, Leveregers and Solution Builders, with each strategy being able to match the type of supply chain strategy. Also, for the incremental level of innovation, three relevant strategies can be distinguished: “Defender”, “Expander” and “Fast Follower”. From the point of view of supply chain management, strategies that focus on flexible strategies are of the greatest interest, since it is in the implementation of these strategies that organizational and process innovations in the field of operations come to the fore, allowing the successful operation of the entire supply chain.

Applying the strategy of a logistics operator of the fourth level, the company leaves the category of service providers, and becomes the "owner" of the supply chain, creating it to meet the needs of the final customers. As an example of such companies, organizations that place orders for production in countries where it is most profitable, still most often in China, then hiring a third-level logistics operator to arrange transportation to markets. Such companies retain solely the management function, which is characterizes them as “owners” of the supply chain. So we can assume these logistics providers as "Solution builder" with a high level of innovation activity and "Fast Follower" with low innovation activity according to the Table 1. The degree of their dependence on any capacity is practically minimal, allowing them to be as flexible as possible, and the market knowledge requirements are extremely high. From the knowledge economy point of view, these innovation models are most closely associated with the competence of logistics providers of the fourth level, which, based on the idea to create full-fledged supply chains to meet customer needs, while maintaining maximum flexibility.

**Supply chain innovators in knowledge-based economy**

Recently, this classification began to include another type of providers - the fifth level. They are also called “virtual” logistics companies due to the fact that they organize the network business using the global information space and operate in the global market. The literature describes as examples of 5PL-providers online stores such as eBay, Aliexpress, Amazon. Nevertheless, it is worth noting that these companies do not position themselves as logistics operators. Other examples of companies that provide integrated supply chain services based on modern information technology capabilities include Küehne + Nagel International AG and DHL, which have so-called Control Towers, that is, information centers that act as platforms for aggregating data on logistics flows and external factors affecting the supply chain system.

Such organizations use the “Control Towers” approach, aggregating huge amounts of information across all streams. Such control centers are used to be information hubs, they can serve the purposes of one client-company, then they are created on its basis, and can serve many different customers, in this case, most often this hub is a "superstructure" of the logistics operator.

This information flow provides maximum transparency of the supply chain, the ability to track cargo, control costs, and also allows to increase the speed of reaction to external factors. These factors could include both demand fluctuations and natural or market changes that affect the supply chain. For example, a hurricane on another continent, which can lead to supplier transport problems, can give an alert for searching an alternative supplier if information is available in advance. Without an information hub, the customer would first be faced with a delivery delay, and only then would he start looking for an alternative provider.

Data from tracking cargo on all transport lines can provide estimation about potential supply on the market. For example, the market price is primarily influenced by the
volume of supply of perishable goods from distant countries like fruits and vegetables, as suppliers do not have an ability to store goods in a warehouse until demand increases. The information hub can have information about upcoming deliveries and use this information effectively.

The complementation of the information hub with the ability to carry out commercial activity makes the company very competitive with the potential for rapid response to any market fluctuations. Thus, the reasons for the growing popularity of the information component in business and the development of big data analysis technologies become competitive advantages based on the availability of timely information. At the moment, the knowledge economy is becoming more focused on information about market demand, and this knowledge is valued most in supply chain management.

In addition, analysis of demand and consumer data allows responding to changes in demand with fewer fluctuations. Analyzing data from all participants in the supply chain also allows greater transparency and, therefore, increasing the level of partner confidence, allowing for a quick and coherent response to changes in the market situation. Companies engaged in the development of innovative products often do not have the ability to use retrospective data. Nevertheless, customer data allows them to bring to market the product at the right time and make it most attractive to customers.

**Conclusion**

Despite the tradition understanding the classification of innovations types, based on product innovation, current knowledge economy shows the transformation of most prolific innovation types as “Solution Builder” and “Fast Follower” facilitating supply chain efficiency instead of product innovations. The research about trends of changing owners of supply chains and role of logistics provider give an understanding of information influence underestimation as a competitive advantage. The focus to the innovations in supply chains oriented to the flexibility should be a specific topic for research. We believe that it could be the niche where new types of innovations could be found and described.

When supplier development initiatives fail: exploring the causes of opportunism and unexpected outcomes

Abstract

Buyers often seek to enhance the capabilities of their suppliers through supplier development initiatives. However, these initiatives are not always successful and may have unintended consequences. This study investigates a ‘dark-side’ of supplier-buyer relationships, specifically the link between supplier development initiatives and supplier opportunism. Agri-food supply chains in Vietnam is the context for the study. We employ an explorative, qualitative methodology, analysing data from 30 interviews with fruit and vegetable buyers. The findings identify different supplier development initiatives and the specific forms of opportunism that may arise from each. Attention is paid to strategies to curb opportunism.

Keywords: Opportunism, Supplier Development, Supply Chain Management, Vietnam

Introduction

Companies increasingly seek to create sustainable competitive advantages in co-operation with suppliers. Suppliers’ capabilities affect, either directly or indirectly, firms’ costs, quality, delivery, and level of technological directly or indirectly (Krause and Scannell, 2002). It is, thus, no surprise that firms often enhance the capabilities of their suppliers through supplier development initiatives, which can be defined as “any effort by a buying firm to improve a supplier’s performance and/or capabilities to meet the manufacturing firm’s short- and/or long-term supply needs” (Krause et al., 1999, p. 206).

The extant literature, informed by theories of knowledge transfer and co-operation, investigates the impact of supplier development programmes on suppliers’ and buyers’ performance as well as on supplier-buyer relationship outcomes (e.g., Li et al., 2017, Humphreys et al., 2011, Lawson et al., 2015). Supplier development can lead to positive outcomes such as product and delivery performance improvement (Wagner, 2010), and increasing suppliers’ operational performance (Krause et al., 1998). In terms of relationship outcomes, capital-specific supplier development can also increase suppliers' satisfaction and commitment to the supply chain (Ghijsen et al., 2010). Overwhelmingly,
the literature presents positive assessments of supplier development initiatives, often characterised as a ‘win-win’ for suppliers and buyers alike.

However, even when both suppliers and buyers accept the importance of supplier development, these initiatives are not always successful and may have unintended consequences. Specifically, supplier development initiatives can prove counterproductive if they stimulate supplier opportunism (Proch et al., 2017). Opportunism, seen as a dishonestly oriented breaching of business obligations, is defined as “self-interest seeking with guile,” (Williamson, 1985). When participating in supplier development initiatives, suppliers may behave opportunistically if they perceive a missing control mechanism (Li et al., 2017) and Transaction Cost Theory (Williamson, 2008) predicts that suppliers will breach supplier development contracts if the benefits of violating them exceed the cost.

To date, very few studies consider the potential downsides of supplier development initiatives and the circumstances under which they stimulate rather than curb opportunistic behaviour by suppliers. Exceptions include Huo et al. (2016), who discern that buyer specific-investments increase the likelihood of suppliers engaging in opportunistic behaviour. Specific-investment induces the investment receiver to act opportunistically because it is a non-transferable investment, and dependent to a specific relationship (Huo et al., 2016).

One-sided investments in relationship-specific assets are sensitive to opportunistic behaviour, especially in an unpredictable business environment (Hawkins et al., 2008, Proch et al., 2017). However, the prevailing view in the literature is that supplier development initiatives provide a “win – win” for suppliers and buyers, especially where the latter seeks greater control over the quality and appropriate incentives are provided (Li et al. 2017).

Given theoretical and empirical uncertainty regarding the effects of supplier development initiatives on opportunism and the circumstances under which investments in supplier development trigger or limit suppliers’ opportunistic behaviours, further research is warranted. This study investigates to what extent, and under what circumstances, do supplier development initiatives curb and/or stimulate supplier opportunism?

The context for the study is agri-food supply chains in Vietnam. Emerging economies often lack strong, formal institutions for contract enforcement(Kirsten and Sartorius, 2002), negatively affecting both suppliers and buyers (Saenger et al., 2014). It is common in agri-food supply chains for processors to provide credit and physical inputs (e.g. seeds, fertilisers) to farmers as part of a contract. However, difficulties of monitoring and contract enforcement may allow farmers to misuse the investment, or sell their product elsewhere (Bellemare, 2010). This can lead to buyers withdrawing support, with negative impacts on the long-term quality, safety and quantity of supply chain outcomes (Gow and Swinnen, 2001). There is anecdotal evidence that such problems beset the Vietnamese agri-food sector. The country has two main types of food supply chains for fresh fruit and vegetables: wet markets and supermarkets. The former comprises numerous small-scale operators, dominates total sales and regulations are poorly enforced (Cadilhon et al., 2006, Shepherd and Tam, 2008, Maruyama and Trung, 2007), raising concerns regarding food safety. The supermarket sector is growing and more likely to insist on suppliers being certified (e.g. VietGap and GlobalGap). Some supermarkets or their suppliers support farmers through credit or training although these have not always delivered the outcomes intended. The Vietnam case is thus exemplary for studying the relationships between supplier development initiatives and supplier opportunism.
Theoretical Background
Prior research on supplier development indicates that buying firms employ various activities to improve suppliers’ performance and/or capabilities (e.g., Zhang et al., 2017, Wagner and Krause, 2009). Initiatives may be introduced in response to a problem (“reactive approach”), or proactively initiated to develop suppliers even though there are no immediate problems (“strategic approach”) (Friedl and Wagner, 2016). Much research classifies supplier development initiatives by the level of commitment from buyers to a specific supplier (e.g., Zhang et al., 2017, Proch et al., 2017, Ghijsen et al., 2010, Humphreys et al., 2011, Wagner, 2006).

Supplier opportunism is an important risk in buyer-supplier relationships. Parties should safeguard themselves against partners’ opportunistic behaviours in supplier development initiatives because they often require relationship-specific investment. If a buyer is unable to introduce satisfactory safeguards, they may reduce the provision of supplier development initiatives, causing underinvestment and possibly impairing the buying firms’ long-term competitiveness (Rokkan et al., 2003).

Transaction Cost Theory, Social Exchange Theory and Agency Theory
Supplier development initiatives involve a collaborative relationship between suppliers and buyers. From a social exchange theory perspective, partners in supplier-buyer relationships prioritise the pursuit of their long-term benefits, which curbs opportunism as the latter may lead to the termination of the relationship (Li et al., 2017). By contrast, according to transaction cost theory (Williamson, 2008), relationship-specific investments suffer from asset specificity, so that the reuse value of the investment would be less or even zero beyond the relationship (Crosno and Dahlstrom, 2008, Wang et al., 2013). Accordingly, dependence on a supplier increases when a buyer makes specific investments in a relationship, and the supplier becomes more powerful in dealing with the buyer, therefore endangering them to more risk and uncertainty (Huo et al., 2016, Humphreys et al., 2004). Hence, specific-investment builds a locked-in environment that induces supplier opportunism (Brown et al., 2000, Liu et al., 2009, Rokkan et al., 2003).

From the perspective of agency theory (Morgan et al., 2007, Jap and Anderson, 2003), indirect supplier development (i.e., supplier management practices) reduces the likelihood of supplier opportunism because it controls directly against self-interest seeking behaviours of suppliers (Maestrini et al., 2018). Furthermore, incentives encourage suppliers to perform in a manner that satisfies the buyer’s performance measurements and should reduce the chances of suppliers misbehaving. Once again, however, transaction cost theory (Williamson, 2008) suggests contrary predictions, looking humans are self-centred, calculative, and only “weakly moral” (Wang et al., 2017), so parties act opportunistically to pursue their self-interests as much as possible, once possible benefits exceed the expected costs (Das and Rahman, 2010, Ghoshal and Moran, 1996). Hence, when linking specific targets to incentive schemes, suppliers are encouraged to bypass or subvert performance measures to their own benefit, consequently reducing favourable outcomes from the buyer’s perspective (Maestrini et al., 2018).

Recognising the contrary views from different theoretical perspectives, we undertake further research on the relationships between supplier development and opportunism, distinguishing between the specific types of each.

Methodology and Data collection
As theoretical and empirical work in business management often overlooks opportunistic behaviour stemming from supplier development initiatives, we conducted an exploratory deep-dive investigation. The study draws on 30 face-to-face, in-depth interviews with
managers in the fruit and vegetable supply chain in Vietnam. The sample is cross-sectional, including nine organisations which solely act as buyers, and 21 organisations which are both buyers and suppliers of fresh fruit and vegetables. The Ho Chi Minh City Department of Industry and Trade, the Business Studies and Assistance Centre, Southern Horticultural Research Institute (SFORI) Vietnam, and Lam Dong Province Agricultural Extension Centre helped recruit interviewees. Potential interviewees received a participant information sheet (outlining the purpose of the research and guarantees of anonymity and data confidentiality) and signed informed consent forms before commencement of interviews. Some interviewees recommended other potential participants (snowball sampling).

Data collection took place in summer 2018. Interview data were coded and inter-code reliability checks undertaken, utilising Nvivo12 software. A start list of code was created from the conceptual framework, a list of research questions, and problem areas of the research, including the structure of the code within supplier development, and opportunism concept. The list has been revising as new codes are generated while coding the materials. Three independent experts were invited to code 19 random transcripts, which accounted for 63.33% of total transcripts. After independently code the transcripts, coders discussed the code to reach the inter-coder reliability at above 75%, which indicates a good level of agreement.

Findings

Supplier Development Initiatives

Most buyers provide feedback on quality to suppliers and provide training to farmers (see Table 1). To a lesser extent, buyers offer cash support in the form of advanced payments or zero-interest loans, and providing physical inputs. Buyers can offer suppliers a guaranteed sale, which means they will purchase all of the supplier’s output of a given good, at a pre-specified price over an agreed period of time. Supplier incentives refer to financial inducements to the supplier to meet particular quantity and quality thresholds. Two cases stated that they do not have the capability to develop suppliers in term of technical processes and skills since they believe suppliers have more experience and knowledge on growing fruit and vegetables.

Table 1 presents the frequency with which buyers employ different supplier development initiatives. The first column lists the initiative, while the next four columns
detailing the number of interviewees stating that they have deployed such an initiative. As can be seen, buyers often employ a mixture of supplier development initiatives rather than just use a single solution. For example, a buyer may provide some physical inputs, as well as training and guaranteed prices to farmers. Although many buyers provide a particular type of supplier development support, implementation in practice may be very different. For instance, quality assessment activities - one buyer may only assess product appearance quality purely visually (i.e., good size, looks good on skin, weight as agreed), another may test quickly for pesticide residues, but another assesses the product’s microbiological index which requires an independent third party and is far more expensive. Evidences include “We can only have a quick test, a quick test on some indicator. We can’t check on everything” (Interviewee 30, Manager, Supermarket), “The supermarket, they have some test periodically, but they also have a quick test. Every day, they have a department, for example, today we supply 10 products, but they choose only one product and perform a quick test, they analyse the result at the time, if they suspect the product has some over-permitted pesticides indicator, they will test, if it serious, they will destroy the product, if it is lightly over-permitted, they will bring back to check at farm, if it acceptable they will buy it, if not they will cancel the whole batch” (Interviewee 26, Director, Vegetable Cooperative), and “During the time of working with suppliers, we go there to take sample to test, for example, occasionally you visit the farm, you will take random sample then send it to test, or you can do a quick test yourself” (Interviewee 16, Manager, Vegetable Company).

The relationship between Supplier Development and Opportunism

Further analysis of the data suggest the supplier development measures can lead to supplier opportunism (Figure 1). Specifically, six supplier development initiatives, represented by six rounded rectangles, lead to six types of opportunistic behaviours displayed in the six ellipses.

Firstly, one common initiative to improve suppliers, namely training for farmers, can fail because farmers may stop following the processes introduced in the training in order to sell products to other buyers who can offer a higher price. For example, as a manager stated “When they are aware of the market price is higher, they stop to follow our process. They do their own thing, in order to keep the vegetable away from diseases, so they can sell to the market at a higher price” (Interviewee 09, Manager, Vegetable Cooperative).

Secondly, supplier assessment and feedback may be susceptible to two forms of opportunistic behaviour. First, a supplier can bypass the assessment criteria, as Interviewee 14, a Manager at Supermarket reported “Suppliers do not deliver quality products. They cover the freshest vegetable on the surface, [...], in the middle they put lower quality ones; we can only test on 1-2 samples, so sometimes it happens”. Moreover, suppliers may mix products from different sources to supply to their buyers, as mentioned by another director “They buy from wholesale markets, then process the product and mix it together. It means the uncontrolled-quality-product in the wet market. They process it, pack it under their name and sell to the supermarket” (Interviewee 13, Director, Fruit and Vegetable Company).

 Buyers can offer suppliers a guaranteed sale, implying that they will purchase the entire output of the supplier at a given price during a particular period of time. This initiative stimulates two different types of supplier opportunism. For example, a director states: “When the market price is low, they mixed products from their relative’s farm to sell to us” (Interviewee 17, Director, Vegetable Cooperative). With the guaranteed price offered, they cheat on product quantity by including output which was not produced by the supplier and maybe of inferior quality. The second form of opportunism involves the
supplier breaking the contract to sell to other buyers when the latter offer a higher price. For instance: "We sign a contract with suppliers with a fixed price for 3-6 months, for example. At the time, we fix the price, for example, 10,000đ per kg, but then when we order, because we fix the price for three months, at that time they agreed. But after one month, the market has some change, the price increases. The price increases, then the farmer will break the contract with us to sell to other buyers, to traders" (Interviewee 01, Manager, Fruit Export Company).

Cash support may also provoke supplier opportunism. Firstly, when receiving cash, a supplier can use it for purposes that are different from other agreed with the buyer, such as “The fact is, there are businesses that use the money for the wrong purpose…that means… they take that money to do something else….” (Interviewee 13, Director, Company). Secondly, the supplier may use the cash support to improve the quality and quantity of production but then not supply the enhanced output to the buyer who provided the support. For example, “when we need to buy from them… with the fresh product in the farm, they harvest the product and sell to somebody else, then they buy products from the wet-market and resell to us […] We look at their dairy and we see that they harvested, but when we ask them for supply, they said they don’t have anything to sell […] We request them to obtain the VietGap certificate many times, but they didn’t do so” (Interviewee 16, Manager, Vegetable Cooperative).

When buyers provide some physical inputs for suppliers, the receiving party may not use the provided inputs for production purposes. Instead, resources may be diverted to other uses as one manager notes “they use 100 trays per day… we lost some of those, they don’t return enough… They use the trays to make a henhouse, use as a bin, in general they use for everything…” (Interviewee 22, Director, Cooperative). As with cash support, a supplier may utilise the inputs for production as intended but then fail to sell the enhanced product to the investing buyer.

Buyers often provide financial incentives to deliver specific volumes of a pre-specified quality. To gain these inducements, farmers may mix products from different sources in
order to meet quantity thresholds, or cheat quality control processes. For instance: “we need 100kg, but they only have 70kgs, and they...if they supply 70, they won’t meet the quantity required, if they don’t meet that, it affects to the reward we offer. So, they think - I will take that quantity from another farm – those products can be safe, can be unsafe, don’t they.” (Interviewee 16, Manager, Company).

To counter problems of supplier opportunism, buyers pursue two main strategies: to increase monitoring and offer a bundle of supplier development measures. Monitoring, via the stationing of some of buyer’s employees at the supplier’s farm can help ensure that cash and other physical inputs provided are used in accordance with intended plans. The interviewee No. 28 remarked: “the farms have contracts with us have to follow us because we monitor very carefully, also there are people think that the process provides by she is fine so we just follow”. However, monitoring is inevitably incomplete – the buyer’s employees cannot oversee every action on a farm and such monitoring costs can be significant. The second response, involves bundles of supplier development measures, so that the combined effect of the support makes the contract more valuable to the supplier and the long-term costs of breaking it more severe. In such cases, opportunistic behaviour can be rare even in markets where it is ubiquitous. As Interviewee No.22 reported “When it comes to the situations that the market price is high. If the farmer collaborates with company X, they have been working together for more than three years, they received so many benefits, and they will...listen to you. Other farmers who haven't been through difficult situations together, never receive any benefit...so benefit is on top, they are willing to sell to any buyer that offer higher prices.”

Discussion
This paper identifies a dearth of studies on the “dark side” of supplier development initiatives. The paper identifies the supplier development activities employed by buyers, and the specific forms of opportunism that may arise from each.

The identified relationships provide a detailed picture of what may go wrong in supplier development efforts. It provides a counterpoint to supply chain perspectives, which merely focus on “win – win” outcomes and the upside of supplier development initiatives. Rather than treating supplier development and opportunism as homogenous concepts, we respond to calls to identify the linkages between specific types (e.g., Zhang et al., 2017, Salimian et al., 2017, Li et al., 2017).

Transaction cost analysis theory emphasises that people will behave in the most profitable way for themselves when opportunities presented (Hawkins et al., 2008). The theory well explains the situation when supplier development initiatives stimulate supplier opportunistic behaviours. First, buyers invest in training suppliers to help them improve capabilities and skills. Consequently, it changes the relative dependence (Wang and Yang, 2013) between the two parties as suppliers become more competent. This creates a spillover effect to other buyers, who now regard the trained supplier as a more desirable supply chain partner. Hence, suppliers may receive offers to break commitments with their existing buyer(s).

The complexity of the knowledge transferred to suppliers through training leads to multiple forms of opportunism. First, training may increase compliance costs (with the trained process). Hence, suppliers may disregard what they have learnt., especially in a market that is dominated by poor standards like the fresh fruit and vegetable supply chain in Vietnam. Second, the impossibility of buyers evaluating fully what they procure leads to suppliers subverting the buyer's assessment criteria in ways that are less costly for them. Third, the offer of guaranteed sale prices offers certainty for suppliers operating in markets often characterised by high price volatility (Romsdal et al., 2011). However,
guaranteed prices will not always be in the favour of suppliers. Hence, they often only keep to a contract terms when the agreed price is favourable compared against market or spot rates.

Overall, the supplier development initiatives create openings for opportunism because the benefits to suppliers from engaging with the initiatives do not outweigh the benefits of opportunistic behaviours. This is in line with transaction cost theory (Williamson, 2008) that focuses on the self-interest seeking behaviours of relationship parties. However, bundling supplier development measures can lessen supplier opportunism. While this involves extra coordination efforts (Yan and Kull, 2015), the long-term costs of violating the relationship increase, where it leads to the supplier losing access to the bundle of measures in the future.

Conclusion
This study closes the gap in the literature relating to the relationship between supplier development and opportunism. It addresses the research question of the extent to which and in what forms may supplier development initiatives trigger opportunism. The study provides a comprehensive view of supplier development efforts as well as the linkages between the different supplier development initiatives and opportunism. The study also contributes to the literature by recognising ways in which buyers seek to address opportunism, so that supplier development initiatives can curb supplier opportunism rather than trigger it. Understanding the impacts of each supplier development initiative offers a managerial contribution, as managers can decide whether they should or should not deploy particular initiatives. The study focuses on fresh fruit and vegetable supply chains and would benefit from consideration of the generalizability of its findings to other sectors. Further research is also warranted to unpack other factors (i.e., relational norms, supplier selection) that may affect the relationships between supplier development initiatives and opportunism.

Faculty of Business Administration, Kindai University

Abstract

In the field of supply chain management, internal supply chain structure has hitherto received minimal attention. This study focuses on two dimensions of internal structure, namely formalization and centralization, and empirically examines the relationship between these structural properties and relative operational performance. Survey data were collected from 108 Japanese manufacturers. Based on structural equation modelling, the correlation between centralization of operational tasks and centralization of strategic tasks, the impacts of centralization of both operational and strategic tasks on formalization, and the effect of formalization on relative responsiveness performance were demonstrated.

Keywords: Supply chain management, Organizational structure, Centralization, Formalization, Operational performance

Introduction

In the field of supply chain management (SCM), there have been empirical studies on the main management elements including supply chain strategy, external structure, and internal and external processes. However, the organizational structure of internal SCM has hitherto received minimal attention; researchers have not sufficiently discussed the design of internal supply chain structure.

This study focuses on two dimensions of internal structure: formalization and centralization. Existing studies use either one or both of these dimensions in the fields of logistics management, operations management, and SCM. On centralization, these studies are mostly concerned with ‘the vertical distribution of decision-making’, specifically, the locus of hierarchical authority. In contrast, the authors pay attention to ‘the horizontal distribution of decision-making’, specifically, the locus of authority between an SCM department and functional departments. By adopting such a definition of centralization, the authors address the research question: how do formalization and centralization affect operational performance in the SCM context. Specifically, the authors examine whether or not it is necessary for a firm to formalize its SCM tasks and centralize the authorities of these tasks in a particular department. Based on the results, the authors discuss the roles of an SCM department.
Theoretical background

Formalization and centralization

In the field of SCM, Kim (2007) is a pioneering empirical study on internal supply chain structure. He defines formalization as ‘the degree to which decisions and working relationships for SCM activities are governed by formal rules and standard policies and procedures’ (p. 325). Similarly, he defines centralization as ‘the extent to which the power to make SCM decisions is concentrated in an organization’ (p. 325). However, these definitions do not reflect the accumulation of vast amount of research on formalization and centralization.

In the field of organizational theory, two groups initiated the research on main structural properties in the 1960s. These are ‘The Aston Group’ including Derek S. Pugh and David J. Hickson, using institutional data (e.g. Pugh et al., 1963, 1968) and ‘The Wisconsin Group’ including Michael Aiken and Jerald Hage, using perceptual data of organizational members (e.g. Aiken and Hage, 1966; Hage and Aiken, 1967). Thereafter, the research expanded not only in the field of organizational theory but also in other fields such as marketing, logistics management, operations management, and SCM. Through a literature review of the various fields listed above, the authors redefined formalization in the SCM context as the following;

- The degree to which SCM activities are clearly written;
- The degree to which SCM activities are governed by rules and procedures;
- The degree to which the discretion of SCM activities is constrained by rules and procedures; and
- The degree to which SCM activities are supervised in conforming to the standards by job codification.

Similarly, referring to the results of our literature review, the authors modify Kim’s (2007) definition as follows: ‘the degree to which the power of decision-making, evaluation, control, and responsibilities for SCM activities are concentrated in a department’.

Roles of an SCM department

Morgan Swink and his colleagues continue to report their studies on SCM organization (SCMO). They define SCMO as the formal organization, or group of organizations, that manages internal supply chain activities and processes for a firm (Swink et al., 2013).

According to Swink et al. (2010), which is an interview-based study, the functions performed by the centralized SCMO are divided into two sets: staff functions and operational functions. The former tends to be more strategic and focuses on issues such as standardization and harmonization of processes, strategic support across the supply chain, and communication efforts. On the other hand, the latter focuses on integration and consolidation efforts with respect to purchasing and logistics functions. Swink et al. (2013) use a survey to further specifically investigate these results and note that a majority of the SCMO managers reported that they maintained ‘full authority’ of transportation, distribution centres/warehousing, purchasing, sourcing, demand/supply planning, make/manufacturing, and long-range planning. All of these would correspond to the operational functions of Swink et al. (2010). On staff functions, for example, strategy/change management, a majority of the SCMO managers reported that they ‘shared authority’ with business heads or other functional managers. However, these studies remain exploratory.
Hypotheses development
In the field of SCM, little empirical evidence is available to construct hypotheses on the relationship between formalization/centralization and operational performance. The case study of IKEA by Jonsson et al. (2013) would be helpful to develop such hypotheses. They regard IKEA as a company having “a high degree of competence with SCM” (p. 346). This company centralizes the authority and responsibility of supply chain planning and demand fulfillment in one group of planners. Such a planning organization facilitates the establishment of standardized working methods. In turn, increased standardization leads to improved operational performance. Specifically, IKEA had less obsolete inventory, led to positive long-term effects on cost, and increased delivery performance. The case of IKEA, which is a leading SCM company, illustrates that high degree of centralization of operational tasks such as supply chain planning leads to high degree of formalization. In addition, this case suggests that firms with high degree of formalization achieve high levels of relative performance on both firm-centric (e.g. inventory, cost) and customer-centric (e.g. delivery performance) indicators.

Based on Swink et al. (2010), high degree of centralization of strategic tasks also results in high degree of formalization. The survey by Swink et al. (2013) reported that 80% of respondent firms had full or shared authority of both operational and strategic tasks. For example, the proportions of firms having full or shared authority are 55.9% and 39.9%, respectively, for demand/supply planning, which is an operational task, and 42.3% and 52.1%, respectively, for strategy/change management, which is a strategic task. This implies that firms with a high degree of centralization of SCM tasks tend to have a broadening span of authority including both operational and strategic tasks. However, centralization does not directly impact operational performance; it has an indirect impact on operational performance through formalization. Thus, the authors propose the following hypotheses:

H1: The higher the degree of centralization of operational tasks, the higher the degree of centralization of strategic tasks.

H2a: Centralization of operational tasks has a positive impact on formalization.

H2b: Centralization of strategic tasks has a positive impact on formalization.

H3a: Formalization has a positive impact on firm-centric relative operational performance.

H3b: Formalization has a positive impact on customer-centric relative operational performance.

H4: Centralization of either operational or strategic tasks does not have a direct impact on relative operational performance.

The above hypothesized relationships are summarized in the following conceptual model (Figure 1). In the figure, a solid line represents a significant relationship, while a dotted line represents an insignificant relationship.

![Figure 1 – Conceptual model](image-url)
Method

Data collection

Data were collected through a survey mailed to Japanese manufacturers. Specifically, the questionnaire was mailed to 2,000 manufacturers selected from the database of a credit research firm in April 2018. To reduce the time and cost of data collection, the authors used only one key respondent per manufacturer, who was a manager belonging to the SCM, production, or logistics department. These respondents were asked to answer questions on the firm’s SCM activities in their main business area. After removing incomplete responses, the total number of effective responses was 108, at a response rate of 5.4%. Non-response bias, common method variance, construct reliability and validity of latent variables, and convergent and discriminant validity were each assessed carefully. In regard to the sample demographics, almost 76% of the respondent firms have annual sales exceeding 30 billion yen (approximately US$273 million). In addition, nearly 73% of the respondent firms have more than 600 employees. These imply that three-quarters of the respondent firms are in the large-size category. A majority of the respondent firms are finished goods manufacturers rather than raw materials or components suppliers.

Measures

The hypothesized model illustrated in Figure 1 mainly comprises four constructs:

1. centralization of operational tasks;
2. centralization of strategic tasks;
3. formalization; and
4. operational performance.

Table 1 lists the observed variables. First, to measure the degree of centralization, this study focused on cross-functional tasks that were difficult to assign to specific functional department such as logistics, production, purchasing, and sales/marketing. On the basis of the literature review, the authors’ previous study (Nakano and Matsuyama, 2016), and the pre-test of the survey instrument, the following six tasks were recognized as typical cross-functional tasks: demand forecasting, demand-supply matching, inventory control, sales and operations planning (S&OP), performance management (key performance indicators (KPIs) definition; goal setting, evaluation, and control), and planning and steering of SCM reforms. Of these, demand forecasting, demand-supply matching, inventory control, and S&OP are operational tasks (C1-C4 in Table 1). On the other hand, performance management and planning and steering of SCM reforms are strategic tasks (C5-C8 in Table 1). These were designed using a five point Likert scale between 1 = ‘strongly disagree’ and 5 = ‘strongly agree’.

Second, based on our redefinition of formalization, the observed variables of the above operational tasks (demand forecasting, demand-supply matching, inventory control, and S&OP; F1-F4 in Table 1) and strategic tasks (defining KPIs; F5-F6 in Table 1) were used. These were also measured on a five point Likert scale ranging from 1 = ‘strongly disagree’ to 5 = ‘strongly agree’.

Third, operational performance was measured using typical indicators that were often employed in prior empirical studies on SCM (Nakano and Akikawa, 2014). Specifically, unit logistics cost, finished goods inventory turnover period, on-time delivery, order fill rate, and delivery lead time were adopted. The first two indicators are related to efficiency (OP1-OP2 in Table 1), while the remaining three indicators are concerned with responsiveness (OP3-OP5 in Table 1). For these items, respondents were asked to indicate their perceptions based on a five point Likert scale ranging from 1 = ‘much worse than
competitors’ to 5 = ‘much better than competitors’. As such, these indicators represent relative performance.

Measure assessment

The authors assessed reliability and validity of latent variables following the guidelines outlined by Anderson and Gerbing (1988). First, the authors conducted an exploratory factor analysis for each construct (Table 2). On centralization, the authors found two factors with eigenvalues greater than 1.0; these were named ‘centralization of operational tasks’ and ‘centralization of strategic tasks’, respectively. Regarding formalization, the authors found one factor with an eigenvalue greater than 1.0. Concerning operational performance, the authors found one factor with an eigenvalue greater than 1.0. The factor was named ‘responsiveness performance’ because the observed variables with factor loadings greater than 0.5 were performance indicators of responsiveness, such as on-time delivery, order fill rate, and delivery lead time. In addition, the authors calculated Cronbach’s alpha and composite reliability, conducted a confirmatory factor analysis (Table 2), and assessed average variance extracted for all constructs (Table 3). These results provided evidence of construct reliability and convergent and discriminant validity.

**Results of hypotheses tests**

The conceptual model shown in Figure 1 was tested using structural equation modelling (SEM) via IBM SPSS AMOS 25. First, the model without the direct effects of centralization on operational performance was tested. Responsiveness performance, which consists of on-time delivery, order fill rate, and delivery lead time, is used as a customer-centric operational performance indicator in Figure 1. Firm-centric operational performance in Figure 1 is divided into unit logistics cost and finished goods inventory turnover period. Figure 2 displays the result. The results of multiple fit indices provide evidence of the overall validity of the hypothesized model.

Specifically, solid lines represent statistically significant paths (p<0.05), while dotted lines represent paths that are not significant. Based on the significant path coefficients, H1, H2a, H2b, and H3b are supported. Centralization of operational and strategic tasks are inter-correlated (H1). Both centralization of operational tasks and centralization of strategic tasks are positively related to formalization (H2a and H2b, respectively). Formalization is positively related to customer-centric relative operational performance.
(observed variables: on-time delivery, order fill rate, and delivery lead time; H3b). Regarding H3a, formalization does not have a significant impact on firm-centric relative operational performance in terms of either unit logistics cost or finished goods inventory turnover period. Hence, H3a is not supported.

Second, the model including the direct effects of centralization on operational performance was tested. As shown in Figure 3, the results of the same alternative indices prove the overall validity of the hypothesized model. Regarding H4, both centralization of operational tasks and strategic tasks do not have a direct impact on any of the relative operational performance indicators. Hence, H4 is supported. Other path coefficients show the same tendency as Figure 2.

Discussion
The support for H1 suggests that there is a positive relationship between centralization of operational tasks and centralization of strategic tasks. This result confirms the exploratory findings of Swink et al. (2013). Specifically, Japanese manufacturers with high degree of centralization of SCM tasks tend to have a broadening span of authorities including both operational and strategic tasks.

H2a and H2b are supported, which suggests that centralization of operational tasks and strategic tasks, both exert positive influences on formalization. The former is consistent with Jonsson et al.’s (2013) case study of IKEA. Specifically, centralizing forecasting and planning tasks in a particular department facilitates the establishment of formalized working methods in Japanese manufacturers. Similarly, the latter is identical to Swink et al.’s (2010) interview-based study whereby Japanese manufacturers centralizing strategic and change management tasks in a particular department increase formalization of SCM tasks.

The support for H3b statistically generalizes a part of the results of Jonsson et al. (2013). This result implies that formalization leads to competitive advantages in customer-centric operational performance for Japanese manufacturers. However, such a relationship does not apply to firm-centric relative operational performance because H3a is not supported. This suggests that many Japanese manufacturers have not realized better logistics costs and/or finished goods inventory levels than their competitors by formalizing SCM tasks. One possible explanation is that Japanese manufacturers tend to undertake higher logistics costs and/or finished goods inventory levels so as to prioritize achieving relatively better responsiveness performance for customers.

The support for H4 also statistically generalizes Jonsson et al.’s (2013) case study. Specifically, centralization of SCM tasks does not directly lead to competitive advantage in terms of operational performance. Formalization mediates the relationship between centralization and relative operational performance.

Consequently, centralization has an indirect impact on relative operational performance through formalization. Hence, it is necessary but insufficient for a manufacturer to centralize the authorities of its SCM tasks in a particular department in order to achieve better operational performance than its competitors. Formalizing SCM tasks, such as demand forecasting, demand-supply matching, inventory controls, sales and operations planning, and defining key performance indicators directly leads to competitive advantages in operational performance. Therefore, the authors insist that one of the important roles of an SCM department is to formalize its SCM tasks. However, operational excellence by formalization among Japanese manufacturers is valid only for responsiveness performance. Future research is needed on internal supply chain structure that can realize the competitive advantages of both efficiency and responsiveness.

Implications and future research
Using survey data of Japanese manufacturers, this study empirically examined the impact of structural properties in internal supply chain on relative operational performance. Specifically, this study focused on two structural properties, formalization and centralization, and classified relative operational performance into firm-centric efficiency and customer-centric responsiveness. The results reveal the correlation between centralization of operational tasks and centralization of strategic tasks, the impacts of centralization of both operational and strategic tasks on formalization, and the effect of formalization on relative responsiveness performance. It is necessary to note that these
results are limited to the main business area of a manufacturer. Nonetheless, this study has important implications for both researchers and practitioners in the SCM field.

For researchers, this study proposes the measures of formalization and centralization in the SCM context. These measures were developed on the basis of literature review not only in the field of organizational theory but also in other fields such as marketing, logistics management, operations management, and SCM. Accordingly, Kim’s (2007) definition of these structural properties were redefined. In addition, as far as the authors are aware, this is the first study that has statistically examined the impacts of these structural properties on both firm-centric and customer-centric relative operational performance. As mentioned in the introduction, there are few comprehensive studies on SCM organization. Swink et al. (2010) propose the roles of a centralized SCM department, while Swink et al. (2013) investigate the functional span of authority of an SCM department. However, these are exploratory rather than confirmatory studies. By conducting the statistical analyses of survey data, this study substantiates that Japanese manufacturers with a centralized SCM department in charge of both operational and strategic tasks can formalize their SCM activities and, as a result, achieve better responsiveness than their competitors.

With regard to the implications for practitioners, as much as possible, manufacturers need to formalize a wide range of SCM tasks to realize the operational excellence of their SCM activities. Specifically, they are required to standardize the procedures of demand forecasting, demand-supply matching, and S&OP process; control inventory using standard inventory quantity; and define both efficiency- and responsiveness-related KPIs for SCM activities. In other words, these procedures and performance management should not be individual-dependent. In order to establish such formalized working methods, it is effective to centralize the authorities of both operational and strategic tasks in a particular department. Swink et al. (2010) mention that creating a functionally integrated organization is a means of managing the various sources of uncertainties related to changing conditions, for example, rapidly changing customer and supply markets, short product lifecycles, short economic business cycles, aggressive competitors, and rapidly changing process technologies. Hence, manufacturers in such dynamic business environments have an increased need for more centralized SCM department.

This study has the following limitations and opportunities for future research. First, the impacts of the structural properties in internal supply chain on relative operational performance may differ depending on specific business contexts. Utilizing multi-group analysis, the authors need to empirically assess possible contingency effects including the above dynamic business factors. Second, this study does not identify an internal supply chain structure that has significant impacts on the competitive advantage of not only responsiveness but also efficiency. More in-depth investigations including case studies would be useful to explore such a structure. Finally, limiting the research setting to Japanese manufacturers is definitely insufficient for generalizing the findings of this study to other regions. By conducting additional analyses using data from different cultural settings, we can discuss the similarities and differences between countries.

Abstract

The purpose of this paper is to empirically analyze the relationships of the Triple-A supply chain (SC) and competitive advantage (CA) in emerging versus developed countries. Consistent Partial Least Squares (PLSc) is applied on an international multiple informant sample of 220 manufacturing plants in developed and emerging countries. The results confirm the positive significant relationship between Triple-A SC and CA, with no significant differences between emerging and developed countries. The present study brings new evidence to the literature on the Triple-A SC and their relationship with CA in different contexts.

Keywords: Agility, Adaptability, Alignment, Triple A

Introduction

Lee (2004) states that only Triple-A (agility, adaptability and alignment) supply chains (SCs) can lead to a sustainable competitive advantage (CA). No empirical research was developed by Lee (2004) and only limited empirical research has analyzed the relationships between the Triple-A SC and performance (Whitten et al., 2012; Attia, 2015) or CA (Alfalla-Luque et al., 2018). These studies conclude that a positive relationship exists but also coincide in stating that further research needs to be done. Whitten et al. (2012) and Attia (2015)’ works have limitations, which have been mentioned by the authors: focus on a single country (Egypt and USA, respectively), data are taken from single respondents, and the scale is exclusively taken from Lee’s (2004) theoretical reasoning, with no analysis of the previous literature. Besides, Attia’s research is done on a single sector (textile).

In order to contribute to theory building on this important SCM topic, this study seeks to overcome the mentioned limitations of previous empirical research and to analyze in greater depth Lee’s statement (Lee, 2004) that “only supply chains that are agile, adaptable, and aligned provide companies with sustainable competitive advantage”. Previous research has still not considered any contextual factors, even
though they may influence the impact on performance (Flynn et al. 2010). Following Contingency Theory (Lawrence & Lorsch, 1967), contextual variables could have an influence on the level of achievement of business practices. The influence of the country or region as a possible important contextual factor has been analyzed in operations management and SC management research (e.g., Katiyar et al., 2018, Miras-Rodríguez et al., 2018). Due to the important role played by emerging countries in global SCs, one crucial point is the growing need to improve SC performance in these economies. However, in spite of this importance, only one of the three mentioned previous works (Attia, 2015) analyzes the Triple-A - SC performance relationship in emerging countries, but in a very limited way (only one country (Egypt) and one industry (the textile sector)). The other two articles focus their analysis on developed countries (Whitten et al., 2012; Alfalla-Luque et al., 2018).

Therefore, the aim of the present research is to fill this gap by using a wider sample of emerging countries to analyze: (1) whether the positive relationship between Triple-A SC and CA exists in different country contexts (emerging vs. developed countries); (2) whether for the achievement of CA there is a difference in the weights of the components of the three Triple-A SC variables between emerging and developed countries.

This paper is structured as follows. Section 2 analyzes earlier studies and establishes the hypotheses to be tested. Section 3 describes the sample and the methodology, followed by data analysis and the results in Section 4. Finally, the main conclusions, contributions, implications for practitioners and academics, limitations and future research are presented.

**Previous research and hypotheses**

Scarce research has considered a Triple-A SC construct formed of the three dimensions (Attia, 2015; Whitten et al., 2012; Alfalla-Luque et al., 2018; Marin-Garcia et al., 2018). Previous research shows a positive influence of Triple-A SC on performance or in CA. In this regard, Whitten et al. (2012), based on a survey to 132 APICS members (USA), conclude that a Triple-A SC-based strategy is positively related to SC performance and that the SC performance - financial performance relationship is mediated through marketing performance.

For his part, Attia (2015) uses data from 153 companies in the Egyptian textile industry. He analyzes the relationships between Triple-A SC and marketing strategy alignment with SC performance (output performance; resource performance; flexibility performance) and organizational performance (operational performance, strategic performance)). His results show that Triple-A SC and marketing strategy alignment are positively related to SC performance and that SC performance is positively related to organizational performance. He compares his results to those of Whitten et al. (2012) and, regarding the relationship between Triple-A SC and, marketing strategy alignment with organizational performance, concludes that the results are similar. In both studies, the need is recognized to test this relationship in different samples and countries.

Finally, Alfalla-Luque et al. (2018) overcome some of the limitations of the previous works by using a wider database from 151 manufacturing plants (with over 100 employees) in three industries (automotive components, electronics and machinery) in 8 developed countries. These authors analyze the Triple-A SC and its relationship with CA (cost, quality, delivery, flexibility, and financial proxy). They found that this relationship is positive and significant for all the CA measures except quality. The strongest relationships are found with financial CA and delivery CA.
The above literature review shows that the analysis of the Triple-A - CA for different contextual situations (e.g., developing vs. emerging countries) is still missing in spite of its importance for facilitating appropriate global SC design. The case by Attia (2015) with only a country (Egypt) is clearly insufficient, as the author recognizes. And a comparison of the results of his work with those found by Whitten et al. (2012) (again only one country, USA) is neither sufficient nor appropriate for drawing robust conclusions on the matter. Consequently, the present research seeks to contribute to the literature on this topic by filling this gap through an analysis of the Triple-A SC - CA relationship in a wide sample of emerging and developed countries. Therefore, the first hypothesis has been formulated as follows:

**H1. There is a positive relationship between Triple-A SC and CA in different country contexts (emerging vs. developed countries).**

To dig deeper into possible improvements to SC design, a further step forward in the contribution to the topic under study might be to analyze whether the Triple-A SC components (SC agility, SC adaptability and SC alignment) act (or not) with different weights in the relationship between Triple-A SC and performance/CA depending on the country context. This could be considered a key element for SC design in global contexts. Unfortunately, very scarce research has been found on this topic.

Although there is no full consensus, the majority of studies (e.g., Whitten et al. 2012; Attia, 2015) seem to show that no differences in the weights of the Triple-A SC components can be confirmed. Therefore, taking into account the previous literature, and in order to contribute to the scarce research on the topic, this work will analyze whether there are any differences in the weights of the three Triple-A SC variables for the achievement of CA. We analyze results for the total sample and also identify whether there are any differences in the way that weights are distributed in plants in emerging and developed countries. The second research hypothesis is therefore established as follows:

**H2. There are no differences in the weights of the components of the Triple-A SC variables (agility, adaptability, and alignment).**

**Methodology**

The empirical analysis uses part of the current database of the fourth round of the international High Performance Manufacturing Project, HPM (data collection completed in 2016), obtained from 220 manufacturing plants (with over 100 employees) in three industries (automotive components, electronics and machinery) in 9 developed countries (Austria, Finland, Germany, Italy, Japan, Spain, Sweden, UK, USA) and six emerging countries (Brazil, China, Israel, South Korea, Taiwan, Vietnam). HPM fourth round questionnaires were developed and updated from the HPM international project (Flynn et al., 1995; Sakakibara et al., 1997; Ahmad and Schroeder, 2002; Cua et al., 2002; Marín et al., 2018), where survey questions were based on a wide-ranging review of the Operations Management literature.

Items for SC agility (SC-Ag), SC adaptability (SC-Ad), and SC alignment (SC-Al) were measured on a 1-7 Likert scale (Marín-García et al., 2018). Informants were asked to indicate their degree of agreement (1—strongly disagree, 4—neither agree nor disagree, 7—strongly agree). As the present study focuses on the specific CA of the operations area, only operational measures were targeted and grouped in four dimensions (cost CA, quality CA, delivery CA and flexibility CA). CA items were measured on a 1-5 Likert scale with informants asked to give their perceptions of their company’s past performance compared to their competitors’ (1—poor, 3—average, 5—much better).
The SC agility, SC adaptability, and SC alignment constructs were operationalized as a composite (Mode B aggregate multidimensional construct) (Hair et al., 2017) with each based on three dimensions; these were the first-order composites calculated from the measures taken from the questionnaires (Marin-Garcia et al., 2018).

CA was modelled as an aggregate multidimensional construct (composite Mode B) formed of four first-order common factors (Cost CA, Quality CA, Delivery CA and Flexibility CA). The CA first-order scales (Mode A) were designed and validated by other authors (Konecny and Thun, 2011; Alfalla-Luque et al., 2012 and 2015). Authors’ operationalizations were strictly followed and each dimension’s indicators chosen so as to be inter-correlated.

As the model contained higher order constructs (HOC), a two-stage approach was used (Hair et al., 2018; Marin-Garcia, 2018). Consistent Partial Least Squares (PLSc) was chosen to estimate the model in the first stage as it is a better proxy when common factors are included in the same model as composites (Sarstedt et al., 2016; Becker et al., 2013; Henseler et al., 2016; Rigdon, 2012 and 2016). PLS was used to analyze the second stage, as all the HOC used were modeled as Mode B composites (regression weights). SmartPLS v3.2.8 was used to analyze the model (Ringle, 2015). Finally, GPower (Faul et al., 2007) was used to test whether the sample size guaranteed a power>= 0.80 for power analysis (Hair et al. 2019; Marin-Garcia et al., 2019).

Results
The full sample used is sufficient to achieve a power above the bottom threshold of 0.8 (0.99 or above in all the dependent constructs in the first stage).

The measurement model meets all the validation criteria specified in the methodology section. However, in stage 1 there are two Triple A-SC composite indicators that are not significant. As their loadings are above 0.5, they have not been omitted from the model. In stage 2 (Figure 1), some weights are not significant (Cost CA, Delivery CA and Quality CA for CA composite; and SC Alignment for Triple-A SC composite), but their loadings clearly exceed 0.5, so no modifications are required to the measurement model.

All lower-order constructs (stage 1) and higher-order constructs (stage 2: see Table 1) present both configural (MICOM step 1) and compositional invariance (MICOM step 2). This is referred to as partial measurement invariance and is the required condition for group-specific comparisons with multigroup analysis. It is, therefore, confirmed that all the measurement model subscales are absolute equivalents in the developed and emerging country samples. This enables conclusions to be drawn as to whether differences in the two samples’ LVs mean and variance values are significant.

Bootstrapping based on n = 5000 subsamples. Multi-group test based on 5000 permutations. Significance at 5% level. Two-tailed test for group comparisons.
In MICOM step 3, stage 1 model, developed country companies present significantly lower mean values in cost CA, use of technology (SC-Ad2), medium- and long-term market knowledge (SC-Ad3), short-term sensitivity to market (SC.Ag1) and incentive alignment (SC-Al1). Similarly, there are no significant differences in most of the constructs’ latent variable score variances, but they are lower in developed country companies than in emerging country companies for flexibility and quality CA. In general, there is a lower dispersion of the developed countries’ values than the emerging countries.

When repeating MICOM analysis step 3 for stage2, there are significant differences between the means of the Triple-A SC latent variable scores for the emerging and developed countries (Table 2). Similarly, plant variances are significantly smaller for CA in the developed countries sample than in the emerging countries sample. Despite these differences in the descriptive statistics, as already commented, there are no significant differences between emerging and developed countries regarding Triple-A component and CA weights. Also, as will be commented below, no significant differences have been noted between the paths of the emerging and developed plants in the analysis of the structural model. Therefore, from here on, only the results for the total sample will be reported.

Bootstrapping based on n = 5000 subsamples. Multi-group test based on 5000 permutations. Significance at 5% level. Two-tailed test for group comparisons.

As the measurement model is adequate, the structural model results can be interpreted to test the research hypotheses. It was previously confirmed that there were no collinearity issues in the structural model (Figure 1) and that the model has an adequate fit. H1 has been confirmed. The in-sample explanatory power of the Triple-A SC (R2adj = 0.217) is weak but significant. The standardized path value (0.469) can be considered to be relevant and in line with the results obtained by previous research for the relationship between these constructs (e.g., Attia, 2015). Thus, a positive relationship has been confirmed between Triple-A SC and CA for the full sample and for the emerging and developed country groups (although the relationship is more intense in emerging countries—path=0.525—than in developed countries—path=0.411—the difference is not significant). Regarding H2, SC adaptability and agility are seen to have the greatest strength in the construction of the Triple-A SC. This has been confirmed for the full sample weights of adaptability and agility, which are significant and greater than the weight of alignment. Consequently, H2 has not been supported, as no difference in the weights of the components of the Triple-A SC variables has been found.
The importance-performance map analysis (IPMA) extends the results and enables managerial actions to be prioritized (Figure 2). As no significant differences were found for the full sample and for the emerging and developed country groups in the previous analysis of the Triple-A SC and CA relationship, the IPMA analysis will only be conducted for the full sample. The results show that practically all the Triple-A SC variables have a similar degree of development (values between 70 and 74) (see performance in Figure 2), around two-thirds of the scale. Despite these values being relatively high, they have not reached the maximum, so plants in the sample have a certain margin left for further development of all three variables. The relative importance of the various variables for CA dictates what should in principle be the order of deployment to follow.

**Discussion and conclusions**

The results of this research confirm Lee’s (2004) proposal and build on the previous literature by showing that the positive relationship between Triple-A SC and CA exists in different country development contexts. These conclusions are in line with the previous research on the relationship between Triple-A SC and performance/CA in developed (Whitten et al., 2012; Alfalla-Luque et al., 2018) and emerging countries (Attia, 2015). After comparing his results in Egypt with the results of Whitten et al. (2012) in the USA, Attia (2015), wrote: “it can be said that the effect of Triple-A SC on the SC performance is the same for both the developed and developing countries”. In
our opinion, for this statement to be established would need more than two single countries. This is overcome by the present research, the results of which confirm this affirmation using a broad international and multi-informant sample of 9 developed and 6 emerging countries. This has been considered an important issue in the (scarce) previous research, which has called for new analyses of different samples and countries to obtain stronger empirical evidence of Lee’s statement.

In relation to the impact of each of the Triple-A SC variable on the Triple-A SC construct and CA, SC adaptability and agility are seen to have the greatest strength in the relationship between the Triple-A SC and CA for the full sample. Therefore, these results indicate that special attention should be devoted to these variables when seeking to build a Triple-A SC. However, caution should be shown in relation to this assessment, as the limited research on this topic does not offer conclusive results. As such, the present results are not in line with those obtained by Whitten et al. (2012) for developed countries and Attia (2015 and 2016) for emerging countries, which show similar weights for SC agility, SC adaptability and SC alignment in their relationships with performance. However, the results of this research are in line with studies in emerging (Dubey et al., 2015) and developed countries (Alfalla-Luque et al., 2018), which show differences in the weights of each Triple-A SC variable on performance/CA. However, the fit is not full, as the weight of each variable differs in these studies. For example, Dubey et al. (2015) find SC alignment strongly related to performance, with SC agility also significant but less strong, and SC adaptability not significantly related to human performance. Alfalla-Luque et al. (2018) conclude that SC adaptability and SC alignment present a significant contribution to the Triple-A SC construct but that SC agility makes no significant contribution (perhaps due to the sample size). Nevertheless, the authors conclude that major differences in the contributions of the Triple-A SC variables cannot be confirmed. The differences between the results of this research and those of Alfalla et al. (2018) should not be seen as surprising. The Alfalla et al. (2018) study includes financial CA as one of the variables in the structural model. This construct reflects a distal outcome, in contrast to the other CA dimensions which should be understood as an intermediate Triple-A SC result when operational CA is focused on and a possible mediator of financial CA. We believe that the inclusion of financial CA distorts the weights of the Triple-A SC components, which were being adapted to optimize the explanation of the two sets of variables with which they have different links. In fact, the best explained construct in that model was, precisely, financial CA. So, the Alfalla et al. (2018) results were skewed towards the Triple-A SC relationship with financial CA and masked the real relationship with the operational CA dimensions, which is the focus of the research presented in this paper. Therefore, it seems clear that further research is needed into the weights of agility, adaptability, and alignment in the Triple-A SC to obtain CA.

The above has major managerial implications. First, new evidence for both emerging and developed countries has re-confirmed the hypothesis that the Triple-A SC is significantly and positively related to CA. Consequently, SC managers involved in the design and development of global SCs in developed and/or emerging countries should have a strategy that recognizes that SC agility, adaptability, and alignment need to be achieved to obtain a CA. This implies coordinating a set of decisions in the long, medium and short term in order to obtain a Triple-A SC. This should be done under a perspective of continuous improvement that takes into account, on the one hand, current accomplishments in the levels of deployment of each of the Triple-A variables and of the CA and, on the other hand, the established targets for the plant in relation to the competitive situation. In this line, the IPMA results offer useful information to be
considered. In the present case, at the full sample aggregate level, the three As were observed to be at a very similar CA deployment level, but their importance for achieving a CA is different. The obtained information (at the aggregate level) for the plants in the sample shows the first step should be to raise the deployment level of adaptability, which is the most important A for achieving the CA. This should be followed by agility, and lastly by alignment. Nevertheless, specific decisions will depend on the actual circumstances of each plant such as, for example, the available resources required for execution and the real deployment level of each of the variables, which can be different from the mean sample value.

For researchers, there is new empirical proof regarding the Triple-A SC and its relationship with CA. These results are a contribution to theory in the sense that they could be considered a clear step forward in the topic since, as has been indicated, the present study overcomes the limitations of some previous studies of the Triple-A SC (Whitten et al., 2012; Attia, 2015; Alfalla-Luque et al., 2018) and provides new evidence on the topic.

This study is not without its limitations, which can be a source for further research. First, the data refer to three specific industries (electronics, machinery, and automotive components). The results should, therefore, be analyzed in this context and cannot be extrapolated to other sectors. Second, the results have been obtained for a sample of emerging and developed countries and so their extrapolation to other countries may not be possible. As the proposed model is hypothesis-based and needs to be confirmed with other samples, it would be interesting to undertake future analyses to dig deeper into the topic by considering countries and production sectors with different contexts. Finally, a further limitation is shared with the majority of studies undertaken in the area: the cross-sectional analysis used does not give the opportunity to observe change and reactions to change in practice. Therefore, it has not been possible to test the effects of the Triple-A SC on obtaining a “sustainable CA”, as new data are necessary to allow a longitudinal study to be undertaken. Due to the mentioned lack of data to analyze the CA’s sustainability component, the current research focuses on the effects of the Triple-A SC on CA as, in any case, it is necessary to first have a CA before it can be maintained in a sustainable position in the future. A longitudinal study would allow the way that the variables evolve to be studied and so enable the evolution of the levels of the variables and the impact on CA to be analyzed. This would determine whether it is indeed Triple-A SC firms that are attaining sustainable CAs, as stated by Lee (2004). It is to be hoped that the database of the next round of the HPM project will make this further research possible.

Abstract

Supply chain (SC) mapping is a stream of research as well as a managerial activity. It is also important in SCM teaching. Despite this importance, very little empirical research has addressed SC mapping and SC maps. Based on a qualitative case study in an industrial company, this paper gives evidence of the discrepancies between how managers define the outbound SC, the SC map they draw and what they say when mapping. It supports the underlying hypothesis about how individual mental representation of SC influences SC mapping. It opens avenues for further research about how using mapping and maps in SCM.

Keywords: Supply Chain Mapping, Outbound supply chain, Case study

Introduction

Since the 1990s, supply chain mapping has been a common practice and an important research topic (e.g. Lambert et al., 1998; Gardner and Cooper, 2003). Many different pictures of supply chains (SC) are made by companies, teachers and consulting firms. However, few studies question the role of these “pictures”, their use in companies and their usefulness for people involved in SC operations or management, as well as their influence on SCM concepts and practice. In line with Carter et al. (2015) or Fabbe-Costes (2017), we advocate that they are not neutral and could play a key role in SCM.

A supply chain map, like a geographical map, is supposed to represent the “territory”. Since no map can represent everything, people who map make choices, and, in particular when there is no mapping convention (Gardner and Cooper, 2003), often adopt personal representation codes, both of which reflect biases. Moreover, since a map is a “model”, it is “projective” (Le Moigne, 1990). Supply chain maps thus might reflect the viewpoint of the people drawing them, as well as their project or expectations related to SCM. Supply chain maps might also be influenced by people’s history, discipline, culture, experience of the territory, etc. They might also reflect the purpose of the mapping, being a sense-making activity (Henneberg et al., 2006)…
