The machines are located inside a metal shed. Guidelines on usage and safety issues are provided by GreenAd and the Global Alliance on Health and Pollution, and are printed out on the wall of the shed. Safety guidelines include recommendations for wearing proper PPE, conducting regular maintenance, and safety measures prior, during and after the operation. Basic machine use guidelines include written information and figures to demonstrate the wire stripping process. These machines deliver long pieces of metal wires separated from the plastic. In front of the machines, it was possible to observe the remaining plastic from this process, which seemed to be there for long.

In 2016, another type of machine was installed due to the need for processing thinner cables (Pure Earth, 2016). This machine is a granulator/separator and chops the cables to separate the metals from the plastic. Therefore, it delivers the metals and plastic with a different shape than the automated machines for large cables.

The challenges regarding the change in operations
During all the on-site visits, I did not observe that any of the wire stripping machines were being used. Instead, the burning of cables was the common practice observed. The machines are located in a fenced area and access is only possible through the person that has the key.

In the specific case of the automated machine for thin cables, the difference in the shape of the material is one of the reasons for its lack of use. Workers pointed out about their mistrust in the amount of material delivered by this machine, which was also highlighted by GreenAd:

“They're used to burning the cables, getting it in one bowl and with the really small cables, you can't strip it […]. They want the good old way that they see it bent up and tied up into knots, which is not possible […] and they don't want it that way, they still want to see it together as one piece. If for the really big cables, then the equipment is good to get it in one long strip, […] but nobody has any equipment that can strip small cables to get it in strands […]. A lot of the boys there are not so educated. The way they see things, that's how they always want to see things. They feel when the machine chops it down and they get it in small pieces, that someone is stealing some.”

Besides the above-mentioned challenges related to the use of the machine for thin cables, there are challenges regarding the resistance to using the machines for large cables as well. Two aspects were highlighted: cost and time. On the first, workers need to pay for the electricity consumed when using any of the machines, while there is no financial cost directly involved when burning. Some workers stated that they were aware of the fact that the burning leads to health consequences. Nevertheless, making the highest possible income on a day-to-day basis was pointed out to be the most important to them in order to maintain their livelihoods.

Concerning the other aspect, workers argued that it is time-consuming to perform the wire stripping process: the machines demand either that each large cable is stripped per time, or that small amounts of thin cables are chopped per time. On the contrary, workers can gather a large number of cables and burn them at once, which is considerably faster. So far, the burning activity continues to be the most appealing to them.

Discussion
In this section, I connect the main findings on the process of wire stripping in Agbogbloshie with the TOC. I focus here on the first two focusing steps proposed by Goldratt (1990): to identify the system’s constraints, and to decide how to exploit them.

As presented in the TOC section, the first step when searching for systemic improvements is to define the purpose of the system, and the factors used to access the...
impact of decisions. The discussion that follows considers that the main purpose of an e-waste management system should be to aim for sustainability. For this reason, the factors used to access the impact of decisions are the main pillars of sustainability; namely social, financial and environmental sustainability (Carter and Rogers, 2008).

From the description of the cable burning, several environmental and social challenges have been presented, including very poor working conditions, and the exposure to toxic gases and other dangerous species. From an environmental and social perspective, the wire stripping machines appear to be the most suited solution to achieve the system’s purpose. As the first focusing step, I focus on identifying the constraints related to using the automated machines.

My investigations in Agbogbloshie have shown that the workers would rather burn the cables instead of using the provided machines. The conversations and interviews with the workers and with GreenAd provided insights into reasons that explain why the machines are not being used to their maximum capacity. These were:

1. The cost of electricity involved to operate the machines,
2. The long-time demanded to strip the cables, and
3. The lack of trust in the amount of copper delivered by the machines.

From the several types of constraints presented in the TOC, the ones identified in the case of the wire stripping machines are all managerial-policy related. The first two reasons identified are related to a financial constraint in the system. Regarding the first, workers are required to pay for the electricity when using the machines, while there is no direct financial cost involved in the cable burning process. Even though it may seem insignificant for some, such amount on a day-to-day basis makes a substantial difference for the ones living with extremely low income. Another crucial factor is that the machines require more time to perform the task of extracting the metals, compared to the burning. This is a financial constraint since workers retrieve fewer metals per time when using the machines than if burning the cables, which has a direct impact on their income.

The lack of trust in the amount of copper delivered by the machines is a policy constraint; this latter considered as the most pressing in this system. The lack of trust was pointed out both by GreenAd and by workers in Agbogbloshie. On this, some aspects deserve highlight: the first one is culture. A well-known cultural pattern is an intrinsic resistance to changes imposed from the outside. When changing the operation toward the use of the machines, the outcome for the workers was unknown to some extent. Another important aspect to highlight here, connected to the previous, is the level of education, which was low among workers processing e-waste in Agbogbloshie. It may seem clear that the input of metals in the form of wires and cables to the machines delivers the same amount of metals in its output. Nevertheless, if the basic functioning of the machine is not understood, misconceptions tend to appear.

Finally, there is a market constraint. According to Schragenheim and Dettmer (2000, p. 261), “market demand is always a constraint – usually to future profitability, sometimes to current profitability”. In the setting of burning cables, the process delivers only the metals, while the setting of using the machines would yield both the metals and the plastic. However, since the market prices for plastic are insignificant compared to the metals, this additional yield is not considered profitable enough in order to make a difference in perception.

Next, I address the second focusing step: to exploit the constraints. For this, I suggest different options for further exploration, all focused on strengthening the machines’ use. To tackle the financial constraint, for instance, an option would be to either improve or optimise the performance of the current machines towards faster processing. Another
would be to adapt them to strip several wires and cables at once. Such options would make the process more efficient, thus addressing the time concerns.

In order to address financial and market constraints combined, the electricity consumed by the machines could be offered free of charge for the workers performing the activity. In exchange, workers would have to forward the plastic removed from the cables to designated recycling companies. This could strengthen the use of the machines and, at the same time, it would ensure that the retrieved plastics were collected and handed at a designated destination.

Concerning policy, the reinforcement of regulations for the non-burning is an aspect that deserves consideration. In conjunction, it is important to address the aspects of culture and level of education. For this, education campaigns are required that aim to explain the functioning of the machines, as well as the health benefits of their use.

This study presents some limitations. First, it is important to make clear that the above discussion is based on data collected through a period of two weeks in Ghana. Even though I visited the Agbogbloshie site several times and, furthermore, collected data from different workers on the site, this considerably short time framework is a limitation. Further data collection would be complementary to this study (e.g. surveys with the workers on the site, and ethnographic research). In addition, the TOC has its own limitations: the most important one for this study being that the improvements are sought among identified constraints only.

**Concluding remarks**

The wire stripping machines implemented in Agbogbloshie have the potential to significantly influence several spheres, in particular, the social and environmental ones. The machines enable the processing of cables without the emission of toxic gases from the burning process, which is responsible for substantial pollution of air, soil, and water in the area. Consequently, this leads to an improvement in the health status of workers processing cables.

Evidence of the machines’ use has been found on the site, such as some plastics resulting from the wire stripping process. However, I did not observe any of the machines being used during my investigations in Agbogbloshie. Instead, the burning of cables persisted, which demonstrates the opportunity for improvements. Particularly, to strengthen the machines’ use.

In this paper, I have used the TOC to identify and investigate the constraints hindering the operational change from the burning process to the wire stripping. The main reasons identified have no connection with any physical constraint. Instead, they are all managerial-policy related: financial, policy and market have been identified as the system’s constraints.

The application of the TOC to the case has enabled to consider the challenges of operational change from a systemic perspective. By looking at the e-waste management system in Ghana, cable processing was identified as one of the most challenging towards sustainable processes. The TOC has enabled to focus on the cable processing while perceiving this as part of a larger system.

The implementation of the machines in Agbogbloshie, although a sustainability-driven example, lacked a systemic perspective. It focused on the need for improvement as an individual process, contrary to the concepts of the TOC. Particularly, it did not focus on one of the most important elements in such operational change: the agents performing the operation. On this regard, it is essential to account for the workers’ reality and needs when aiming for more sustainable processes and systems.
Acknowledgements
I would like to thank Prof. Dr. Martin Oteng-Ababio, Louis Kusi Frimpong, and Alexander Buertey of the University of Ghana, for their support in my data collection. For sharing time and knowledge, I thank Dr. Maja van der Velden and Dr. Hanne Cecilie Geirbo of the University of Oslo. Finally, gratitude is due to the workers in Agbogbloshie and the organizations that participated in this research.

Abstract

This paper aims to elicit the understanding of improvement project success by researching the effects of organizational motivation and central coordination in continuous improvement (CI) implementations. The data analysed using structural equation modelling (SEM) comes from a sample of 387 respondents which are responsible for improvement project execution in the financial services sector. This research shows that a strong organizational motivation drives the embeddedness of improvement methodology in, and alignment to the CI implementation of, the organization and thereby affects project success. Next to that, central coordination is found to affect the alignment of the organization to CI implementation activities.

Keywords: Continuous improvement, Organizational motivation, Organizational coordination

Introduction

The organizational ability to continuously improve and optimize processes and products is commonly developed by the implementation of improvement methodologies such as Lean, Six Sigma and Lean Six Sigma. Despite the reported successes of such implementations there has also been criticism and these mixed results provide the motivation for this research.

The process of continuous improvement (CI) implementation is recognized as a multilevel initiative that consists of activities at the organizational- and the project level (McAdam and Lafferty 2004; Nair et al. 2011). On one hand there are the organizational
level activities, whereby senior management takes on pivotal challenges such as creating the motivation for change and subsequently coordinating the organizational change process, known as CI implementation. On the other hand CI implementation is commonly shaped in a project-by-project fashion. Organizations that commence with CI implementation form a portfolio of improvement projects that are initiated based upon their impact on corporate strategy realization (McAdam and Lafferty, 2004). The actual improvements are delivered at the project level where improvement project leaders are trained in CI methodologies and take up a leading role in delivering improvement projects.

The purpose of this research is to determine if and how the organizational level constructs of motivation and central coordination in the CI implementation process have a positive effect on improvement project success. To understand how both organizational level constructs affect improvement project success, mediating constructs that capture how an organization changes in the process of CI implementation and are hypothesized to affect improvement project success are designed.

**Theoretical background**
Continuous improvement (CI) implementation is a process of organizational transformation aiming for adoption of a “planned, organized and systematic process of focused and company-wide continuous incremental innovation and change of existing practices aimed at improving company performance” (Bessant and Francis, 1999). The reasons for CI implementation lay in the ever increasing complexity and pace of business environments and scholars have increasingly recognized CI as sound operations management practice (Jonsson and Johansson, 2011). Inconclusiveness on the bottom-line results that CI implementation yields however remains: prior studies have reported significant benefits (Bessant and Caffyn, 1997) and significant disappointments (Pay, 2008).

**Determinants of continuous improvement implementation outcome**
In order to better understand success or failure scholars have started to investigate CI implementation processes to explain their outcomes and systematic literature reviews have emerged in which critical success- and failure factors for CI implementation are summarized (Arumugam et al. 2014; Albliwi et al. 2014). Two interesting points stand out in these reviews. For one, the reviews confirm that organizational level constructs have an important effect on CI implementation outcome. Among others management commitment, customer focus and links to corporate strategy and human resource management strategies are named. The other interesting point is the acknowledgement of failure or success of factors at the project level as predominant determinant of CI implementation outcome, such as the rightful selection of projects, the adequacy of project leader skills and the structured approach of improvement projects (Arumugam et al. 2014; Albliwi et al. 2014). It is important to note that CI implementation is thus for one determined by organizational level success factors and secondly by the success or failure of factors at the project level. Hence CI implementation has a multilevel character, nevertheless most of the research on CI implementation adopts a single unit of analysis at either the organizational level (Shafer and Moeller 2012) or at the project level (Linderman et al., 2003). Our argument is that there is a causal relation whereby organizational level factors in the process of CI implementation affect the success of improvement projects. Improvement projects are a dominant operational manifestation of CI implementation in organizations and are therefore recognized as an important determinant of organization performance resulting from CI implementation.
Organizational motivation, coordination and improvement project success

The first organizational construct of interest is the organizational motivation, or sense of urgency, prior to and in the process of implementing CI. Prior CI research has highlighted the importance of making CI implementation core to business strategy realization and strong management commitment to the CI implementation as manifestations of organizational motivation (Arumugam et al. 2014; Alblawi, 2014). Although a strong and widely felt motivation is likely to influence how organizational actors will behave and affect improvement project outcomes (see Ajzen and Fishbein, 1980, for their Theory of Reasoned Action), the argument here is that strong and lasting organizational motivation for CI implementation principally drives the embedding of CI philosophies and principles in the organization. This line of reasoning is derived from research by McAdam and Lafferty (2004). In their research the authors have found that a holistic approach (inclusion of people and organizational criteria instead of a mere focus on tools) needs organization wide support and commitment for the implementation and enabled the embedding of improvement methodology in the organization. Embedding is the process whereby organizational staff is empowered and provisioned with the appropriate CI methods and tools to be used in an empowered manner. Thereby the organizations’ CI implementation objectives were found to be achieved (McAdam and Lafferty, 2004). The positive effect of embedding (or adoption) of CI methodologies on organizational performance however is supported but also criticized by several researchers.

The primary interest here is in how embedding of CI methodology leads to improved performance, and research by Choo et al. (2007) on CI project execution revealed how learning and the creation of knowledge plays a pivotal role. Based on this finding it is argued that the gradual embedding or adoption of CI philosophies, principles and routines drives a change from an “old way” of working, before CI methods were implemented to a “new way” of working where CI methods are part of everyday work at the process level. Thereby a growing number of organizational staff involved in, or subject to, the CI implementation has gone through multiple learning cycles of how to apply improvement methodology.

![Figure 1: Conceptual model of the research](image-url)
The application of improvement methodology to solve operational problems and improve process, product or service performance is performed more frequently and hence knowledge and routinization in the application of CI methodologies starts to grow. Therefore the following hypotheses are proposed (see Figure 1):

H1. Organizational motivation for CI implementation is positively related to the degree of embeddedness of improvement methodology in the organizational operations.

H2. Embeddedness of improvement methodology in the organizational operations is positively related to the degree of organizational routinization in improvement methodology application.

The second organizational construct of focus is the degree of coordination of the CI implementation process. Earlier research has emphasized the importance of coordinated selection and prioritization of improvement projects and training of improvement project leaders as a proxy for the degree of coordination of CI implementation activities (Arumugam et al. 2014; Albliwi, 2014). Prior research on improvement methodology implementation has recognized the importance of a parallel-meso CI management structure for the coordination of the implementation efforts (Schroeder et al. 2008). Such a CI management structure is parallel to, but outside of, the typical organizational structure and integrates multiple levels of seniority by the use of teams, improvement specialists, steering committees and other structures, roles and methods (Schroeder et al. 2008).

Here it is argued that the degree of orchestration of CI implementation efforts by means of a substantial central core-team positively impacts the degree of organizational alignment to the CI implementation. Organizational alignment boils down to the degree of improvement methodology dissemination throughout the organization in terms of business units involved, organizational staff trained and importance of CI for the success of the organization. The concept of organizational alignment or dissemination of improvement methodology based on organization specific characteristics has been previously studies by Ansari et al. (2010). In their research, Ansari et al. (2010) concluded that the fidelity to- and extensiveness of methodology adoption varies based on several organizational characteristics such as cultural fit, political fit and technical fit. Based on this research it is argued that central coordination by means of a core-team in CI implementation processes enables influence on the degree of organizational alignment. Vehicles to do so are among others central corporate training programs, communication strategies and leadership development. Subsequently it is argued that widespread organizational alignment and involvement of the organization in the CI implementation leads to more experience and acceptance of improvement methodology application throughout the organization, operationalized by the construct of routinization (Figure 1):

H3. Organizational coordination of the CI implementation is positively related to the degree of organizational alignment to the CI implementation.

H4. Organizational alignment to the CI implementation is positively related to the degree of organizational routinization in improvement methodology application.

The remainder of our arguments is that organizational routinization with improvement methodology application ultimately explains the likeliness of improvement project success. There are several empirical studies that have related routinization and improvement in ability over time (i.e., learning-by-doing) in a variety of business contexts. In a case research by Easton and Rosenzweig (2012) the effect of multiple types of routinization on improvement project success is researched. The authors find
that predominantly project leader routinization and organizational routinization (operationalized as the knowledge on improvement methodology application generated by other organizational members) are explaining the outcome of such projects.

Here it is argued that organizational routinization is determining project success, because the experience of an organization with the application of improvement methodology affects the ability and willingness of organizational staff to contribute, as project team-leads and members, to improvement projects. As more operational staff and selected CI specialist involved in improvement projects possess a degree accumulated learning, experience and knowledge on how to effectively execute improvement projects, the chances for success are expected to be higher. Additionally, the more improvement project stakeholders have knowledge of or have been involved in improvement projects, the more likely that improvement projects will be successful:

H5. Organizational routinization in improvement methodology application is positively related to the degree of improvement project success.

Data and research methodology
The sample is formed of improvement project leaders from financial service organizations in predominantly Europe comprising both banks and insurance firms. The respondents are selected via the authors’ university alumni networks and professional social networks. Searches for discussion forums containing “Lean” or “Six Sigma” or “TQM” or “improvement” in combination with “deployment” or “implementation” or “implementing” in the title were performed. The unit of analysis is improvement projects in financial service organization and the questionnaire was developed based upon a review of the existing literature related to CI implementation and improvement project success and followed a two stage scale development procedure.

A total of 387 respondents showed interest and in the process of data preparation, incomplete responses were completely deleted and the imputation of missing values for less than 5% of the remaining sample by means of single regression imputation in IBM AMOS 25 was performed (Kline, 2011). A total sample of 198 usable cases for data analysis remained (descriptive statistics available as table).

Although sufficient research has addressed the topics of study and supported in construct definition, we concluded that to date no research could provide the scales needed for our study. Therefore, we have developed scales according to the sequence presented in a review of operations management studies that used scale development by Hensley (1999), comprising the stages of item generation, scale development and finally scale evaluation (process steps and outputs available as table).

The first step in item generation was creating focus groups stemming from the population, being CI leaders and practitioners from financial service organizations in Europe, Asia and North America comprising both banks and insurance firms. This first stage resulted in over 20 items per construct and additionally we have added control variables. After having established a first set of items per construct, subsequent content validity assessment was performed. This process revealed a high consistency of classification and items for which an incoherent classification remained after discussion were eliminated to mitigate multi interpretation risks. After the second round in between 7-18 items per construct remained.

After the data was gathered the stability of the scales was determined. Subsequently reliability of the proposed scales was assessed in IBM SPSS 24 by measuring the internal consistency of the items. Items that remained after principal component analysis were subjected to Cronbach’s Alpha (α) assessment. The final step of construct validity assessment is performed in the model specification and optimization sequence where
both convergent and discriminant validity of the scales are assessed and optimized. Finally common method bias is assessed to exclude the possibility of bias due to the data gathering technique and we conclude that common method bias is not problematic in our sample.

Data analysis
Structural equation modelling was performed in a sequence of path model identification, optimization and finally structural regression model testing (Anderson and Gerbing, 1988). We follow Kline (2011) for reporting model fit indices. Reported and recommended values for model fit are presented in Table 1.

Initial confirmatory factor analysis (CFA) model identification was performed in IBM AMOS 25 and convergence was achieved using maximum likelihood analysis after 11 iterations. To compensate for the risk of non-normality bootstrapping was performed (200 samples) and resulted in good final CFA model fit indices. Discriminant validity of the constructs was good (all constructs < .85 correlated) (Kline, 2011). Following sufficient CFA model fit, a structural regression (SR) model to test the hypothesized causal relations was developed and consecutive SR model identification and optimization was commenced.

![Figure 2: Final model with coefficients and significance (10% (*), 5% (**) and 1% (***) level)](image-url)
The model modification indices signalled potential effects between embeddedness and organizational alignment, and between organizational motivation and organizational alignment. For the intermediate SR model we have followed the hypothesized relations and added the discovered direct effect of motivation on alignment (“A” in Figure 2) and (“B” in Figure 2) in the model, which resulted in good model fit. As presented in Figure 2, four of the five hypotheses are supported.

Firstly, we find that the degree organizational motivation to implement CI significantly and positively influences the degree embeddedness of improvement methodology in the organizations’ operations (H1), which subsequently does not significantly influence routinization with improvement methodology application (H2). As discussed before embeddedness is, although not directly, related to organizational alignment.

Secondly, we find that coordination of the CI implementation significantly affects organizational alignment to the CI implementation (H3). This effect however only occurs when the discovered direct effect between organizational motivation and alignment (“A” in Figure 2) is added. Hence when the organizational motivation to implement CI and execute improvement projects is not present, coordination has no significant effect on the degree of organizational alignment to the CI implementation.

Additionally the effect of coordination on alignment slightly deteriorates (lower coefficient and slightly higher, still significant, P value) when the indirect relation with organizational embeddedness (“B” in Figure 2) is included. Hence when embeddedness of improvement methodology in the organization is lower, coordination combined with a strong motivation is positively affecting the degree of organizational alignment to the CI implementation and vice versa.

The degree of organizational alignment to the CI implementation is subsequently significantly affecting routinization (H4). The coefficient is negative, though this relation is positive as organizational alignment is a reversely scaled construct. Finally, routinization is found to significantly and positively affect improvement project goal achievement (H5).

Discussion and future research directions

The objective of this research is to study the effects of organizational motivation and coordination on improvement project success in CI implementations.

First our results show that strong and widely shared organizational motivation to engage in CI implementation positively influences the embedding of improvement methodology application and adoption in organizations. Organizational motivation is embodied by for instance the need to digitalize and innovate processes and embeddedness is manifested by practices such as continuous performance monitoring, ongoing communication and a degree of process-thinking in the organization. This implies that a strong and widely felt motivation to implement CI leads to greater adoption and embedding of CI methods by organizational staff in day-to-day operations. This effect is negatively related with the size of the firm, meaning that achieving higher degrees of embeddedness need more organizational motivation in larger firms (our findings suggest roughly above 2000 employees). Differences between larger and smaller organizations in organizational processes have long been recognized and researched, for instance for competitive behavior (Chen and Hambrick, 1995). However, confirming Bessant et al. (2001) it is concluded that little research on the effects of firm size and the CI implementation process is available to date.

The concept of motivation or sense of urgency as prerequisite for organizational transformation processes is widely acknowledged (Todnem By, 2005). For Lean Six
Sigma implementation specifically the need for change has been recognized as first implementation step by Kumar et al. (2011). Their findings are corroborated by this research and provide empirical insight into factors that might specifically create a compelling need for change. Hence we propose that future research should focus not so much on identifying if- but more on what- is most persuasive in creating the organizational motivation for CI implementation.

Evidence for the subsequent effect of embeddedness on routinization is not found. Greater embeddedness is however related to the degree of organizational alignment, manifested by greater management attention, an increasing demand for improvement projects and greater perceived importance of CI for the company’s success. Hence acceptance and embedding of CI methods by organizational staff in day-to-day operations is related to the degree of perceived importance of the CI implementation by organizational staff. This finding complements the previous findings by McAdam and Lafferty (2004). In their research on Six Sigma implementation, the importance of embedding CI methods and tools in organizational staff their day-to-day operations is signalled. The authors report that by extending the scope of the implementation from just solving the problem or defect areas (the instrumentalist approach) to empowering organizational staff in resolving and preventing root causes of defect areas (joint people and process approach), Six Sigma objectives were achieved. This finding provides understanding of how the empowerment of organizational staff may contribute to improvement project goal achievement. Namely by first creating a degree of management attention and perceived importance (alignment), leading to acceptance and consecutive routinization or experience of organizational staff with improvement methodology.

Second, our results show a positive causal relation between coordination of the CI implementation and the degree of organizational alignment to the CI implementation. Alignment is embodied by greater management attention, an increasing demand for improvement projects and greater perceived importance of CI for the company’s success. Our finding provides empirical support and corroborates prior predominantly case-based research that acknowledged the value of central selection, prioritization and coordination of improvement projects (Schroeder et al. 2008). Previous research proposed that having a parallel-meso hierarchal structure where business leaders initiate and review improvement projects and where more senior project leaders coach and support junior project leaders creates value in CI implementations (Schroeder et al. 2008). We find that the effects of central coordination however are only significant when strong motivation to implement CI is present. Conversely, when little motivation to implement CI is present, the effect of a central core-team leading the implementation is insignificant. Future research opportunities lay in understanding how the value of central coordination is created and should focus on the specific activities or roles that central coordination fulfils over time.

Third our results reveal that increasing organizational alignment affects the degree of routinization or experience with business improvement methodology application by organizational staff, and positively affects improvement project goal achievement. Goal achievement contains among others improved- customer satisfaction, process operations, quality levels and changes in the business culture. Hence increased organizational staff experience with improvement methodology and improvement projects is found to positively affect success of process improvement projects.

Routinization or experience in improvement project teams is found to positively influence success of process improvement projects. Research by Easton and Rosenzweig (2012) examined how various types of experience affect the success of...
improvement projects and concluded that especially experience of the project leader and organizational experience is crucial. Our findings corroborate the importance of experience in the organization, though does not specify the type of experience and the exact workings. Prior case-based research did acknowledge that routinized process improvement methodology application is associated with knowledge creation and learning (Linderman et al. 2010). Future research opportunities lay in further empirical examination and understanding of how increased organizational routinization leads to success of process improvement projects.

Fourth is the relatedness between the constructs for organizational motivation, embeddedness and alignment. Together these three constructs capture how a strong need to implement CI, increasing levels of improvement methodology embedding in day-to-day operations and increasing attention and perceived importance seem to affect higher levels of routinization and project success. Prior research addressed the topic of CI infrastructure and thereby the creation of a dynamic capability (Anand et al. 2009). The authors found that characteristics of a CI infrastructure are among others a strong relatedness of the implementation to business strategy, a culture of constant change, standardized processes and improvement methods, and parallel participation structures that drive improvement project involvement. Several of these infrastructural components hold similarities with our second order construct identified in the process of model optimization. Hence, future research should further investigate and provide empirical support for the infrastructural components that jointly capture continuous improvement as dynamic capability.

Conclusions, implications and limitations
This study contributes to the empirical knowledge of process improvement project outcome in continuous improvement implementations in organizations. Specifically it revealed the positive effects of strong organizational motivation and central coordination on improvement project success via the creation of organizational alignment to- and experience with improvement methodology and principles.

Several implications for managing the CI implementation process and improvement project execution arise from this study. First CI implementation leaders are advised to ensure strong organizational motivation and support for the implementation. Second, the installation of a central core-team directing and overseeing the CI implementation process is advised. Finally, a focus on embedding improvement methodology adoption and application by organizational staff is influencing the levels of experience with improvement methodology application in the organization and thereby explains improvement project goal achievement.

Limitations of this research lay for one in the sample size as we were not able to adhere to the ideal sample size-to-free parameters ratio (Jackson, 2003). Although attention is paid to developing valid scales, the process of model identification revealed several items that displayed limited explanatory power for their respective constructs. Despite the fact that data from multiple continents was gathered, we were not able to make comparisons between different groups due to the dominancy of German and Dutch respondents. Hence the applicability of our findings for CI implementations outside of Western Europe remains uncertain.

Abstract

Based on a literature review, this study investigates to what extent and how changes with curriculum internationalization in higher education have been researched. This paper discusses 21 peer-reviewed articles, 9% of the total number published between 2011 and 2018. The main findings show that these articles are mostly about the process perspectives (441 references), and less so about the context (236) and content (77) of change. Curriculum internationalization is described as a mix of planned/rational and emergent/affective change processes, with many relevant content issues, highly contextual, and with human resources as a recurrent issue (115 references).

Keywords: change process, human resources, curriculum internationalization in higher education

Introduction

Since internationalization came to prominence in higher education around 1995 (Altbach & Knight, 2007), several literature reviews ((Kehm & Teichler 2007, Yemini & Sagie 2016) reported on the main topics and developments. Universities worldwide have recruited international students, built international networks and joint programs, facilitated student and staff mobility across borders, and translated many programs of study into English (Yemini & Sagie, 2016).

“Curriculum internationalization” is a more recent phenomenon, which first received attention in English-speaking countries like Canada (Bartell, 2003), UK (Caroll & Ryan, 2005), and Australia (Leask, 2009). In Europe, the relevance of curriculum internationalization, also known as “internationalization of the curriculum” (Leask, 2009, 2015), “internationalization at home” or the “international classroom” (Beelen, 2017) has only been acknowledged more recently.

In this paper, we use the term “curriculum internationalization”. Recent studies reveal
that 78% of all students at universities in the Netherlands do not study abroad and can therefore only benefit from internationalization at their home university (van Gaalen & Gielesen, 2016). This percentage illustrates the relevance of curriculum internationalization (Leask 2009, 2015, Green & Whitsed, 2015). In a commonly accepted definition developed by Leask (2009), curriculum internationalization has been defined as:

“the incorporation of international, intercultural and/or global dimensions into a program of study so that it will engage students with internationally informed research and cultural and linguistic diversity and purposefully develop their international and intercultural perspectives as global professionals and students” (based on Leask 2009, pp. 209).

In short, curriculum internationalization is a process to make a program of study more international. This process can be undertaken in different ways at the individual, course, program and institutional level. It can involve changes in curriculum design, pedagogy, and in individual and collective beliefs (Leask 2015, Carroll 2015). As such, curriculum internationalization can be approached as a complex organizational change process (Smith & Graetz, 2011).

In educational practices in universities, it appears difficult to internationalize programs of study (Leask, 2015). Despite enthusiasm of individual academic staff, problems experienced are a lack of shared understandings, not knowing what to do, or how to do it to make it successful (Green & Whitsed, 2015).

Given the problems experienced in practice with a phenomenon which is increasingly relevant for all students, it seems interesting to take a closer look at what we can learn from change theories to overcome typical problems with the implementation of curriculum internationalization in higher education. Our research question is: ‘to what extent and how has curriculum internationalization been researched as a change process?’

Change theories
Theories of change ought to explain the balance between continuity and change through general patterns (Pettigrew et al, 2001). Studies on organizational change can be divided into three major themes: content, context and process (Armenakis & Bedeian, 1999). Pettigrew et al (2001) also depart from the assumption that content, context and process are interrelated and need to be consistent at different levels for a successful process.

Kuipers et al. (2014) signal a lack of change studies for public organizations. They observe that the specific nature of public organizations with values and services and a more political, juridical context with much bureaucracy (von Nordenflycht, 2010) requires different patterns of change. Universities, as regulated professional service organizations (von Nordenflycht, 2010), have complex, much informal structures and a highly professional workforce with unique knowledge and skills, high internal ownership and much informal power. Following increased globalization and competition (Altbach & Knight, 2007), universities have faced demands for urgent and radical institutional change (Trondal, 2010). Universities need to balance between instrumental design and the logic of hierarchy on the one hand, and academic autonomy and professional neutrality on the other (von Nordenflycht 2010, Trondal, 2010).

While the dynamics of the internal context have not yet been researched much with change theories, the external context for universities has been characterized by many different developments such as; changing demands, new technologies, financial crises, and for Europe; EU regulation, and particularly the Bologna process for higher education (Kuipers et al., 2014).
Theories of organizational change have focused primarily on planned, rational, top-down change (Kuipers et al., 2014), ignoring the complex and contradictory nature of professional service organizations and the diverse range of people working in them (Smith & Graetz, 2011). Armenakis & Bedeian (1999) signal that emergent change with non-intended, possibly negative affective outcomes such as stress or cynicism can seriously undermine or even defeat change.

For organizational change studies overall, the framework developed by Pettigrew et al., (2001) with the concepts of content, context and process has been widely applied in case study research, for example on the implementation of health care innovations (Boonstra et al., 2014). We now discuss each of these concepts.

Firstly, in theories of change the content issues related to successful or unsuccessful change have been defined rather broadly, at different levels (Kuipers et al., 2014), in terms of strategy, structures, management practices, policies and procedures, task requirements and individual abilities (Armenakis & Bedeian, 1999). Secondly, the context can be categorized in internal and external (Kuipers et al., 2014). Thirdly, the process of change in the literature can be divided into planned/rational versus emergent/affective change (Smith & Graetz 2011, Kuipers et al., 2014).

Further, Smith & Graetz (2011) advocate to combine these planned/rational and emergent/affective processes with different, interrelated process perspectives of change, to create a richer understanding. They distinguish the perspectives of: rational/planned, biological/emergent, resource-based (determined by access to resources), institutional (relevance of environment), psychological (individual impact), systems (interconnected with all aspects of the organization), cultural (values, beliefs and norms), critical (contradictions, conflict and power based) and dualities (dynamic, complex, managing tensions) (Smith & Graetz, 2011: 16-17).

The aim of this paper is to present a review of the recent literature about curriculum internationalization in higher education as a change process positioned within a conceptual framework of change. To our knowledge, there has been no systematic review of the literature concerning curriculum internationalization in higher education as a change process.

![Figure 1. Conceptual framework of change, based on Pettigrew et al., (2001)](image)

**Conceptual framework**

This paper draws on a conceptual framework of change (Pettigrew et al., 2001) with the concepts of process, context and content (see figure 1 above). This framework has been widely applied in research into organizational contexts, but has not been applied much in the public sector (Kuipers et al., 2014). Building on literature reviews of change until 2010 (Armenakis & Bedeian 1999, Pettigrew et al., 2001, Kuipers et al., 2014), we identified 21...
articles in the period from 2011-2018. This is 9% of the total number of articles on curriculum internationalization in higher education for that period.

With the software of NVivo, we identified systematically how often the words of process, context and content appeared in these 21 articles. Next, we analyzed those sentences. First, we looked at the process with planned/rational, emergent/affective and the different, interrelated process perspectives of change (Smith & Graetz, 2011). Secondly, we screened for context with internal and external (Kuipers et al., 2014). Thirdly, we analyzed content including the curriculum, strategy and policies, structures and practices, task requirements and individual abilities (Armenakis & Bedeian, 1999).

Method
For this literature review, we searched the databases of SCOPUS, Web of Science and Pro quest. Only peer-reviewed articles in English were included. The search terms were: internationalization of the curriculum, curriculum internationalization, internationalization at home, change process, and variants. Articles were excluded from the set where these did not directly relate to higher education. Duplicates were also removed. Decisions about inclusion and exclusion were frequently discussed between the researchers (Karlsson, 2016).

With our conceptual framework of change (figure 1, page 3), we analyzed the concepts of process, context, and content. After our analysis, we come back to our research question: ‘To what extent and how has curriculum internationalization been researched as a change process?’.
Analysis
Overall, most references are on process or processes (441), followed by context(s) (236), and content (77). The process is the dominant concept of change in 14 articles, followed by context as the main concept in 7 articles, and content in 2 articles. The resources (115) also received frequent attention (see figure 2 above). We will now discuss each concept.

Process
All 21 articles discuss curriculum internationalization as a process or processes of change. The references vary from 93 (Bradford et al., 2017) to 8 (Tsuruta, 2013). Following our conceptual framework (page 3), we discuss planned/rational and emergent/affective change, and the other, interrelated process perspectives.

Overall, curriculum internationalization is described as a dynamic, deeper, transformative process (Leask 2013, Qureshi et al., 2014, Mertkan et al., 2016). The transformative character implies both planned/rational and emergent/affective change, at multiple levels, with a combination of process perspectives. In all 21 articles, change is represented as a planned/rational process. In total there are 349 references to
rational/planned change, with a maximum of 80 in one article (Bradford et al., 2017). Planned/rational change is described in different ways. For example with plans, strategies, rationales, goals, models, stages, steps, patterns, blockers and enablers. The qualifications used are: active, iterative, adopting, adjusting, rational, cognitive, defined, designing, predictive, leading, managing, directing, controlling, evaluating, improving (Bradford et al. 2017, Leask 2013, Qureshi et al., 2014, Takagi 2015).

Despite this dominancy of planned/rational change, emergent/affective change is also present in 20 articles, varying from 1 to 16 references in an article (Mertkan et al., 2016), adding up to 127 references in total. Mertkan et al., (2016) picture emergent change as a “rolling snowball, getting larger and undergoing a metamorphosis”. Leask (2013) incorporates emergent change with planned change through reflection and imagination, while stressing the overall complexity and sometimes chaotic character of the process. Tsuruta (2013) describes the complexity of curriculum internationalization with vulnerability, uncertain factors, ambiguity and competing priorities.

The most dominant process perspective is the systems perspective (145), followed by the institutional (112), the psychological (78), the cultural (64), the resource-based (53), the critical (9) and the dualities (9) perspectives. We will now discuss each perspective.

The systems perspective is present in 19 articles, most frequently with 40 references in Bradford et al., (2017). Bradford et al., (2017) draw on theories from the business domain, with a resource-based, multi-process perspective with a focus on systems and institutional elements, and financial and human resources. In other articles, the systems perspective is described as “a complex range of interacting factors with the challenge to make the tacit explicit within informal university structures” (Leask, 2013). In the context of quality assurance and accreditation, the systems perspective is illustrated with techniques and mechanisms (Qureshi et al., 2014). Further, the systems perspective often associates with successful implementation (Bajada & Trayler 2013, Siska et al., 2013), described as interactive (Robson 2011, Mak et al., 2014), integrative and coherent processes (Whitsed & Green, 2014), with indicators and dimensions for monitoring (Chang, 2015).

The systems perspective is closely related with the institutional process perspective (Smith & Graetz, 2011). The institutional process perspective is worded in globalization (Green & Mertova, 2016), in competitive processes (Bajada & Trayler 2013, Takagi 2015), or with the global versus the local (Said et al., 2015, Lumby & Foskett 2016). There are frequent references to the European Bologna process (Bajada & Trayler 2013, Haigh 2014, Lumby & Foskett 2016, Saarinen & Taalas 2017), or to accreditation (Qureshi et al., 2014). Other studies refer to national reforms and co-operation with partner institutions (Siska et al., 2013), external politics (Tsuruta, 2013), or historical processes and legitimacy (Lumby & Foskett, 2016).

The psychological and cultural process perspective are also closely related. The discussed transformative process character (Mertkan et al., 2016) implies both the psychological and cultural perspective. The differences are in the individual learning experience (Leask 2013, Mertkan et al. 2016, Takagi 2015) versus cultural processes in disciplines, programs, teams and communities (Agnew 2012, Lamberton & Ashton-Hay 2015, Leask, 2013, Mertkan et al. et al. 2016). The individual process is characterized through interpretation (Takagi, 2015), reflection, imagination, engagement (Leask, 2013), with disorienting dilemmas (Kahn & Agnew, 2017), ethics and specific behavior (Haigh, 2014). The cultural process incorporates values, beliefs and attitudes beyond individuals (Green & Mertova, 2016), with inclusion and exclusion mechanisms (Lumby & Foskett, 2016), and disciplinary and institutional identities (Robson 2011, Lamberton & Ashton-
The resource-based process perspective (53 references) is less present. Yet, resources as such are frequently discussed (115). The key resources noted are knowledge, leadership, staff and students (Leask 2013, Tsuruta 2013, Said et al. 2015, Bradford et al. 2017). Leask (2013) positions resources as essential to support the staff, the process of curriculum internationalization, and relevant policies. Financial resources are a separate category (Leask, 2013). Only Bradford et al., (2017) draw on resource-based theory, while they discuss resources in terms of essential, sustainable, scant and superior, creating advantages for a specific organization. Bradford et al., (2017) use the distinctions of human and non-human, internal and external, and the terms firm-specific, financial and superior.

Lastly, a critical (9) or dualities process perspective (9) is present in only 8 articles. Often, both perspectives are represented together. The critical process perspective is described through consultation, collaboration, empowerment and challenging dominant paradigms (Agnew, 2012), maintaining power and previous truths (Whitsed & Green, 2014), through contradictions (Haigh, 2014) and in the power to block or resist (Green & Mertova, 2016). The dualities perspectives is depicted as dynamic (Whitsed & Green 2014, Mak et al. (2014), and with points of tension (Leask, 2013).

**Context**

All articles discuss context or contexts (236 references in total) but much less than process(es) (441). In 7 articles, context or contexts is the dominant concept, with references varying from 24 (Siska et al., 2013) to two (Haigh 2014, Mak et al., 2014, Qureshi et al., 2014). We found almost the same number of references for the internal (147) as for the external context(s) (155).

For the internal context(s), we found different levels; the individual, course, program, conceptual and institutional level. The individual level includes subjects, agents, individual differences, skills and the academics (Green & Mertova, 2016). The course level includes classes, teaching, practices and the classroom (Bajada & Trayler, 2013), while the program level notes pedagogy, assessment and interdisciplinary (Mak et al., 2014). At the conceptual level, we found quality, equity, inclusion, efficiency, effectiveness and human resources (Maringe & Sing, 2014). Lastly, the institutional level frequently reports culture and policies (Saarinen & Taalas, 2016), and to a lesser extent, methodology, philosophies and research (Tsuruta, 2013).

For the external context, we found that the references can be categorized in cultural, ideological, historical, economic, political, financial, educational, reputational, ethical, social, and academic (Green & Mertova 2016, Chang 2015).

**Content**

Only 13 articles discuss content, with maximum 14 references in an article (Bayada & Trayler, 2013). The focus is clearly on the curriculum (50/77), with the sub categories of program, course and discipline (Bajada & Trayler 2013, Lamberton & Ashton-Hay 2015, Siska et al. 2013). The content is also discussed with the curriculum in relation with ethics, sustainability, graduate attributes, design, culture, skills (Bajada & Trayler 2013, Leask 2013), and strategy and policies (Robson 2011, Saarinen & Taalas 2017). There is an overlap between content and context.
Conclusions and discussion
What we can learn from this literature review is that curriculum internationalization can only be fully understood as a mix of planned/rational and emergent/affective processes of change, with interrelated process perspectives incorporating different levels (Smith & Graetz, 2011). The content of what to change involves the curriculum with many different issues, highly depending on the context. In line with Pettigrew et al. (2001), we found similar levels with each concept of change, including the individual level and several organizational levels, with deeper levels situated in informal and hidden structures and power (von Nordenflycht, 2010). Adequate facilitation through particularly human resources is needed to support and improve this change process (Leask 2013, Tsuruta 2013, Bradford et al. 2017).

Coming back to our research question, ‘to what extent and how has curriculum internationalization been researched as a change process’, we conclude that with 9% of all articles selected for the period 2011-2018, curriculum internationalization has not yet been investigated much as a change process. Theories from organizational change studies have not yet been employed much with curriculum internationalization. Further, the focus is on the process, while the context, content and levels overlap.

Many of these articles (66%) concern conceptual studies. More empirical research is needed to research how the process, context and content of change are interrelated with different levels for the implementation of curriculum internationalization in higher education. Further research with these interrelated process perspectives needs to be done to find patterns of change and investigate how the process can be undertaken most successfully. A focus on human resources seems to be required. For practitioners, further research into change processes and resources can help to overcome typical problems in the implementation of curriculum internationalization. For change management, the application of change theories in the different context of higher education could provide new insights. Additionally, this study fits with the increasing interest in operations management with change, internationalization and intercultural issues (Karlsson, 2016).

Abstract

This paper's theoretical contribution is in reporting an innovative privacy management method designated as PRIMROSE - PRIvacy Management Responsibility On a Scrutinized Environment. Research contribution is in introducing a supported process concerning the effective efficient management of privacy requirements occurring in organizations. PRIMROSE was the outcome of deductive reasoning subjected to a focus group and eight DPO interviewees scrutiny. Practical contribution is in setting the missing link regarding a generally recognized privacy management method to guide practitioners in which the elements originate from the qualitative research supporting root definitions semantics, considering, among others, principles, stages, processes, enablers and composite requirements.

Keywords: PRIMROSE, privacy management method, data protection.

Introduction

The European Union’s General Data Protection Regulation (GDPR) was enforced on 25 May 2018 and demands that organizations, i.e. data controllers and processors “implement appropriate technical and organizational measures” to safeguard the “ongoing confidentiality, integrity, availability and resilience of processing systems and services” (Regulation EU, 2016), regarding the management of personal information of EU citizens (Costa et al., 2018).
In this context, the research sponsor, i.e. the DATASHIELD DPBCS is a company that provides consultancy services and solutions for data protection. It supports the investigation of a holistic privacy management method, designated as PRIMROSE. As trained facilitators of strategic privacy thinking, the research sponsor follows a predetermined process and uses predesigned techniques and practices to keep organizations on track regarding the privacy forum and brings in objectivity to clients and to the discussion of legal and regulatory issues and concerns of data protection.

If we consider the analysis and implementation of privacy and data protection solutions alone, the issue itself is complex in nature. Combined with the legal imperative, the challenge is increased. For example, the US approach to privacy is sectoral, different from the approach of the European Union (EU) countries, which has a comprehensive Regulation for member states. Another jurisdictional example, the General Law of Protection of Personal Data from Brazil, inspired in the GDPR also imposes a set of rules that have to be fulfilled. If we take the example of an organization that performs in these three geographical areas, the management of privacy and data protection include a specific and demanding use of resources that must be managed effectively and efficiently. In addition, organizations have different forms and configurations of management.

So, what organizations want is a method that involves the strategic thinking of their own people that are part of the overall privacy solution (Robert, 1998). Moreover, the terms of reference coming from the Regulation to set what should be done, designated as the “permanent enablers” (Costa et al., 2017), are thoroughly examined in order to address the needed requirements. Depending on their timescales, organisations are either permanent or temporary. Thus, projects are temporary.

Therefore, this investigation presents a summary of the PRIvacy Management Responsibility On a Scrutinized Environment (PRIMROSE), a privacy management method for addressing the following research questions: [RQ1] What are the high-level requirements of the permanent organization to be GDPR compliant? and [RQ2] How should the GDPR requirements be managed in the permanent organisation? PRIMROSE is expected to keep the data protection requirements on track, to bring objectivity to privacy work and, simultaneously, to involve all relevant interested parties to the discussion. Moreover, PRIMROSE principles, strategy, stages, processes, enablers, composite requirements and continuous service improvement, developed as a function of the privacy environment, are described in this paper.

The required organizational changes will not occur overnight. This qualitative investigation revealed that, for organizations to be effective and efficient in the matter of data protection throughout time, specifically in what concerns the Regulation requirements, its variables should be managed through a privacy method to ease the achievement of their planned benefits. Thus, the following section describes PRIMROSE, a holistic and multidisciplinary method for privacy management. The elements of the method are detailed and described. Finally, the theoretical, practical and managerial implications of the model are examined.

Proposal of a method for privacy management
PRIMROSE is a rival approach of OASIS Privacy Management Reference Model and Methodology that has not become enough widespread and popular. Rival approaches compete to explain the same phenomenon and cannot be mixed.

Privacy and data protection issues are complex to deal with. Therefore, PRIMROSE’s first goal is to make the complex and irreducible privacy elements as simple as possible, by: (i) contributing to support privacy by design and by default (Cavoukian, 2013), (ii) addressing organizational privacy factors and mechanisms with effectiveness and
efficiency, and (iii) considering the respect for user privacy and utility as quality components.

By doing so, PRIMROSE contributes to privacy management holistically, supported by the reasoning that privacy has multiple dimensions.

Moreover, these multiple dimensions exhibit cross-impacts that may require an interrelated analysis. For example, the dimension of privacy concerning “behaviour and action” (ISACA, 2016), put together with the dimension of privacy concerning “data and image” (ISACA, 2016) may enable the identification of someone’s specific lifestyle pattern. So, an increasing number of commercial apps might be used to register and disclose a broad variety of their users’ individual behaviours.

Thus, these dimensions can be used to classify privacy issues, concerns and problems, according to shared qualities or characteristics, e.g. of behaviour and action, of communication, of data and image (i.e. information), of thoughts and feelings, of location and space, and of association (ISACA, 2016).

Privacy dimensions are therefore examined as a synergetic interaction that intend to prevent harm to individuals by investigating the relations of two or more privacy dimensions, to produce a combined privacy solution greater than the sum of their separate parts. This interpretation recognizes that dimensions are multivalent in their nature and complex in their dynamics. Moreover, PRIMROSE considers processing, i.e. "any operation or set of operations which is performed on personal data or on sets of personal data" (Regulation EU, 2016), as well as the impact of that processing on individuals that use any "service" (Vargo and Lusch, 2004) provided by the organisation. So, organisations’ role and accountability in protecting people, processes, and technology are strengthened by rationalizing and managing privacy and data protection requirements.

Figure 1 – PRIvacy Management Responsibility On a Scrutinized Environment (PRIMROSE)
Therefore, scrutinizing, examining or inspecting privacy issues and concerns, closely and thoroughly, in a complex privacy environment characterized by a diversity of laws and regulations, in different social-cultural and organizational configurations that are challenged every day, is of paramount importance.

For the reasons mentioned above, PRIMROSE considers relevant interested parties, internal and external, and encompass in a holistically, integrated and multidisciplinary way, principles, strategy, stages, processes, permanent and temporary enablers, composite (Ohnishi and Agusa, 1993) requirements, and continuous service improvement, in order to support organizational privacy strategic objectives, risk appetite and tolerance (vide Figure 1).

Principles
The first integrated layer of the method encompasses the fourteen PRIMROSE core principles. Together, they are the “strategic heartbeat” of the method and act as a “driving force or strategic drive” (Robert, 1998) that pushes or propels the organization toward certain privacy results, maturity level or profile. Moreover, they form the foundation base that the rest of the method adheres to.

These privacy principles have existing standards and principles as a foundation support. Therefore, the privacy principles are described in Table 1. Moreover, the standards and principles that supported the PRIMROSE principles were obtained from the BS10012:2017, GDPR, ISACA privacy principles, OECD 2013, ISO/IEC 29100:2011 (last reviewed and confirmed in 2017), APEC and GAPP (in Table 1).

It is important to underline that certain privacy principles, for example, regarding the ISACA privacy principles, namely monitoring, measuring and reporting, third-party/vendor management, and breach management were not considered principles in its true sense. Instead, the aforementioned principles are reasoned and described as management work. Therefore, they are organized in one of a reasoned set of composite requirements of the PRIMROSE method, and, among which, all variables having a determined number of characteristics might be distributed and put together.

In short, the PRIMROSE privacy principles set the tone and provide orientation towards the privacy goals, and indicate what your organization should do to protect personal information.

Privacy strategy
According to Mintzberg (1979) strategy may be viewed as a mediating strength between two dynamic variables; the organization and its environment. The conception of strategy, includes the "interpretation of the environment and the development of consistent patterns in streams of organizational decisions ("strategies") to deal with it" (Mintzberg, 1979). The fundamental question has to do with "strategic thinking" (Robert, 1998) and it boils down to elicit from people’s thoughts and reasoning’s, who lead or manage the business, their finest rational judgment regarding what is indeed happening in the organization; what conditions, events or circumstances are taking place or occurring in the organization external environment, and "what should be the position of the business in view of highly qualitative variables” in order to “produce a vision, a profile, of what an organization wants to become” (Robert, 1998). Thus, PRIMROSE provides a method for privacy professionals interfacing with the organisation, as well as aligning its culture, processes, methods and strategic orientation with privacy and data protection requirements.

Stages
PRIMROSE stages ensure interested parties commitment and organizational assets, as well as authority to apply organizational resources and capabilities. Moreover, stages provide a significant way to help the privacy steering committee monitor privacy work at C-Level. At the end of each PRIMROSE stage, the privacy board can review the organizational privacy work and decide whether to commit assets to the next stage. Two benefits are highlighted: first benefit is planning, because there is, at all times, a planning horizon; secondly, there is no need for the c-level executives that are taking on roles in the privacy steering committee to get involved with the everyday’s management of the stages, however, they can maintain the power to influence or direct people's behavior or the course of events of privacy work, by giving official permission for or approval to progress. PRIMROSE stages can be described as follows (in Table 2):

<table>
<thead>
<tr>
<th>Stages</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diagnosis</td>
<td>To “move forward, it is crucial that we understand the current state” (Kerzner, 2017). Therefore, this stage provides a formal examination and reasoning, e.g. through privacy impact assessments, regarding privacy assets, i.e. “any resource or capability” (TSO, 2012) to determine where the organization is at, i.e. to ascertain the privacy maturity level.</td>
</tr>
<tr>
<td>Design</td>
<td>It is the stage in the PRIMROSE lifecycle that turns a privacy “strategy into a plan for delivering the business objectives” (TSO, 2012).</td>
</tr>
</tbody>
</table>
Implement

It is the stage where all approved privacy assets change requests are implemented, e.g. may be through privacy programs and projects to address privacy requirements, issues and concerns.

Operate

Privacy objectives are lastly fulfilled through the “operate stage”, calling for an effective and efficient support of the organizational services to simultaneously ensure privacy and business practices.

Monitor and control

The “monitor and control stage” enables “tracking, reviewing, and reporting the progress to meet the [privacy] performance objectives defined” (PMI, 2017) in the business case and in the privacy management plan.

Each stage logically selects and organizes the privacy processes that concur to achieve the fulfillment of one or multiple objectives and requirements.

Processes

PRIMROSE processes comprise an organized set of inputs, practices, activities, techniques, that concur for the achievement of certain privacy requirements and objectives (ISACA, 2016). Moreover, they are undertaken to produce a set of required outputs, e.g. products, services, results (PMI, 2017). Therefore, circumstances that form the setting for a specific privacy commitment, and in which permanent or temporary organization they occur, aim at obtaining privacy requirements that provide value for the organization. Thus, privacy requirements should be fully understood, assessed, and clearly defined from the outset. However, they may be subject to change, but this variation must be formally controlled and managed.

Processes cover distinct needs and responsibilities which may co-exist simultaneously in any organization. Since, “becoming privacy compliant is a journey” (AICPA/CICA, 2009), they are iterative and may or may not occur in different timescales in which the organizations are required to whether diagnosis, design, implement, operate, and continuously improve their privacy requirements, as well as their intrinsic challenges.

In addition, these processes are meant to construct a more manageable and increasingly optimized organizational privacy environment. The seventeen PRIMROSE processes can be described as follows (in Table 3):

<table>
<thead>
<tr>
<th>Stage</th>
<th>Processes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diagnosis</td>
<td>Access privacy assets</td>
<td>Assess privacy gaps and vulnerabilities in the organization assets as compared to corporate strategy and policies, applicable laws and regulations, and data impacted.</td>
</tr>
<tr>
<td></td>
<td>Perform risk analysis</td>
<td>Risk analysis is the “process to comprehend the nature of risk and to determine the level of risk” (ISO31000, 2009).</td>
</tr>
<tr>
<td></td>
<td>Determine the “as-is” state</td>
<td>The “as-is” state has to be determined in order to represent the current situation that might need to be changed according to laws and regulations requirements.</td>
</tr>
<tr>
<td>Design</td>
<td>Direct and manage privacy budget</td>
<td>Budget concerns must be examined. Contingency and management reserves must be scrutinized and decisions about including them in the cost baseline should be made.</td>
</tr>
<tr>
<td></td>
<td>Direct and manage privacy portfolio</td>
<td>This process describes the solutions currently being considered and being developed by the organization, along with its present contractual commitments, and retired solutions (TSO, 2012).</td>
</tr>
<tr>
<td></td>
<td>Perform privacy design package</td>
<td>Defines all aspects of a privacy product, service, or result and its requirements through each stage of its lifecycle. A privacy design package is produced for each new privacy</td>
</tr>
<tr>
<td>Implement</td>
<td>Perform privacy integrated change</td>
<td>It is the process where all approved privacy assets change requests are implemented and communicated (PMI, 2017).</td>
</tr>
<tr>
<td>Direct and manage privacy assets and configuration</td>
<td>The purpose is to guarantee that the assets required to deliver products, services, or results are controlled in a truthful and correct way, &quot;and that accurate and reliable information about those assets is available when and where it is needed&quot; (TSO, 2012).</td>
<td></td>
</tr>
<tr>
<td>Perform privacy release and deployment</td>
<td>The purpose is to &quot;plan, schedule and control the build, test and deployment of releases, and to deliver new functionalities required by the business while protecting the integrity of existing&quot; (TSO, 2012) products, services, or results.</td>
<td></td>
</tr>
<tr>
<td>Operate</td>
<td>Direct and manage incident and breach work</td>
<td>The purpose is to decrease the harmful impact on individuals and, on organization reputation, image and its assets, satisfy communication requirements to interested parties, and reinstate normal service operation as swiftly as possible (TSO, 2012).</td>
</tr>
<tr>
<td>Direct and manage privacy service desk</td>
<td>As the single point of contact for Data Subject Access Requests (DSARs) both for employees as for customers on a daily basis, the purpose is to direct and manage this organizational interface.</td>
<td></td>
</tr>
<tr>
<td>Direct and manage data life cycle</td>
<td>It is the process that organizations use to direct and manage the flow of data and information throughout its life cycle, i.e. from collection, use, share, retention, and deletion.</td>
<td></td>
</tr>
<tr>
<td>Direct and manage information security work</td>
<td>This process is focal for all information security controls. It ensures that the information security policy is communicated and enforced, enabling an adequate management of the organization’s data and information regarding its confidentiality, availability and integrity (TSO, 2012).</td>
<td></td>
</tr>
<tr>
<td>Monitor and control</td>
<td>Plan privacy improvements</td>
<td>Provides guidance and instructions regarding intended privacy improvements.</td>
</tr>
<tr>
<td>Do</td>
<td>This process deals with the execution of the plan.</td>
<td></td>
</tr>
<tr>
<td>Check</td>
<td>This process works toward the monitoring and measurement of progress against the privacy improvement plan.</td>
<td></td>
</tr>
<tr>
<td>Act</td>
<td>The purpose is to identify deviations against the plan and act in accordance with its prevention or correctness definition.</td>
<td></td>
</tr>
</tbody>
</table>

Each stage and process address risks and opportunities and may have internal and external interested parties, which are shown in a responsibility assignment matrix (RAM), e.g. the use of a RACI (responsible, accountable, consult and inform) chart may be useful to ensure explicit and unequivocal assignment of roles and their essential responsibilities. Moreover, “RAMs can be developed at various levels” (PMI, 2017).

**Enablers**

Organizational “enablers are all that [singly or jointly] contribute and seek to construct the purpose in a positive-sum manner” (Costa et al., 2018). Thus, it includes “any [assets, i.e.] resources or capabilities” (TSO, 2012) that could contribute to the achievement of privacy requirements. The literature review has showed that there is a commonly agreed-upon definition and categorization of organizational enablers, e.g. Müller et al. (2016);
ISACA (2016); Costa et al. (2017); leading us to adopt and adjust existing categories for PRIMROSE use. Therefore, privacy enablers are grouped into eight categories: (i) people, skills and competencies, (ii) organizational culture, (iii) laws and regulations, (iv) organizational structures, (v) frameworks, (vi) physical design and networked infrastructure, (vii) rules and codes of conduct, (viii) information technology and applications. These privacy enablers can be organized into two parts: process facilitators and discursive abilities (in Table 4).

Table 4 – Privacy enablers (After Costa et al., 2017; Müller et al., 2016)

<table>
<thead>
<tr>
<th>Privacy Enablers</th>
<th>Process Facilitators</th>
<th>Discursive Abilities</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Factors</strong></td>
<td>Touchable characteristics, conditions, and variables that directly impact the effectiveness, efficiency, and viability, e.g., laws, regulations, standards</td>
<td>Effective communication and interpersonal skills that influence the mindset and behaviors of individuals, e.g., people, skills and competencies</td>
</tr>
<tr>
<td><strong>Mechanisms</strong></td>
<td>Trigger or accumulate actions in organizations to increase the likelihood of a certain output, outcome and benefits, e.g., structures, rules and codes of conduct</td>
<td>Structures that support effective communication (discourse), e.g., synchronized communication structures, dedicated network structures, e.g., shared beliefs, corporate culture</td>
</tr>
</tbody>
</table>

According to Costa et al. (2018), whilst effectiveness is defined as the expected organizational satisfaction of the privacy requirements (permanent enablers), efficiency has to do with the employees and collaborators of the organization, seeing that if they are educated and trained in privacy, data protection and security of processing, to what extent can they rapidly perform activities towards the resolution of privacy issues, concerns and problems, i.e. to be effective (temporary enablers).

**Composite requirements**

Composite requirements, i.e. high-level requirements “does not have its own testable fit criteria, but it rather "summarizes" a number of other individually testable requirements” (Robertson and Robertson, 2006). Therefore, the privacy composite requirements or themes are, as follows: (i) Governance structure, (ii) Inventory, (iii) Policies, (iv) Training, awareness and indoctrination, (v) Personal information life cycle, (vi) Security of information, (vii) Communication, (viii) Data subject access request, (ix) Incident and breach management, (x) Legal, third parties and transfers mechanisms, (xi) Monitoring, measurement, analysis and evaluation, (xii) Risk management, (xiii) Evolution of legislation and practices, and (xiv) Service level agreements. Moreover, they should coherently group several fundamental and distinct requirements. There are controls associated with these requirements that can be obtained from the Regulation, the BS10012 and the ISO27001.

**Continuous service improvement**

The purpose of the service improvement layer of the PRIMROSE method is to align privacy related business services with variable environment requirements, e.g. new laws and regulations, making the bridge between the external environment and the organization and, its internal environment, by acknowledging and communicating legislation updates to interested parties. These alignment activities support the PRIMROSE lifecycle approach through diagnosis, design, implement, operate, monitor
and control, constantly searching for ways to improve the "effectiveness, process effectiveness and cost effectiveness" (TSO, 2012) of privacy related services.

**Method**
The pursued research purpose is exploratory mainly because the scope of the study focuses on the situation under analysis and no concerns for generalization are made explicit at this stage.

In addition, the presented research questions were used to guide a literature review, which supported the definition of the questions to be asked in two exploratory qualitative data collection situations, as follows: (i) one focus group made up by four participants and one moderator, one of the researchers. All participants are part of the sponsor company, i.e. the DATASHIELD DPBCS, and they act professionally as Data Protection Officers (DPO); (ii) eight semi-structured interviews led by the same researcher made to DPO working within the Portuguese context. DPO are individuals designated by the organization on the basis of professional competencies and, in particular, of expert knowledge on data protection law and practices (Regulation EU, 2016).

Data treatment and analysis was positioned under an interpretivist stance. It was supported by the use of the Vivo12 Plus software. In addition, visual representations were used adding more meaning to the findings. Moreover, the data analysis process occurred in the following steps: to produce audio transcriptions and to become familiar with the data, coding, and searching for themes, patterns and relationships. Chosen themes will be strongly justified by extant research. Finally, the themes were refined in order to be able to progress towards valid and firm foundation conclusions regarding the initial research questions.

**Illustrative results and conclusions**
This research addresses the [RQ1] *What are the high-level requirements of the permanent organization to be GDPR compliant?* and [RQ2] *How should be the GDPR requirements managed in the permanent organisation?* Thus, a qualitative study was carried out. An interdisciplinary literature review on the General Data Protection Regulation (GDPR) recitals and articles, on the data protection and privacy body of knowledge, and on security of processing was pursued. The interdisciplinary approach resulted into the melding the aforementioned knowledge with the literature related to privacy management. Outcomes are, as follows: (i) privacy requirements are supported by privacy principles and by privacy strategy [RQ1], (ii) organizational enablers (permanent and temporary) contribute and seek to construct the privacy purpose in a positive-sum manner [RQ2], (iii) privacy maturity models are acknowledged as a means by which organizational privacy progress can be measured against their organizational and technical implemented measures [RQ2], (iv) there is a gap regarding a generally recognized privacy management method [RQ2], i.e. a means by which the elements of the method described are applicable to most organizations most of the time, and there is agreement about its value and utility. The authors argue for PRIMROSE as an organised way to decrease the probability of risk occurrence, as well as its negative impacts, that are associated with this privacy management gap [RQ2].

Moreover, the focus group that was put together and eight semi-structured interviews confirmed these findings from the literature review. In addition, interviewees added new perspectives, namely: (1) they referred the existence of a common set of requirements on a relevant number of organizations most of the time. However, they also raised the need for specific descriptions of sectoral sets of requirements, e.g. health, education, insurances and so on; it is recognised that this sectoral set of requirements should be developed as
extensions of PRIMROSE, by interpreting additional specific issues and risks and by expanding the precepts of privacy management defined in PRIMROSE to specific sector needs [RQ1]. (2) Interviewees confirmation also allowed to explore and develop the semantics of the method root definitions, e.g. the proposed principles, stages, processes, enablers and high-level requirements elaborated as a function of the privacy environment [RQ1;RQ2]. (3) Multidisciplinarity [RQ2] was required to face the challenges that privacy and data protection demands. However, findings from the focus group brought forward for reflection interdisciplinarity instead [RQ2], in order to draw a bridge between disciplines and to become a truly integrated and coherent whole. Further research reflections also suggest transdisciplinarity as a required configuration of knowledge in the privacy and data protection curriculum to be analysed. (4) At the time of this investigation, the lack of national legislation, i.e. in Portugal, both in the public and private sectors, is often highlighted as an argument for the organizational leaders and executives postpone and not allocate the necessary resources to satisfy the privacy requirements in their business. (5) Interviewees clearly expressed that the State should give the example. (6) Careful consideration should be made regarding the primacy of the European Union law, as it functions as a principle aiming to assure uniform appliance of European Union legislation within the Member States.

As recommendation for further work, this investigation suggests that the pursued paths should be improved and further extended. The method should be progressively more elaborated, as far as optimizations and adjustments might occur, and as details and relationships become clearer. Moreover, it is expected that the presented descriptive model should generate several analytical ones with more limited scopes.

Finally, the meaning of what constitutes the success of data protection or privacy measures should be further investigated from the perceptions of the relevant interested parties, i.e. the stakeholders (Costa et al. 2017; Costa et al. 2018).

In summary, this assignment operationalised an exploratory research to address the general high-level requirements for organizational privacy resilience by proposing an innovative privacy management method positioned within the scope of an original conceptual model previously introduced by the authors (please vide Costa et al., 2017; Costa et al., 2018). It is believed that this might suggest a relevant contribution to the practitioner, because guidance to a more systematic diagnosis, design, implementation, operation, monitoring and controlling procedure concerning privacy management might come out. This method is also considered as an advancement to data privacy theory due to its originality. In addition, research as a path to avoid abusive prescriptions to real world problem-situations has also been valued through the outlined investigation.

Abstract

The aim of this paper is to provide new perspectives on the implementation of new operations management practices by applying three different but interrelated frameworks: Human Interaction Dynamics, Normalization Process Theory, and Professional competence as ways of being. The empirical material in this paper is based on a case study within a global manufacturing company, and more specific the development and implementation of a new OM practice for knowledge sharing at one of the sites in Sweden. A mixed-method approach is used, and the empirical material is collected through analysis of a database, two group interviews, and a survey.

Keywords: Knowledge sharing, Human Interaction Dynamics, Normalization Process Theory, Professional competence

Introduction

In the pursuit of maintaining competitive production systems, manufacturing companies make great efforts to develop and implement new operations management (OM) practices that actually make a difference. In this draft paper, we explore an implementation of a system for knowledge sharing, intended to increase the level and quality of knowledge sharing within a global manufacturing organization. All staff, in all parts of the organization, can ubiquitously both share what they have experienced as good practices, and retrieve information that have been shared by others.

However, the reality of many companies indicates that there are major challenges when trying to implement new OM practices as an integrated part of the established
production system, which also is the situation in the case used in this paper. Thus, finding the keys to an agile integration of new OM practices then becomes an essential capability for companies to possess. Following this, the aim of this paper is to provide new perspectives on the implementation of new OM practices by applying three different but interrelated frameworks: Human Interaction Dynamics (Hazy and Backström 2013), Normalization Process Theory (May et al 2009, May et al 2016), and Professional competence as ways of being (Sandberg 2000, Sandberg and Pinnington 2009). The following research question is addressed: To what extent and how are the new OM practice for knowledge sharing integrated in the current production system?

Theoretical framework
In this section, the three perspectives that constitutes the theoretical framework are introduced. A common ground for all three perspectives is that they address different aspects of how human action and interactions in organizations can be explained. However, what differentiates the frameworks is the level of analysis and its primary unit of analysis.

Human Interaction Dynamics
Implementation of new OM practices usually occurs as a mean to bring change into an established production system. A production system is constituted by a web of OM practices, which together creates an organizational whole that emerge over time (Hazy and Backström 2013, Backström 2017). From a human interaction dynamics perspective, An OM practice – such as a system for knowledge sharing – are based on three structural elements (Fundin et al 2019): a) External structures, which refers to structures external to the specific situation. In a company, the external structures are embodied as formal work descriptions, SOP’s, tools (e.g., machines or IT-systems), laws and other national or international regulations. b) Internal group structures, which refers to the structures that emerge from the interaction between group members in terms of norms and values, and c) Cognitive structures, which refers to the individual actors internal dispositions in terms of knowledge, skills, and attitudes. All three level of structures are of a temporal character, and, as indicated in figure 1, social interaction is the key for both modifications and emergence of new structures, and, reinforcement and continuation of established structures. Thus, implementation of new OM practices requires modifications of structures on all three levels.

![Figure 1. Basic building blocks in human interaction dynamics (Fundin et al. 2019)](image-url)
Normalization process theory

How new OM practices actually affects a company and make a difference, depends on if and how it becomes an integrated part of the already established production systems (cf. May and Finch 2009, May et al. 2016). From a Normalization process theory (NPT) perspective, a successful implementation is a normalization process in which a new practice becomes 1) Embedded, that is routinely incorporated in everyday work i.e. in the cognitive and internal group structures, and over time becomes 2) Integrated, that is reproduced and sustained among the external structures of an organization. According to May and Finch (2009), implementation is operationalized through four generative mechanisms: Coherence: The sense-making work that people do individually and collectively when faced with the problem of operationalizing some set of practices. Cognitive participation: The relational work that build and sustain a community of practice around a new technology. Collective Action: The operational work that people do to enact a set of practices, whether these represent a new technology. Reflexive Monitoring: The appraisal work that people do to assess and understand the ways that a new set of practices affect them and others around them.

However, from an organizational perspective, a core issue is to achieve a fast and smooth implementation where new OM practices rapidly becomes an integrated and functional part of the production system, without losing the benefits of already established practices. In this respect, the current NPT does not provide sufficient empirical based knowledge on agile integration of new OM practices in manufacturing organizations. A proposition in this paper is that an important feature of agile integration is the plasticity of OM practices and the elasticity of the production system (May et al 2016). Thus, agile integration emerge in the interaction between the new and existing OM practices.

Professional competence as ways of being

Furthermore, to understand the implementation of new OM practices from an individual point of view, Sandberg and Pinnington’s (2009) theory on professional competence as ways of being provides a pertinent perspective. Sandberg (2000, p. 20) concludes that: “workers’ knowledge, skills, and other attributes used in accomplishing work are preceded by and based upon their conceptions of work.” (Sandberg 2000, p. 20). That is, professional competence implies they ways knowledge and skills are used in the particular situation. However, in Sandberg and Pinnington (2009, p. 1162), the authors also conclude that individual attributes – such as knowledge and skills – only constitute one aspect of competence, used to perform a certain work. Instead, professional competence emerges in any given situation as ways of being, based on the individual’s self-understanding (e.g., identity as an operator), his or her understanding of work, relations to other people, and different tools that are accessible.

Research Design

The empirical material in this paper is based on a case study within a global manufacturing company, and more specific the development and implementation of a new OM practice for knowledge sharing at one of the sites in Sweden. A mixed-method approach (Merriam & Tisdell 2015) was used, and the empirical material was collected through content analysis of the database, two group interviews, and a survey.

First, to understand how the new OM practice for knowledge sharing was used, we conducted a qualitative database-analysis of what was shared in the database. The database-analysis was conducted in collaboration with one employee at the case company, working at the department of Operational Excellence.
Second, two semi-structured group interviews were conducted. As respondents in the two interviews, we invited the top ten contributors of good practices shared in the database. Seven of the invited accepted, and at the first interview four of the respondents participated, and at the second interview, the last three respondents participated. The interviews covered three main topics: General thoughts about the new OM practice; Their own experiences of using the OM practice; and, Other arenas for knowledge sharing.

Third, to understand to what degree the new practice for knowledge sharing has been embedded and integrated in the production system the NoMad survey (Finch et al 2015) was used, for measuring the implementation processes from the perspective of the managers and employees who are the potential users of the knowledge sharing system. The survey was distributed to 100 respondents (managers and staff) within one Swedish operations unit, with a response rate of 40%.

Findings
In this section, we provide some tentative findings related to our RQ: To what extent and how are the new OM practice for knowledge sharing integrated in the current production system?

A new system for knowledge sharing
Since a couple of years, a new OM practice for knowledge sharing is used in the case organization. The OM practice is based on an open database to which all staff, in all parts of the organization, can both share what they have experienced as good practices, and retrieve information that have been shared by others.

According to one of the process owners, an overall intention with the new OM practice for knowledge sharing is to lower the threshold to share ideas and good practices among different sites and units. To avoid “inventing the wheel” again, is also used as an expression to describe the purpose of the OM practice, based on the idea of re-using knowledge and good practices developed throughout the organization. Since the introduction of the OM practice, global level SOP’s are in place and the technical system is functional, although there are some reports on being slow and hard to find on the internal web. The system contains already over 15000 contributions shared worldwide, and almost 1700 good practices are shared from staff at the Swedish sites to due date.

Each month the global process owners of the new OM practice has a meeting were one or more of the new good practices are promoted, which means that it becomes highlighted and easier to find in the database. Further, when a good practice is ‘used’ or ‘adopted’ by anyone in the organization, he or she notes that in the database, which later has been measured and used as a KPI.

Distribution of power through an open and accessible system for knowledge sharing
Both the responses from the survey and the group interviews indicates that the basic idea of the OM practice for knowledge sharing seems to be well received in the organization. During the group interviews there are a lot of positive assertions about what the system brings in terms of added value. For example, the system is open and accessible to everyone in the organization, which can be described as contributing to a distribution of power. Everyone is allowed to share his or her good practices to anyone in the organization. However, when it comes to the practice of using the system for knowledge sharing in the Swedish organization, a different picture appears in the empirical material.
A brief look at the good practices shared in the system
To get an overview of what kind of practices that has been shared in the system, a content analysis on a number of practices was conducted. As the number of good practices shared was relatively high, we selected the shared practices that were most frequently ‘used’ or ‘adopted’ by anyone in the organization.

To understand what type of benefits the good practices served, we divided them into four themes: Inspiration, Improve process, New process, and, Transform system. The analysis indicates that the two themes in which most of the practices can be placed was ‘Inspiration’ followed by ‘Improve process’. Further, we also analysed to what degree 'evidence of value' was provided as information when describing the good practices. The results indicates that very few of the shared practices provided any evidence of potential value (2 out of 21). However, information about ‘evidence of value’ was not requested from the system when the good practices was entered into the database.

Constraints for using the system for knowledge sharing
The results from the NoMad-survey indicates that the use of the OM practice for knowledge sharing is relatively low. Only a few individuals seems to be continuous contributors of good practices. Over 70 % of the respondents had never contributed to the database, and the rest responded positive to the statement that they had contributed to the database only “a couple of times a year”. In terms of searching information in the system, over 50 % responded that they never had used the database, 47,5 % responded that they had searched for good practices “a couple of times a year”, and only 2,5 % had searched “a couple of times a month”.

This picture of how frequently the OM practice for knowledge sharing is used is supported by the group interviews, both when it comes to contributing to the system, and retrieving information from the system. Although people seems to be positive to the basic idea of the system for knowledge sharing, a number of reasons why the system is not used as intended emerge in the group interviews. First, technical constraints, are identified both in the survey and the group interviews as one problematic issue. The system is lagging and experienced as slow when entering new good practices into the database. Also, it is not obvious how to label the things that are entered into the database, which becomes an obstacle that might scare people of. That is, the system is not intuitive enough for people to use without having proper knowledge about how it works. Second, time constraints, are experienced, which means not having the proper time to use the system. Partly, this can be explained due to the technical issues in terms of delays when entering good practices into the system, but also due to not having the time to prioritize the sharing. Third, management constraints, in the sense that in the group interviews it becomes obvious that the use of the system is mainly driven by the fact that they are measured on it by senior management, and not due to experienced benefits from using it. One of the respondents concludes that “Unless it is not requested it will die, if it is not really good”. Another aspect of managerial constraints, is that there is an insecurity of what is acceptable to share, that is, what are the requirements on the good practices entered into the database? According to one of the respondents, there seems to be different views of when something is mature enough to share, while some share things that still is work in progress, others seems to wait until they have a proof of concepts.

Other mediums for knowledge sharing
In the group interviews, the respondents were also asked what other mediums for knowledge sharing they are using. A recurring answer on the question was the relational networks in which the respondents are a part. The relational networks refers both to
personal networks – colleagues and friends at work –, and different professional
networks, which frequently were used when the respondents needed to find a solution to
a problem they had encountered. Through the interaction with different colleagues, they
many times manage to solve the encountered problems and gain new knowledge in the
area.

Conclusion
The aim of this draft paper is to provide new perspectives on the implementation of a new
operations management practice by applying three different but interrelated frameworks:
Human Interaction Dynamics, Normalization Process Theory, and Professional
competence as ways of being.

Previous research using Normalization process theory has mainly been conducted in
the healthcare sector, which makes it interesting to see how it can be used and adapted to
a manufacturing context. Although there are differences between implementing evidence-
based methods in healthcare compared to implementing new OM practices in
manufacturing industry, there are also many similarities. One such similarity is the top-
down initiative for most of its potential users. In both contexts it is possible that the
implementation has been preceded by a pilot study, which in one way or another has
proven to be successful. Followed by a decision that the new practice should be rolled out
and serve as a new standard operating procedure in its domain.

As stated earlier, a successful implementation implies a process of normalization (May
and Finch 2009), that is, when a new practice becomes integrated in the production system
as a part of the routines of how work is done. A key to integration then is sustained
behavioural changes. From the perspective of NPT, it is reasonable to conclude that the
new OM practice presented in the paper has not become normalized. How then can this
be further explained?

From a human interaction dynamics perspective (Fundin et al. 2019), the top-down
decision made to use the new OM practice for knowledge sharing render modified formal
structures – a globally dispersed digitalized tool and new SOP’s –, which set the context
for the staff in all parts of the organization. However, in terms of internal structures –
norms and values – and cognitive structures – knowledge and skills –, the new OM
practice still imply an additional set of tasks to conduct, and is not perceived as a tool that
supports and help solve different problems that are encountered. Using the words of
Sandberg (2000), the general understanding of work does not include the new OM
practice for knowledge sharing as a mean to solve problems. This can be compared to the
relational networks, which are frequently used as a mean to gain new perspectives on a
problem, and not seen as a task in itself.

Finally, to become a functional OM practice for knowledge sharing, the new OM
practice needs to be embedded into the routines of everyday work, which not seems to be
the case now. Previous implementation research have provided knowledge on whether or
not organizational interventions are effective, but less focus have been on how, when or
why interventions have a positive impact on organizations (Biron and Karinka-Murray
2014). Thus, there is a need for further empirical research that address the role of process
and contextual variables, and how it influences the implementation of new OM practices.

Abstract
Changes related to the information age or Industrial Internet of Things (IIoT) have led to new opportunities, which influence the internationally distributed manufacturing networks. The derived results show that IIoT initiatives are based on five dimensions (digital technologies, connectivity, data, capabilities and management), which are highly interrelated. The analysis reveals that if the level of standardisation in products, processes and systems is high and headquarters takes the responsibility to centrally manage the network and give little autonomy to the plants, a company can unravel the potential of its IIoT initiatives more than without taking the manufacturing network coordination into account.

Keywords: Industrial internet of things, manufacturing network coordination

Introduction
The pace of change in information and communication technologies (ICT) is still accelerating and influences every industry (Alcácer et al., 2016). International business literature defines these changes as the information and communication age and discusses influences on the geographical distribution of the international business activities...
Alcácer et al. (2016) highlight that the changes go beyond location and enfold, for example, organisational decentralisation or modularisation. Innovations in ICT heavily influence the MNEs’ international production processes (Chen and Kamal, 2016). Researchers and practitioners agree that ICT influences multinational enterprises (MNEs) and that the transformation is still ongoing.

As many medium and large manufacturing companies have gone from producing at single sites to having multiple production plants spread around the globe, ICT not only influences a single site but the manufacturing network. Manufacturing networks enfold multiple plants of one organisational company, most often, scattered around the globe in order to gain access to new skills or low-cost resources. If a company is not satisfied with the manufacturing performance, a variety of improvement suggestions is available. These improvement programs are usually on the site level, concentrating on optimising single sites in isolation. The improvement programs seldom take into account that today’s companies are often composed of multiple manufacturing sites, which are connected and affect one another (Manyika et al., 2012). Subsequently, there is a need to jointly manage and optimise these sites as a network (Feldmann et al., 2013). Hence, manufacturing network coordination remains one of the key challenges (Scherrer and Deflorin, 2017).

One of the improvement areas for manufacturing companies results from innovations in ICT. Whereas in international business (IB) the changes related to ICT is widely known as the information age, operations management (OM) summarises similar changes as industrial internet of things (IIoT), digital manufacturing or Industry 4.0. Despite differences in the exact definition, two commonalities are the internet enabled information and communication technologies and the achieved connectivity. Many researchers have analysed the influence of ICT on a single manufacturing site (e.g., Kang et al., 2016). Others analysed the influence of new technologies, such as additive manufacturing, on the global supply chain (Laplume et al., 2016, Vereecke, 2017). Despite some research on the supply chain level, the influence of ICT or IIoT on manufacturing network coordination is unclear. Hence, we focus on the influence of IIoT on the coordination of internationally distributed plants and shed light into how manufacturing network coordination is influenced. Thus, we answer the following research question: “How does IIoT influence manufacturing network coordination?”.

**Literature review**

*Information Age, Industrial Internet of Things, Industry 4.0, Digital Manufacturing*

New technologies influence the way industrial companies compete. The changes are labelled information age (e.g., Alcácer et al., 2016) (Alcácer et al., 2016), industrial internet (Posada et al., 2015), digital manufacturing (Wang and Wang, 2016) or industry 4.0 (Posada et al., 2015).

One commonality of the concepts is the internet of things (IoT) (Annunziata and Evans, 2012). Although there is not yet a common definition, the core concept is “that everyday objects can be equipped with identifying, sensing, networking and processing capabilities that will allow them to communicate with one another and with other devices and services over the internet to achieve some useful objective” (Whitmore et al., 2015, p.261). Hence, central to this perspective is the connectivity or interconnection (Hermann et al., 2016).

Analysing the key components relevant to the information age, industry 4.0, industrial internet of things and digital manufacturing highlights similarities, which can be grouped into (1) technology, (2) data and (3) people (e.g., Whitmore et al., 2015). Technology enrolls the hard- and software needed (i.e. sensors and actors) and the connectivity (i.e. interfaces, WLAN and protocols). The digital technologies combined with the
connectivity allows the generation of data which are the key driver of the information age. The combination of digital technologies, connectivity and data build the basis for visual analytics, augmented reality or simulation/visualisation (Posada et al., 2015). Besides the similarities in technologies and connectivity, another cross-cutting theme is the people at work, enfolding the changes in capabilities or human-machine cooperation (Hermann et al., 2016, Posada et al., 2015, Whitmore et al., 2015). In addition to the capability perspective, the people dimension covers the management perspective. Westerman et al. (2014) highlight that in order to turn technology into business transformation, four dimensions need to be covered from the management: (1) framing the digital challenge, (2) focusing investments, (3) mobilising the organisation, (4) sustaining the digital transition. Whereas the discussion of capabilities (i.e. data analytics) is present in all the described concepts, the management perspective did not receive the same attention. We determine that in order to successfully coordinate new potentials based on IIoT, the management perspective should be included.

Hence, we conclude that although the main vision of the concepts differs, the underlying factors related to digital technologies, connectivity, data, capabilities and management are similar. Hereafter, we use the term Industrial Internet of Things (IIoT) to summarise the dimensions, which serve as triggers for changes in companies.

Manufacturing Networks
Many studies have demonstrated the importance of understanding business networks (e.g. Andersson and Forsgren, 2000). Business networks are composed of subsidiaries that enfold different functions (e.g. R&D, manufacturing, sales). In this, manufacturing networks are dedicated to manufacturing plants and emphasises operations. In both network forms, the coordination of the subsidiaries or plants is important and especially, how the coordination of multiple subsidiaries/plants influences performance.

To analyse this, the study at hand does not employ measures of performance such as innovation or growth in sales, but focuses on operational performance as defined by Flynn et al. (2010), Vereecke et al. (2006) and Szász et al. (2016). We refer to two classes of operational performance: efficiency (cost and lead time) and effectiveness (quality, delivery, flexibility). These categories are also found in the OM literature (Szász et al., 2016).

Manufacturing Network Coordination
Coordination defines how to link, integrate, and organise manufacturing plants in order to reach strategic business objectives (Cheng et al., 2011). In their literature review on manufacturing networks, Scherrer and Deflorin (2017) distinguish between two main research areas of manufacturing network coordination: (a) how the physical and non-physical flows between sites in the network are designed and managed and (b) how rules and mechanisms for interaction between the sites, the sites and headquarters, or the sites and central network management are designed and established.

The study at hand emphasizes on coordination mechanisms of plant interactions, operationalised through the level of operational and strategic autonomy (Kawai and Strange, 2014) and parental control (Van Dut, 2013), the level of standardisation of R&D, production processes, and quality control (Maritan et al., 2004), coopetition and target setting and incentives (Luo, 2005).

Industrial Internet of Things and Manufacturing Network Coordination
The literature review on IIoT and the related concepts (information age, digital manufacturing, Industry 4.0) highlights the relevant underlying dimensions. In order to
be able to gather and distribute information, there is a need of digital technologies such as sensors and actors, image transmission, software and data storage (Porter and Heppelmann, 2014). In addition, there is the need to connect the devices, products or processes. Connectivity enfolds the ports, antennae and protocols which enable wired or wireless connections (Porter and Heppelmann, 2014, Hermann et al., 2016, Whitmore et al., 2015). The generation, storage and analysis of data builds another relevant cornerstone.

Finally, every transformation has a people side. There is a need to develop new capabilities such as data analytics or the human-machine cooperation (Hermann et al., 2016, Posada et al., 2015, Whitmore et al., 2015). In addition to the new set of capabilities needed, the new possibilities need to be steered and pushed from top management (Westerman et al., 2014).

Our aim is to understand how the IIoT enabler influence manufacturing network coordination. Thus, based on the above-described dimensions, we derive the research model as demonstrated in Figure 1.

Methodology
As we aim at understanding how IIoT influences manufacturing network coordination, we need to gain profound understanding of the relevant elements of IIoT and the manufacturing coordination mechanism. Subsequently, we follow a qualitative research approach (Eisenhardt, 1989). The advantage of gaining deep insight into IIoT ideas of one company was more important than having a broad but superficial data set. In doing so, the company, and more specifically, the manufacturing network level, serves as unit of analysis. The company chosen for analysis is a leading European manufacturer with eight business units, which occupy 2.000 employees in production sites and sales offices around the world. The company was chosen because of its qualification to generate usable results rather than because of its representativeness (Miles and Huberman, 1994). Eisenhardt and Graebner (2007) recommend that the case study approach is particularly suitable for topic areas not well documented and rather unknown, which suits our topic of interest. We have conducted an explanatory research approach (Eisenhardt, 1989, Eisenhardt and Graebner, 2007) that started in March 2016 and finished in July 2017. It involved eleven semi-structured group interviews with seven employees of the general management board. All interviews were attended by three researchers of the field of operations management to gain as much objectivity in result interpretation as possible. The interviews lasted between two and four hours. In addition to the interview data, we used multiple data sources such as archival data, industry publications, manuals, and company documentation. To analyse the collected data, we used Miles and Huberman’s (1994) four-step approach.
Case Analysis
IIoT initiative “digital workflow and digital product”
The company under investigation faced two challenges, which they want to overcome. First, the assembly process was time-consuming because of missing information, poor quality and search for information. Second, there was a lack of customer specific information. This contained lack of information about the production history of the product, or lack of information about installed software updates since the product was handed over to the customer. Especially, technical and service engineers complained time-consuming information seeking, since customer-specific information was not available across all divisions (R&D, manufacturing, assembly, sales, customer service, etc.). To overcome these issues, the company decided to launch the IIoT initiative “digital workflow and digital product”.

The core idea of the initiative “digital workflow and digital product” (see Figure 2) is to develop and engineer the product virtually and to collect all information of each product of the company’s portfolio digitally. Based on this digital product, a digital workflow is derived. The digital workflow serves as guideline throughout each supply chain step. It steers and monitors the activities as, for example, the assembly employees digitally confirm each process step and save additional data about the production process, if necessary. These data are saved in the customer’s history of the produced product in the product life cycle management (PLM) system. Thus, the company has a virtual dataset of the delivered machine. After installation at the customer’s site, additional data, such as software updates or maintenance that the customer conducted, are also saved in the customer history of the product. Thus, the initiative “digital workflow and digital product” not only gathers data from production, assembly and customer service but also provides information about the digital product (customer neutral) and the customer specific data. Both data (customer specific and neutral) are saved in the PLM system. The issue-tracking systems guarantees the backflow of information from the customer or customer service to the company. This supports the continuous improvement of the processes. However, there is no continuous monitoring of the product’s condition at the customer’s site and thus, the company cannot exploit the full potential of a digital twin.

![Diagram of Product Lifecycle Management](image)

Figure 2 – Initiative “digital workflow and digital product”

Headquarters is responsible for the implementation of the “digital workflow and digital product” within each production site. Thus, headquarters is responsible for the definition of the IT-system and its implementation at the sites. In addition, each process step has an assigned owner, responsible for the provision of the needed data and the continuous improvement of the digital workflow and the digital product. The process owner is also responsible to coordinate the operating activities at each production site of the company’s network. Thus, headquarters is able to transfer production capacity between their internationally distributed production sites.
Enablers of the IIoT initiative
The following section summarises the enablers for the IIoT initiative “digital workflow and digital product” according to the five dimensions of the research model: (1) digital technologies, (2) connectivity, (3) data, (4) capabilities and (5) management.

(1) From the technological point of view, the product-lifecycle-management system (PLM) is the backbone of the “digital workflow and digital product”, in which all information is accumulated and the product data including the customer specific production, maintenance and service data are stored. It is extended by the “digital instruction creator” and an “interactive process monitoring” software, all based on web-technologies, dashboards and interfaces to e.g. virtual reality technologies.

(2) Connectivity over-spanning the complete manufacturing network is one of the key elements of the “digital workflow and digital product”.

(3) The technologies and the achieved connectivity between systems, processes and functions allows gathering data. The digitally available data, stored in the PLM-system, allows having up-to-date information on products and processes. In addition, the data from the issue-tracking systems allows, based on data-analysis, to derive improvements for processes and products. In the long run, the data allows the derivation of patterns of customer preferences, suppliers or cost structures which provide new insights for the company’s development.

(4) On the human side, requirements on capabilities and management have to be distinguished. The initiative needs a change in the mind-sets of the company’s employees. The new initiative “digital workflow and digital product” is based on three underlying philosophies. (a) The digital assembly philosophy, consists of a paperless workflow. (b) Cross-functional information- and knowledge-exchange. (c) The third philosophy takes all phases of the product-lifecycle into account, from the first ideas up to the disposal of the product.

The capability of data analysis is inevitable. Especially the capability to analyse and structure all gathered data to generate useful knowledge is key. This capability is central in order to learn from the issue-tracking system and to enhance the knowledge base further. Additional capabilities enclose software and hardware (i.e. sensors) capabilities.

(5) A key task of the management is the definition of responsibilities. Therefore, system- and process-owners have to be defined and project management has to be set up. Likewise, the management has to picture a clear vision of the three underlying philosophies and to communicate its importance. Finally, a concept of human resource development is established in order to ensure the development of the needed capabilities.

Another change encountered concerns the project management activities. The stage-gate-related project management (i.e., Cooper et al., 2002) or the very detailed planning requirements of six-sigma or lean management is adapted to an agile project management philosophy. Due to the fact, that many technologies are still new and the cause-effect-relation unclear, the company changed its project-management philosophy to a step-by-step and trial-error approach.

Network Coordination and the “digital workflow and digital product”
The initiative “digital workflow and digital product” is centrally developed (i.e., headquarters) and implemented at each production site. Thus, the initiative influences not only the production site but also the international manufacturing network. The following section covers the manufacturing network coordination mechanism and analyses the influence of the “digital workflow and digital product”.
Autonomy vs. parent control

Headquarters drives the initiative and, in cooperation with the production sites, defines the (software) systems and processes. Thus, strategic decisions are all done centrally (high level of parental control). Although the process owner is located at a production site, the responsibility is clearly defined and thus, the level of operational autonomy is low.

Standardisation

The initiative “digital workflow and digital products” needs a high level of standardisation in processes, products and systems.

Coopetition (degree of cooperation and competition)

In former times, some of the business units that belong today to the company under investigation were competitors in similar fields. Thus, the transfer of knowledge and information was difficult. Different initiatives concerning the level of standardisation have led to a higher level of cooperation between the plants (i.e., product modularisation). The initiative “digital workflow and digital products” asks and enables a high level of cooperation as the products should be transferred easily between the production sites. In addition, the continuous improvement based on the data gathered (e.g., issue-tracking-system) allows every plant to improve. Thus, each plant has an incentive to cooperate.

Target setting and incentives

As described above, the level of standardisation in processes, products and systems is high. To achieve that plant managers accept the high level of standardisation and the low level of strategic and operative autonomy, the target setting and incentive systems need to include network level goals (i.e., improvements of the overall network).

Performance

We discuss the performance effect of the IIoT-initiative based on the two dimensions efficiency (cost and lead time) and effectiveness (quality, delivery, flexibility). The main interest is on performance improvements on a network level as we are interested to know how IIoT initiative influence manufacturing network coordination and performance.

Efficiency

The globally available data allows accessing information wherever needed without searching costs. In addition, the high level of standardisation in processes, products and systems should ensure that the level of quality is high and hence, accessed data can be used without further re-work. Compared to the previous system, product transfer costs between production plants can be neglected due to the digital workflow.

From a manufacturing network perspective, the flexible allocation of production capacity may also improve lead time. The company is an equipment manufacturer of large machines. Hence, the possibility to choose a production site, which is nearest to the customer, allows saving transportation costs and lead time. Furthermore, as the company already produced products in batch size one, there is no loss of economy of scale-benefits after the implementation of the initiative “digital workflow and digital product”, as the batch size is still one.

Effectiveness

One of the key changes from a manufacturing network perspective concerns manufacturing network flexibility. The high level of standardisation and parental control allows to allocate capacity where needed. Although, the flexible allocation of production capacity is possible without a digital workflow, the main improvement is that this flexibility does not negatively influence quality and delivery. In point of fact, the quality at each plan can be increased as the digital instructions and the available technologies enable the employees of each site to produce a high-quality product even without extended training. The key enablers are the new technologies, connectivity, capabilities and management activities of the initiative “digital workflow and digital product”.

1532
Discussion
The IIoT initiative “digital workflow and digital product” highlights the composition of the five IIoT dimensions digital technologies, connectivity, data, capability and management. The digital technologies are needed to feed the product lifecycle management system, the digital instruction creator and the interactive process monitoring.

Connectivity reveals itself in technological solutions (platforms, interfaces, WIFI, protocols) as well as in the process level. The connectivity of processes exists between different functions of the company and between the company and the customer. However, without the underlying technological solutions, the connectivity would not be possible. Hence, we conclude that connectivity is one of the most important enablers of IIoT.

To gather data, technology and connectivity are needed. Within the case study, the data is collected throughout every process step. In addition, the data are crucial for the lifecycle management of the products and the transparency of the installed machinery base. One of the most important aspect is the data from the issue-tracking system, which collects incidents within the company (throughout assembly, production, installation) or at the customers site (maintenance, service). The analysis of this data helps to understand how to improve products and processes. The analysis of the supply chain related data (suppliers, product cost structure, customer preferences) may lead to additional insights.

Hence, data is another central dimension of IIoT.

In order to successfully implement the initiative, new capabilities are needed. First of all, data analysis is an IIoT specific capability, which in the case of the analysed company needs to be build up. In addition, there are challenges which are more philosophical in nature and thus, need longer time to adapt. Change needs to be supported from top management. In addition, the need to apply a agile project management philosophy with its trial-and-error culture (Conforto et al., 2014) is another important learning.

The analysis exemplifies that the IIoT enabler are interrelated and hence, need to be taken into account jointly. Thus, an isolated analysis of the new technologies needed is not enough.

The main influence of the IIoT initiative on manufacturing network coordination stems from the digital technologies and connectivity. More specifically, investments in the systems ask for a high level of standardisation. This is mirrored in the level of plant autonomy which, compared to the beginnings of the initiative, is lower. The higher level of parental control is needed to achieve the high level of standardisation in product, processes and systems and with this to being able to exploit the potential of the IIoT enablers.

The higher level of parental control is also needed when it comes to knowledge exchange. The initiative allows to link different production sites. Due to the high level of standardisation in processes and products, headquarters has a high flexibility in deciding where to produce and assemble the products. Accordingly, headquarter can set targets for the collaboration between these plants.

Without cooperation, the joint collaboration on the digital workflow and digital product is not possible, as the initiative aims to implement a company wide system with a high level of standardisation. The cooperative behaviour needs incentives as the high level of standardisation does not always fit to the plant management goals.

The analysis reveals that the enablers and the respective measures in manufacturing network coordination positively influences performance. However, without adapting the manufacturing coordination mechanism, the full potential of the IIoT initiative may not be exploited.
Conclusion
Even though there exists literature that states that headquarters is a relative outsider of the manufacturing network and with this, not able to know which plants should, for example, exchange knowledge with each other (e.g., Van Dut, 2013), later results show differently (e.g., Golini et al., 2016). Their results show that a low level of autonomy is beneficial if the company aims at profiting from the manufacturing network (Golini et al., 2016). The analysed IIoT initiative reveals a similar relationship as a low level of plant autonomy seems to be needed to exploit the initiatives potential.

The results of Golini et al. ’s (2016) study also refer to cooperation. The more a plant embeds itself in its manufacturing network, the more effectiveness benefits such as increased flexibility, quality and dependability can be achieved. Nevertheless, the company’s management needs to pay attention who suitable exchange partners are.

From a managerial perspective, the analysis provides interesting insights. In combination with digital technologies, connectivity is needed to gather and store the needed data. Managers need to decide which processes, functions and supply chain steps to connect. Another decision to be made covers the open versus closed system.

Data is one of the key enablers of an IIoT initiative and reveals an interesting insight as there is a shift from documents to data. The two systems (interactive process monitoring and digital instruction creator) create and transfer data to the PLM system. In order to visualize the data, the two systems pull the data which are stored in the PLM system. This is only possible if data is gathered and stored and not documents. Thus, in order to implement IIoT initiatives, software providers are needed which are aware of this philosophy shift.

Another understanding reveals itself in the project management philosophy. The shift from stage-gate project to an agile project management supports the successful implementation of an IIoT initiative.

The study at hand has its limitations, as it is case study based and the company under investigation is still in the process of implementation and hence, the performance effects need to be evaluated after the manufacturing network coordination mechanism are adapted to the IIoT’s need. Furthermore, the decisions on the manufacturing coordination mechanism are done based on a single IIoT initiative. Further research should consider multiple IIoT initiatives in order to get insights into possible trade-offs.

Overall, the paper at hand shows that companies with internationally dispersed plants can gain benefits from IIoT. It is important to take all dimensions into consideration and to know how to coordinate the manufacturing network. If the level of standardisation in products, processes and systems is high and if headquarters takes the responsibility to centrally manage the network and give little autonomy to the plants, a company can unravel the potential of its IIoT initiatives more than without taking the manufacturing network coordination into account.

Abstract

Due to business uncertainty, both public and private organisations need to adapt to change. Therefore, this study analyses the differences in change operations and proposes key success factors for organisational operation in the case of mergers and acquisitions. In-depth interviews and content analysis are used to collect and analyse data from one state-owned enterprise, and two private organisations. The performance measurement system, equal treatment, employee attitudes, and communications were found to be the success factors supporting operational change but all four factors differ among organisational type and employee level.

Keywords: Change operations, State-owned enterprise, Private organisations

Purpose

Due to instability and uncertainty in the current business environment, such as political, economic, social, and technological development, both public and private organisations have continuously attempted to align their operations with changing situations (Al-Haddad and Kotnour, 2015). The main reasons for organisational change originate from mergers and acquisitions (M&As), government legislation, and strategic reorganisation (Edmonds, 2011). However, M&As have the most impact on organisational change (Brakman et al., 2013). Most organisations tend to fail at managing change (Hodges and Gill, 2015). Moreover, the failure rates are higher than 70% for change initiatives (Erwin and Garman, 2010; Isern and Pung, 2007), which is the same as the failure rate for the post-integration stage of M&A deals (Brakman et al., 2013; Muchlfeld et al., 2012). The majority of these failures are employee-related (Kotter, 1995). Therefore, active operational support for employees is crucial during the change implementation process (Self et al., 2007).

Previous studies have also demonstrated that the particular characteristics of an organisation, including public sector organisations, state-owned enterprises (SOEs), and
private organisations have led to differences in the way organisational change is managed (MacLeod, 2009; Van der Voet, 2015). These differences depend on factors such as organisational goals (social responsibility and profit expectations), culture, structure, and systems. However, most studies related to organisational change focus on the private sector only (Coram and Burnes, 2001), excluding the public sector. In addition, literature on change management in SOEs is limited compared to that available on private sector operations, particularly regarding M&A situations. This study aims to identify the differences between SOEs and private organisations in relation to change situations, as well as analysing the key factors for successful change in both SOEs and private organisations.

Change operations
Skalik (2016) mentioned that change operations are related to organisational policies and general strategies. A company’s policy demonstrates its global vision in relation to operational conditions and guidelines as to how it should behave when undergoing a major change. The strategic principles for change relate to effective employee management, and how the change is designed and implemented depending on the organisational situation (Skalik, 2016). Many researchers have studied successful change operations. These studies reveal that the operational factors to consider during change include an identified vision and goal for the direction of change, stated roles for all employees involved, leadership guidance for those directly involved, employee training, and the implementation of a strong performance measurement system (Ackerman et al., 2001; Bridges, 2003; Kenny, 2006).

Holbeche (2006) stated that a successful change operation is defined by a variety of stakeholder needs. The success of a change operation is measured by short-term financial goals, but there are other considerations for a successful outcome which can be classified into six areas: improvement of business performance in the industry market, positive financial performance with sustained growth, improvement of customer notice for services or products, customer happiness and loyalty, benefits gained from continuous innovation and an increase in industry knowledge, and a better brand image with a good market position.

Key success factors for change
First, organisational performance measurement is an increasingly important issue in many areas such as international business and change management (Larimo, Nguyen and Ali, 2016). The most important decision when facing change involves defining and setting performance measurement goals (Al-Haddad and Kotnour, 2015). Performance measurement helps organisations to evaluate their general progress towards objectives and the management of operations by providing the necessary information to make key decisions (Gunasekaran and Kobu, 2007). Performance measurement systems are also essential for analysing the current development of organisational activities (Schmid and Kretschmer, 2010). Many researchers mention the benefits of performance measurement in relation to three main areas: first, formulation, implementation, and review of an organisational strategy; second, communication of the results achieved to stakeholders; and third, employee motivation at all levels to create a performance improvement culture (Micheli and Mari, 2014).

Second, based on the equity theory (Adams, 1965), employees are concerned not only with the treatment they receive during a change situation, but also that received by others. When employees are forced to change, they compare the effect on their daily
work with that of their colleagues. This can affect employee morale and work behaviour (Williamson and Williams, 2011). Moreover, equity theory also relates to employee motivation and the perception of their input and output ratio in comparison to that of others (Ryan, 2016). When an employee perceives their input and output ratio to be the same as that of others, the perception of equity remains. On the other hand, if an employee feels there to be a difference between themselves and other employees, the perception of equity declines (Taylor, Kluemper, and Sauley, 2009). Employees will try to adjust their input, output, or employee comparisons to justify any effect on their working behaviour (Adams, 1965).

Third, recent study by Fernandez and Rainey (2006) found that change agents should consider eight factors during a change situation: analysis on the need for change, creating a plan, building internal support systems and overcoming resistance, ensuring the support and commitment of top management, building external support systems, providing resources, institutionalising change, and pursuing comprehensive change. Luecke (2003) stressed the significance of accepting the necessity for urgent change, as well as the importance of strong leadership to support change and encouraging employees to accept change. He proposed that change operations should start with joint identification of existing problems and their solutions, followed by the development of a shared vision, identification of leaders, implementation of the change, and finally the monitoring and adjustment of strategies to cope with any problems that occur during the change operation (see also Al-Haddad and Kotnour, 2015).

Fourth, a number of scholars found communication to be the key to organisational success in a change situation. Alas (2008) emphasised that a willingness to change is strongly related to the information received by employees. Additionally, Lewis (2006) suggested that the provision of better quality information to employees leads to more willingness for change. Erwin and Garman (2010) also found that communication throughout the change process influences any resistance to change. They suggested that an organisation should provide ample, clear, and quality communications regarding change initiatives, associated implications, and implementation actions. Husain (2013) suggested seven key factors for an effective communication model in relation to change management: tackling queries, community spirit, trust, employee commitment, employee participation, lessening uncertainty, job security, and feedback.

Although these operational factors are crucial, their level of importance may differ for various types of SOEs. This leads to the main research question:

RQ: Do the key success factors for change differ between SOEs and private organisations?

**Methodology**

This study adopts a qualitative research approach, focusing on M&A situations in large organisations. The most impactful change issue for organisations involves M&A situations, creating complications in obtaining research contributions for this study from large companies. In-depth interviews were used to answer the research questions with data collected from one SOE and two private organisations which have recently experienced an M&A in Thailand. According to Dion et al. (2007), the effect of an
M&A should be studied within three years of the event. The organisations selected for this case study passed this criterion.

The SOE used in this study is the agricultural support organisation; the result of a merger with three previously established entities: a commercial organisation, a public support organisation, and a research institution. This M&A primarily occurred to comply with government policy, resulting in a company with approximately 2,400 employees: 84% from public support SOEs, 13% from commercial SOEs, and 3% from research institutional SOEs.

The first private organisation in this study merged with two transportation companies related to the provision of expressway and metro services including commercial development. This M&A primarily occurred to extend the company to make it more competitive with other fast-growing businesses, and increase returns. The merger involved a total of approximately 2,500 employees: 31% from motorway services and 69% from the underground.

The second private organisation, in the food production industry, was a merger between two companies: a tapioca products manufacturer and a vermicelli and noodle products manufacturer for local and international distribution. This organisation currently employs over 1,400 employees: 50% from each original company. These employees are from both production and support departments. The primary reason for the M&A was to expand the company to improve competitive advantage.

The participants selected for interview held senior management, middle management, and operational positions in one SOE and two private organisations (transportation and food production) affected by M&A. A total of 19 employees from these three organisations were interviewed for this study (8 men and 11 women). Nine employees were selected from the SOE and ten from the private organisations. Table 1 illustrates the position of each employee in the three categories.

| Table 1 – Interviewees by employee level from SOEs and private organisations |
|-------------------------------------------------|----------------|----------------|----------------|----------------|----------------|
| Organisational type                            | Employee level | Total          |
|                                                 | Top | Middle | Operational |                 |
| SOEs                                           |     |        |             |                 |
| 1. Commercial                                  | 1   | 1      | 1           | 9               |
| 2. Public Support                               | 1   | 1      | 1           |                 |
| 3. Research Institution                        | 1   | 1      | 1           |                 |
| Private I (Transportation)                      |     |        |             |                 |
| 1. Expressway                                  | 1   | 1      | 1           | 6               |
| 2. Metro                                       | 1   | 1      | 1           |                 |
| Private II (Food Production)                   |     |        |             |                 |
| 1. Tapioca                                     | -   | 1      | 1           | 4               |
| 2. Vermicelli                                  | -   | 1      | 1           |                 |
|                                                 |     |        |             | 19              |

The interview questions were created based on the literature review with two experts confirming the content validity. The main questions for this research were divided into three parts. The first group of questions related to participant information such as position, work experience, and job responsibility. The second group of questions involved the change situation and impact of change. An example of a question from this
section is “What is the effect of M&A on your organisation?” Finally, the third group of questions on operational factors during change situations, consisting of four main parts, are adopted from Fernandez and Rainey’s (2006) study. These four parts included questions about an effective performance measurement system, equal treatment for all employees, the encouragement of employee attitudes towards change, and communication. An example of a question from this section is “What are the important operational factors for a successful change situation in your organisation?”

After revising the interview questions and requesting permission from the organisation, appointments were made with the employees. The participants were briefed about the objectives of the interview prior to commencement, and each interview lasted approximately 30 to 45 minutes. All audio interview recordings were transcribed and the transcriptions carefully checked by the interviewer. This study adopts the qualitative data analysis approach with content analysis performed to answer the research questions. The process of analysing the interview transcripts began with condensing all the raw data into code, categorising this into themes, and finally verifying the central themes into categories and sub-categories. The data obtained in this research was discussed and validated to ensure inter-coder reliability (Kurasaki, 2000). In addition, experts reviewed and discussed all processes before proposing the final results.

Findings and Discussion

Upon analysing the research interviews, it was discovered that the factors supporting the operations of SOEs and private organisations in change situations include having an effective performance measurement system, equal treatment for all employees, encouraging employee attitudes towards change, and communications within all levels of the organisation. All four factors differ between organisational type and employee level. Table 2 summarises the interview results:

| Table 2 – Operational factors by employee level for SOEs and private organisations |
|------------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Operational Factors               | SOEs            | Private organisations |
| Top                                | Middle          | Operational     | Top            | Middle          | Operational     |
| 1. Effective performance measurement system | ✓               |                 | ✓              | ✓               |                 |
| 2. Equal treatment for all employees | ✓               | ✓               | ✓              | ✓               | ✓               |
| 3. Encouragement of employees’ attitudes towards change | ✓               | ✓               | ✓              | ✓               | ✓               |
| 4. Communication                  | ✓               | ✓               | ✓              |                 |                 |

Employees from SOEs and private organisations suggested both similar and different operational success factors in a change situation.

Firstly, an effective performance measurement system was considered differently at employee level between SOEs and private organisations. Only top management in the SOE mentioned an effective performance measurement system as a key success factor, while both top and middle-level management in private organisations, mentioned it, with some respondents stating:
“I think the performance measurement system and a promotion plan that reflects real employee performance and potential are the keys for us….“ (response from top management at an SOE)

“Under the M&A situation in our company, we are revising the performance measurement system to align with all parts of the organisation. It will help considerably in driving the goal of the organisation to become a single company….“ (response from top management of a private organisation)

“It’s a clear performance measurement system. Our performance measurement system is quite clear now compared to the last system that did not link to employee performance….“ (response from middle management of a private organisation).

These results indicate that both SOEs and private organisations mentioned an effective performance management system but differed according to employee level. Top management recognised that a performance measurement system provides a link between employee performance and rewards. It was an important factor in motivating high performers within organisations. On the other hand, employees at operational level working on daily tasks focused only on salary and rewards received after the change.

An effective performance management system is another tool for promoting change within an organisation. Furthermore, a performance measurement system should be linked to reward. Outstanding employees should be recognised and rewarded for promoting change. This practice will motivate employees to put additional effort into their tasks and overcome difficulties under change situation. Consequently, an effective performance measurement system is an important factor for promoting motivation in change situations.

Secondly, all interviewees from both SOEs and private organisations state that equal treatment for all employees is a key operational factor during change situations, with the exception of operational-level employees in private organisations, and some respondents stating:

“The management principle under M&A, for me, is equal treatment for all employees because it will affect employee morale and commitment. If they think that it’s not fair for them, they will not change….“ (response from top management of a private organisation)

“I will change, if my boss and organisation treat me the same as my colleague, or everyone feels the same effects, not only me….“ (response from an operational-level employee at an SOE)

“I think that fairness to all employees is the key. The organisation has to give us reasons why we have to change and everyone should be treated the same….“ (response from middle management at an SOE).

These findings follow the equity theory by Adams (1965), in that employees are concerned not only with the treatment they receive during a change situation, but also the treatment others receive. When change is forced on employees, they compare how it affects themselves compared to other employees. Thus, organisations must communicate the change message to their employees, and especially the reasons for
change, to increase their willingness towards it. Private organisations have more effective management systems, leading to equal treatment for all employees. Moreover, employees in SOEs suggest that the working environment is an important operational factor. They focus on colleagues, supervisors, and subordinates since the people around them have a greater effect on their opportunities for promotion and career growth.

Thirdly, all employee levels from both SOEs and private organisations mentioned employees’ attitudes as an operational factor in change situation. However, top management-level employees in SOEs and middle-level managers in private organisations felt that they did not observe any encouragement in the attitude of employees towards change with some respondents stating:

“The main factor is the employees. Their involvement and support will lead to a successful change. Without employee support, the change will not happen…” (response from top management of an SOE)

“Employee attitude is the key if we mention change as an advantage for both the employee and organisation, we will accept the change…” (response from an operational-level employee of an SOE)

“Employees have to accept that they must change with an organisation. If an employee accepts change, they will be willing to learn new ways of thinking and follow the organisational goals…” (response from middle-level management of a private organisation)

These findings indicate that employee attitude and employee involvement are key to a smooth change operation. Employees who face a change situation must consequently alter their daily routines, develop new knowledge, and handle additional workloads (Tummers et al., 2015). Therefore, if employees do not possess a good attitude or think of change as a challenge to improve their skills, ability, and knowledge, they will be resistant to it. Organisations should encourage employees to change by giving them an opportunity to develop themselves, providing a coaching support system for challenging tasks, particularly the middle management of a private organisation.

Finally, all employee levels in SOEs and middle-level management in private organisations remarked that communication between management and all levels of the organisation regarding change is an essential operational factor, with some respondents stating:

“Management teams have to clearly communicate change strategies, policies, and goals to all employees so they can show the direction of an organisation…” (response from an operational-level employee of a private organisation)

“Communicate to all employees why we have to change and what we can expect after the change. Employees have to know the real situation of an organisation…” (response from top management of an SOE)

“I think communication to all employees, unifying the whole organisation is important to organisational success…” (response from an operational-level employee of an SOE)
These results indicate that comprehensive communication is a key success factor when handling change, in addition to perceived utility, the perception of personal gain, and a lack of resistance to change (Erwin and Garman, 2010; Sreekeessoon, 2010). The management team should communicate information about the benefits of change, efforts made during the change, and organisational direction to all employees.

Conclusion

Under a change situation, SOEs and private organisations mentioned the key factors affecting change management at employee level. Firstly, the effective performance measurement system was mentioned by the management team only. For SOEs, only top management focused on the performance measurement system, while in private organisations it was mentioned by both top and middle management. Due to private organisations experiencing a competitive business environment, the performance measurement system is an important tool for monitoring organisational performance. Secondly, all employees of both SOEs and private organisations state that equal treatment for all employees is a key operational factor during change situations, except for operational-level employees at private organisations. Private organisations use more effective management systems, leading to equal treatment for all employees. Thirdly, top management-level employees at SOEs and middle-level managers from private organisations felt that they did not observe any encouragement in employee attitudes towards change. It can be argued that organisations will succeed in change operations when employees have a positive attitude towards change. Finally, all employees at SOEs and middle management at private organisations remarked that communication between management and all levels of the organisation regarding change is an essential operational factor.

Managing Inter-firm Relationships in Supply Chains
Managing Co-opetitive Relationships in Supply Chains: A Narrative Review

Abstract

This paper aims to provide a review of the process and mechanisms of collaborating with competitors, i.e. ‘co-opetition’, in the supply chain management (SCM) context. For this reason, a narrative review of the literature on co-opetition in supply chain and logistics management fields is conducted. The paper identifies the process and mechanisms in three categories: initiating phase, management phase and facilitators of co-opetition. This research contributes to the body knowledge on inter-organisational relationships in SCM by filling the current gap on the process and mechanisms of co-opetition.

Keywords: Co-opetition, Logistics, Supply Chain.

Introduction

The growing intensity of market competition and the development of increasingly complex global supply chains make companies become more involved in cooperating with their competitors as a feasible way of coping with these challenges (Schmoltzi and Wallenburg, 2011). ‘Co-opetition’, coined by Brandenburger and Nalebuff (1996), is a phenomenon explaining the win-win situations which can be created when competitors with complementary resources and capabilities cooperate with each other. A well-known example of co-opetition has taken place in mobile phone industry, where a supplier as Samsung is also a direct competitor of Apple (Sodhi and Tang, 2013).

For more than two decades, co-opetition has been a topic of study in different fields of business including marketing, innovation and operations management (Ritala and Hurmelinna-Laukkanen, 2009; Meade et al., 2009). However, the potentials of co-opetition for improving supply chain performance of companies is increasingly recognized in recent years (e.g. Kovac and Spens, 2013; Hobson, 2014; Pathak et al., 2014). For contemporary firms, the level of vertical integration of actors across supply chains is usually already high and further improvements in their operational efficiency is possible only through horizontal collaboration with the companies which are outside their
firms’ supply network, and even through co-operation with their direct competitors (Hobson, 2014).

According to Granata et al. (2018) there are several challenges for firms when managing co-opetition including: finding the right balance between competition and cooperation, asymmetric earnings resulting in more advantage for one firm in the alliance, separation of tasks between companies, and tensions created due to the emotional ambivalence of such a paradoxical relationship. However, despite extended literature in different fields of management and business addressing these issues (e.g. Fernandez and Chiambaretto, 2018; Fernandez and Chiambaretto, 2016; Le Roy and Czakon, 2016; Le Roy and Fernandez, 2015; Fernandez et al., 2014) the SCM literature still needs much further elaboration on finding suitable process and mechanisms for co-opetition to overcome these barriers.

Despite its theoretical and practical importance, in the SCM field there is still limited research (both in terms of number and depth of studies) on process and mechanisms of co-opetition (Pathak et al., 2014; Sodhi and Tang, 2013). This calls for a review to clarify the body of knowledge in this area so as to pave the way for more research in the future. Therefore, this paper aims to explore the existing processes and mechanisms of managing co-opetitive relationships and the factors impacting them in the SCM context through a narrative review of literature.

**Methodology**

In this paper, a narrative review of literature on co-opetition in SCM context is conducted. First, we carried out a comprehensive search for relevant published peer-reviewed journal papers in key business and management journal databases (including, Google Scholar, Science Direct, and Ebosco). This search included empirical studies, conceptual papers, and theoretical papers. We did not include conference papers, book chapters and working papers in consideration that inclusion of those may reduce the adequacy of search routines due to the fragmentation of data sources and increase the risk of including studies that have not met the required quality threshold. We adopted the definition of co-opetition of Brandenburger and Nalebuff (1996), to identify the search strings, which included: “co-opetition”, “cooperation and competition”, “collaborating with competitor”, “co-opetitive”.

Second, our search was supplemented by tracking citations, checking the reference lists of reviewed papers, personal enquiries with authors, and online searching in press. In total 103 articles were identified focusing co-opetition in management and business fields (including logistics and SCM).

Third, these papers were cross checked between two researchers on the title, keywords and abstract. As a result, 31 relevant articles were identified which focused on coopetition in logistics and SCM area, which are from established journals (such as Production and Operations Management, Journal of Operations Management, Industrial Marketing Management, Supply Chain Management: An International Journal, and European Journal of Operational Research). These articles are published over 18 years from 2000 to 2017.

The process of selecting papers is shown on Figure 1. The small number of published journal papers on co-opetition in logistics and SCM (N=31) does not allow a large-scale systematic review to be conducted (Tranfield et al., 2003), therefore, a rigorous narrative review process is applied (Seuring and Gold, 2012). This narrative review involved extracting, contrasting and synthesizing the focus and findings of the published journals, so as to provide a framework on processes and mechanisms of managing co-opetition in SCM. The review process of involved two researchers checking and then cross checking
the themes emerging from the articles, which ensures the consistency and reliability of the review (Haddaway et al., 2015; Belur et al., 2018). Although the 31 papers focusing on logistics and SCM are analysed in depth, other papers on co-opetition from other areas of management (among the total 103 identified papers) are used in our discussions through the paper especially when co-opetition in different contexts are discussed.

![Figure 1 - The process of paper selection and narrative review.](image)

In the following sections, the main themes emerging from the reviewed articles are discussed in details.

**Managing co-opetitive relationships in supply chains**

According to Xu and Beamon (2006: p.4) “A coordination mechanism is a set of methods used to manage interdependence between organizations. By definition, there are a number of different people, entities, and processes that interact in order to execute supply chain objectives. Coordination mechanisms, then, provide tools for effectively managing these interactions.” In SCM literature, knowledge about the mechanism and process of managing co-opetition is fragmented, and lacks appropriate generalisation and elaboration. As one of the few studies addressing this topic, Cetindamar et al. (2005) identifies co-opetition mechanism in SCM by a number of aspects including: communication methods, aligned performance measures, common procedures, having collaborative teams, and inter-organisational trust. Through this study, the process and mechanism of co-opetition in SCM are categorised into three aspects including: initiating factors, management factors, and facilitators. These factors are introduced in the next sections.

**Initiating phase**

For studying the mechanism and process of managing co-opetition, first we need to identify the motivations and objectives of companies for becoming involved in such relationships and the degree to which competitors should collaborate. Almost always a strong business case leading to financial savings or enhanced profit is needed for initiating co-opetition. A suitable business case leading to co-opetition is presented by Kotzab and Teller (2003) where they show how through collaboration of companies in retail industry, e.g. by utilising standardised loading units, costs of transportation will decrease as a result of achieving economy of scale. In another case in farming industry, collaborative logistics, shared research projects, joint subsidy applications, and sales scheduling has led to financial advantages for firms (Galdeano-Gómez et al., 2015). A strong motivation for co-opetition could be outsourcing non-core business functions to a competitor, resulting in improving efficiency and reducing the costs of operations for a company (Zhang and Frazier, 2011). In some sectors, survival of an industrial community can be the reason for co-opetition, e.g. when clusters of regional rival wine manufacturers shared knowledge
in sales and production, enabling them to compete with wine manufacturers from other regions of the world (Dana et al., 2013).

Besides having strong motivations, companies should set reasonable and aligned objectives and well-defined scope or boundaries for their co-operation, considering their competing situation (Cetindamar et al., 2005). Co-operation takes place at areas in supply chains which are not close to customers, because companies are competing in downstream of supply chains over a ‘larger slice’ of the market (Bengtsson and Kock, 2000). An example on this is joint return logistics operations by breweries on collecting empty bottles, while they compete on sales at bars’ and supermarket’s shelves (Bengtsson and Kock, 2000).

After having sufficiently strong motivations and reasonable objectives, companies decide to select a partner. The literature in SCM has provided limited elaboration on this aspect. Song et al. (2015) examined the important factors in partner selection in logistics co-operation which include: size of partner companies, the level of their competition, operational synergies between them in terms of their logistics facilities, equipment and vehicles, location of their facilities, and similarities in their services.

Sometimes a non-partisan third-party can be a key facilitator to help initiating a co-competitive relationship (Pathak et al., 2014). IGD, a British non-profit organisation, has played a key role in facilitating the co-operation between Nestlé and Pladis (Mirzabeiki et al., 2017).

**Management phase**

Managing co-operation is a sensitive task, given that collaboration between competitors are based on selected areas with functions and strategic priorities.

If managed well, co-operation creates a co-learning process between partners (Peng et al., 2017). Higher levels of cooperation among companies lead to increased knowledge acquisition by firms which can make value for their customers (Song and Lee, 2012), e.g. when co-operation enables companies to cover a geographically larger market. For achieving such positive results, strong top management support is needed to overcome the operational and psychological barriers which are existing by default when working with competitors (Kotzab and Teller, 2003). Joint decision making and governance by partners are widely used in supply chain co-operative partnerships (Pathak et al., 2014; Lejeune and Yakova, 2005). When managing co-operation, it is important to separate the collaborating and competing parts of operations (Bengtsson and Kock, 2000; Shockley and Fetter, 2015). As an example, in logistics collaboration between leading rival UK food manufacturers the teams form both companies were advised and trained to protect sensitive information, e.g. on marketing and sales, when interacting with each other (Mirzabeiki et al., 2017). This leads to creation of a right balance between the cooperative and the competitive aspects of co-operation which is necessary for success of such initiatives (Eriksson, 2008). Agreeing on using consistent standards, e.g. for transported load units, is a key for success of logistics co-operation as well (Kotzab and Teller, 2003).

Configuration of inter-organisational relationships can also be a factor in determining the structure and complexity of co-operative relationships. Therefore, managing co-operative relationships in triadic settings can be different from dyadic relationships. Co-operation in triadic supply chain relationships has been studied in more depth (compared to dyadic co-operation) in SCM literature (e.g. see Wu and Choi, 2005; Choi and Wu, 2009; Wu et al., 2010). These studies indicate that a buyer can ask its two rival suppliers to collaborate on product development, however, it can play them against each other for
its own advantages (Wilhelm 2011). In such a situation when customer participation and customer value is high among suppliers, a higher level of knowledge sharing between the buyer and its suppliers takes place (Ho and Ganesan, 2013). In automotive industry, lack of influence of a buyer on the relationship between its suppliers, which are in rivalry situation with each other as well, can lead to reducing the understanding of the buyer from its suppliers, causing negative consequences including diminishing its bargaining power (Wu et al., 2010). Direct material exchange and communication between the two competing suppliers of the same buyer will lead to improving the efficiency and competitiveness of both of them (Choi et al. 2002).

The continuation and effectiveness of any co-opetitive relationships depends upon fair allocation of cost and profit between partner firms. Differentiation of product lines and segmentation of geographical markets between competitors is a mechanism leading to success of co-opetition (Peng et al., 2017). Joint investments by competing firms, e.g. on technology, is needed for overall supply chain benefits from co-opetition (Bakshi and Kleindorfer, 2009). Motivations for gaining high levels of reward and avoiding losses or punishments in joint innovative projects are also affecting success of co-opetitive relationships (Nasr et al., 2015).

Communication can be a barrier in any supply chain horizontal collaboration (Cruijssen et al. 2007). This can be a significant issue to overcome in co-opetition (Shockley and Fetter, 2015) because there are concerns regarding leakage of sensitive data to competitors in this form of relationship (Mirzabeiki et al., 2017).

From a legal perspective, co-opetitive relationships should not lead to breaching any anti-competition regulations including market manipulation or price fixing (Cullinane and Song 2003; Shockley and Fetter, 2015).

*Facilitating factors*

In general, mutuality and symmetry between partners are very important in facilitating co-opetition (Mirzabeiki et al., 2017). Networks or companies are suitable co-opetition matches which have compatible but different structures and resources; and second, can create separated fields of coopetition and competition (Peng and Bourne, 2009). Simplicity of relationship structures make co-opetition take place easier. An example is in food industry where competing farming companies can collaborate with less difficulties when they are directly selling their products to retailers, compared to when there is a wholesaler involved in their supply chains (Galdeano-Gómez et al., 2015). On the other hand, lack of common technology and shared performance measures among partners can hinder co-opetition (Cetindamar et al., 2005).

Personality of people representing companies can also facilitate co-opetition. Goodwill and trust are the key components needed to overcome the barriers set by default against working with competitors (Mirzabeiki et al., 2017). For co-opetition, informal arrangement between boundary spanners sometimes can play a more important role in creating trust rather than formal contractual relationships. In line with that, Kotzab and Teller (2003) suggest that social exchange is more important than economic exchange in co-opetition.

Special care and maintenance are needed in co-opetition because of preventing any potential conflicts or tensions in different organizational levels between the companies (Bengtsson and Kock, 2000). According to Peng et al. (2017) higher similarity in competitive actions by rivals in a competitive relationship is a major cause of conflict.
Socializing through group activities is effective in creating shared understanding and common values among partners (Eriksson, 2008). Niceness, i.e. cooperative behaviour, versus meanness, i.e. competitive behaviour, of partners towards each other are seen as strategies influencing success of co-opetitive innovation-led projects (Nasr et al., 2015).

**Discussion**
Among previous studies on co-opetition, the main focus has been on the business advantages gained, e.g. in terms of expanding the logistics networks of companies (Song et al., 2015), reducing the costs of reverse logistics (Bengtsson and Kock, 2000), lowering the load units’ expenses (Kotzab and Teller, 2003), and improving supply chain security and risk management (Bakshi and Kleindorfer, 2009). However, the literature has not been paying enough attention to the development and management process of this challenging and paradoxical strategic form of relationship (Park et al., 2014) and the mechanisms involved in it (Kvac and Spens, 2013). Despite the small number of publications on this topic, there is generally a lack of systematic understanding of the associated management processes in co-opetition (Bengtsson & Raza-Ullah 2016).

The specific issues or gaps regarding the current research on co-opetition in SCM field and the areas which demand further exploration are presented below:

*Lack of consistency in terminology*

Literature review on co-opetition in the SCM context highlights a lack of clear and consistent definition of the phenomenon. This issue is not only limited to the SCM literature and other management and business fields suffer from it as well (Bengtsson and Kock, 2014; Peng et al., 2017). As an example, authors have used the term ‘co-opetition’ when explaining vertical relationships, e.g. between buyers and suppliers, which involves simultaneous competition and cooperation (Gurnani et al., 2007; Kim et al., 2013; Lacoste, 2012; Li et al., 2011; Nair et al., 2011). While this type of relationship is different from ‘horizontal’ co-operation, i.e. when two types of similar actors compete and cooperate at the same time, (Gnyawali and Madhavan, 2006; Peng et al., 2012), still the same terminology is used for studying both types of relationships. Furthermore, in a number of papers, the relationships studied under the title ‘co-opetition’ were not representing any of these two mentioned types of configuration (vertical or horizontal). This separation should be made in the SCM literature for clarifying the path of research in the area.

In some cases, authors have used the term co-opetition when they have studied cooperation and competition, however while they have not been occurring simultaneously (e.g. see Iida and Zipkin, 2010). Such a lack of consistency in terminology causes confusion and ambiguity when studying the phenomenon.

*Co-opetition management in SCM compared to other business fields*

Although the co-opetition literature in SCM still does not provide a clear picture of process and mechanisms of management of such a relationship (Bengtsson & Raza-Ullah 2016), this topic is discussed in much more depth in the other fields of business and management including marketing, product development and innovation management (e.g. see Granata et al., 2018; Fernandez et al., 2018; Pellegrin-Boucher et al., 2018).

Regarding the initiating phase, criteria for making appropriate partner selection in SCM literature demands further elaboration when we compare it to to the other business areas (e.g. see Gnyawali and Madhavan, 2006).

Another gap in the SCM field is on the dynamics of co-opetition, i.e. changes taking place in the relationship through time which is discussed in details in the marketing research (see Raza-Ullah et al., 2014). The impact of analytical capabilities for successful
execution of co-opetition is also a timely topic which is covered in the other areas of management much more than SCM (Gnyawali et al. 2016). Tensions in co-opetition and the factors influencing them are explored in business research through a relatively large number of publications (e.g. Fernandez et al., 2014; Le Roy and Fernandez, 2015). Among these researches, Dahl (2014) discusses the ways that confrontations and conflicts can change the nature and dynamics of co-opetition over time.

The importance of separation of collaborative and competitive sides of co-opetition in SCM also needs further exploration compared to the other business and management fields (e.g. see Bengtsson et al., 2010; Le Roy and Czakon, 2016). Co-management as a key factor in success of co-opetition and the mechanisms and process involved in that, as studied by Czakon and Czernek (2016), needs to be explored further in SCM. Information sharing as a facilitating factor for co-opetition also need further exploration in SCM field. Mention (2011) shows that how restricted information sharing in co-opetition can lead to generating outcomes with lower degree of novelty in innovation-related projects.

Areas for further research

On the organizational and managerial aspects, partner selection in co-opetition with focus on the types of resources, capabilities and areas of SC expertise among co-opetitors needs to be studied in much more depth. Setting or adjusting the aims and scopes of co-opetition is also an area with very limited research.

The mechanisms for balancing cooperative and competitive sides of the relationship in horizontal dyadic co-opetition and process and methods for co-management of co-opetitive partnerships is another area for future research.

There is little knowledge on the soft aspects of managing co-petition between companies, e.g. inter-personal interactions, which demand further research. Legal governance mechanisms, e.g. explaining how service level agreements or contracts should be written to make sure that companies can benefit from co-opetition and on the other hand can leave the relationship easily if necessary, is another avenue for research. Also, compliance with anti-trust regulations and checks and the ways this could be avoided needs to be explored much further.

Conclusion

Body of knowledge on co-opetition in SCM research is fragmented and limited. Among these literature, little attention is paid to the mechanisms and process of managing co-opetition. This paper, through a narrative study, provides a review of the current research on the initiating phase, the management phase and the facilitators of co-opetition in the context of SCM. The paper identifies the gaps in the current literature on co-opetition management in SCM by comparing the literature in this field with the publications in the other areas of business and management.

From a theoretical perspective, the paper fills a gap in SCM literature on inter-organisational relationship management. Also, it provides useful practical knowledge for supply chain managers about the specialities and challenges of initiating and managing co-opetition.

Abstract

This working paper explores buyer involvement in managing supplier’s personnel as a complimentary mechanism to assure supplier service delivery performance in service triads. We analyzed two service triads cases embedded in the setting of an international airport that outsources several services to third-party suppliers. Thirty in-depth interviews to informants both from the airport and the service suppliers, and review of relevant documents was conducted. Our analysis demonstrates that in a specific type of service triads (i.e., core service and a high degree of contact), buyer’s involvement in supplier’s HR practices is relevant to assure the supplier’s service delivery performance.

Keywords: Service triads, HR practices, quality management

Introduction

Ensuring suppliers service performance is an essential concern for buyers in service triads (Sengupta, Niranjan and Krishnamoorthy, 2018). In this context, where a supplier serves a customer on the buyer’s behalf, customers will perceive the quality of service delivered by the supplier as (part of) the buyer’s performance (Li and Choi, 2009). Thus, the customer’s ongoing satisfaction with the buyer company is mainly dependent upon the service supplier’s performance. This state of relationship establishes an interdependency of the performance of different actors involved in service triads (Li and Choi, 2009; Wynstra, Spring and Schoenherr, 2015).

Several studies thus investigated the buyer’s mechanisms/possibilities to assure and control supplier’s service performance, with an emphasis on the use of contract and service level agreement (Van Iwaarden and Van der Valk, 2013), contract and monitoring activities (Van der Valk and Van Iwaarden, 2011), and combination of performance-oriented and behavioral-oriented contract terms (Broekhuis and Scholten, 2018). More recently, Bastl, Johnson and Finne (2019) propose to differentiate between
control and coordination mechanisms in managing the quality of service performance in service triads. In short, the current literature highlights the use of formal and informal governance mechanisms to ensure the supplier’s service outcomes.

While without any doubt these approach are appropriate, for example, to mitigate the risk of supplier opportunistic behavior (Van Iwaarden and Van der Valk, 2013) and to influence the satisfaction of both buyer and suppliers in terms of meeting the needs of the customer (Broekhuis and Scholten, 2018), we argue that relying on these mechanisms sometimes is insufficient in a service triads. As services endure the inherent characteristics of inseparability and heterogeneity, customers define quality not only based on the outcome but also on their experiences during the service delivery process (Verhoef et al., 2009; Jaakkola, Helkkula and Aarikka-stenroos, 2015). Moreover, suppliers’ employees often embody the intangible nature of services in the eyes of the customers. Employee’s attitude and behavior significantly impact the customer’s view of the service (Schneider and Bowen, 1993; Zeithaml, Berry and Parasuraman, 1993). However, managing and controlling an employee’s attitude and behavior by pre-defined rules and protocols is a very challenging process, and its effectiveness is questionable (Schepker et al., 2014). Therefore, a complementary mechanism to induce appropriate behaviors from suppliers’ employees through direct involvement in human resource (HR) practices might be relevant in assuring the quality of service delivery in service triads, because practices like selecting the right employees and providing them with training, will influence employee’s performance and thus the service delivery (Fitzsimmons, Fitzsimmons and Bordoloi, 2013).

In organizational settings, HR practices are known to be positively related to -supply chain - performance (e.g., Foerstl, Hartmann, Wynstra, & Moser, 2013; Huo, Ye, Zhao, & Shou, 2016). However, although extending these approach to inter-organizational settings, such as supply chains and service triads, seems attractive, surprisingly, research into that direction has been almost absent (Yaqoub, Broekhuis and Van Donk, 2018). Consequently, this research aims to understand when and how are buyers involved in the supplier’s HR practices, and what is their impact on assuring the quality of service delivery in service triads?

To investigate this question, we adopted a multiple case study research with service triads as the unit of analysis. Two service triads within the airport (service buyer), passenger (end-customers), and service providers (i.e., aviation security and airport cleaning service) were selected.

This paper seeks to contribute in two ways. First, to the development of literature in service operations by providing empirical evidence of the use of HR practices in managing and controlling the quality of service delivery in service triads. Second, to the literature of strategic human resource management. While previous work focused on the intra-organizational view of HR practices in affecting performance, this paper provides an empirical assessment whether HR practices are effective in assuring the supplier’s service performance in an inter-organizational setting, i.e., service triads.

The remainder of this paper is organized as follows. We begin by reviewing the relevant literature that we use to build our arguments, followed by a comparative case study of the two different service triads within an airport setting to explore how different service triads characteristics can affect buyer’s decision to involve in managing supplier’s HR practices. This paper concludes with a discussion of the results and potential avenues for further research.
Literature review
Managing service quality in service triads

In this study service triads are business constellations where a service buyer relies on a service supplier to deliver service which requires maintaining an ongoing interface to buyer's end-customer (Hartmann and Herb, 2015). In line with this, we consider service triads as transitive, meaning that the three actors in the relationship (buyer, supplier, and end-customer) are connected to each other without the presence of structural hole. The interconnectedness of the three actors implies performance interdependency (Li and Choi, 2009).

In service triads, buyer dependence on the supplier is more substantial due to the presence of direct contact between supplier and customer (Li and Choi, 2009; Hartmann and Herb, 2015). This direct contact between supplier and customer is inevitable, since “…the key characteristics that separate services operations from manufacturing operations are the direct contact between the services provider and the customer” (Li and Choi, 2009 p.32). This ambiguity and dependency are stated as antecedents that increase the risk for supplier opportunism in service triads compared to dyadic relationships because a certain distance is created between the buyer and the end-customer.

In order to reduce this distance between buyer and end-customer, initiatives to affect supplier's internal processes can be undertaken. Supplier development initiatives arise from supplier deficiencies, or the buyer’s wish to ensure service quality (Krause and Ellram, 1997). These initiatives that often also consist of supplier feedback, supplier incentives, and audits, but also (direct) investments by buyers in suppliers, have shown to increase buyer control over quality (Krause and Scannell, 2002). However, even though supplier development is applied to services, most of these do not form service triads, since the suppliers are upstream to the buyer. To control the downstream service in service triads, the buyer should try to control the moment of service delivery. Holmlund (2007, p. 853) states that customer contact employees hold a ‘key position’ because: “They are able to influence how the customer perceives interaction with the company.” Direct involvement through, e.g. training supplier employees is an example of gaining control over the expected service delivery (Van Iwaarden and Van der Valk, 2013). Getting involved in the supplier's employee relations and HR practices could, therefore, be a promising way to influence service delivery. Because, especially in services that rely on human assets, HRM can provide a competitive advantage (Schneider and Bowen, 1993; Swart and Kinnie, 2003).

While the interaction of supplier’s employee and end-customer are potentially present in all types of service triads, the intensity can be different from the type of service that is outsourced in a service triad. For example, in case high-contact services are outsourced to a supplier, supplier-customer interaction is more frequent and related to customer experiences than in case low-contact services are outsourced (Van Iwaarden and Van der Valk, 2013b). This variability might require or provide different forms of buyer’s HR involvement to safeguard supplier's service quality.

Inter-organizational HR practices
We conceptualize HR practices as "planned HR deployments and activities intended to enable [an organization] to achieve its goals" (Boselie et al. 2005, p. 67). A considerable effort has been displayed to grasp conclusive evidence of the relationship between HR practices and performance. There is little disagreement about how HR practices affect organizational performance. Mainstream research found convincing evidence that strategies that influence organizational performance involve "coherent
sets of HR practices that enhance employee skills, participation in decisions, and motivation” (Batt 2002, p. 587). These practices may, for instance, include activities in the fields of job design, recruitment, training and performance management.

Even though not much has been written about inter-organizational HR and even less about the role of HR practices in service triad settings, some initiatives have been put forward to understand how HR practices can/might operate beyond organizational boundaries. Literature shows different configurations of inter-organizational (for instance buyer-supplier) relationships in which buyer involvement in supplier’s HR practices is present. For example, (Kinnie, Swart and Purcell, 2005) report that an organization’s choice of HR practices is frequently influenced, and sometimes controlled, by relationships in which that organization operates. In other words, “networks influence [HR] strategic choice” (Kinnie, Swart and Purcell, 2005 p.1006).

Inter-organizational HR practices might be part of multiple practices conducted by a buyer company that aims to improve supplier performance (Handfield et al., 2000). Supplier development activities are conducted in both production and service organizations and often encompass HR activities (Krause and Scannell, 2002; Nagati and Rebolledo, 2013). A buyer can either involved in direct or indirect in a supplier’s HR. Specifying a supplier's employee competence and attitude as a requirement for business cooperation is one example of indirect intervention. Another example is by being involved in the development of supplier's HR programs and procedures (e.g., preparing manuals for employee selection and reviewing supplier's employee performance evaluation standard). Direct involvement might entail the provision of training to the suppliers' contact employees, giving performance incentives, and involving in employee recruitment (Handfield et al., 2000). Direct buyer influence might also be in the form of funding specific types of training and dictating performance management in terms of employees that should stay or leave. Another option a buyer can choose is no involvement at all and relies on the supplier's expertise to manage its employees.

Methodology
Research setting and case selection
We adopted a multiple case study with service triads as the unit of analysis. Case-based research is pertinent when little is known about a phenomenon and when the existing perspective is insufficient and have frequently been used in service triads research (see for example Van Iwaarden and Van der Valk, 2013b; Karatzas, Johnson and Bastl, 2017). The case setting is an international airport in an emerging country that outsources several services to third-party suppliers, forming multiple service triads. Services in an airport are diverse in terms of relevance, complexity and degree of customer contact, ranging from a core (e.g., executive lounge, aviation security) to facilitating services (e.g., contact center, cleaning, passenger assistance). A single service triads structure comprises of the relationship between the airport (as service buyer), a service supplier, and passenger (as end-customer).

Among the various service triads structures in our case setting, we purposefully selected two cases to be analyzed in this study. The case selection criteria following the replication logic including both literal and theoretical replication-oriented criteria (Eisenhardt, 1989). In terms of theoretical replication, the following case selection criteria were applied:

1. The presence of different buyer involvement in supplier’s HR practices. As the focus of our study is to understand buyer motivation to get involved in the
supplier's HR practices, we have chosen cases that have different variance in this characteristic.

2. Different degree of customer contact. Since theoretically buyer involvement in supplier’s HR practices is influenced by the degree of customer contact (Van Iwaarden and Van der Valk, 2013b), we also maintain contrast in this characteristic of selected cases.

Regarding literal replication, we maintain the similarity of the selected cases in these following criteria:

1. Both have identical transitive structure, where the buyer, supplier and end customer are connected in a complete relationship, and there are no structural holes.
2. Both have an equal buyer-supplier relationship, measured by the length of the relationship between buyer and supplier.
3. Both services are part of the buyer’s value-proposition to end-customers.

By using this case selection strategy, two cases were selected; they are aviation security (AvSec) and cleaning service (CleanServ) triads. The background information about the two cases is provided in table 1.

Data collection

Data collection were conducted in two waves. The first wave was taken place in June-July 2018 with the main focus to explore service contexts, buyer’s overall strategy to manage supplier’s service quality, and buyer’s involvement in supplier HR practices. The second data collection was carried out in February 2019 to the more selected key informants identified in the first data collection. The second wave aimed to validate the draft of analysis that has been prepared based on the data from the first wave. In total, this research involved 30 informants within the airport and the providers across different organizational levels (i.e., strategic, managerial and operational) and functions (i.e., service, human resource, and corporate strategy).

Interviews lasted around 60 minutes on average. In order to further increase triangulation, we also collected documents (contracts, service level agreements, training programs customer's quality reports, instructions for personnel) and observed buyer involvement in supplier's HR practices. We did not interview customers but relied on written documentation for information such as customer satisfaction reports.

After coding all materials, we combined within-case and cross-case analysis. In the next section, we present the findings from the within-case analysis which focuses on the service characteristics, buyer-supplier relationship, and the way the buyer involves in managing supplier’s personnel.
Findings
Within case description: AvSec
Maintaining the safety and security of the passenger, worker, airport facility, and an airline is one of the core functions of an airport. Aviation security personnel delivers this function. Security checking in an airport involves multiple layers of integrated processes to detect and mitigate security risks. The smooth running of security examination plays a vital role in the passengers’ overall airport experience. Therefore, aviation security personnel are not only responsible for ensuring the safety and security of the airport, but also contribute significantly to overall passenger experience.

Aviation security service is highly regulated. Although categorized as a routine service, it requires professional knowledge. Personnel working in this field needs to have a license which reflects their skills and competencies in recognizing potential security breaches and their understanding of aviation security regulations and laws. There are three levels of aviation security license, basic, junior, and senior. These three levels of license reflect the level of competencies of the holder. For example, in the case of passenger body screening, the junior and senior levels have the competence to operate an x-ray detector. While the basic level only capable of carrying out body screening by using a handheld detector.

Aviation security personnel and passengers have intensive contact during service provision. The value delivered by aviation security personnel to a passenger is depended on the way the service is performed, i.e., the speed of the security check, politeness, and courtesy of the personnel. Although the passengers’ role is passive during service delivery, the quality of security checks is strongly influenced by their knowledge and behavior. For example, the speed of security checks is strongly dependent on the passenger’s compliance not to carry items that are considered dangerous for flight safety. The ideal range of security check should be around 20-30 seconds per passenger. However, the extent of negotiations that take place between personnel and passenger is the leading cause of delays in the “ideal” throughput scenario. Figure 1 shows a complete value exchange in aviation security service triads.

The aviation security service in the airport was previously entirely carried out by the airport’s internal employees. Driven by mostly the motivation of cost efficiency and regulation opportunity, a large proportion of the aviation security operation has been delegated to a third-party provider since 2013. “The average cost of recruiting internal personnel is equivalent to three times of the cost of outsourcing personnel” [Buyer Manager]. The current supplier has been performing the service since 2015 with the number of supplier’s personnel that deployed in the airport’s facility is around 1.800 persons, constituting more than 70 percent of total aviation security personnel in the airport. In this condition, one can say that the buyer and supplier are bound in an interdependent relationship. “if the supplier’s employee behave badly to the passenger, the effect will be damaging to us. Conversely, if we decide to switch suppliers, it will also bring much harm to them, because a large portion of their revenue came from our company” [Buyer Strategic].

Despite delegating the operation of security service to the subcontractor, the airport still holds up control over the service delivery by involvement in the supplier’s HR practices. For instance, the supervisory role is still managed by the airport’s internal employees. Among the three levels of aviation security ranks, the airport outsources the basic and junior levels.

The recruitment process consists of four stages; initial screening (e.g., body mass index measurement and documents verification), psychological test, discipline test, and interviews. The airport gives a clear direction to the subcontractor about their desired
qualifications and competencies of the new hires. The subcontractor conducts most of 
the hiring process; however, the airport is involved in the final interview.

The airport conducts a daily briefing at the beginning of each working shifts to 
ensure the employees understand buyer service values. During the briefing, supplier 
employees are required to recite the airport’s service pledge. The content of the pledge 
includes promises of the personnel to maintain behavior in accordance with the airport’s 
corporate values. “

Every aviation security officer must periodically renew his/her license within five 
years. Typically, the renewal cost is paid by the supplier. Personnel training and 
development is also the responsibility of the supplier. However, the airport still involves 
in the development of personnel through what they called as “local training” which 
conducted after the night shifts. The local training materials include updates on aviation 
security technical knowledge. For example, update on customer handling methods, 
familiarization of dangerous goods, X-ray machine operation, body search techniques, 
explosive trace detection, narcotics trace detection, and baggage screening system.

In carrying out the daily jobs, the subcontractor employees wear the almost identical 
uniform as the internal airport employees. Therefore, the passenger can hardly 
differentiate between supplier and internal aviation security personnel.

The subcontractor pays the monthly salary and other benefits (for example holiday 
allowance). However, the minimum amount of the salary and the types of benefits are 
regulated in the buyer-supplier contract. Additionally, the airport also provides monthly 
financial incentives from their budget for outstanding employees regardless of the 
employment status (subcontractor or internal employees).

**Within case description: CleanServ**

Cleaning service in an airport can be categorized as non-core service but essential to 
achieving overall airport service performance. Cleanliness of the terminal area and 
restrooms is regarded as the most basic physiological airport needs. Many reports from 
customer satisfaction measurement have established a direct link between the 
cleanliness of an airport and overall customer experience (Airport Council International, 
2016).

Managing a cleaning service in an airport is different from other industries, take a 
hotel as an example. Besides the fact that a general airport has a more extensive space 
than a typical hotel, an airport is also a public space. Consumers who use airport 
services, i.e., the passengers, have more various demographic backgrounds, for instance, 
in terms of the level of education, country of origin, and social, economic status. This 
wide range of customer profile has consequences to the range of broader spectrum of 
airport consumers' cleanliness expectations and hygiene standards.

Besides, there are not so many passengers who are very familiar with every corner of 
the airport facilities, which caused numerous passengers to have difficulties in finding 
their point of destination. As stated by the Terminal Manager, a lost passenger tends to 
be more confident of getting information from people in uniform. Cleaning service 
employees are not an exception. That is why in an airport, cleaning service officers also 
act as "touch points" of passengers who need information.

"We train our employees to read passenger's gestures. When an employee sees a lost 
passenger, he/she must offer help... If the passenger asks for the employee's favor to 
send him/her off to a certain location, the employee must help him/her. If the employee 
at that moment holds a (cleaning) tool, he/she must put the tool down and help the 
passenger" [Supplier Manager]
The selection of the existing cleaning service subcontractor is more motivated by the effort to improve cleanliness performance at the airport. The existing cleaning service supplier is a joint venture between the airport’s subsidiary company and one of the leading multinational facility services providers. This multinational provider has an excellent reputation in facility service and operating in more than 40 countries worldwide.

The relationship between the airport and the existing subcontractor has been running for three years. The quality requirements and performance indicators are agreed upon in the service level agreement (SLA). The SLA also includes an agreement about penalties for non-achieved performance.

The subcontractor started providing this service at one of the airport's terminal. Within the past year, there has been an expansion of cooperation. All of the three airport's terminals are now using subcontractor's service. Overall, the number of the subcontractor's workers for the airport is more than 3000 persons who work 24 hours a day in three shifts.

The existing cleaning service employees were absorbed from the former supplier. The transition was taken place in 2016. The existing supplier trains and standardizes the employees to meet their standards. The supplier provides technical skill as well as attitude trainings for the employees. The airport does not involve in employee training. As for the performance monitoring practices, the buyer monitors the quality of service, not the performance of personnel. This performance monitoring is done through routine inspections conducted by buyer’s designated personnel and establishes the customer evaluation system to assess the cleanliness of the facilities. Moreover, the buyer involves in a regular briefing at the beginning of each working shift to ensure the supplier's employee understand and implement company values. Supplier employees are also required to recite the service pledge prepared by the buyer.

Based on the within case description, buyer involvement in supplier's HR practices can be summarized in table 2. Our initial analysis reveals that the buyer involvement in managing the supplier's employees is more substantial when the degree of customer contact is higher, and buyer-supplier relational strength is stronger (the case of AvSec).
At this time, further analysis is being carried out and is expected to be presented during the EurOMA conference.

Port supply network strategies: An ERBV perspective

Nikolaos Valantasis Kanellos (nikolaos.valantasis@dit.ie)

Abstract

Increasingly supply networks are recognised as the most meaningful level of analysis in many industries. Yet few studies examine the additional capabilities and revenue options generated by such alliancing. ERBV is one perspective that addresses how these alliancing related opportunities can create competitive advantage. The ERBV perspective and notion of relational rents is used empirically to understand three distinct port supply network strategies. Whilst this study is confirmatory regarding the basic tents of ERBV, beyond studying ERBV in a new context the study contributes to theory by reporting that, paradoxically, temporary relational rents can be generated without close partnerships.

Keywords: Extended resource base view, ERBV, logistics value added services

Introduction

Since the 1980s the growth of new inter-firm alliances has transformed the business environment; firms are now considered as parts of networks, engaged in “social, professional and exchange relationships” with other firms embedded in the same network (Gulati et al., 2000, p.203). More recently, hyper globalisation has created ever more complex supply networks and markets. These trends create a resource gap in organisations, particularly between the strategic goal of a firm and its idiosyncratic resources (Lewis et al., 2010). Consequently, in dynamic and fast cycle markets firms acting independently often cannot possess the resources and capabilities which would enable them to compete equally or seek competitive advantage (CA) (Park et al., 2017). Therefore, firms develop external relationships to acquire resources and develop capabilities (Squire et al., 2009).

Researchers acknowledge that superior performance derives from strategic partnerships between firms (Dyer and Singh, 1998). Dominant theoretical frameworks from organisational sciences, such as transaction cost economics (TCE) and the resource based view (RBV), which have frequently been utilised in operations and supply chain management research (Hitt et al., 2016), focus on the single firm and its control over proprietary resources. As such they do not consider the contribution of resources residing
outside of firm boundaries, and rent generating capabilities that emerge from inter-organisational partnerships (Squire et al., 2009; Spring and Araujo, 2013; Xu et al., 2014; Prajogo et al., 2016; Park et al., 2017). Therefore, a potential conceptual disconnection between those firm based frameworks and the view of firms as members of business networks is created (Lewis et al., 2010). This theoretical gap between the so called traditional theories of the firm is where the Extended Resource Based View (ERBV) sits, enabling research on the strategic behaviour and performance of allied firms (Lavie, 2006; Prajogo et al., 2016). Therefore, ERBV is considered the most appropriate theoretical framework to underpin this research, which aims to investigate the competitiveness of supply network strategies of interconnected organisations in an infrastructure network context. The literature review of this research reveals that ERBV studies are scarce in comparison to the predominant view of RBV and the predominant notion of rent generation derived by proprietary resources. Additionally, the analysis of the few studies that do apply ERBV reveals that ERBV has not been applied in research in the context of infrastructure networks such as ports. This creates a research opportunity considering the view of ports as business networks.

**Literature review**

ERBV is based on the concepts of complementary assets, the relational view, and network resources, and questions the origin of value generating resources. Complementary assets are additional resources that are needed in conjunction with existing know-how and capabilities for the achievement of innovation (Teece, 1986). The relational view emphasises dyad/network routines and processes which are considered as significant units of analysis for the explanation of CA (Prajogo et al., 2016). This aspect differentiates the relational view (and in extension ERBV) from theoretical frameworks, which explain CA in a single industry or company. CA in the case of the relational view is realised by the creation of relational/quasi rent; which is defined as “**supernormal profit jointly generated in an exchange relationship that cannot be generated by either firm in isolation and can only be created through joint idiosyncratic contributions of the specific alliance partners**” (Dyer and Singh, 1998, p.662). However, relational rents cannot be generated by adversarial commercial relationships, as these relationships are not rare or inimitable. Therefore, partnerships and inter-firm relationships are crucial for CA creation based on relational rents (Dyer and Singh, 1998; Hitt et al., 2016). Relational rents can only be created from resources that are intentionally committed and mutually possessed within the alliance. These resources would involve all shared idiosyncratic assets, knowledge, and capabilities of the firm and its alliance partners. Therefore, the value of the shared resources determines the contribution of relational rents to the outcomes of the alliance (Lavie, 2006). The employment of effective governance, and organisational centrality also affects the creation of relational rents (Dyer and Singh, 1998; Arya and Lin, 2007; Moxham and Kauppi, 2014).

In addition to relational rent, literature identifies three additional types of rent that can be realised by the firm from shared and non-shared resources. The first is the internal rent, which is the combination of Ricardian and quasi rents that can be realised by the proprietary resources of the company, and are exclusively retained by the firm (Moxham and Kauppi, 2014). The Ricardian rent will derive from the rare internal strategic resources of the company, and the quasi rent will derive from added value extracted from the company’s strategic resources, given the possibility to access the complementary resources of the interconnect alliance firms (Lavie, 2006; Arya and Lin, 2007). The second rent type is inbound spillover rent, which is an additional type of rent private to the firm (Moxham and Kauppi, 2014). This rent relates to the unintended gains of the
firm, such as reputational and knowledge gains (Arya and Lin, 2007; Lewis et al., 2010; Moxham and Kauppi, 2014), derived from both the shared and unshared resources of the network partners. Thirdly, outbound spillover rent, refers to unintentional beneficial leakage from the firm that can be appropriated by its alliance partners for the creation of spillover rents (Lavie, 2006; Moxham and Kauppi, 2014). Together, under ERBV, these are the four types of rents that can be realised by the firm regarding shared (network) and non-shared resources within an alliance that determine the financial and strategic impact of the supply network strategy of the firm.

The third theoretical construct of ERBV is network resources. Network resources emerge from inter-firm networks that the firm belongs to, and are information rich resources that differ from internal resources (Gulati, 1999). Network resources can be considered as a specific form of a firm’s resource, which can represent the strengths upon which a firm will realise and apply its strategy. Moreover, the unique historical experience and path dependency related with the frequency of past ties and partners’ identity are crucial components which can result in the creation of network resources (Gulati, 1999). Grounded in the term network resources, Gulati et al. (2000, p.207) argue that the network a firm is part of “can be thought of as creating inimitable and non-substitutable value (and constraint!) as an inimitable resource by itself, and to access inimitable resources and capabilities. Therefore, organisations, which are members of network structures, can enjoy CA and benefits in comparison to organisations that are not members of such structures (Arya and Lin, 2007). Moreover, business-networks are idiosyncratic and path dependent. Thus, imitation or substitution of business-networks by competitors is difficult. Consequently, network resources are also idiosyncratic, because they are generated through the unique networks of the firm. Therefore, network resources are relatively inimitable and non-substitutable. Consequently, the combination of a firm’s network and network resources leads to sustainable competitive advantage (SCA) (Gulati et al., 2000). From the above discussion it is evident that one of the main arguments of ERBV is that resources which exist outside the boundaries of the firm can be sources of CA. Additionally, it can be argued that alliances enable firms to develop a bundle of value creating resources which could not be developed by the firm in isolation and that these resources in combination with the path-dependent and idiosyncratic network of the company can potentially lead to SCA. Reviewing extant ERBV literature also reveals that ERBV has previously been applied in research in manufacturing, IT, non-profit organisations, petrochemical, and pharmaceutical contexts. As such ERBV has not been applied in research in an infrastructure network context such as ports. In an effort to re-establish their role within supply networks, ports implemented various supply chain integration practices and focused on provision of value added services (VAS) (Demirbas et al., 2014), facilitating a new view of ports as business (Van der Lugt et al., 2013) and infrastructure networks. For example, port operators realised that increased benefits could be derived by the on-site provision of logistics-VAS (e.g. container unloading, cross-docking, warehousing), in addition to their core offerings. This strategic shift of ports is defined as Port Centric Logistics (PCL). PCL literature does not investigate both “why” and “how” ports move beyond core offerings and implement strategies enabling them to co-create value with customers. Therefore, the present study by linking ERBV literature to PCL, and to infrastructure networks, combines research gaps in applying ERBV and the rent generating capabilities of inter-connected firms.

Methodology
An abductive research approach is employed (Ketokivi and Choi, 2014). A qualitative multiple multiple case study research strategy was adopted to investigate the dynamic and complex
research phenomenon in-depth, and to provide clarification concerning the actors and mechanisms that create an augmented offering within a dynamic environment (Yin, 2011). Furthermore, a multiple case study design augments the external validity of the research and reduces the potential researcher’s bias (Barratt et al., 2011). When following an abductive approach, Dubois and Araujo (2007) suggest that cases should emerge during data collection and analysis, permitting contextual idiosyncrasies to shape the unit of analysis, and facilitating a more pragmatic conceptualisation of the researched phenomenon. This novel approach within operations and SCM research is defined as casing (Spring and Santos, 2015). As such, the exact definition and number of cases of this research were not predetermined, but rather emerged during data collection and analysis, particularly at the point that the data collection reached theoretical saturation. Following a disciplined desk-based identification of companies that met the specified company selection criteria, 25 semi-structured interviews among 18 organisations were conducted. The semi-structured interviews ensured a systematic approach to data collection but did not preclude pursuing emerging threads. Additionally, observations within 4 organisations and extensive secondary data allowed for verification of informants’ responses. The multiple data sources increase the reliability of the research by the achievement of data triangulation (Yin, 2011; Barratt et al., 2011). Combining interviews with observations and company documents is common in case study research in operations and SCM research (Barratt et al., 2011; Ketokivi and Choi, 2014). Finally, template analysis (King and Brooks, 2016) allowed for a rigid yet flexible data analysis method combining theoretical assumptions (a-priori codes) with empirical observations (emergent codes).

Data analysis
The data analysis, in accordance with the process of casing (Spring and Santos, 2015), allowed the development of three emerging cases studies. Each represents a distinct competitive supply network strategy for ports and intermediaries involved with the provision of on-port logistics-VAS. Each positively impacted on the competitiveness of the ports and intermediaries, however, the impact varied depending on the type of strategy. These supply network strategies are: leasing, operator, and lease and operate. Due to space constraints only the first two strategies are reported on here.

Case study 1: Leasing supply network strategy
Analysis of the data revealed two organisations with similar supply network strategies. Both organisations do not actively provide logistics-VAS, or manage port-centric warehousing facilities per se. Instead, their role is limited to leasing land and/or warehousing facilities to intermediaries that wish to provide on-port logistics-VAS. The leased land and facilities can either be within the premises of the port, or in logistics parks adjacent to- and owned by the port. Implementation of leasing supply network strategies is either path dependent, as it is inherited from the traditional functions of ports prior to containerisation or is a “risk averse” approach to meeting market demand.

Forms of leasing supply network strategy extend from the basic leasing of land to a tenant through to the construction of warehousing facilities by the port according to customer requirements, or the co-finance of facilities in joint ventures (JV). However, in no circumstance will the port be actively involved with the provision of logistics-VAS. Therefore, the leasing supply network strategy related revenue is only from leasing land and/or facilities to third parties, not from operation. There are marketing benefits: on the one hand the success of tenants’ operations results in increased container throughput. On the other hand, successful operations lock-in tenants for longer leases.
Analysing the data also revealed that a leasing strategy gives the capability to offer a joint value proposition (i.e. bundle of port services and logistics VAS), which can confer CA, and that it enables the development of a network of interdependent organisations, which also enables the creation of network resources. These network resources are the bundles of services that comprise the joint value proposition of the port, and its network partners. The combination of those elements creates the conditions for the realisation of SCA. The Head of Commercial of Port4T reported that a lease strategy positively affects their competitiveness because it enables the offering of a joint value proposition to cargo owners tailored to the individual requirements of cargo owners, and the characteristics of the cargo itself. The Commercial Manager of Port5 argues “...it definitely has enhanced the competitiveness of the port in the sense that our end to end product is so much better with the fact that these facilities are in the port and the companies that use them are able to drive efficiencies”. Respondents reported that the combination of capabilities derived from the lease strategy, and other intrinsic strategies enable the ports to differentiate and achieve CA. The Head of Commercial explains how Port4T differentiates itself from competitors “...where we safeguard our revenues is through the fact that we are able to be quite diverse, it is not just containers for us it's about what's in the container, and how it flows through the port”. She further argued for a lease strategy with PCL enabling other forms of diversification into niche markets and how it helps to lock in either importers, end customers, distributors or LSPs; “We like to lock them in so that they are obviously reducing their SC cost, but it also forces them to put their bill of lading at [Port4T]” ibid. In addition to the financial and strategic benefits reported above, the data analysis also shows that a leasing supply network strategy allows ports to leverage marketing opportunities and yields two marketing benefits. The explicit marketing benefit is that a port can directly lease land and/or facilities to LSPs. The implicit marketing benefit; is that the existence of LSPs at port premises enhances the market proposition of the port, which leverages the organisational resources and capabilities of its tenants to promote a bundle of port and logistics-VAS.

Case study 2: Operator supply network strategy

Analysis identified that twelve organisations actively operate logistics-VAS, either as providers (external use: revenue from the charges for logistics-VAS), or as providers and consumers (internal use of logistics-VAS) or as organisers of logistics-VAS (i.e. the port/intermediary is the trading entity but subcontracts part or the entirety of the offering to counterparties). This strategy is labelled operator supply network strategy.

An operator supply network strategy is a response to market requirements, i.e. demand from cargo owners for logistics-VAS at points of import. Furthermore, organisations implemented an operator supply network strategy to enter new markets. Distinct examples are LSP8, LSP4 and LSP5 who entered the fresh fruit and frozen foods market, the wine bottling market, and e-commerce market respectively. All of these market segments were new to these organisations. Another reason for implementing an operator network strategy is the capability to extend control over the SC by incorporating another SC segment. These were organisations with existing national distribution networks whose investment in PCL enables them to extend SC control by capturing imported products at the point of import (e.g. LSP8, Retailer1 and Retailer2). Finally, implementation of an operator supply network strategy can be path dependent (e.g. LSP4 developed from a freight forwarder to an asset based LSP).

All twelve companies reported positive financial impacts from an operator strategy; broken down into two components. The first component regards the increased revenue opportunities; such organisations realise increased revenue from higher charges for
logistics-VAS, and increased demand for logistics-VAS and enhanced marketing capability (The Group Sales Director of LSP5; the Sales and Marketing Director of LSP8). The higher charges for logistics-VAS will increase the revenue of those who implement an operator strategy. The higher charges are justified by offering specialist services, and because a PCL solution can rationalise the SC of cargo owners and reduce inland distribution costs. Analysis of the data shows that these value-added capabilities can create CA. The Commercial Manager of LSP7 argues that an operator supply network strategy enables them to become more competitive by eliminating non-value-added distribution segments; the Sales and Marketing Director of LSP8 argues that the operator supply network strategy enables them “to facilitate an end-to-end supply chain using a facility for goods coming in the SE of England”; the Commercial Director of LSP6 argues that the ability to handle products at “the first point of landing” increases visibility and control of cargo owner’s pipeline inventory levels. That is because they “have it on their stock system potentially 3 to 5 days earlier rather than if they have to send it to the middle of the country”. Additionally he asserts that the possibility to handle products at “the first point of landing” gives the value-added capability to offer flexible SC solutions to customers. He comments: “...with the model we’ve got here, we can delay containers on quay, we can fast track containers, we can put into holding areas, so we can help manage the flow of work at this point”.

The second component of the positive financial impact regards the stability of the revenue derived from an operator supply network strategy. This revenue stream can be regarded as relatively stable due to the loyalty of cargo owners to the “port-centric” benefits, and the length of contracts between cargo owners, and ports and intermediaries. LSP6’s Systems Project Analyst claims that the company differentiates itself from other LSPs that do not implement an operator strategy. He maintains: “Having a port centric operation enables us to reduce some of the haulage charges. For example, for [wine importer], we save around £3,000,000 per year, by having a port centric operation that allows the use of [curtain-side trucks] for delivery of the stock and improves about 19% the efficiency because they use backloads to return”. A view supported by the Commercial Director of LSP6 in terms of on port location and collaboration opportunities. The second differentiator lies in how the operator strategy investment in this resource enables LSP4 to focus on particular market segments, and thus, differentiate itself from other LSPs that implement an operator supply network strategy. In summary, the operator supply network strategy differentiates the LSP because it enables the LSP to provide product specific logistics-VAS within a port’s environment, and because the particular investment enables LSP4 to differentiate itself from competitors in the PCL market.

Discussion

Case study 1: Leasing supply network strategy

Major revenue streams are associated with the leasing of warehousing facilities to intermediaries that have established operations at the port. The presence of those intermediaries at the port attracts more customers for the port. Subsequently, the leasing supply network strategy implicitly secures cargo owners for the core services of the port. The increased number of cargo owners enhances the revenue derived from core services in addition to the revenue derived from the leasing of land and/or facilities. Concerning the higher revenue that derives from increased demand for core services of the port, it can be argued that the port leverages its own idiosyncratic resources (port land) by accessing the complementary assets of its tenant. In this case complementary assets are regarded as the tangible and intangible resources of the tenant that are necessary for the innovation in question (i.e. logistics-VAS). According to Lavie (2006) and Moxham and Kaupi (2014),
if the firm leverages the value of its proprietary resources (i.e. port land, financial resources for development of the building and marketing capabilities), by accessing its partner’s complementary assets, then the firm realises internal rent.

The joint value proposition identified in the leasing strategy above is a bundle of core services (offered by the port), and logistics-VAS (offered by the port’s tenants), which positively affects the competitiveness of the ports that implement a leasing supply network strategy. The joint proposition of the port with its tenants is the outcome of the combination of the port’s idiosyncratic resources (port land, and physical and human capital resources responsible for the accommodation of cargo from/to sea), and the organisational capabilities of the port’s tenants (derived from the idiosyncratic resources of the tenant that enables them to offer logistics-VAS). This argument confirms the theoretical views of ERBV, in that value generating resources reside beyond the boundaries of the firm (Lavie, 2006; Spring and Araujo, 2013; Prajogo et al., 2016).

Furthermore, services are intangible resources of the firm; therefore the joint proposition of the port with its tenants is an intangible resource residing within the port’s network. However, according to Gulati (1999), the resources that are emergent from inter-firm networks that firms belong to, are network resources. It can be argued that a leasing supply network strategy enables the establishment of a network around the firm; and within this network the development of network resources. The combination of the network that a firm belongs to, and the network resources, can lead to the realisation of SCA. That is, because networks are considered idiosyncratic to the firm, are relatively inimitable and non-substitutable, and their development is path dependent (Gulati, et al., 2000; Arya and Lin, 2007).

From case study one it appears that a leasing supply network strategy does not confer CA based on differentiation for the port per se; it is the combination of the capabilities derived from the leasing supply network strategy, and other intrinsic strategies that enable the port to differentiate. These intrinsic strategies enable the port to focus on specific market segments, select business partners, and develop networks, both for maritime and land transportation. These networks create differentiation. Thus, the leasing supply network strategy is only a fragment of a broader strategy that enables differentiation of the port based on the utilisation of the organisational capabilities of business partners. This argument complements the ERBV literature (Lavie, 2006; Lewis et al., 2010; Prajogo et al., 2016); in that the organisational capabilities of network partners assist the differentiation strategy of the port. The responses suggest that a leasing supply network strategy enhances the marketing capability of the port by implicitly or explicitly leveraging the environmental benefits that are associated with the organisational capabilities of its tenants. Capabilities are considered a particular form of organisational resources, and they can generate value on their own, or increase the value of a resource. It can be concluded that the organisational resources of intermediaries enhance the value of the marketing capabilities of landlords. This argument confirms the theoretical view of this research; that value generating resources can reside beyond the boundaries of the firm (Lavie, 2006; Spring and Araujo, 2013; Prajogo et al., 2016).

Case study 2: Operator supply network strategy
An operator supply network strategy creates a twofold positive strategic advantage for firms. Firstly for all the companies populating this case study, CA or SCA can be achieved by the value-added capabilities that derive from an operator network strategy. These value added capabilities, which can create CA, are associated with the underlying efficiencies of the port-centric warehousing and distribution model. However, this CA is also identified as dependent upon two non-exhaustive factors; the location of the intermediary,
and the level of collaboration (from close to arm’s length) with the port. Interviews with participants from LSP8, LSP4, and Retailer 1, reveal that the combination of the location of port centric facilities, and the intrinsic processes and capabilities of intermediaries can result in CA. However, the interviews with participants from LSP5, and LSP3, highlight that such value-added capabilities can be attributed to intermediaries that are marketed as port-centric, but are not located on port land and have only an arm’s length relationships with the ports.

This argument contradicts the ERBV literature (Lavie, 2006; Lewis et al., 2010; Prajogo et al., 2016); in that organisations can leverage resources of other organisations without formal collaborative agreements. Consequently, the possession of logistics-VAS provision capabilities, and the location of the intermediary are not exhaustive factors for the realisation of CA. An operator supply network strategy can confer CA even if one of those factors is fulfilled. Prior to any conclusive arguments the sustainability of such CA needs to be evaluated. Conditions for the realisation of SCA can be achieved by the inimitable and ambiguous nature of services due to their dependency on labour. However, only very niche logistics-VAS require highly skilled workers. In this case the complexity of interactions between the tacit knowledge that resides in the human resources, and the assets of the firm, will result in increased causal ambiguity, which is positively related with the imitability of a firm’s CA. Inimitability of resources can contribute towards the sustainability of a firm’s CA. It follows that human capital resources can contribute towards the realisation of SCA if their interactions with the assets of the firm are complex, because added complexity will impose higher imitation barriers. Services are also less imitable due to their ambiguous nature. In our context the provision of logistics-VAS is based on the bundle of the intermediary’s idiosyncratic resources and the resources of network partners or counterparties. Considering the concept of network resources, it can be argued that the combination of the firm’s network and the network resources can lead to SCA (Gulati et al., 2000). Thus, intermediaries who engage in collaboration with other network partners can realise SCA, because the logistics-VAS derive from a bundle of idiosyncratic and network resources and capabilities. Subsequently, the offerings of intermediaries that are not located within a port, or do not collaborate with network partners is more imitable, because they provide services based only on their idiosyncratic resources, and the exploitation of the marketing power of the PCL model.

The operator case study shows that intermediaries leverage marketing opportunities by the provision of on-port logistics-VAS which result from a combination of the idiosyncratic resources of the port, with the idiosyncratic resources of the LSP. This confirms the theoretical assumptions of ERBV (Lavie, 2006; Spring and Araujo, 2013; Prajogo et al., 2016). In this case the value generating resources are the idiosyncratic resources of the port that enable intermediaries to implement such a strategy to leverage marketing opportunities. However, intermediaries can not lease land from a port and instead, advertise themselves as port centric and compete in this market without being involved in a contractually defined collaborative agreement with a port. Consequently, the idiosyncratic resources of a company can confer value to another company without those two companies being engaged in a partnership. This argument complements the ERBV literature. In summary, it can be argued that an operator supply network strategy can confer SCA if the logistics-VAS derive from a bundle of idiosyncratic and network resources. Additionally, it can be argued that even though a port centric operation can result in a competitive edge based on differentiation, this edge is temporary, due to imitability of the offering. The competitive edge is more sustainable when the differentiation derives from a combination of factors, such as collaboration with the port for the development of services and processes, and/or focus on a niche product market.
The data presented above reveal that the marketing capabilities of intermediaries that implement an operator supply network strategy are positively affected. The logistics-VAS inherent in an operator supply network strategy enable firms to fulfil the demand of cargo owners for on-port logistics-VAS, and enter new markets, attract more recognisable cargo owners, and quote to competitors’ customers. Therefore, an operator supply network strategy enables intermediaries to leverage marketing opportunities. In a PCL context, the logistics-VAS are designed to facilitate the movement of product through the SC and are offered in combination with port services. Intermediaries combine the offering of two organisations to provide this bundle of services. The combined offerings can be bilateral (intended) (i.e. formal collaborative agreement between firms) or unilateral (opportunistic) (i.e. LSP exploits its proximity to the port). The development of logistics parks close to ports negates the entry barriers set by the limited availability of on port land. Additionally, LSPs not located on port land increase the level of imitability of this resource. Thus, even though the possession of a state-of-the-art facility could lead to CA based on differentiation, this CA is imitable. Consequently, LSPs that implement an operator supply network strategy should be located directly within the port and collaborate closely with it.

Conclusion
This research has used ERBV to understand the adoption of port centric strategies by UK ports, where new levels of service are offered at, or close to, the port. The use of ERBV theory mirrors the contemporary perspective of ports as parts of wider business networks (Van der Lugt et al., 2013), who now compete with rival supply networks (port networks) not standalone ports. Two of three strategies identified were reported on here. In case 1, ports that implement a leasing supply network strategy leverage the value of proprietary resources (i.e. port land, monetary resources for the development of facilities, and marketing capabilities) by accessing organisational resources of business partners (i.e. relationships with cargo owners) for the realisation of internal rents, CA, enhanced marketing proposition, and widened customer base. It was reported that the combination of the network that a firm belongs to, and the network resources, can lead to the realisation of SCA; because such networks are considered idiosyncratic to the firm, are relatively imitable and non-substitutable, and their development is path dependent. In case 2 an operator supply network strategy will only generate SCA when there is a formal collaborative relationship between port and logistics intermediaries, which has developed their idiosyncratic resources and network resources. However, only one of the two factors influencing the capabilities of intermediaries is necessary for CA; if an intermediary is not located within the port’s premises nor/(or does not) collaborate with a port for the provision of logistics-VAS, then its CA is prone to imitation by competitors. Thus, CA can be conferred if one of the two factors is achieved. However, the fulfilment of both factors can lead to the realisation of SCA. In summary, it can be argued that an operator supply network strategy can confer SCA if the logistics-VAS derives from a bundle of idiosyncratic and network resources. If intermediaries and ports share resources that result in the creation of a rent that cannot be realised by either firm in isolation, then conditions for the appropriation of relational rent, and SCA are created. This research confirmed the theoretical arguments of ERBV in a new context, by proposing that in an infrastructure network context value generating resources can reside beyond the boundaries of the firm. This study also identified that the organisational capabilities of network partners can assist the differentiation strategy of the firm. This finding contributes to extant ERBV literature by highlighting differentiation as an additional positive outcome of resources/capabilities sharing among network partners.

Abstract

This paper addresses supply chain transparency improvement in a manufacturer-supplier relationship. It investigates the problem of improving transparency is using a set of interviews; then, a detailed problematization and a simulation model is formulated based on the results. There are two key issues: information systems issues related directly to transparency and capability issues related to utilizing transparency. The simulation supports developing capabilities by illustrating the effects of different options for coordinating material flow. While solutions to improve transparency are straightforward to implement, developing the capability to benefit from it can be more challenging, even in a well-established close partnership.

Keywords: supply chain management, transparency, responsiveness

Introduction

Issues, such as transparency, responsiveness, real-time transfer of demand data, and just-in-time (JIT) delivery, are all interrelated and remain topical in the research field of supply chain management (e.g., Prajogo et al., 2016; Singh, 2015; Yu et al., 2018; Zhu et al., 2018). In particular, transparency remains one of the main managerial challenges, even though information is ample and easier to share than ever before (Butner, 2010; Francis, 2008). However, scientific research on transparency still lacks a strong empirical basis (Egels-Zandén et al., 2015; Francis, 2008). Barriers to transparency have been recognized, suggesting that supply chains could be smarter through information technology (IT) solutions as well as processes (Butner, 2010). In this paper, we discuss this phenomenon through a detailed study of transparency improvement efforts in a selected manufacturer-supplier relationship.

The dyad under investigation consists of a leading machinery manufacturer and one of its key suppliers. The two companies are physically located near each other, enabling delivery in a short time span. It was found that improved transparency, with methods such as real-time availability of demand data, could further improve the timeliness of deliveries and reduce inventory levels in the supply chain.
We utilized a mixed methods study design to investigate this practical problem; first the situation was investigated in more depth through interviews with all the stakeholders and by analyzing the data related to supply chain operations. A simulation model was created based on this understanding to illustrate the effects of some possible improvement efforts. A case study design with multiple methods allows for the investigation of practical behaviors and their effects, addressing the methodological gap noted by Fayezi et al. (2017).

In the following sections, we first describe the case study situation and present the methods and materials we used. Next, the stakeholders’ views of the situation are presented and some of the key differences are compared. This is followed by a discussion of the simulation results. In the conclusion, we discuss potential opportunities for improvement in the studied case, as well as the implications and limitations of our results.

The case study situation and research methods

The starting point for the study was the manufacturing company’s interest in improving information transparency, and, consequently, the responsiveness and material flow in its supply chain. In initial discussions, it was also decided that choosing a local key supplier (Supplier A) as a pilot case would be a good way to begin these efforts. The choice was also influenced by experiences from earlier co-development projects, and by perceived open information sharing and mutual trust. During the initial analysis, another supplier (Supplier B) was included in the study, because it welds and paints some of Supplier A’s products into sub-assemblies for the manufacturer. These three businesses are located within 1 km of each other. This relationship is illustrated in Figure 1.

Figure 1 – The case environment

The manufacturer produces configured machines for customers worldwide; it is one of the market leaders in its niche with a turnover of around 500 M€. Its production and factory are built around JIT concepts. Roughly half of the materials used in production are sourced from local suppliers, a vast majority of which are from domestic suppliers.

Supplier A is a medium-sized subcontracting partner for machine building companies and other companies in the metal industry. It focuses on system and component deliveries as well as various cutting methods. Supplier A delivers different sheet metal parts and machined parts to the manufacturer.

Supplier B is a small short-run contract manufacturer of metal products and their sub-assemblies. It produces welded and painted sub-assemblies for the manufacturer’s products.
To further understand the current situation from the viewpoint of these three companies, interviews were conducted in February 2019. Additionally, the courier responsible for the logistics between the three companies was interviewed. A summary of the interviewees is presented in Table 1.

Table 1 – The interviewees

</table>

The interviewees received a short list of topics that will be discussed in this paper; these topics varied depending on the person’s title/position/working area. The interviews lasted between 45 minutes and 1.5 hours. A total of 10 interviews were conducted with 13 participants. All the interviews were recorded, except for the telephone interview with the courier. The manufacturer and supplier A also shared supporting materials, such as inventory, order, and production data, via email.

A more detailed view of the problem was obtained based on that information, and it is presented after the description of the current situation. A simulation model was created, using the AnyLogic simulation software, to further analyze and illustrate the coordination of materials between the manufacturer and Supplier A. The assumptions for this model were based on the collected data.

The current situation from all perspectives

The manufacturer

The order-to-delivery process begins when a customer confirms the order and a bill of sale and the machine configuration chosen by the customer are sent to order processing. The order is entered into the factory’s production system and scheduled according to the agreed upon delivery date. This information is also visible to the suppliers through the Extranet. After the sale, the customer can change the order up to three months before the shipping date. Typically, the 12-week production schedule is only subject to minor changes.

Fixed four-week production plans are generated based on the 12-week plan, and they include detailed production plans that are scheduled backwards using the target shipping dates. After an order is entered into the four-week plan, orders for the suppliers’ parts are generated automatically. The four-week plan is changed only in special conditions, such as material shortages. For example, the production sequence can be changed to avoid idle time. Suppliers can view the 12-week and four-week production plans via the Extranet.

The manufacturer purchases components from Supplier A in two ways. Cut parts for welding form 80% of the quantitative order volume. These are ordered through the Extranet as automated orders, and the system provides shipping documents that the supplier attaches to an order. If the supplier meets the required quantity and delivery date, no further communication with the manufacturer is needed. The courier visits the suppliers’ premises four times daily, so the suppliers do not have to order deliveries; they only prepare them for pick-up. Bulk items are ordered manually via the Extranet based on their re-order points; they have to be manually processed by the supplier’s buyers. In
terms of order lines, the volume of these orders is very small in comparison to automatic orders.

The four-week production plan can fall behind the target date, for instance due to a sequence of particularly demanding machines, breakdowns, material shortages, or faulty materials. Weekend shifts are scheduled to catch up. This provides a significant temporary boost to the weekly capacity. These fluctuations are not visible in the Extranet, so suppliers are unaware of manufacturer’s current demand; they follow the orders from the four-week plan. This problem is caused by the interface between the manufacturer’s and the supplier’s IT systems; schedule changes do not update existing requests; instead, they create new material requests without removing the now outdated ones. Deliveries arriving earlier than needed create extra inventory. This is particularly troublesome because the production facilities are designed for JIT deliveries, and there is no dedicated inventory space in all of the production line steps. Moreover, this requires extra manual work for coordinating production and communicating changes to the suppliers.

**Supplier A**

Supplier A reads the automated orders from the manufacturer seven workdays in advance from the Extranet using an automatic order-reading tool. The orders are scheduled in line with the logistics arrangement (date and time of delivery) between the manufacturer and Supplier A. A large percentage of A’s parts are needed for early production stages, meaning that deliveries are scheduled for 1.5 weeks before a machine is finished. For the four-week plan, this means that Supplier A’s effective planning window is 2.5 weeks. In practice, Supplier A has chosen to use the first week from that window because accuracy decreases as the number of weeks increases. The delivery capability is managed with safety stocks to allow timely delivery and reaction to fluctuations in demand. Because Supplier A’s lead times, including order processing and production planning, vary from four to nine days, this is seen as a necessity. Safety stocks usually accommodate six days of estimated average demand.

Even in a one-week planning window, schedule or quantity changes in orders are sometimes needed. The more changes are required, the more challenging it is for a supplier to schedule production and manage inventories. Every day, Supplier A receives 400 to 500 new order lines. A line is a specific item for a specific machine, and the quantity varies depending on how many units is required for a product. The production planner relies on the automated order-reading system to determine if a line is not in stock or if it will drop the stock level below the re-order point. Consequently, roughly 50 to 80 lines need to be scheduled for production/day. The time required for the planner to process these orders is about one hour/day. The manual orders are handled by sales; these require a similar amount of work.

**Supplier B**

The manufacturer orders sub-assemblies from Supplier B via the Extranet; these orders are also processed using an automated order-reading tool. As with Supplier A, these are scheduled so the date and time of delivery are indicated. The materials that Supplier B needs to produce the sub-assemblies come from Supplier A. Their lead times can be up to 2.5 weeks, including Supplier A’s lead times; however, Supplier A keeps safety stocks to expedite the lead times. Supplier A can see the manufacturer’s demand for Supplier B’s sub-assemblies in the Extranet. This view is offered by the manufacturer, but it does not include a bill of materials for Supplier A’s parts. Consequently, Supplier B orders parts from Supplier A via e-mail, and the orders must be processed manually.
Logistics
Logistics between the manufacturer and the suppliers are handled by a local logistics operator. Deliveries to the manufacturer are made four times/day; deliveries between supplies are made twice daily. The courier picks up materials at Supplier A, then at Supplier B, before driving to the manufacturer’s receiving dock.

When a supplier prints out the packing list to pack an automatically generated delivery, the manufacturer’s buyer can see the status of the order as “Packing list generated”. Once orders are packed, the courier picks them up during the supply runs. The delivery pick-up times are color-coded. Delivered orders are signed in at the manufacturer’s receiving dock, and entered into the inventory system. However, this information is not visible to the buyer. If a delivery is missing from production, emails and phone calls are required to determine its location.

A more detailed problematization
Based on the interviews and auxiliary data, we were able to summarize the key issues affecting transparency, responsiveness, and material flow in this case. Some of the issues are not strictly about transparency; rather, they are about the prerequisites for extracting value out of improved transparency. A summary of these key points is presented in Table 2.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Manufacturer</th>

<td></td>
</tr>
</tbody>
</table>

As seen from Table 2, the key issues are related to IT systems and production capabilities. The IT-related issues relate directly to transparency and indirectly to operations. The production capability issues hinder the utilization of transparency.

Simulation modelling
A simulation model was constructed to support additional analysis of the information and material flows between the manufacturer and Supplier A. The model was based on the available data and discussions with the manufacturer and Supplier A. It addresses several of the issues listed in Table 2: transfer of real-time production status, production rate variability, lead times, and stock levels. The simulation interface is presented in Figure 2.
In the model, the manufacturer has a demand that is relayed to the supplier. The supplier’s operations are defined by three parameters, production lead time, re-order point (ROP), and a re-order quantity, which can be interactively varied. The resulting view compares four different scenarios of how supply and demand is coordinated with the supplier’s inventory levels on the left (xA) and the manufacturer’s inventory levels on the right (xB).

Scenario 1 has the supplier delivering according to the manufacturer’s next-day demand. The one-day delay is based on an actual situation; the time required for picking and packing makes it too challenging to pack and deliver on the same day.

Scenario 2 shows the supplier delivering according to the production plan, without knowing if the manufacturer is on schedule.

Figure 2 – The simulation interface
Scenario 3 is Scenario 1 with the addition of the supplier accounting for backlog in the manufacturer’s production. If backlog exists, the supplier’s ROP increases with the amount of backlog.

Scenario 4 features a ROP at the manufacturer’s end; the supplier delivers an order with a one-day delay when the manufacturer’s inventory falls below the ROP. The amount delivered will increase the manufacturer’s inventory level to the target level. A comparison of these four scenarios is presented in Figure 3.

![Graph](image_url)

**Figure 3 – Comparison of the four scenarios**

When only the inventory levels are considered, Scenario 4 is optimal for both the supplier and the manufacturer. For the manufacturer, the maximum inventory level in Scenario 4 will be equal to the target level. Scenario 2 is the least optimal because it has the highest maximum and average inventories.

Considering stockouts, Scenario 2 is the best option with zero stockouts. Scenario 1 is the worst scenario with the highest stockout rate. Scenario 3 has four stockouts, but that is less than the stockouts in Scenario 1.

The simulation model results suggest that if the supplier delivers according to the manufacturer’s estimated demand for the next day (Scenario 1 and Scenario 3), counting the backlog decreases the stockout risk at the supplier’s end. Although this leads to increased inventory at the supplier’s end, it is needed to respond to the demand peak that occurs when the manufacturer produces the machines in the backlog during an extra shift. If the supplier only follows the production plan and the manufacturer does not share its actual demand, this causes high inventories at the manufacturer’s end if production is not on schedule (Scenario 2). Scenario 4 is the best solution; the supplier delivers based on real-time information about the manufacturer’s inventory level. However, if the delivery delay increases from one to two days in Scenario 4, the supplier’s stockouts decrease but
the manufacturer faces a stockout (Figure 4). It is also important to note that changes in the parameters will cause different outcomes. Moreover, it is easy to implement additional scenarios in the model, such as a hybrid of Scenario 3 and Scenario 4.

**Discussion**

Based on the results, actions can be proposed to improve transparency and the readiness to benefit from transparency. These proposals are presented in Table 3.

**Table 3 – Development proposals and possible outcomes**

<td>Create an IT solution between Supplier A and Supplier B to relay order information</td>
</tr>
</tbody>
</table>
As seen in the results and the proposed solutions, transparency is already at a reasonably good level in this case study, apart from some gaps in the systems. Transparency could be further improved by enabling the relay of the current production status, improving the visibility for Supplier A for the bills of materials required through Supplier B, and integrating the inventory system. Solving these issues would primarily be work related to systems; thus, it would not require major changes in policy or processes. Solving the IT-related issues would be the proverbial low hanging fruit, with some immediate effects related to reducing the amount of manual work.

However, moving towards better responsiveness and JIT deliveries is more complex. As the adage goes, inventories are used to cover up issues in the supply chain; this also applies to our case study, at least to some extent. The supply chain works very well as is, and the process is well established. However, Supplier A’s inventory is an important link in the chain. It serves both the manufacturer and Supplier B, allowing them to keep little or no inventory, and it safeguards the supply chain from issues, such as not being able to respond to fluctuations in demand due to the lengths of the lead times.

To exploit the full potential of improved transparency, the responsiveness of the supply chain should be improved according to JIT and lean principles. This includes, for example, the reduction of production setup and lead times (e.g., Anand & Kodali, 2009). A key challenge is how to motivate the suppliers to improve their performance in this area. This issue is related to the larger concept of supplier development, which should be of interest to the manufacturer and the supplier if they want to invest in their collaboration. One practical approach would be to explore the utilization of comprehensive collaboration frameworks, such as collaborative, planning, forecasting, and replenishment (CPFR). However, using CPFR also requires supply chain members to have shared targets, interoperable IT systems, and mutual trust (Panahifar et al., 2015).

This study addresses a methodological gap indicated by Fayezi et al. (2017); it provides insight on how transparency and responsiveness issues manifest in a fairly mature supply chain partnership. It also contributes to the literature (e.g., Hilletoft et al., 2016; Sandhu et al., 2013) on using supply chain simulations as “a communicative means between the analyst between the analyst and stakeholders” (Van der Zee & Van der Vorst, 2005, p. 66). The results confirm some challenges related to taking advantage of transparency, such as IT system limitations, internal capabilities, and motivation. These are in line with previous findings (e.g., Akkermans et al., 2004; Butner, 2010; Morgan et al., 2018; Prajogo & Olhager, 2012).

In regards to managerial implications, the results are a good reminder that transparency has limited value. While it has some direct positive effects, such as a reduction in the amount of manual work, to maximize its benefits, the supply chain must be capable of transparency. Managerial tools to achieve this include strategic supplier development (e.g., Krause et al., 2007) and collaboration frameworks, such as CPFR (Panahifar et al., 2015). This is similar to the current hype around digitalization, Industry 4.0, and the Internet of Things: the fundamentals must be in place. The use of digital twins is a recurring topic in the Industry 4.0 discussion; a simulation model could be seen as a digital twin, albeit a simplified one. Simulation can be a powerful tool for analyzing the effects of different collaboration models, such as changes in inventory levels and stockout risks in different scenarios. This is applicable to short-term demand and supply management, as well as long-term planning in cases where significant changes in demand are expected over a longer period of time. The use of simulation can be an important stimulus to motivate improvement.

This paper presents a single case study utilizing mixed methods to investigate a practical supply chain problem. We discussed a set of practical issues related to
transparency, and we presented a case example using simulation models in development work. In a single-case study, the findings are naturally context-related, with limitations on generalizability. Further studies using a similar approach would allow for a comparison between cases and providing the ability to draw more generalized conclusions.

Abstract

This study seeks to investigate the creation of value in the supply chain, primarily dealing with the Origin Segment. From this, a qualitative approach was carried out to understand how the inter-organizational relational structure contributes to the creation and appropriation of value in these supply chains. Thus, it was concluded that even in a similar relational configuration, the supply chains presented different mechanisms, that in essence facilitate or create barriers in the development of practices that create value, based mainly on two main categories of analysis, being: a) Relationships and b) Identity regional.

Keywords: Multistakeholder Governance, Value creation, and Agroalimentary Chains.

1. Introduction

In recent times, supply chains have allied with new technologies, that allowed them to expand their national boundaries, reaching global levels of production and distribution. However, despite recognizing advances allowed by technology and globalization, there are still a number of problems that persist in reports provided by NGOs such as: asymmetry of power in interorganisational relations, poor working conditions, child labor, among others (Lee, Gereffi, Beauvais, 2010, Oxfam, 2018 and Danwatch, 2016).

Global Value Chain (GVC) is used as a basis to understand the dynamics of supply chains in these markets, especially considering the changes in the field of organizations that have developed new configurations driven by globalization. A GVC consists of the activities by which a product goes through to its end use and thus the importance of interorganisational relationships with different configurations in global context (Lee, 2017 and Gereffi et al. al. 2005).

This study focuses on domestic supply chains which are also embedded in a global supply dynamic. They are supply chains in a specific segment, considering the standard such as Geographical Indication (GI) - denomination given to the products that have
reputation and quality linked directly to a region, that is, to its origin (National Institute of Industrial Property - INPI, 2018).

These agrifood supply chains involve different social actors, not exclusively from the private sector, but also from the local community, the public sector and the third sector, within a complex dynamic of exclusively local production that meets both a niche market of the origin segment and a commodity market, from this, a research question is: How does the interorganisational relations contribute in the value creation and capture in the GI agro-food chains?

Two Brazilian agrifood chains were investigated, the Coffee of Cerrado Mineiro and Cocoa of the Southern Region of Bahia. Specifically, these producing regions present different levels of maturity and are interwoven in different cultural and social contexts.

2. Value in relational structures of multi-stakeholder governance

Agricultural products in recent years have come to use a new approach to governance in their supply chains, mainly driven by addressing sustainability (Schouten & Glasbergen, 2012). A sustainable approach in agrifood chains accompanies a greater interest in the consumption of origin product, valuing certified products, of traceable origin and often with a narrative involved.

Thus, firms have adopted production standards aligned to sustainability, enforcing standards systems and other distinctive labels, often in partnership with NGOs and other local institutions. These collaborative alliances are defined as non-hierarchical and self-organized, in which they use the market as a coordination mechanism to achieve the agreed objectives (Glasbergen, 2007).

Governance from the GVC perspective looks at industries, and therefore can serve as an initial overview to extend the discussion of value creation to other stakeholders along the chain. Thus, in the face of the various organizational and societal challenges, one must go beyond the limits of business in isolation and understand the complexity of collaborative networks in a multistakeholder perspective of value co-creation (Reypens, Lievens & Blazevic, 2016).

Value creation can be proposed in different ways, in the literature the most common types are: a) Value in Exchange (VIE), in which value is the value in monetary and financial terms of a service or product that a company receives in exchange for what they pay for what the market offers (Anderson & Narus, 1998, 54); b) relationship value (RV), the sum of the benefits and the reduction of costs generated in the ongoing exchanges with partners (Lefaix-Duran et al., 2009; Raval & Grönroos, 1996). As well as, c) Value in use (VIU), the result, purpose or objective reached by the partner from a service or product (Macdonald et al., 2011; Eggert et al., 2018). More recently other types of value have been discussed in the literature, being: a) value of innovation; b) value of knowledge; and c) relational value, among others (Reypens, Lievens and Blazevic, 2016).

The origin supply chain can be interesting to analyze the products related to quality such as GI, it is can be a way to understand these products with high specifications, closer to the fashion and luxury industries (Carvalho et al., 2016). These supply chains operate under a different logic of commodities or mass consumption; it is organized to specific segment of consumption market with price premium. This type of supply chain can create value from the tight relationships between the actors involved in this dynamic, it was showed in the organic segment (Vieira et al, 2013; Carvalho et al., 2016).

Geographical indication has been identified as a possible rural livelihood based on local resources, from the interaction between local knowledge (selection, production and processing) with environmental conditions such as climate and soil. However, the
value create in these products does not accrue for the producers, this can occur due to the lack of regulation and mechanisms of control, the GI can also serve as a tool to face this difficulty of appropriation of value by the producers, providing opportunities to rural communities in order to create and appropriate value, whether economic or other types of value (Pacciani et al., 2001; Bramley et al., 2009).

The structures involves in GI can be characterized as multistakeholder. According Hemmati (2002), the term "Multistakeholder" describes a process aimed at bringing together key stakeholders in a new form of decision-making tackling wicked problems. There is a horizontal relationship of responsibility, dialogue and representativeness in this relationship, based on principles such as transparency, participation, partnerships, collaboration and networks of common interest. They may be associated with policies, consensus building, decision making or practical solutions, depending on the nature of the initiative as to the objectives, participants, scope, time and other associated factors. This type of initiative which there is a mobilization of several actors in obtaining and consolidating this distinctive seal, which can be an important catalyst in value creation.

They stand out as the main reasons for participation in value creation in multi-stakeholder initiatives: more reputation enhancement, experimentation and relationship building, and may be linked to innovative practices of resource integration and individual characteristics. It also highlights elements such as trust and social inclusion (Pera, Occhiocupo, Clarke, 2016).

3 Methodology

This study has a qualitative approach, with research design based on multiple case studies (Yin, 2014). From a researched question based on "how", this study can be classified as an explanatory approach. A combination of methodological resources that is capable of providing rigor and reliability to research has been used (Eisenhardt, 1989, Yin, 2014, Stuart et al., 2002, Eisenhardt, 2007 and Machado et al., 2018)

3.1 Selection of cases

The cases were selected from the criteria: products produced in regions protected by geographical indications, which showed growth in the segment of origin, and which are inserted in global value systems. For this, two cases were chosen for analysis, which according to Stuart et. al. (2002), depending on the objective of the study, up to three cases may be satisfactory for analysis.

It is also worth noting that the cases were chosen because they demonstrated different levels of maturity, or management of the geographic indication badge and differences in the type of GI protection, while the Cerrado Mineiro region protected their products through the type of IG "denomination of origin" in 2013, the Southern Bahia region only achieved the same achievement for the type of GI "indication of origin" in 2018. The choice of multiple cases may provide more basis for the construction of a theory, more grounded, accurate and generalizable. Moreover, the choice of polar cases may be an interesting type of structure of analysis (Yin, 2014).

The agrifood chains of origin chosen represent types of products that are part of the historical construction of Brazil, being: coffee and cocoa, located in different regions of the country, one in the southeast and another in the northeast Brazilian.

3.1.1 Case 1 - The Coffee by Cerrado Mineiro
Coffee has a strong historical heritage in Brazil, for a long time the first Brazilian republic had its policy based on the elite of the country concentrated in the southeast region, which controlled the country through an agreement known as "coffee latte policy", this aspect demonstrates the importance that this product had in the country.

The Cerrado Mineiro region is one of the pioneers among the regions protected by geographical indication in Brazil, having been recognized in 2005 as an indication of origin and in 2013 as a designation of origin. The Cerrado Mineiro region encompasses 55 municipalities and involves 4,500 producers and partners, with production reaching 5 million bags with the quality seal of origin, representing 12.7% of the national coffee production. The structure of the Federation of Coffee Growers of the Cerrado has 6 associations of producers, 9 cooperatives and 1 foundation.

The coffee produced in the region is Arabica type, with characteristic marked as coffee of altitude, produced in areas that vary between 800 and 1,300 meters that attributes a very typical flavor of the region. To determine the quality of the drink, it is necessary to achieve a minimum score of 75 quality points in the sensorial analysis. (SEBRAE, 2018, INPI, 2018, Federation of Coffee Growers of the Cerrado, 2019).

3.1.2 Case 2 - Southern Bahia Cocoa

Cocoa has considerable relevance for Brazil, being the fifth largest producer in the world, a large part of its production (90%) is for export (CEPLAC, 2018). For many years’ cocoa was a symbol of prosperity for Bahia, where its climate and soil had a good adaptation. Despite this, in the 1980s the region was hit by a disease known as "which broom", which decimated the plantation in the region, however, recently the region has consolidated as a producer of quality almonds.

The southern region of Bahia is made up of 83 municipalities. In addition, it has 14 associations, cooperatives and sectoral institutions, representing more than 3,000 producers in the region. is of humid tropical climate, characterized by the Atlantic forest, with latitudes of 20 degrees to the line of the equator, highly favorable to the production of cacao. The species of cocoa produced is Theobroma cacao. The product of the region has characteristics such as: fermentation index of 65%, and moisture content less than 8% (SEBRAE, 2018; INPI, 2018; Association of Southern Bahia Cocoa, 2019).

3.2 Data collection

The data collection followed a research protocol. We used semi-structured interviews with the main stakeholders involved in the products of origin, being carried out locally in the two regions of analysis (Barratt et al., 2011). In addition, secondary data such as public reports, products of the segment of origin documents, sectors reports and from organizations as a way of triangulating the data were used (Stuart et al., 2002). Thirteen interviews were conducted in Cerrado Mineiro and twelve interviews in the South of Bahia, with an average of 40 minutes, conducted face to face with different local stakeholders, such as producers, cooperatives, government and associations. As can be seen in Table 1.

<table>

3.3 Data analysis

Data analysis was done using content analysis and case analysis (Eisenhardt, 1989; Duriau et al., 2007). And, therefore, the following steps were followed: a) transcription of the interviews; b) organization and renaming of interviews; c) data coding; d) interpretation of the data through categories.

From the interviews, governance and value issues were grouped, and thus, they initially formed the subcategories, later they were grouped into larger dimensions, forming the categories of analysis.

4 Results

Value chain literature has been based on relational value, the relationship through the integration and cooperation between several players can create more value (Miguel et al., 2014). The interorganisational relationships found were between producers, between regions (benchmarking) and between public and private institutions (in the form of local partnerships). The research data evidenced the importance of relationships and regional identity in the supply chain for value creation and capture, highlighting four constructs that influenced in the value from relationships: partnerships, cooperation, benchmarking and communication, and three constructs that influenced in the value from regional identity: natural ability, regional narrative, sense of belonging.

In the Relationships category, each subcategory represent base to understand how occurs these relations in producer region for value, such as: cooperation is fundamental objective of supporting the other members of the supply chain, characterized as interaction, collective marketing and legitimation from standards. Benchmarking is used in relationships between individuals in the supply chain, in this category the observation and replication of other stakeholders or other agrifood chains about experience and maturity. Communication is the ability to articulate either by conducting training or events in the region that stakeholders have the opportunity to learn from the exchange of information, these spaces of dialogue facilitate the capture of value, through the exchange of knowledge and experience that these environments provide.

In the Regional identity category was an attribute highlighted by interviews in the process of creation and capture of value as these agrifood chains have high dependence on regional and natural factors, such as climate, soil and other factors, they have been categorized as a natural ability. The second subcategory observed in the interviews was the capacity of narrative through regional history, an asymmetry in the capture of value in these chains was perceived, as a basic characteristic of the geographical indication to communicate the history of the region. The third subcategory is about sense of belonging,
the importance of this feelings is to involves the local actors in the same main questions, it can be important for the regional narrative. In the Figure 1 is possible to observe the organize of categories of analysis.

**Figure 1** – Categories of analysis

Source: The authors.

**4.1 Inside the categories**

*4.1.1 Relationships*

The importance of interorganisational relationships is already highlighted in the literature through relationships and interfim with different configurations (Lee, 2017; Gereffi et al., 2005). This means that the value generated by the relationship between the companies can not be obtained individually by the agents; they are the result of the combined resources of the agents. Developing relationships, alliances with vendors that have the key features, or even additional features that will be added, are essential in the competitive landscape (Dyer & Singh, 1998).

The importance of the relationship in the supply chain for generation and capture of value was highlighted through cooperation, partnership development, benchmarking and training in an integrated and formalized way.

In the cocoa chain relationships are not yet structured to capture value, there are benchmarking initiatives and cooperation with purpose to create value. However, in general the perception of value creation in relationship structures such as cooperation, partnerships and benchmarking are not sources of value capture, the main reason is highlighted as the disarticulation between members with greater technological capacity and know-how.

"A lot of people from here sell from there ... not can I get there" (RC).

The relationships in the coffee chain are structured with the purpose of creating and capturing value, the links are engaged and articulated so that the practices are disseminated to the links. This value created through relationships enables a strengthening in operations, bargaining power and is mainly perceived as an improvement in quality.
"That alone will never be too much more difficult to achieve as well. So if we unite, we, the union makes the force, the union makes us strong" (SPSH producer).

In these regions, the presence of the universities, innovation centers and public agencies are important to share the knowledge through events and others initiatives to mobilize the local stakeholders to exchange information’s, experiences, best practices, these dynamics can be explained by knowledge value in this type of network (Reypens et al., 2016). It is can reinforce the sense of belonging and helps in the construction of narratives.

Benchmarking was captured in the interviews to demonstrate the importance of the other cases in the same structure from GI, but in the other maturity level. The coffee chain used the practices from wine chain - Vale dos Vinhedos, the first GI recognized in Brazil as example of structure in interorganisational cooperation, technical infrastructure and local narrative. The cocoa chain has been inspired by practices from the Cerrado Mineiro to strengthen the communication about the region.

4.1.2 Regional Identity

For agrifood chains, regional identity has a specific character, based on the interaction between local know-how (including selection, production and processing) and specific environmental conditions such as soil and climate (World Bank Report 2004). The value of traditional products has increasingly been associated with products that can be associated with a particular location and / or special means of production (Ilbery and Kneafsey (1998)).

A process of crisis of regional identity in the cocoa chain has been identified, local actors have highlighted challenges to better structuring the standardization and communication in the region. The cocoa chain, although historically well-defined is still little explored by the actors as a reputational differential, the crises that marked the sector are present in the discourse of the interviewees as a negative attribute to the region, increasing the insecurity and credibility. The reputation is indicated by the quality of the product, however the process proposed by the geographical indication, corroborates for a formalization of the relationship between the product and the region and / or tradition, in this process the use of legal instruments guarantees the capture of due value (Arora, 2009).

"And that was historic, a long time ago it was very bad, but no one ever proved that it had already changed." (University)

"It's a region that has suffered a lot from the past" (Company 1).

However, it was noted that there is a process of reformulation in the value proposition in the region with private initiatives, for example the tree-to-bar proposal in which the producers themselves manufacture chocolate, the events also as a way to attract visibility to the region and strengthen relationships in the chain.

An influence of the natural vocation of the chain was verified as an important and determinant factor for the quality of the product, however this character is little explored in the creation of value for the region.
The issue of belonging is associated with the reputation that the chain has, the ability to recognize itself as an actor in the chain causes a greater disarticulation between the actors. According to the interviewees' discourse, this is one of the main factors hindering the capture of value in the region.

In the coffee chain, this scenario is the opposite, regional identity has been highlighted by the positioning of value capture, the region has a greater structure of communication focused on the specifics, as well as narrative to create a value for the product to the external public, less focused in the regional social aspect, but in the quality of its product.

5 Conclusion

On supply chain relationships literature from Lee (2017) and Gereffi et al. (2005), that can be extended to the dynamics of supply chains in the origin segment, more specifically the geographic indications, is possible to observe that do not have partnerships in the cocoa chain through projects between cooperatives and leader’s companies in the industry (Considering the presence of these companies in the region such as Barry Callebaut, Cargill and ADM). The relationships are not integrated along the supply chain, there is a greater need for presence and performance of public institutions. Likewise, governance is guided by the incentive of public institutions to strengthen the generation of value through natural resources and the narrative of the region.

On the other side, in the coffee chain occurs predominantly through investments, innovations and a variety of standards (public and private) categorized by a value enhancement. Some multinational companies have projects in partnerships with local stakeholders such as cooperatives and producer’s association. The Governance is driven by the performance of private companies, promoted and the most presence of leader players.

According to Pacciani et al. (2001) and Bramley et al. (2009), it can be concluded that in the case of origin coffee and cocoa, the GI is mechanisms to protect the local producer, it is can facilitate the development of practices that create value, the formalization of the geographic indication standard can be considered as a first step value-oriented. It must be considered that all the local effort in obtaining the geographical indication seal presents a first avenue in the creation of value at the network level, mainly because it is linked to issues such as quality, reputation, traceability and sustainability, however, only the seal does not ensure that the value is perceived and that larger financial gains have been made on a large scale.

However, about the GI and value appropriation as proposed by the authors Bramley et al. (2016), in the cocoa chain the producers do not appropriate for value added along the supply chain, it is different in the coffee chain, here the producers have more presence, and can be observe more organization to add economic value in the origin products.

The Relationships within this type of supply chain are essential if local organizations are to take ownership of the value that is created, so these points become clearer when looking at issues such as cooperation, partnerships, and information sharing. Cerrado’s coffee has performed better in creating partnerships with multinational companies, especially in projects related to sustainability and environmental recovery, as well as private seals that are also adhered to by cooperatives and producers, according to Carvalho et. al (2016), these seals are as high specification guarantees for the market.
It is possible that the result of this study contributes to the understanding of the interorganisational relationships in the value proposition in configurations as in the agro-food chains in the segment of origin. Thus, each category found from this study has an explanatory character about the local dynamics, considering the global circuit from which these chains are inserted.

Abstract

For customizations where individual customers are involved as early as in design stages, referred to as engineer-to-order (ETO), the ability to effectively share knowledge across organizational boundaries is a necessity. This concerns knowledge shared both in the customer interface and the supplier interface. Different situations may however require different processes for knowledge to be effectively shared. This research proposes a framework for analysing knowledge sharing complexity in ETO scenarios from a triadic perspective. Combined with empirical illustrations, the analytical framework supports in describing scenarios and their implications for effective knowledge sharing.

Keywords: Customization, Knowledge Sharing, Engineer-to-Order

Introduction

Many efforts have been made to understand how knowledge can be created, shared and utilised which has been manifested by the emergence of knowledge management research. Generally, knowledge management research is focused on knowledge itself e.g. its creation or conversion (Nonaka, 1994; Nonaka and Von Krogh, 2009) and/or on the activities involved in creating and managing knowledge to gain competitive advantage (Alavi and Leidner, 2001; Martelo-Landroguez and Cepeda-Carrión, 2016). The ability to create new knowledge enables companies to innovate and it has been suggested that knowledge creation is reliant on the personnel’s collective ability to share and combine knowledge (Nahapiet and Ghoshal, 1998; Del Giudice et al., 2013). Furthermore, a shared interpretation of knowledge among personnel supports unified responses that improves operational performance (Fugate et al., 2009). Thus, it can be argued that knowledge sharing is essential for a company’s innovativeness (Nonaka, 1994; Del Giudice and Della Peruta, 2016) and ultimately its competitiveness (Crossan and Apaydin, 2010).

To be competitive, a company’s governing premise should be to primarily focus on the customers rather than on maximizing shareholder value (Martin, 2010). In embracing the principle of being customer driven, many companies offer customizations and this can be done in various ways and to varying degrees (Lampel and Mintzberg, 1996; Wortmann et al., 1997). When customizing, the specific needs of individual customers must be considered for some of the production-related activities that is to be performed (Wikner and Rudberg, 2005). As the desired outcome is to provide a product that is
satisfactory to the customer, it is of importance that the needs of the customer are clearly understood (Du et al., 2003). If the product is engineered-to-order (ETO), individual customers are involved as early as in the design stage (Gosling and Naim, 2009) and the novelty of these circumstances requires knowledge to be shared across organizational boundaries, but there is limited research into knowledge sharing in the ETO sector.

In ETO settings, knowledge is shared with customers to, for example, reveal flawed reasoning and challenge preconceived ideas about the product requested (Engström and Käkelä, 2019). Conversely, customers share details of their knowledge that must be accounted for, but the importance of knowledge sharing does not only apply to the customer interface. Knowledge must also be shared with suppliers as some procurement activities are performed in line with the individual customer’s needs and as engineering decisions made in agreement with customers may be dependent on supply (Tate et al., 2015). If knowledge is not shared effectively in these interfaces, costly errors can be made that has a negative impact on customer satisfaction and this can ultimately deteriorate competitiveness.

To get a holistic view of knowledge sharing in ETO scenarios, and due to the interdependency between knowledge shared in the customer interface and the supplier interface, this research takes the analytic perspective of the supply chain as a triad (See Figure 1). With the triadic perspective on the supply chain, the analysis is focused on the focal actor (FA). The focal actor functions as a supplier to the customer actor (CA) but as a customer to the supplier actor (SA). From the FA’s perspective, consideration need to be taken both to the customer interface and supplier interface.

In ETO scenarios, knowledge sharing is an everyday, practical concern. The products are often ‘one-of-a-kind’ which means that different customer requirements must be met for the fulfilment of each customer order. In novel circumstances such as these, the complexity and effort required to effectively share knowledge across boundaries increases (Carlile, 2004) but the actors in the triad may have different views on what knowledge that is difficult to share. The purpose of this research is to develop a framework for analysing knowledge sharing complexity in ETO scenarios from a triadic, inter-actor, perspective. Empirical illustrations are made to demonstrate how knowledge sharing complexity can manifest itself in practice. Two research questions have been formulated to respond to this purpose:

**RQ1:** How can inter-actor knowledge sharing complexity in ETO scenarios be differentiated?

**RQ2:** How can inter-actor knowledge sharing complexity manifest itself in practice in ETO scenarios?

Combined, the analytical framework and the empirical illustrations supports in differentiating ETO scenarios, suggesting that an important skill for ETO companies is the ability to recognize what is required for effective sharing of knowledge across organizational boundaries in different situations. To be able to promptly identify circumstances that impacts knowledge sharing complexity can be critical for a company’s ability to provide products that satisfies customer’s needs.
Methodology
This research has been carried out in two main segments; the first adopting an analytical conceptual approach for theory development (Wacker, 1998), resulting in the development of an analytical framework, and the second relying on empirical data to check the validity of the framework. The research therefore has a deductive approach, where the analysis of empirical data has been based on the analytical framework.

In the first segment, the analytical framework (see Figure 3) was developed to describe the phenomenon of interest. The framework was based on current literature on knowledge sharing complexity and integrated with a triadic, inter-actor perspective on ETO scenarios. With the intention to not only accurately describe the phenomenon as such but also to explain how it works, the second segment of the research included empirical illustrations from four ETO companies. The empirical illustrations act as examples of how different scenarios discerned in the analytical framework may manifest themselves in practical embodiment. The empirical data used for these illustrations are of qualitative character and have been collected from two workshops where representatives from the four companies have jointly discussed issues related to knowledge sharing in their customization practices. In the workshops, the researchers and company representatives shared experiences and jointly discussed the problem at hand. As illustrated in Figure 2, the first workshop consisted of general discussions about sharing knowledge across organizational boundaries. After the first workshop, the company representatives were given an assignment to prepare and present at the second workshop. The assignment was based on the critical incident technique (see e.g. Flanagan, 1954; Davis, 2006). The participants were instructed to select and describe customer order incidents or scenarios they had perceived as challenging in terms knowledge sharing with customers and suppliers. In this way, the discussions in the second workshop revolved around concrete descriptions of situations where the complexity of knowledge sharing became apparent.

![Figure 2 – Data collection procedure](image)

The four companies represented in the workshops are all industrial business-to-business companies of which large parts of the business is comprised of ETO deliveries. The companies are however quite different in other respects, such as number of employees and type of product, as seen in Table 1. Each company had one or two representatives participating the workshops, all with managerial roles with a holistic understanding of their customer order fulfilment process.

Theoretical framework

Knowledge sharing complexity

Knowledge sharing is a knowledge management-related issue. As the centrality of knowledge in organizational practices has been more evidently recognized, knowledge management research has gained interest in a variety of scholarly domains (Paulin and Suneson, 2015). Efforts to manage knowledge are taken by organizations with the intention to leverage between differentiated knowledge held by employees, to integrate knowledge that exists outside the organization, to develop new knowledge, or to put knowledge into use in ways that advance organizational goals (Davenport and Prusak, 1998; Barley et al., 2018). In other words, the essence of organizational capability relies not simply on the possession of unique knowledge, but rather on the ability to integrate individuals’ specialized knowledge to achieve capabilities that other firms do not possess (Nonaka, 1994; Grant, 1996). Accordingly, to understand how knowledge can be effectively shared is of utmost importance.

Knowledge sharing is a frequently used term in knowledge management research but there are some sources of confusion regarding its precise meaning (Paulin and Suneson, 2015). One issue concern how knowledge sharing relates to knowledge transfer. These terms are sometimes discussed interchangeably (see e.g. Jonsson, 2008; Liyanage et al., 2009) but they can also be seen as having different meanings based on the view and understanding of knowledge (Paulin and Suneson, 2015). A distinction can be made between the view of knowledge as an object and the view of knowledge as a subjective contextual construction. When knowledge is viewed as a subjective contextual construction, researchers tend to be more drawn to the term knowledge sharing (Sveiby, 2007), resulting in a clearer emphasis on e.g. sensemaking of situations and creation of shared meaning in this stream of research. Another important distinction made is between knowledge sharing and information transfer. While information transfer explicitly refers to the relay of codifiable information or knowledge, knowledge sharing also includes the contextual understanding required to effectively interpret the information and make sense of it.

Activities that supports sensemaking is critical in contexts where there is a need to create and maintain coherent understandings for collective action (Weick, 1993; Weick et al., 2005). Working across functional or organizational boundaries is a key source for innovation but it also implicates that actors with different specializations or interests join in a common task. To effectively share knowledge across boundaries can be challenging as the heterogeneity among the involved actors may require an integration of incompatible perspectives for a shared meaning to be attained (Bechky, 2003). The complexity of the processes required to share knowledge across boundaries is relative to the difference, dependency and novelty of the circumstances around the boundary (Carlile and Rebentisch, 2003). Carlile (2004) suggested three progressively complex processes for sharing knowledge across boundaries; to transfer, to translate and to transform knowledge. When it is insufficient to just transfer knowledge, interpretative differences as to what for example a word or a customer requirement means calls for processes or mechanisms that help translate the differences to create shared meanings (Dougherty, 1992). If there are substantial discrepancies between the different interests that hinders the development of shared meaning, the involved actors must negotiate, make trade-offs, adapt and transform their knowledge to define a common interest (Brown and Duguid, 2001). Such discrepancies can for example occur when knowledge developed in one domain are incompatible or have a negative impact on knowledge developed in another...
domain. To understand what consequences domain-specific knowledge can have on the task at large is thus crucial as it allows for the knowledge to be transformed accordingly (Carlile, 2004).

**Differentiating ETO**

To offer customizations can contribute to companies’ competitiveness as customer get the opportunity to influence the form of the product they procure. Customers can get involved at different stages of the production and if they are involved as early as in design stages, it is commonly referred to as an ETO scenario (Giesberts and Tang, 1992; Hoekstra and Romme, 1992). In ETO scenarios, products are tailored according to the needs of individual customers which means that design, engineering and production activities are performed in response to a customer commitment. The operating environment is therefore to a large extent characterized by the uncertainty of not knowing what to produce in advance (Bertrand and Muntslag, 1993; Gosling et al., 2013; Gosling et al., 2015).

While there are similarities between individual ETO scenarios, there are also factors that distinguish them. ETO does not only concern cases where completely new designs are developed for the individual customer but also when modifications are made to existing designs (Wikner and Rudberg, 2005; Gosling and Naim, 2009). Distinctions between ETO scenarios have also been made based on the degree of vertical integration, source of competitive advantage and core competencies (Hicks et al., 2001). Product complexity and level of detail in specifications from customers are also aspects that differ (Bertrand and Muntslag, 1993). For example, functional specifications that merely describe what the product should do enables the supplier to propose innovative solutions and their own design. On the other hand, detailed specifications also describe how the product should do it, which may limit the suppliers influence on design (Hicks et al., 2000). The information available for the product may also vary in commonality, some being only applicable for the specific customer order, some being applicable to a certain customer and some that is independent on the customer or customer order (Wikner and Bäckstrand, 2012). There are also differences in terms of relationships with suppliers, varying degrees of customization for purchased components, extent of collaborative measures, balance of power and the importance or value of particular components (McGovern et al., 1999).

**Sharing knowledge for customization: an analytical framework**

The triadic perspective of this research is adopted to account for that knowledge shared in one of the FA’s interfaces sometimes need to be considered in the other interface. Knowledge shared by the SA may for example have a major impact on the product at large and can sometimes force the FA to involve the CA in redesigning the product and vice versa. To fulfill the customer order and provide a product that is satisfactory to the customer, the FA must together with the SA and CA take initiatives to make differentiated knowledge (e.g. domain-specific knowledge) integrated knowledge (knowledge held in common). However, the efforts required to effectively share knowledge across boundaries differ. In Figure 3, a triadic perspective of knowledge sharing is considered with regard to Carlile (2004) three levels of complexity for sharing knowledge across boundaries.
Empirical illustrations

The empirical illustrations in this section serves as support for the applicability of the analytical framework. All illustrations are based on the customer order incidents the companies described in Workshop 2. Relating to Figure 3, they are presented from bottom left to top right with the sub-headings indicating that the SA-interface is followed by the CA-interface as logical in the down-stream materials flow direction. However, the actual illustrations are described in the opposite order to better represent the sequence of events, as logical in the up-stream information flow direction.

Transfer - transfer:
This is a situation that can occur in ETO settings when the FA’s relation to both customer and supplier is established and stable. The organizational routes for knowledge sharing are known and knowledge that are specific for the customer order can be shared in codifiable form. For Company Beta, this is a typical scenario when they sell doors to end-customers through one of the qualified carpenters they collaborate with. They have long-term relationships to the carpenters that shares a common understanding of the product to the degree that they can discern what knowledge that needs extra attention when shared. The level of novelty and difference is hence low. In the supplier interface Company Beta purchases standard wooden raw materials and only need to transfer what they need, when they need it and how much they need. In the supplier interface it is hence usually sufficient for Company Beta to transfer knowledge.

Transfer - translate
Company Beta have another type of relationship with customers that purchases doors as a representative of a tenant owner cooperation. These customers are usually novice when it comes to knowledge about the product and the relation to the customer is usually new. Company Beta’s ability to translate knowledge about the product to the customer that can support the customer’s decisions about product requirements is of critical importance for this customer segment. When the customer expresses their needs, there is usually a process of translation as the explanations sometimes leave room for interpretative differences. As stated in the previous paragraph, the knowledge shared in Company Beta’s supplier interface can simply be transferred as there are no considerable novelty in terms of supply.

Transfer - transform
Once again Company Beta will be used as an illustration, which emphasizes that it is sometimes beneficial for a company to have different approaches to knowledge sharing depending on the circumstances of the boundary, in Company Beta’s case dependent on
the customer segment. Company Beta’s third customer segment is large construction firms and although these relationships are rarely entirely new, these firms usually have several liaisons which complicates knowledge sharing. Additionally, the liaisons are often changed during the order fulfillment process. The customer requirements are received from architects and they generally call for a high degree of customization which sometimes conflicts with the construction firm’s emphasis on timed deliveries that are to be coordinated with other deliveries to the construction site. Company Beta is hence dependent on their customer to be able to deliver. Neither the large construction firm nor the architect is novice per se, but their knowledge can sometimes be incompatible with each other but also with the product specific knowledge held by Company Beta. This requires negotiation and trade-offs, often in terms of product design, cost and delivery time. This is demanding and since there are several liaisons involved with different interests, there is usually someone who is not entirely satisfied. As stated previously, the knowledge shared in Company Beta’s supplier interface can simply be transferred as there are no considerable novelty in terms of supply.

Translate - transfer
For Company Epsilon, this situation occurs when orders received are just slightly different from existing designs. It is therefore sufficient for the customer to transfer their knowledge about their needs as long as Company Epsilon is familiar with the context of which the product is to serve in. The novelty in the customer interface is therefore not significant and the adaptations to the existing designs is relatively easy for Company Epsilon to understand. However, if the customer demands for example a material certificate for the product, Company Epsilon must make efforts to translate knowledge about what this implies for the specific customer order to its suppliers. Requirements that are seldom demanded, such as a material certificate, implies a novelty and Company Epsilon cannot assume that the suppliers are knowledgeable about why the material certificate is of great importance in some cases, but not always. For this reason, Company Epsilon makes effort to translate knowledge about the customer’s context so that the supplier shares an understanding of its importance for the delivery.

Translate - translate:
The following example is a case of knowledge sharing gone bad due to misrecognition of complexity. Company Delta often develop completely new designs for customers they have not dealt with before and they are known for being able to deliver high quality and conform to strict standards. In this case, a customer from a business segment they had no previous knowledge about requested a seemingly simple product. However, it turned out that products for this business segment were required to follow specific laws and regulations that were unlike those standards Company Delta had experience of. This knowledge was not shared or requested until it was too late, as the novelty of the circumstances were not recognized by either Company Delta or the customer. Consequently, this knowledge was not shared to Company Delta’s suppliers either, who delivered parts that did not comply with the regulations for this specific customer order.

Translate - transform
Company Delta also has a recurring customer that have particularly high demands on quality and documentation. The products ordered are complex, and the customer usually have a lot of knowledge about it. Due to their high demands on quality, this customer tends to be persistent in adhering to requirements established early in the process. As knowledge have been developed at Company Delta during the order fulfillment process, these requirements may however not be compatible. This force Company Delta and their customer to resolve their different interests and transform their respective knowledge
accordingly. In the supplier interface, Company Delta had to translate this knowledge so that the suppliers could adapt.

*Transform - transfer*

In this scenario, Company Gamma were to provide a relatively simple product which was a view initially shared by the customer and Company Gamma. Company Gamma had developed similar products before, and the customer order were for this reason taken somewhat lightly. During the process it did however become clear that several conflicting interests from the suppliers had to be resolved which was not anticipated from start. One of the main reasons as to why these issues were not anticipated was because the standards of the encompassing systems that the product were to be integrated to were quite different from what Company Gamma had experienced before. There was this a high degree of dependency between this product and its interfaces. While Company Gamma had to engage in negotiations with suppliers, the customer was still under the impression that there were no significant complexities that Company Gamma would have to confront. Company Gamma knew that the customer had high quality requirements and that they were not willing to settle for less than was agreed to from start. Rather than approaching the customer to explain or negotiate, Company Gamma put a lot of pressure on their suppliers to solve problems which was possible due to the power balance between the actors.

*Transform - translate*

For this scenario we did not identify an illustration through the critical incidents presented by the companies in Workshop 2 but will instead present a scenario based on logical reasoning. This scenario can occur when the FA has an established relation with the customer. The customer has high demands and is requiring something novel to the extent that knowledge must be translated in the customer interface. Let’s now assume that this specific customer order requires a new supplier to be included. The knowledge from the customer about the novel product must be shared to the new supplier who may have knowledge that does not comply. This would require transformation of the knowledge shared by the customer and the knowledge shared by the supplier.

*Transform - transform*

In this case, Company Delta were awarded the business to develop a customer’s prototype to a manufacturable product, to find and establish supplier relationships and to develop Company Delta’s own manufacturing so that it could ramp up to full production volume. There was considerable novelty both in terms of the relationships with customer and suppliers but also for the product itself. Along the process, Company Delta encountered several issues that required negotiation between the actors to be settled, both with the customer and supplier respectively but also all three parties jointly due to the dependence between the different actors.

**Conclusions**

The purpose of this research was to develop a framework for analysing knowledge sharing complexity in ETO scenarios from a triadic perspective. This framework was presented in Figure 3 and complemented with empirical illustrations to demonstrate how knowledge sharing complexity can manifest itself in practice in ETO scenarios. A contribution has been made in terms of further differentiating ETO, demonstrating that different ETO scenarios have diverse implications for how knowledge is to be effectively shared across organizational boundaries. A first step towards efficient knowledge sharing for customization in both customer and supplier interface is awareness from the focal actor regarding the current situation. As can be seen from the empirical illustrations, problems occur when an actor underestimates or misjudges the complexity of sharing knowledge.
across a boundary. Companies providing ETO products can thus benefit from improving their ability to promptly and effectively identify circumstances in specific customer order scenarios, or for specific customer segments, which impacts the measures required for effective knowledge sharing. This way, the company can plan resources and competences accordingly and build structures for a variety of modes for communication. By being responsive and adaptive to the circumstances, the ability to provide products that satisfies the needs of different kinds of customers can be improved, which is an important factor for the company’s competitiveness.

An Alternative Explanation of Inter-Organizational Management Control: The Psychological Contract

1. Purpose

The construct of the psychological contract has been developed in an attempt to explain why BPO arrangements that resemble each other in terms of the promissory contract between client and supplier can display important differences in relational methods of coordination, conflict resolution, commitment, communication behaviour and cultural adaptation. Recent research (Lioliou et al (2014) into relational governance has used the concept of the psychological contract to provide a more in depth assessment of the phenomenon. Koh et al (2004) noted that research on managing outsourcing relationships had concentrated either on contractual control methods or on promoting partnership-type arrangements; albeit with later research arguing for a compliment of the two approaches. Lahiri (2016) highlighted that the work of Koh et al (2004) suggests that partners’ obligations and their fulfillment predict outsourcing success in a significant way. Lahiri (2016) emphasised that how outsourcing affects the client–provider partnership has not been adequately examined. Koh et al (2004) felt that the body of knowledge overplayed the role of the client i.e. that the supplier was obligated to satisfy the client. Rather, they argued, the client-supplier relationship was an arrangement with mutual obligations. This displays similarity with social exchange theory. However, Koh et al (2004) adopted the theory of the psychological contract as espoused by Rousseau (1989) from the organization behaviour field to support their argument. Contrary to the legally stipulated obligations in the written contract,
the psychological contract focuses on individuals’ beliefs concerning mutual obligations resulting from a contractual relationship. Whilst social exchange theory overlaps with the concept of trust as a sociological construct, the psychological contract has more similarity with trust as a psychological construct. Three principles of psychological contract theory are fundamental: (1) a concentration on mutual obligations; (2) emphasis on the psychological interpretation of obligations rather than legal ones; (3) a focus on individual-level analysis rather than at the organization or inter-organization levels. Therefore if the concept of the psychological contract is to be relevant to providing better understanding of outsourcing relationships, these three principles must hold. The purpose of this study is to investigate if such expectations are valid.

2. Design/methodology/approach

A multiple case study approach using several units of analysis was deployed in this study. The unit of analysis was the operational BPO arrangement. This dyadic relationship was studied from the perspectives of the client recipient and the service provider. The case studies were: (1) National Broadcaster – BPO1, 10 year contract worth £100 M to provide HR administration, EU; (2) Healthcare Provider – BPO 2, 7 year contract worth £48 M to provide HR administration, USA; (3) Investment Bank – BPO 3, 10 year contract worth £63 M to provide HR administration, USA; Oil Company – BPO 4, 5 year contract (value undisclosed) to provide F&A, HR and C&P administration, India. From the client perspective, the sub-units of analysis were the managers responsible for managing the outsourcing contract and its implementation; generally HR personnel. From the service provider perspective, the sub-units of analysis were
front line management and staff; team leaders and team members who had the greatest levels of interaction with the client across a range of management layers. The case study protocol resulted in the same interview schedule being used throughout the research study. To enhance the validity of the information collected in this research study, multiple sources were used. The perspectives of at least two managers from each of the client and supplier organizations were collected; in the case of the supplier organization, at least one of the managers would be a first line Team Leader with greatest levels of interaction with the client. Data was collected from at least two client-facing team members involved with service delivery in the supplier organization. In addition, each participant was offered the opportunity to read and comment on their interview transcription and the researcher’s field notes in an attempt to reinforce the internal validity of the data collected. Some informants did make additional comments after the initial interview and this helped to clarify their opinions.

3. Findings

It had been the expectation at the commencement of the data collection process that an investigation of four similar transactional BPO arrangements with comparable outsourcing objectives would have exhibited similar methods of management control by the client and supplier firms if not necessarily similar levels of performance. However, the results reveal significant differences in how both clients and suppliers went about achieving management control in this context. The results revealed both positive and negative evidence relating to coordination. The findings support the view that increased coordination improves performance against contractual metrics and general satisfaction with the BPO arrangement. The findings indicated a spectrum of coordination with
very little coordination at one end through coordination on specific projects to extensive coordination combining joint problem solving and team working. At the team working end of the coordination spectrum, the evidence was supportive of cooperation in terms of process design and quality practices.

The results also revealed very interesting results with regard to conflict; the largest source of conflict being due to poor supplier performance against contracted measures and at times of such conflict hostage penalties were generally imposed by the client firm. The results of the multiple case study indicate that conflict between exchange partners is a common aspect of on-going transactional BPO arrangements. With the exception of the Investment Bank-BPO 3 case study, suppliers tried to smooth over problems to avoid them escalating in the client firm. By contrast, the clients’ approach depended on the seniority of the person experiencing the problem. More senior personnel tended to report problems loudly and formally where more junior personnel could often be influenced by suppliers’ staff to keep the issue informal to generate more time for the issue to be resolved without penalty. Even when issues of conflict were highlighted to client contract management staff, there were differences observed in how it would be handled; this hinged to a large extent on the presence or absence of joint problem solving. The general supplier perspective revealed a hope that clients would engage in joint problem solving. That said, only Investment Bank in their arrangement was motivated to do so. They felt that it helped avoid on-going conflict and improved performance generally.

There was a mutual desire to avoid unnecessary contact, to practice clarity of behaviour and to avoid provocation. That said, Investment Bank generally, but
not always, imposed hostage penalties despite their use of joint problem solving. Such behaviour needs to be explained.

4. Relevance/contribution

This work has been influenced by the small body of extant studies (Koh et al, 2004; Miranda and Kavan, 2005; Hill et al, 2009; Kingshott and Pecotich, 2007; Kingshott, 2006; Blancero and Ellram, 1997) that have attempted to integrate the concept of the psychological contract into outsourcing and other inter-organisational contexts. As stated earlier, Guest (1998) argued that the concept of the psychological contract was unreliable in terms of validity and parsimony. Both Guest (1998) and Koh et al (2004) argued that no definite list of dimensions had been determined for the psychological contract thus limiting the potential for theory development. It is hope that this research can go some way to addressing this gap in existing knowledge and to developing a theory of the psychological contract as an inter-organisational construct.

The belief that inter-organisational relationships are controlled by more than legal arrangements has been long argued (MacNeil, 1980; Macaulay, 1963) often with reference to the notional and unwritten “spirit” of the contract. Rousseau and McClean-Parks (1994) argued that the working of a contractual relationship was influenced by subjective interpretation by individuals involved in its implementation. Koh et al (2004) went as far as to argue that:

“Ultimately, it is the individual’s beliefs and perceptions of these obligations (i.e., the psychological contract), rather than the actual written contract, that drive her behaviour”

(Koh et al, 2004, p 358)
This is potentially an argument stretched too far; it is arguable that both the written contract and unwritten interpretations of it will influence behaviours. For example, specified performance metrics will influence behaviour to achieve the required outcomes. In fairness, Koh et al (2004) did propose that the psychological contract was a broad concept that incorporated beliefs about explicit and implicit contractual terms. However, by doing so there is a risk that the probable importance of the legal promissory contract gets downplayed.

The theoretical model presented above assigns primary and direct impact on outsourcing performance to the use of the explicit promissory contract but also proposes a secondary and direct impact on performance from the use of the implicit psychological contract. This work builds on the recent work of Lioliou et
al (2014) which demonstrated that the psychologically binding nature of the psychological contract makes it a particularly forceful substitute to formal governance while its links with other relationship aspects make it a forceful complement.

Abstract

This research investigates the relationships between supply chain relationships/integration, innovative capabilities and manufacturing performance. Data was collected from 171 organisations based in three rapidly developing countries – Brazil, India, China. Data was collected as part of the International Manufacturing Strategy Survey (IMSS VI) and analysed using Structural Equation Modelling. The findings indicated that supply chain relationships and integration relate positively to both product and process innovative capabilities. The study also found that there were positive relationships between both product and process innovative capabilities and manufacturing performance. Finally, there was a positive relationship between product innovative capabilities and process innovative capabilities.

Keywords: Innovative capabilities, Supply chain management, Developing countries

Introduction

This study investigates the relationships between supply chain relationships and integration, innovative capabilities and manufacturing performance within the context of three rapidly developing countries - Brazil, India and China. Previous studies including those by Back, Parboteeah, and Nam (2014) and Ren, Eisingerich, and Tsai (2015) have highlighted the necessity for more research on innovative capabilities and product development in developing countries. Developing countries such as Brazil, China and
India are increasingly seeking to improve their global economic presence and influence. To this extent, many organisations in these countries focus extensively on the development and exploitation of innovative capabilities. This study seeks to investigate if the supply chain relationships that manufacturers in these countries develop discourage them to develop their innovative capabilities. In addition, the study investigates if the development of these innovative capabilities result in improved manufacturing performance. Hence, the key questions that motivate this research are as follows:

- Within the context of manufacturers in rapidly developing countries, do supply chain relationships and integration relate with the development of product and process innovative capabilities?
- Do product and process innovative capabilities drive manufacturing performance in these rapidly developing countries?

**Literature Review and Hypotheses**

According to Tsai and Hung (2016), supply chain performance can be improved by developing a well-integrated supply chain. In essence, organisations that become more integrated or which develop better relationships with their suppliers and customers improve co-dependency and can develop an innovative advantage (Day, 2000; Souitaris, 2001). However, despite increasing evidence that manufacturers are under increasing pressure by their customers to adopt innovative practices and improve their innovative capabilities (Laosirihongthong, Punnakitikashem, and Adebanjo 2013), the relationship between customer relationship and integration and the development of innovative capabilities of manufacturers remains largely unexplored. The key hypotheses investigated in this research are now presented.

The study by Ren, Eisingerich, and Tsai (2015) suggested that within the context of developing countries like China, organisations tend to lag in technology development and are under the control of their western customers. The impact of the control of western customers is that the manufacturers in developing countries are necessitated to tailor their innovation-related activities to meet the needs of their customers (Bullinger, Auernhammer, and Gomeringer 2004). Increasingly, these customer needs include the ability to develop their innovative capabilities (Mishra, Chandrasekaran, and MacCormack 2015). Such innovative capabilities can be either product-related or process-related. Hence the following are hypothesised:

- **H1.** Improvement in supply chain relationship and integration will relate positively with improvement in product innovative capabilities in manufacturing organisations in developing countries.
- **H2.** Improvement in supply chain relationship and integration will relate positively with improvement in process innovative capabilities in manufacturing organisations in developing countries.

Product innovation is important to organisations because it has the potential to deliver new streams of income (Kleinschmidt and Cooper 1991; Teece 2010). However, Martínez-Ros and Labeaga (2009) and Ballot et al. (2015) noted that while product
innovation and process innovation are different, they could have a complementary relationship and could lead to each other. Linton (2015) also suggested that that product innovation is likely to result in process innovation. Therefore, the following hypotheses are proposed:

\( H3a. \) Improvement in product innovative capabilities will relate positively with improvement in process innovative capabilities in manufacturing organisations in developing countries.

\( H3b. \) Improvement in product innovative capabilities will partially mediate the relationship between supply chain relationship and integration and Improvement in process innovative capabilities.

The main reason why organisations focus on the development of product innovative capabilities is the need for organisations to maintain a competitive edge in the market place (Leskovar-Spacapan and Bastic 2007). This relationship between product innovative capabilities and organisational performance has been explored in previous studies. The study by Yang et al. (2015) concluded that supply chain performance is influenced by innovation capability. This argument also extends to process innovative capability. The potential impact of developing process innovation on the performance of an organisation was investigated by Oke and Kach (2012) and they found that the benefits included improvements in the production process, efficiency and cost. Hence the following are hypothesised.

\( H4. \) Improvement in product innovative capabilities will relate positively with improvement in manufacturing performance in developing countries.

\( H5. \) Improvement in process innovative capabilities will relate positively with improvement in manufacturing performance in developing countries.

Methodology
The study collected data from Brazil, India and China through the International Manufacturing Strategy Survey (IMSS) version VI between June 2013 and June 2014. For this study, manufacturing performance was measured using a combination of quality and flexibility because these two dimensions of performance should be of major concern for all organisations that are focussed on product and process innovation. The responses for manufacturing performance were assessed using a five-point Likert scale that compared organisational performance to the main competitor. The measures for all other constructs were developed from established scales and were measured on a five-point Likert scale as well. The study collected 171 valid survey responses which were used to test the hypotheses presented above. The dataset comprised of 28 (16.4%) responses from Brazil, 56 (32.7%) from India and 87 (50.9%) from China.

The study performed a principal-component exploratory factor analysis for each survey item to check for the specified constructs. The results showed that all the items of each construct had factor loadings between 0.725 and 0.896, exceeding the recommended coefficient of 0.50 (Hair et al. 2010). The constructs were also examined for internal consistency and the results showed that every construct had Cronbach’s Alpha ranging from 0.840 to 0.900, meeting the desirable value of 0.70 (Hair et al. 2010). In addition, the study also checked the composite reliability of all constructs and the results showed
that the values of composite reliability for all the constructs ranged between 0.894 and 0.928, which are above the recommended value of 0.60 (Bagozzi and Yi 1988). The values of average variance extracted (AVE) for each construct were above 0.50, indicating convergent validity. To address the problem of multicollinearity, the study evaluated multicollinearity through the variance inflation factors (VIF) and the values of all variables were between 1.287 and 1.942, lower than the recommended thresholds of 3 (Hair et al. 2010), thereby confirming there was no multicollinearity problem in this study.

The study then used structural equation modelling to test the hypothesized relationships. The SEM results showed a good model fit with normed chi square ($\chi^2$) = 1.114, GFI = 0.923, AGFI = 0.893, RMSEA = 0.026, RMR = 0.053, NFI = 0.928, TLI = 0.990, and CFI = 0.992

**Findings**
The study found that supply chain relationship and integration had a significant and positive relationship with product innovative capabilities ($\beta$=0.682; $p$-value < 0.001). Supply chain relationship and integration was positively related to process innovative capabilities ($\beta$=0.294; $p$-value < 0.01). There was a positive relationship between product innovative capabilities and process innovative capabilities ($\beta$=0.475; $p$-value < 0.001). Product innovative capabilities was positively related to supply chain relationship and integration ($\beta$=0.270; $p$-value < 0.05). Process innovative capabilities ($\beta$=0.305; $p$-value < 0.05) was found to have a significant and positive relationship with manufacturing performance. The results provided evidence to support hypotheses H1, H2, H3a, H4 and H5. These results are shown in table 1.

The significant positive relationship between product innovative capabilities and process innovative capabilities resulted in the testing of a mediating effect for product innovative capabilities. The bootstrap approach (Preacher and Hayes, 2004) was adopted to test the mediation hypotheses. The indirect effect of product innovative capabilities on process innovative capabilities was calculated as the product of the path coefficients between supply chain relationships and integration and product innovative capabilities ($\beta$ = 0.682) and between product innovative capabilities and process innovative capabilities ($\beta$ = 0.475). This indirect effect coefficient was equal to 0.324, which can be validated for significance using a bootstrap approach. The indirect effects were significant given that the lower confidence interval of the bias-corrected bootstrap does not contain zero. As both direct and indirect effects were significant, the partial mediating effect (H3b) was supported for product innovative capabilities.

**Conclusion**
The study shows that for manufacturers in Brazil, China and India, the ability to develop supply chain relationship and integration will significantly and positively impact on their ability to develop their product innovative and process innovative capabilities. The study also found that, product innovative capabilities have a strong positive relationship with process innovative capabilities. The implication of this finding is that organisations that develop strong product innovative capabilities are also likely to develop process innovative capabilities thereby improving the overall level of innovativeness in the
organisation. Finally, the study found that both product and process innovative capabilities have significant positive relationships with manufacturing performance. From a theoretical perspective, the findings suggest that institutional pressures that affect manufacturers such as pressure from supply chain customers can lead them to develop new capabilities with respect to product and process innovative capabilities. From a competitive perspective, the findings show that manufacturers in the countries that were studied are increasingly beginning to focus on product and process innovative capabilities. If and when they develop such capabilities to an advanced level, the impact on global manufacturing and trading relationships could become very significant.

Value dimensions and value capture in B2B relationships: A general framework with moderation effects

Claudio Minerbo (claudiominerbo@gmail.com)
Fundação Getulio Vargas – São Paulo School of Business Administration, Brazil

Luiz Artur Ledur Brito
Fundação Getulio Vargas – São Paulo School of Business Administration, Brazil

Abstract

This research investigates how value creation and moderating factors can be combined to increase value capture. Based on a dyadic case study and qualitative comparative analysis (QCA) with a firm in financial payments and five suppliers, it recognizes the existence of core and non-core dimensions of value creation and demonstrates the principle of equifinality through six combinations that increase value capture. Limitations are the use of only three theories and constraints when QCA is based on judgement. It brings practical understanding of mechanisms and options available to increase value capture and shows how to apply QCA method in qualitative settings.

Keywords: Value creation and capture, buyer-supplier relationships, QCA analysis

Introduction

Value creation and capture are central concepts of business-to-business (B2B) relationships in the marketing and operations management (OM) disciplines (Pinnington, Meehan, & Scanlon, 2016). Over the past decades research has proposed several definitions for the dimensions (or sources) of value creation (Ulaga & Chacour, 2001), investigated different forms of value capture (Bowman & Ambrosini, 2000), the factors that moderate these relationships (Anderson & Narus, 1990) and the interdependency between price and volume (Lindgreen & Wynstra, 2005). However, these streams have mostly run independently without much interaction (Su & Yang, 2017) and further empirical investigation is needed to better understand how the components of value creation interact to increase value capture.

This study brings several theoretical, empirical, methodological and managerial contributions. Based on grand theories, it recognizes the existence of core and non-core dimensions of value creation. It advances the knowledge about how contextual variables identified in previous models influence value capture and demonstrates the principle of equifinality through six different combinations that increase value capture. From a methodological perspective, it fulfills Su & Yang (2017) need to move towards QCA to study complex B2B relationships, a method that has been accepted in important journals (Schneider & Eggert, 2014). It also shows how to conduct QCA when starting with a
qualitative approach using interviews (Russo, 2019), a method rarely found in the literature. For buyers and suppliers it brings more practical understanding of the value capture mechanisms, how business is divided among suppliers, and options available to increase value capture (Ellegaard, Medlin, & Geersbro, 2014).

The research was conducted in two phases, an embedded case study and QCA, to clarify how the dimensions of value creation and moderating factors can be combined to increase value capture in B2B relationships. The analysis was based on a focal firm in the financial payments industry and five key suppliers responsible for supplying specialized services.

Theoretical background
In this study, value creation was defined based on three theories commonly used in OM research. TCE (Williamson, 1981) brings an economic approach to predict exchange governance structures and performance of an exchange. Exchanges are conducted by transactions that have a cost associated to them and firms will conduct an activity internally as long as the transaction costs are lower than conducting the same activity in the market. Examples of value dimensions are operational efficiency, asset efficiency and financial efficiency. RBT (Barney, 2001) focuses on internal or outsourced heterogeneous resources. Organizations that own, access or control valuable, rare, costly to imitate and imperfectly substitutable resources can sustain a competitive advantage. Examples of value creation are capabilities, innovation and time reduction. In the SET (Granovetter, 1985) actors enter and maintain relationships with the expectation that value will be exchanged through cost or social reputation and prestige. As the duration and intensity of interactions between actors increase, it is expected that opportunism and malfeasance decrease and lead to more informal governance and lower transaction costs. Examples of value creation include the quality of relationships, access to information and access to market.

Value capture is the portion or share of the value created which is held by each focal firm and is independent of value creation. Buyers and suppliers can capture value based on three distinct forms: (i) by getting a larger share of the transaction value at expense of the relationship partner through price negotiation (Bowman & Ambrosini, 2000; Lindgreen & Wynstra, 2005); (ii) by shifting volume at expense of other competing firms inside the supply network (Ellegaard et al., 2014) or (iii) by increasing the total value in the relationship through collaborative efforts at no one’s expense because new value is created (Ellegaard et al., 2014).

Four factors moderate value capture. Power and dependence have been recognized as a primary source of value capture and are particular to the individual dyad because the powerful party tends to appropriate a larger share of the created value at the expense of the weaker through price negotiations, direct reinforcements or indirect manipulative ways (Bowman & Ambrosini, 2000; Ellegaard et al., 2014). Attraction (or attractiveness) is the force that pushes a buyer and a supplier closer in a dyadic relationship and is an opposing mechanisms to power because a firm that is attractive in the eyes of another also has power within the dyad (Hald, Cordón, & Vollmann, 2009). PSM practices are defined as "activities that [directly or indirectly] relate to the purchasing–supply base interface". They are crucial to achieve effects on buying firm performance, have a significant role in cutting the total costs (Narasimhan & Das, 2001) and mediate the effect of relational practices (Foerstl, Franke, & Zimmermann, 2016). Changes in the supply strategy are inevitable and the most prominent reasons why an organization initiates change are tensions caused by the external environment (i.e. cost competition), customer’s demands (i.e. a new channel strategy), performance issues, or internal changes at the individual or
organizational levels (i.e. a new manager) (Flint & Woodruff, 2001). Although client-specific knowledge suggests that the buyer requirements are likely to be fulfilled by suppliers that already provide and can adapt their services and not new suppliers (Chatain, 2010), cases like that are often followed by a new bidding process that impact both volume and price.

Methodology – Phase 1: dyadic case study

The objective of Phase I was to identify the cases and consisted of a dyadic case study (Miles, Huberman, & Saldaña, 2014) because there are hardly theoretical frameworks that explain the relationship among value creation, value capture and moderating factors within B2B relationships. The unit of analysis was the buyer-supplier relationship.

The focal firm (FIN) was a leading Brazilian company in the financial payments industry and the six dyads supplies strategic services. The suppliers consisted of two Software Factories (SW- and SW-B), two Independent Sales Organization (ISO-C and ISO-D) and two Logistics Service Providers (LSP-A and LSP-B). At least a procurement (buyer), commercial (supplier) and operations representatives (buyer and supplier) were interviewed. A total of 27 interviews with 32 participants were conducted based on a mirrored interview protocol, leading to 28 hours of recording. Interviews were transcribed and managed with the CAQDAS software Atlas TI. All interviews were read in detail and the passages coded based on a provisional list that was revisited and refined during the analysis (Saldaña, 2015) until a final list containing 41 codes was assembled.

The specific dimensions of value creation used in this study were identified based on the count of how many times they appeared in each interview and total mentions. Three dimensions were repeatedly identified across all interviews and dyads and defined as “core”. Each one was grounded on a theory: operational efficiency (TCE), quality of relationship (SET) and capabilities (RBT). Other seven dimensions were mentioned less often or only in specific interviews or dyads and were defined as non-core. They are based on TCE (asset efficiency, financial efficiency and risk management), SET (access to information) and RBT (firm reputation, innovation and time reduction).

The next step was to define the cases. A case was composed of three elements: a condition related to the outcome (value capture), the variables associated to the condition (dimensions of value creation or moderating factors) and the outcome. A specific case was considered when the coded text could clearly identify the specific condition, describe in an open-ended manner one or more variables associated to that condition, and be associated to a positive or negative outcome (Farrell & Marsh, 2016; Russo, Confente, Gligor, & Cobelli, 2019). A qualitative interpretation of all quotes coded as context information and value capture was performed and different conditions were associated to generic price/volume decisions, a specific supplier increasing/ decreasing price or volume, new supply strategies and collaborative projects. Then, all quotes related to each specific case were connected into one unique string that represented the case, independently of the person interviewed. Finally, each case was copied and represented a line in an MS-Excel spreadsheet for further analysis.

Thirty different cases were identified and were fairly distributed across the dyads and outcomes, and therefore considered satisfactory. However, four cases related to collaborative efforts were not considered for further analysis because the sample was too small to obtain a meaningful conclusion and in all cases the value created was totally captured by the buyer. Therefore, the final samples consisted of 24 cases.
Phase II – QCA analysis
Based on the results of Phase I, a QCA was conducted to identify the causal conditions that lead to value capture (Fiss, Peer, 2011). Unlike traditional regressions or correlations, QCA uses set relations and formal Boolean logic to find commonalities between different cases with the same outcome (equifinality) and determine which conditions are necessary and sufficient for the outcome (Rihoux & Ragin, 2009). A sufficient condition ensures that the outcome will occur when present, although it may be one of many conditions that produce the outcome. QCA is traditionally considered appropriate for small samples in the range of 10 to 50 cases (Schneider & Eggert, 2014) and has been used to evaluate complex supply chain phenomena (Russo et al., 2019). The crisp-set methodology (Rihoux & Ragin, 2009) was used because the variables had only two possible values (0 and 1), and the model was analyzed with the Fuzzy Set Qualitative Comparative Analysis (fs/QCA) software.

Assembling a truth table containing the cases was the first step. In the truth table each attribute is composed of binary variables coded 1 for “present” (high score) and 0 for “absent” (low score) (Rihoux & Ragin, 2009), and it was necessary to transform the text into “1” or “0” because the variables were based on verbal reasoning. The outcome was considered “present” when the case pointed to an increase in volume or to an increase in price. For the other variables, a “present” condition was considered when the quote had a positive relationship with the outcome.

Validity of the truth table was based on frequency and consistency. The cut-off criteria for frequency for samples between 10–50 cases was 1 and considered acceptable. The consistency measure should be above acceptable levels of 0.8 (Rihoux & Ragin, 2009) and two cases showed measures of 0.5. The first was a contradictory price configuration and was removed because it was only a conjectural (not real) situation mentioned by a supplier, and the second was adjusted after reexamining all quotes and interviews associated in more detail.

The existence of a necessary condition that could simplify the model was tested and not found. A necessary condition implies that when you observe the outcome you will always observe the condition (Schneider & Eggert, 2014). A sufficiency analysis was performed and results were below 0.83, less than the conventionally accepted threshold of 0.9 (Rönnberg, Parida, & Kohtamäki, 2016). Two variables were excluded from the conditions tested. The moderating factor PSM was excluded because no heterogeneity was found on the different cases and the non-core SET dimensions was excluded because it was not mentioned in any of the cases.

At the end of this process two truth tables were built (one for each outcome: price and volume) with a total of 23 cases, 12 for volume and 11 for price. Outcomes were analyzed for the presence or absence of eight conditions: three core value dimensions (Core-TCE, Core-RBT and Core-SET), two non-core value dimensions (Non-core-TCT and non-core-RBT), and three moderators (attraction, power and change).

QCA Results
Findings are presented using the notation method found in the literature (Russo et al., 2019). The presence of a condition is marked by a filled circle (●), the absence of a condition is noted by a circle with an “x” (@) and there is no notation if a condition is not involved in a solution. For the configurations, the symbol * represents the logical operation AND, the symbol ~ represents the absence of the condition.

Interpreting the results requires a dialogue between the QCA results, the theoretical background and concrete examples of the solutions at work (Farrell & Marsh, 2016).
Eight combinations (I to VIII) of conditions associated with change in volume were identified and demonstrate the principle of equifinality (Table 1). The solution had overall consistency and coverage scores of 1, meaning that they are sufficient to produce the outcome, and the coverage of the sample was adequate (Rihoux & Ragin, 2009). A logical simplification was conducted to reduce the eight configurations presented by the QCA (Rihoux & Ragin, 2009) and resulted in three business situations that lead to a change in volume (A, B and C).

</table>

Circles “●” indicate the presence of conditions, and circles “○” indicate absence.

Situation A contains configurations I to V and indicate that a combination of high operational performance and capabilities is sufficient for increasing or decreasing volume. Although only configuration III showed that capabilities do not necessarily need to be present, it was included because all other situations were absent of operational performance and results would remain the same. In specific situations, other core dimensions (quality of relationship), the non-core dimensions and moderators (attraction, power and change) had high or low levels depending, and therefore they do not need to be present in all situations to capture volume. In the absence of operational performance (situation B) change was a sufficient condition to impact volume capture since higher or lower scores of the other core and non-core value dimensions and moderator factors were not always present. Situation C shows that when both operational performance and change are absent, an increase or decrease in volume depends on the presence of high capabilities, relationship and power. Again, the non-core dimensions were not relevant for volume capture.

Eight combinations (I to VIII) of conditions associated with change in price were also identified (Table 2). The overall consistency and solution coverage was 1, implying that they are sufficient for the outcome. The logical simplification showed that these eight configurations can be combined in three main business situations that lead to a change in price (A, B and C). Situation A contains configurations I to IV and indicate that high levels of operational performance alone is sufficient for increasing or decreasing price. The other core dimensions (capability and quality of relationship), non-core dimensions and moderators (attraction, power and change) do not need to be always present since they showed high or low levels in specific configurations. In the absence of operational
performance, high levels of change are sufficient to impact price (situation B), since higher or lower scores of the other core and non-core value dimensions and moderators were present. When both operational performance and change are absent (situation C), high levels of power are sufficient to affect price. In that case, high levels of core and high levels of non-core value dimensions or other moderators (attraction and power) do not need to be present.

In summary, the results (Table 3) show that high levels of operational performance, change or power are a sufficient condition to capture value through price. In other words, there is no need for a combination of factors to capture price, but only one of these. Value capture through volume follows a slightly different combination. Although high levels of change is also a sufficient condition, volume is captured by combining operational performance and capabilities, or by combining capabilities, relationship and power. Non-core dimensions of value creation (TCE, RBT or SET) and attractiveness were not relevant in any combination.

Discussion: Operational performance and value capture

High levels of Operational Performance is a sufficient condition to capture value through price and bring more light to the contrasting views on value: while some authors provide a common and simplistic conceptualization of value-for-money as the ratio...
between quality and price, others suggest that viewing value as a trade-off between only quality and price is too simplistic (Sweeney & Soutar, 2001). Different theoretical explanations support the simplistic view. For the past three decades buyer-supplier relationships were driven by operational performance (Terpend, Tyler, Krause, & Handfield, 2008) and supplier's quality performance of service activities were used to choose a particular vendor (Gassenheimer, Sterling, & Robicheaux, 1996). High levels of other dimensions do not affect price because they seem to be antecedents to performance, relevant only in specific situations or too subjective. For example, the quality of relationships is a social and subjective mechanism and capabilities that a partner brings to the relationship have already been linked with the ability of an organization to achieve superior performance (Barney, 2001).

These arguments were found in the software factory, ISO and logistics cases. Prices were based either on commoditized umbrella contracts with standard rates or specialized services with specific and higher rates. In these cases, high levels of operation efficiency acted as a certification that the partner already had the capabilities, and therefore prices were not driven by them. According to the managers:

“If a supplier has better quality and delivers [the service] with fewer errors, I would not be uncomfortable in paying a little more”;

“I could pay a little more to have a better quality”

Value capture through volume requires high levels of operational performance and capabilities. While operational performance is a necessary condition for assigning volume to a supplier due to the same reasons explained in the price discussion above, the reason why capabilities must be present can be explained by TCE and RBT. Resources are assets, processes, information or knowledge of a firm that enable development and implementation of strategies to improve efficiency and effectiveness (Barney, 2001). As the buyer shifts more volume to a certain supplier, he increases his dependency and need to secure the supply (or reduce risk) in case the supplier fails to deliver (Aminoff & Tanskanen, 2013). Therefore, before shifting volume it is expected that the buyer will assure that the supplier has the specific capabilities, can deliver the additional volume without affecting operational performance and not increasing risk.

High levels of operational performance and capabilities increased or decreased volume in the software, logistics and ISO services cases. In the day-to-day business, suppliers that performed also had a pre-defined scope that could be a geographical region, a technology platform or a technical expertise. In these cases, additional demand was automatically given to that specific supplier. According to the ISO managers:

“we really want suppliers that can allocate a larger number of sales representatives. However, it does not help bring a very large supplier if I’m not sure that his team knows how to do my door-to-door sales”

Although it would be expected that suppliers with good relationships would also be able to capture more volume (Anderson & Narus, 1990; Granovetter, 1985), it was not a necessary condition to capture volume and the reason was found in the cases. Quality of relationships seems to be an antecedent to performance, since the suppliers that increased volume had good relationship with the buyer while the ones that lost volume not. According to the buyers, suppliers that lost volume had a “relationship sickness” and were “bureaucratic and had a lot of friction”.

**Discussion: Change in supply strategy and value capture**

In the absence of operational performance, a change in supply strategy is a sufficient condition for capturing value for both price and volume. Changes in buyer–supplier relationships can be initiated due to the external environment, new customer’s demands,
performance issues, or internal organization changes (Flint & Woodruff, 2001). The reason for a having only change in supply strategy as a condition seems to be because it tends to involve a new bidding process that may lead to positive or negative effects on price and volume depending on the situation. Although in a bidding process the buyer requirements are more likely to be fulfilled by exiting suppliers (Chatain, 2010), it is also an opportunity for new suppliers to invest and get additional business.

These situations were found in different cases. When the ISO managers decided to implement a new supply strategy due to changes in FIN’s channel strategy, they first reduced the number of suppliers to keep the best performers and then planned to conduct a new bidding that would change the operational and remuneration model and attract new suppliers to reduce dependency on the fewer suppliers that remained. According to a buyer:

“The request for proposal will be new because we will quote everything since the beginning, starting from zero”.

A situation of volume decrease occurred in the software factory after the implementation of a disruptive strategy. In that case, a new large supplier that had global reputation for managing strategic projects in technology and other small software boutiques was contracted based on his specific capabilities and as a consequence the remaining suppliers decreased their share of the business.

The cases showed although high levels of performance, capabilities and relationship were determinants for value or price capture, they were specific to each situation and therefore do not necessarily need to be present at in all situations.

Discussion: value capture in the absence of operational performance and change

In the absence of operational performance and change, power is a sufficient condition for capturing value through price. This is not surprising from an academic point of view because in this situation there is no differentiation left. Differentiation helps suppliers to compete, achieve a temporary monopoly, increase buyer’s willingness to pay or help buyers discriminate competing suppliers (Ulaga & Eggert, 2006). When absent, the party that has the strongest bargaining power determines who captures the largest amount of value, (Bowman & Ambrosini, 2000; Ellegaard et al., 2014).

This was found in the software and ISO cases. The focal firm (FIN) has relative high power within its supply base because suppliers are relatively dependent of FIN’s volumes and need to do business with them to develop unique capabilities that are valuable in the market. Within the cases, suppliers that did not show high levels of operational performance were forced to reduce price regardless their level of capabilities and relationship because the buyer was not willing to pay higher prices to suppliers that do not perform. For example, one supplier mentioned that prices did not change in the last two years despite inflation, and according to another supplier:

“Price renewals are happening like this: I renew [the contract] with you but will pay 30% less. Do you agree?”

Value capture through volume requires a combination of high levels of power, capabilities and relationship. The theoretical relevance of each of these factors has already been discussed and explains why this combination is applicable in specific situations. When there is a lack of differentiation the party with stronger bargaining power who captures the largest amount of value (Bowman & Ambrosini, 2000; Ellegaard et al., 2014), and the firm that controls valuable, rare, inimitable, and non-substitutable capabilities holds a strong power position. Therefore, even if one party has high levels of power, volume will not be shifted unless the other party has the necessary capabilities. The SET complements this combination because in dyadic relationships there is tendency
for commercial relationships to be interwoven with personal ones (Zaheer & Venkatraman, 1995) and as the duration and intensity of interactions increase the embedded relationships generate trust, discourage opportunism and lead to more relational and informal governance, thus reducing transaction costs and increasing performance (Zaheer & Venkatraman, 1995). As a result, when a partner has low levels of operational performance and high levels of power and capabilities, relationship quality may be an additional and complementary value needed to increase volume.

Specific cases found in this study support this argument. For example, the more informal governance helped an ISO supplier to quickly set-up a promotion for the buyer and get the additional volume. According to the supplier:

“several times they called me and said: I need [to set-up] a promotion with five sales people but do not have the sum to pay you. In this situation the supplier responded: Ok, I will send the people and we can settle the situation later, in another promotion”

Conclusions, limitations and future research
This paper combined an embedded case study and QCA to investigate different combinations between the dimensions of value creation and moderating factors that increase value capture. The findings recognize that the TCE, RBT and SET can explain the core and non-core dimensions of value creation and demonstrate the principle of equifinality through six different combinations that increase value capture. From a methodological perspective it showed how to conduct QCA starting with a qualitative approach using interviews (Russo, 2019) and fulfilled the need to move towards QCA methods (Su & Yang, 2017). For managers, it brings a practical understanding of the mechanisms and options available to increase value capture (Ellegaard et al., 2014).

The limitations can be addressed through future research. Value was explored only through three dominant theoretical perspectives and future research can consider other theories found in OM research, such as the resource advantage, contingency or agency (Soosay & Hyland, 2015), to determine other combinations that increase value capture. The combined methodology has its own limitations and constraints because the cases and truth tables were based on judgement, thus replicating this method in different contexts would help to better understand QCA. The sample consisted of firms within the financial services industry in Brazil and future research should test other industries, countries, cultures and settings to increase the generalizability of the findings.

Abstract

This study investigates a reasonable sharing rule for a strategic alliance based on a hub-and-spoke network. Individual firms cooperate to gain additional benefits and the distribution of the joint profit is crucial for a sustainable partnership. Our research is an application of cooperative game theory which suggests proper profit allocation methods. The link-based integer programming model calculates extra outcome of horizontal cooperation between logistics companies, which benefits from better resource utilization with aggregative demand. Insight into reasonable allocation methods provide an academic and practical intuition for further research.

Keywords: Cooperative game theory, Supply chain collaboration, Profit sharing

Introduction

The rapid change of industrial structure and the acceleration of technology development including information and communications technology have a great impact on the business ecosystem. Coopetition, a term coined for cooperation with a competitor, is all about evolution. In particular, self-interested firms choose a strategic alliance which is mutually beneficial and collaborate to gain extra outcome. A variety of benefits of the strategic alliance leads companies to cooperate and to strengthen their competitiveness (Baum et al., 2000; Dyer and Singh, 1988; Gomes-Casseres, 2015; Kogut, 1988; Powell et al., 1996; Shapiro and Willig, 1990). Specifically, the cooperation of logistics companies improves profitability through vehicle utilization and economies of scale. For example, an airline joint venture, which involves tight cooperation, is an emerging strategy in the airline industry. Back in 1997, the first joint venture between KLM and Northwest airline was formed over the transatlantic routes. Even though the antitrust law concerns of dominance by big carriers in the early days, the consumer benefits generated by airline cooperation (Brueckner, 2001) allow for granting an antitrust immunity and airlines to collude in the contract routes. Today, passengers receive benefits of increased frequencies or diverse schedules (Armantier and Richard, 2008; Dennis, 2005; Weber,
and airlines get extra revenue improved from enlarged network (Park et al., 2001; Wright et al., 2010).

The existence of additional profits is the main purpose of the relationship between the individual firms, while maintaining the relationship is a different story. In other words, whether profit is generated or not is most important in alliance-formation, on the other hand, the distribution of profit among members should be reasonable for sustainable relationship.

A primary interest of our research is based on how to allocate the joint outcome among incumbents and cooperative game theory provides frameworks for analyzing situations in which players interact as well as collaborate. By comparing various solution concepts in conventional cooperative game theory, we investigate the distribution and validate the possibility of sustainable partnership.

Model

In most transportation systems, including the airline services, which are based on a hub-and-spoke network, economies of scale and economies of scope are main advantages by cooperation. Therefore, aggregated demand and resources based on an extended network are the key to achieve extra outcome from an alliance. Through cooperation participating firms get increased demand as well as reduced costs. In our study, we examine passengers’ path along with the decision of aircraft types, considering transfer in hub airports. Assuming horizontal cooperation between airlines, a mixed integer programming model presents the optimal value of joint profits of the profit maximization problem.

The customer demand is known for each origin-destination pair and the costs, which consists of the fixed cost of aircraft type on a specific line segment and the variable cost based on each passenger for their whole path, are also known. The number of passengers traveling on a particular aircraft type of each link, which means a line segment of a direct trip between two airports, and the number of aircraft types utilized on each link are the decision variables of our model.

The objective function is assumed to be the same regardless of cooperation, that means all coalitions have same profit structure related to the demand and the cost presented in the model. Note that we presume identical costs in both airlines and the coalitional demand is aggregated followed the new network since we does not account for any other impact on demand. Our proposed mixed integer programming model is presented as follows after notations including all sets, parameters and decision variables as shown in Table 1.

Notations

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
The model

Maximize \[ \sum_o \sum_p (r_{op} - c_{op}) x_{op} - \sum_a \sum_t f_{at} y_{at} \]  \hspace{2cm} (1)

subject to

\[ \sum_o \sum_p x_{opat} \leq U_t y_{at}, \ \forall \ a \in A, \ t \in T_a \]  \hspace{2cm} (2)

\[ \sum_p x_{op} = D_o, \ \forall \ o \in O \]  \hspace{2cm} (3)

\[ x_{op} = \sum_{a \in A^S_o} \sum_t x_{opat}, \ \forall \ o \in O, \ p \in P_o \]  \hspace{2cm} (4)

\[ \sum_{a \in A^S_o} \sum_t x_{opat} = \sum_{a \in A^S_o} \sum_n x_{opat}, \ \forall \ o \in O, \ p \in P_o, \ n \in N \]  \hspace{2cm} (5)

This model solves the number of passengers on the assigned aircraft \( t \) between each airport which is presented as an arc \( a \), and total demands are satisfied with achieving the maximum profit. We let \( Z(S) \) be the total maximum profit (i.e., the maximum value of the objective function in the above model) of coalition \( S \). Constraint (2) is bounded at the upper capacity levels of aircraft type which means the maximum number of seats allowed. Constraint (3) aims to satisfy the required demands for each origin-destination pair \( o \) of coalition \( S \) by employing each path \( p \). In our model, we assume that the transfer is allowed and even mandatory for the origin-destination pair \( o \) with more than two links.

Numerical illustration

In order to figure out a reasonable allocation rule which can guarantee the sustainable partnership with all alliance members, we illustrate a numerical example of an airline joint venture in a basic two-hub network. In our example, each link is demonstrated as a player and thus a player is a link between one hub airport and one non-hub airport or two hub airports only. For the sake of brevity, the whole network consists of only two hub airports and one non-hub airport connected each. Figure 1 shows the network example.
There are four types of aircrafts with different capacities; two long-haul aircrafts are only travelled between hub airports, while links between a hub airport and a non-hub airport are allowed for all aircraft types. Same aircraft types have homogeneous costs in the same distance without reference to different airlines. Demands from collaborating are defined from the joint network, which means the network expansion considered, and be aggregated by each demand before cooperation. Both costs and demands are known. From our mixed integer programming, we find the optimized maximal profit and calculate profit increasing in fifteen possible coalitions. Table 2 summarizes the results.

Using three different solution concepts of cooperative game theory, i.e., the Shapley value, the τ-value and the nucleolus, we suggest the allocation of increased profits in Table 3. The profit distribution by the τ-value and the nucleolus is similar, while the Shapley value allocates lower distribution value to player A and higher distributions to player B and C.

Based on above allocations, we suggest a new index, the expectation, coined for the possibility of deviation. The expectation ($E_s(V)$) of each coalition $S$ is derived as the excess value of the sum of distributions among coalitional players in the grand coalition compared to the profit increasing of that coalition. For example, the expectation of a coalition $\{AB\}$ with the nucleolus is $0.4732 (= 1.8238 + 0.3534 - 1.7040)$. This is calculated exactly in the same manner as the satisfaction (Lozano et al., 2013; Yea et al., 2018). By comparing the expectation of all coalitions, we can infer whether the grand coalition maintains. In Table 4, we compare the expectation values of each coalition scenario as the absolute term $E_s(V)$ and the relative term $E_s(V)/Z(S)$, which is a percentage of total profits $Z(S)$ in the corresponding coalition. Understandably, in our example, the maximum values exist in a coalition $\{AD\}$, which is cooperation of both players having a link between a hub and a non-hub node. This means that a coalition $\{AD\}$ is willing to create the grand coalition to have the extra benefit. On the contrary, all the case of the minimum expectation is presented in a coalition $\{ABD\}$. This implies that once a coalition $\{ABD\}$ is formed and then they do have little incentive to invite an extra link, the player C, because the network of player A, B and D has enough profit increasing. For example, when the grand coalition is formed, total distributed values to a player A, B and D is $2.2862 (= 1.2323 + 0.6430 + 0.4180)$ based on the Shapley value, which is even smaller by 3.0% than the profit increasing of the corresponding coalition $\{ABD\}$ in itself (i.e., 2.552).

Table 4 – Coalition expectations for the Shapley value, the $\tau$-value and the nucleolus.
Interestingly, more satisfied players are links having a non-hub node. In other words, a link between two hub nodes is allocated with relatively lower contribution on profit increasing. In our example, player B and C are links connecting the hub airports, which means that they are backbones of the whole network. This might be the reason of the network expansion effect by additional links in the network game. More demand, the origin-destination pair as well as the number of demand, raises the revenue in an extended network. Nevertheless, the whole network is completed with the backbone link and even benefits from the network expansion are not realized without them. Because, for example, those links deliver not only the demand of their own, direct trip between hub nodes, but also the demand of collaborating, transfer trip via the link. The result of our research that the maximum expectation of the alliance \{AD\} changes to the minimum of \{ABD\}, just by inviting a player B, reveals the significant contribution of a player B, which is the link connecting two hub nodes.

Suppose that an airline considers creating a joint venture with other airline and decides how much effort to put in the coalition. In practice, if the rewards for pooling resources are not satisfied and there is another way to get more rewards, a firm doubtless chooses the latter strategy. For example, an airline who operates a link traveling between two hub airports might reduce frequencies or capacities of the trip, due to adding a link from a hub node to another node outside results in higher profit allocation than putting extra effort into the existing link. Then, that airline gains competent profit distributions even though the whole network works but not efficiently. What is worse, a firm prefers to exclude that link if anticipated advantage from joining of a particular segment is not relevant.

This supports needs of another sharing rule imposed of contribution through existence itself. Because with the above distributions, which are suggested in a conventional cooperative game theory, we might ignore some important point of a specific situation, the network game. Although our example is limiting in homogenous marginal cost between airlines and assuming the simplest network, the result shows that the network game has a characteristic of a value of connecting. In this context, we could infer the maintenance of the grand coalition has the value. Although network expansion by attaching a new route is compensated, most distribution methods of cooperative game theory are a flagrant disregard for the existence value of the link connecting the hubs. Thus we need to present a new allocation scheme designed for sustainable cooperation, which emphasizes the significance of maintaining the grand coalition.

**Conclusion**

In this paper, we attempt to examine the sustainable relationship through reasonable allocation scheme of an airline joint venture by comparing different solution concepts in conventional cooperative game theory. We set an airline joint venture which is a horizontal cooperation between airlines to enlarge their networks and to reduce costs. Since our model, based on each link as a player, assumes passenger trips on the transfer at hub nodes, benefits from cooperation include revenue growth by extended network and cost savings by efficient utilization of the resources. A mixed integer programming model
solves the maximum profits of all possible coalitions in a numerical example and the profit increasing of each alliance is derived as the characteristic function value of cooperative game. Then we apply three different allocation solutions in cooperative game theory to split the profit increasing among the coalitional members. In particular, we apply the Shapley value, the $\tau$-value and the nucleolus for the profit-sharing scheme. In our numerical example, expectations of all possible coalitions present that the alliance between players having non-hub nodes is the most satisfied incumbent in the grand coalition, whereas the minimum expectation exist in the coalition having the whole network, which excludes the duplicated link. This result highlights a momentous impact of cooperation in a network game and the structure of a network could be the most critical for the long term.

Research area applied cooperative game theory still remains relatively underexplored. Our study addressed the validity of a logistics collaborating, which is quite limited research topic. The numerical illustration provides practical guidance to existing airlines and also to logistics managers on how to assign the distribution of joint profits. In a continuous work, we undergo the research targeting to propose a new allocation rule for sustainable partnership which guarantee properties of the core. As further research, we plan to supplement the limitations such as homogeneous costs and airfares, constant demand without consideration of influence based on increased customer utility caused by cooperation.

Abstract

Supply Chain Finance (SCF) is often praised as a tripartite-win arrangement. However, its adoption rates by suppliers are surprisingly low. This raises an important question around why suppliers hesitate to participate in such a beneficial arrangement. SCF allows buyers to extend payment terms to improve working capital while suppliers can receive early payment. However, SCF relationships are rather complex, despite being initiated by buyers, the target adopters are suppliers. This study employs an inductive multiple-case study approach to examine why UK SMEs are not using SCF and seek to understand how SCF adoption decisions and supply chain relationships are interrelated.

Keywords: Supply Chain Finance, SMEs, Transaction Cost Economics

Introduction

Limited availability of funding after the 2008 financial crisis led many corporate firms to employ a “squeezing strategy”, either paying their less powerful suppliers late or negotiating extended payment terms to improve their own working capital and financial performance (Boer et al., 2015). SMEs suppliers are often helpless and end up involuntarily accepting longer payment terms. This results in suppliers needing to borrow money to bridge a wider gap between getting paid by large buyers and paying their own suppliers. As suppliers typically pay higher interest rates compared to corporate buyers, this squeezing practice poses a higher risk to suppliers and may eventually lead to financial instability. Deferred payment can also affect service levels or quality of products delivered (Hofmann and Kotzab, 2010).

Supply chain finance (SCF), a form of financial collaboration between large buying firms and SME suppliers through third-party financial institutions, has increasingly gained attention from both scholars and practitioners as a potential solution to fund the gap and ease the tension between buyers and suppliers in managing cash flow and working capital (Templar et al., 2016). SCF is initiated by a buyer who arranges with its bank a pre-agreed loan (overdraft-like) for its selected suppliers, giving the suppliers an option to receive early payment for any
approved invoice(s). Upon request, the bank pays the invoice(s), less interest or fees, instantaneously to the suppliers. At the due date of each invoice, the buyer pays back the bank the face value of the invoice(s). Figure 1 illustrates how SCF works.

SCF is repeatedly praised as a tripartite-win arrangement. However, SCF adoption rates by suppliers are surprisingly low (Boer et al., 2015, Wuttke et al., 2016). This raises an important question around why suppliers are hesitant to participate in such a beneficial arrangement. Although potential benefits of SCF can be subject to the nature of individual supply chains, especially in terms of relationships and collaboration between trade partners, previous studies give most attention to financial activities and monetary benefits of SCF, ignoring relations and collaboration aspects (More and Basu, 2013). To address this gap, this paper investigates SCF adoption decisions and SCF relationships through suppliers’ perspective.

The remainder of the paper is structured as follows. Firstly, SCF and related literature is reviewed. This is followed by research objectives, design and methodology. Next, the results of semi-structured interviews, observation and documentation are presented. The final part is our conclusions where limitations of this study and future research are also discussed.

**Literature review**
Supply Chain Finance (SCF) has been introduced in literature in 1990s (Nienhuis et al., 2013). Although SCF has been a topic of interest for decades, the definitions and scopes of SCF are acknowledgedly inconsistent and confusing. Global Supply Chain Finance Forum, GSCFF (2016) admittedly states:

“The novelty of the subject matter of Supply Chain Finance led to the usage of a range of expressions, terms and terminology that were – and remain today – often inconsistent, opaque and even contradictory”.

In general, there are three main definitions/scopes of SCF. First, SCF is generally referred to research in relation to management of financial flow in supply chains. Alternative terms include financial supply chain management (FSCM) and financial supply chain (FSC) (Pfohl and Gomm, 2009). Second, SCF is used as an umbrella term encompassing several finance options for supply chains such as factoring, invoice discounting and letter of credit.
The third definition/scope, SCF is referred to a rather new tripartite financial arrangement between a buyer, suppliers and a financial institution, often referred to as reverse factoring. This definition is arguably confusing as this so-called reverse factoring is also categorised as one of several finance options under a SCF umbrella in the second definition/scope.

These definitions/scopes are also in line with the two main streams of SCF research proposed in literature, supply chain-oriented and finance-oriented perspectives (Caniato et al., 2016, Gelsomino et al., 2016). The former is consistent with the first definition whereas the latter fits with the second definition. The third and our definition is the combination of the two perspectives in response to the earlier call for future research by Gelsomino et al. (2016) who argue that there is a lack of a SCF framework taking both supply chain oriented and finance-oriented perspectives into consideration. Figure 2 illustrates the three SCF definitions and scopes.

Although this paper adopted the third definition/scope where SCF is a tripartite financial relationship, given the inconsistency and confusion of definitions and scopes of SCF, we were open to all terms, definitions and scopes that were mentioned by the participants to ensure that we did not miss important information. Furthermore, various finance options currently used by SME suppliers or provided by financial institutions were also explored.

In this definition, SCF is often referred to as “reverse factoring” indicating that SCF is a reverse process of “factoring” which is a short-term financing where suppliers sell their invoices at a discount to receive immediate cash from a financial institution (Klapper, 2004). However, we argue that SCF is neither just a finance option nor a reverse process of factoring. Rather, SCF is a tripartite relationship approach aiming to integrate physical, information and financial flows to reduce cost and increase the competitiveness of the supply chain as a whole. There are several key differences between SCF and factoring, particularly in terms of parties involved and their relationships as well as an initiating and obligatory party.

SCF relationships involve three parties. First is a buyer, an ordering party and also an obligatory party (borrower) who is a large organisation with a high credit rating. Second party is suppliers (sellers) who supplies goods and services to the buyer. Suppliers can be any size from micro, small to medium which are generally referred to as SMEs. The third party is a service provider who is either a financial institution partnering with a SCF platform provider or vice versa. In contrast, factoring and its newly similar finance option, invoice discounting (ID), involve only two parties: a supplier as a borrower and a financial institution. Unlike factoring and ID which can be initiated by a supplier without the buyer’s involvement, SCF must be initiated by a buyer who subsequently selects target suppliers to participate so the
financial institution (typically the buyer’s bank) can offer the suppliers option to sell their invoices once approved by the buyer (Klapper, 2004).

Both factoring and ID start when a SME arranges with its bank or other financial institutions to sell all of its invoices (from all buyers). The bank advances 75-90% of an invoice amount within 1-2 days without the need for approval and the remaining 10-25% of the invoice paid once the full payment is received from the buyers (GSCFF, 2016). On the contrary, SCF allows suppliers to receive 100% of an invoice upon request from the day the invoice is approved by the buyer (GSCFF, 2016).

The key difference between factoring and ID is who collects the payments from the buyer. For factoring, financial institutions collect payments on SMEs’ behalf whereas SMEs can maintain their own credit control processes by collecting payments themselves when using ID. This makes ID preferable for SMEs than factoring since most suppliers believe selling invoices indicates financial problems in which they do not want buyers to know. Moreover, the costs for using factoring is higher than ID since financial institutions charge the costs for payment collection. Only SMEs with good credit control process and credit rating can opt to use ID.

SCF also differs from factoring and ID in terms of risks involved and costs of finance. Regarding risks, by entering SCF relationships, a supplier can transfer its risks to the buyer’s bank while this is not the case in factoring and ID where risks of buyers’ default are still with suppliers (Lekkakos and Serrano, 2016). In terms of costs, the interest rate or discount rate paid by suppliers in SCF arrangements is calculated from the buyer’s credit rating whereas a SME’s credit rating is used to calculate interest rate in factoring and ID. This means, theoretically, SCF is much cheaper than factoring and ID (Wuttke et al., 2013). Nonetheless, since buyers often offer SCF in exchange of payment extension, this may affect the cost of finance paid by suppliers. Table 1 compares traditional invoice finance and SCF.

</table>

As mentioned earlier, the monetary benefit of SCF may be compromised by how long the payment term is extended. The longer the extended duration, the higher the interest rate suppliers need to pay to receive early payment. For example, if the buyer extends the payment term from 30 to 60 days, suppliers will be charged the interest rate for approximately 60 days. If the buyer extends to 90 days, the interest rate is charged for about 90 days. Figure 3 serves as an illustrative example for calculating finance costs.
Suppliers receive £10,000 early payment on day 7, Interest rate is 5%

- Extended payment term: 60 days, suppliers pay interest 60 - 7 = 53 days. Thus interest = \( \frac{5}{100} \times 10,000 \times \frac{53}{365} \)

- Extended payment term: 90 days, suppliers pay interest 90 - 7 = 83 days. Thus interest = \( \frac{5}{100} \times 10,000 \times \frac{83}{365} \)

**Figure 3 – An illustrative example of finance costs**

Nonetheless, SCF have both quantitative and qualitative benefits (see Table 2). Quantitative benefits are only gained from the difference between higher cost of finance of the supplier and the lower cost of finance of the buyer taking into account the duration of extended payment terms. There are also several qualitative benefits such as real time accurate information and transparency through automation of invoice process. It is also suggested that SCF may enhance supply chain relationships through collaboration between buyers and suppliers (Templar et al., 2016). These benefits take both supply chain oriented and finance-oriented into consideration.

**Theoretical framework**

This paper employs transaction cost economics (TCE) as a theoretical lens to examine SCF adoption decisions and SCF relationships for several reasons. First, a supplier’s decision to adopt SCF means they choose to enter into a longer-term relationship where they often need to invest in relationship-specific assets (asset specificity) (Williamson, 1975). There are two main types of asset specificity: human specificity (e.g. training staff for specific purpose) and physical specificity (e.g. invest in IT or equipment) (Williamson, 1975).

In addition, as the primary objective of the buyer in initiating SCF is to extend payment terms, suppliers are prone to opportunistic behaviour. Literature identifies the possibility of lock-in effects which are often caused by high switching costs (Bals, 2018). These effects are comparable to hold-up problems in TCE where suppliers are locked in the relationship and become more vulnerable to opportunism (Holcomb and Hitt, 2007). This opportunistic behaviour may occur over time due to changes in relationships where suppliers may be negotiated to extend payment terms or reduce price in exchange of being in SCF relationships.

**Research objectives, design and methodology**

Given TCE theoretical background, our research objective is to understand why suppliers are not using or hesitate to adopt SCF. We seek to understand how SCF adoption decisions and supply chain relationships are interrelated.

UK SMEs are the focus of this study. It is acknowledged that SMEs are vital to any nation’s economy. UK SMEs account for about 99% of all businesses, 60% of employment, and 50% of revenue (BEIS, 2017). The unit of analysis is an individual firm rather than a triad, to avoid
influences from powerful buyers. We employed qualitative multiple case studies to explore hold-up problems and opportunism among suppliers (Williamson, 1975). We aim to interview 30 - 40 SMEs from diverse industries, combined with insights from financial institutions, buyers, SCF platform providers, and SCF experts to triangulate the findings.

Interviews were conducted with 15 informants from SMEs, financial institutions as well as experts both academics and practitioners. We used a semi-structured interview approach to ensure that certain aspects of SCF were covered while being flexible to explore any theme emerged in the interviews. Based on literature review, the second definition/scope of SCF was also examined (i.e. other finance options used by SMEs or offered by financial institutions).

Within-case and across-case analyses were used to identify similarities and differences between SCF stakeholders’ views of SCF adoptions, in particular SMEs’ views. In this preliminary phase of the research, we analysed primary data from interviews and secondary data drawn from financial institutions’ as well as SCF platform providers’ websites, and documentation provided by the participants.

**Findings**
In total, we have interviewed 15 participants including 8 SMEs (2 micro, 6 small), 3 financial institutions (2 banks, 1 non-bank) and 4 experts (2 scholars, 2 practitioners). We intend to include buyers and SCF platform providers in future interviews.

SMEs’ participants were founders, directors or managing directors from both production and service businesses. All of them have large, powerful customers. While late payments from large customers are common among these SMEs, the reasons could be either the buyers’ intention or their unreasonable bureaucracies. Table 3 gives details of SMEs’ participants.

**Finance options**
Table 4 shows SCF and other finance options used by UK SMEs. It is clear that personal fund and overdraft were the two most popular finance options among these SMEs. Three established SMEs (S2, S3 and S5) found traditional invoice selling –ID handy as they are currently growing their businesses and having several invoices that can be sold to financial institutions for early payment. S6 also agreed that ID is useful. However, ID cannot cover a huge gap between production and delivery due to the nature of his business that needs to invest a lot of cash in production and inventory. This takes weeks before invoices can be issued thus invoice finance or SCF is not a viable option.

Apart from S1 who has no access to ID due to its size, S4, S7 and S8 despite being established SMEs were avoid using traditional invoice finance due to their negative perception of selling invoice. They believed that invoice finance indicates cash flow problems to their
customers although they know that ID is confidential. However, all of them are interested in using ID and SCF for growing their business in the near future.

Established SMEs seemed to have good access to invoice discounting and overdraft with relative low interest rate compared to early stage firms. Despite its expensiveness compared to other finance options, most SMEs have had overdraft “just in case” as they found it was straightforward in terms of access and use (S3, S5, S7 and S8).

**Table 4 – Finance options used by SMEs**

**Awareness and perception**

Among these eight SMEs, three of them had been offered and perceived pressure from the buyers to adopt SCF. S4 managed to decline while S2 and S5 unwillingly participated. SCF offers came with the extension of supplier payment terms. S5 found using SCF is more expensive, compared to ID. As he had already used ID, participating in SCF meant he had to move one big buyer from the portfolio of buyers for ID. This action could have raised the interest rate charged by S5’s bank. Fortunately, he was able to negotiate to maintain the interest rate due to his good credit history. He also found the need to withdraw 100% of an invoice inflexible and expensive. Nonetheless, S2 found SCF a good option because he did not have a better finance option.

Apart from the three SMEs who were offered SCF and one SME who was acknowledged by a financial institution, other SMEs were not aware of SCF. Two experts (1 scholar and 1 practitioner) had not heard about SCF as well. In contrast, all 3 financial institutions had good awareness and knowledge about SCF even though the terms and definitions differed among themselves as well as from our definition and scope.

**Third Party: Financial institutions**

We interviewed three financial institutions: two were banks (F1 and F3) and one was non-bank (F2). All financial institutions adopted the second definition/scope of SCF where SCF is an umbrella term for various finance options as shown in Figure 4. The tripartite SCF is currently provided by F1 and F3 with totally different names and criteria. All the three financial institutions did not use the term “reverse factoring” as well. We can differ our SCF definition from other finance options by looking at the process and relationships of the parties involved. Both F1 and F3 partner with SCF platform providers who provide a system that matches invoices with purchase orders.
Examples of the criteria for a buyer to initiate SCF include turnover at least £100 million, facility at least 5 million, being in Business Grade 1-11 (this is the bank’s own credit rating/scoring system ranked from 1 the best to 21 the worst), and a maximum term 180 days of drawing down (F1). These criteria are totally different from F3 where SCF is available for a business trading for at least three years with a turnover of £2.5 million. In contrast, ID is available to SMEs with a turnover of £250,000 at one financial institution but another non-bank financial institution requires a turnover of £500,000 and above.

Experts’ views
Two experts (E2 and E4) define SCF as any finance involved up and down supply chains which is the second definition/scope and consistent with the three financial institutions. E1 and E3 were not aware about SCF but able to comment about finance in general. Regarding opportunities, SCF allows two companies to have different payment terms but it is only appropriate when circumstances are right. With regard to obstacles, interestingly, E3 acknowledged that UK SMEs are normally stuck with only one bank. They are only a few bigger SMEs who may use more than one financial institution (E3). This is in line with S2 who argued that banks were the main obstacle in SCF adoptions. Similarly, all financial institutions (F1-F3) also mentioned that typically they would require SMEs to use one bank only for the reason of visibility. It is also costly to change banks due to the need to refinance all the facilities (i.e. finance options in use). There are also exit penalties if SMEs wanted to leave early.

Discussion

Why suppliers are reluctant to use SCF
It appears that lack of awareness regarding availability, nature, benefits, and drawback of SCF among SMEs is the primary reason for SMEs not currently using SCF. SMEs who often have limited resources rely upon accountants or financial institutions to educate them about available finance options. Since SCF is rather new, awareness and knowledge about SCF mainly comes from third parties (banks and SCF platform providers) who tend to give most attention to large companies who are initiators, overlooking the target adopter, SME suppliers.

Unlike dynamic discounting where buyers offer early payment in exchange of a discount (buyer-supplier) or most finance options (supplier-bank) which are dyadic relationships, SCF is a triad where all the three parties play important roles. In particular, financial institutions play a key role either as an enabler or inhibitor. In addition, SMEs’ decisions to adopt SCF mean they need to work with both the buyer’s bank and their own bank concurrently. As mentioned earlier, this can affect costs of finance for the existing finance options in use.
Furthermore, most established SMEs already have other finance options such as overdraft or ID. Compared to ID, SCF may not be a much better option in term of flexibility and costs. In contrast, early stage SMEs and very small SMEs (micro) often have limited access to most finance options. Thus, SCF seems to be more appropriate and beneficial to these types of firms than established SMEs. However, they often too small to be included in SCF programme by the buyer.

What’s more, nature of business also indicates whether SCF is right for SMEs. For example, businesses that have a year-round stable level of orders are more suitable for invoice finance both traditional and SCF. However, this is not the case if the company’s products are seasonal in which invoices may not available for selling when SMEs need cash. Construction businesses were also mentioned as inappropriate for invoice finance due to their unique contracts. Since there is a certain period after the work is done before suppliers can actually receive money, SCF might not be an appropriate option.

Transaction Cost Economics
Suppliers who agree to adopt SCF need to register with the buyer’s bank and undergo the due diligence process which involves a lot of paperwork. This is generally referred to as onboarding process which takes time and effort. Although there is no need for installing IT-related equipment at the suppliers’ side, there is still the need for training staff how to use SCF platform to upload invoices and request for early payment. Suppliers typically have limited resources especially staff to invest in this specific relationship.

It can also be costly for UK SMEs to change or use more than one banks. Adopting SCF means SMEs have to use the buyer’s bank at the same time they still have to use their bank for other finance options (e.g. factoring, ID). As a result, SMEs’ banks often increase interest rates and fees for the existing facilities (e.g. factoring, ID) in order to cope with an increase in risks since the large buying firm’s invoices are excluded.

It is evident that all the four SMEs have learnt about SCF from their buyers and a financial institution. They were also to some degree pressured to adopt SCF. Since SMEs can choose whether they want to withdraw early payment, if SCF is more expensive than the existing finance options they have, SMEs may rarely withdraw the money. This can affect the duration need to compensate the setup costs invested in the SCF technology/platform. As the costs may be allocated to interest and fees, suppliers are prone to be charged higher costs to use SCF.

Conclusion
Insights from the interviews corroborate high asset specificity in SCF relationships, particularly human specificity due to the need for training. There are also high setup costs for installing a technological platform, known as SCF platform that may need to be allocated among the three parties and suppliers may be suceptible to opportunistic behaviour over time. Furthermore, the lack of standard terms and procedures, combined with paperwork needed can be challenging for resource-constrained suppliers or even discouraging them from adopting SCF.

Although SCF is often praised as a tripartite-win arrangement where all the three parties: buyer, supplier and financial institution are supposed to benefit from the relationship, our early investigation suggests that suppliers, the target adopter of SCF may not benefit from SCF relationships. This is because SCF is often offered by large buying firms in exchange for payment term extension. The longer the payment terms the higher the cost of finance suppliers need to pay to receive early payment. Moreover, SCF may not enhance buyer-supplier relationships since it seems most SME suppliers are forced to adopt SCF by powerful buyers.

SMEs are reluctant to use SCF because most of them are unaware of the availability and lack an understanding of the benefits and drawbacks of SCF. As the information regarding finance options and eligibility primarily comes from SMEs’ banks, these banks can become an
inhibitor of SCF adoption depending on each bank’s available products and policies. In addition, most banks who offer SCF pay more attention to a large buying firm who initiates SCF rather than suppliers who are target adopters or end customers.

Furthermore, SCF currently targets established SME suppliers who often have other finance options in place. This not only makes SMEs end up using two banks concurrently, but also makes the cost of existing finance options, especially traditional invoice finance (e.g. ID) more expensive. Our findings suggest that SCF appears to be more beneficial to newly started firms who do not have sufficient historical record to use other finance options or a rather small SME who is not eligible for a cheaper option such as ID.

Our initial findings are limited in terms of number of SMEs who were aware of or had used SCF since we intended not to approach SMEs through large buyers to avoid bias. Moreover, financial institutions who are key sources of information regarding costs and criteria of SCF are often unwilling to reveal the information due to confidentiality and competition. Not all financial experts know about SCF as well. This study is so far based on initial empirical data from SME suppliers, financial institutions and experts. As a next step, we will be interviewing more participants in these three groups of stakeholders as well as including large buying firms and SCF platform providers to gain a thorough understanding of SCF relationships and SCF adoption.

Buyer-Supplier Conflict Resolution: Timing, Tactics, Resources, and Relationship Quality

Meriem Bouazzaoui (mb912@bath.ac.uk)

Abstract
Buyers are often faced with supplier-induced conflicts. Literature on conflict resolution has primarily explored aggregate conflict resolution strategies using cross-sectional surveys. However, little is known about specific resolution tactics and their effectiveness over time. Using a multiple case study, we explore a more fine-grained taxonomy of tactics throughout the entire conflict episode. We identify a) a taxonomy of resolution tactics deployed based on tactics’ content and temporal orientation, b) factors that impact conflict resolution dynamics including resolution misalignment, relationship quality, and buyers’ resources availability, and finally c) the effectiveness of resolution tactics over the conflict episode.

Keywords: conflict resolution tactics, relationship quality, resources, and time.

Introduction
Buyer-supplier exchanges always include the potential for conflict (Deutsch, 1994) that, if not properly managed (Griffith et al., 2006), can generate significant dis-benefits for all parties. For example, in 2016, the German automaker Volkswagen (VW) experienced a major conflict with two of its critical suppliers: CarTrim, which makes seats, and ES Automobilguss, which produces gearboxes cast iron parts. VW cancelled orders without providing any justifications, thereby affecting suppliers’ revenues. In return, the suppliers withheld their deliveries resulting in production stoppages across six of VW’s 10 German factories costing VW over £86m in production losses. To resolve the conflict, VW had to pay the suppliers nearly $15m in compensation but not before causing severe long term damage to the relationships (Reuters, August 23, 2016).

Although the above anecdote illustrates the important role of conflict resolution in purchasing and supply management, extant research in this area is scant and incomplete. Indeed, a review of major publications in the interorganisational conflict literature has revealed that the conflict resolution process has not been sufficiently studied, and studies “only scratch at the surface of what is critical to consider when examining the conflict and conflict resolution processes in interorganizational exchanges” (Lumineau et al., 2015, p. 52). Most extant research has adopted a macro perspective on conflict
resolution by analysing general dispositions, e.g. partners seek confrontation or collaboration (Koza & Dant, 2007). Although this approach has made significant contributions to the literature, using a “strategy” conceptualisation does not illustrate specific conflict resolution interventions (e.g. compensation) that parties use to manage conflict (Carton and Tewfik, 2016). Therefore, it could make it difficult to understand the complexities of the conflict resolution process.

Further, although prior research emphasised the dynamic nature of conflict (Frazier, 1999), prior studies have mainly based their research on static levels of conflict, largely ignoring the “twists and turns” in a conflict episode. Nevertheless, we argue that conflict may move in an escalatory direction, and that an examination of conflict intensity is necessary. The resolution of different degrees of conflict represent a core theoretical and managerial concern that should be dealt with adequately to advance conflict research (Ellegaard and Andersen, 2015).

In an effort to fill the above gaps in the buyer-supplier conflict literature, this paper proposes and then, using multiple case studies of buyer-supplier conflict in the Automotive sector, refines a model of the factors that determine the level of intensity of a conflict, and the contingent mechanisms that moderate its dynamics. Specifically, we investigate a series of (supplier-originated) exchange problems that resulted in varying levels of conflict intensity over the entire conflict episode; from emergence to resolution. This helps us unpack the conflict resolution process and analyse process elements that are not accessible through traditional quantitative methods (e.g. illuminate how certain resolution tactics lose/gain effectiveness over time). In so doing, we respond to calls for more dynamic exchange conflict research (Ellegaard and Andersen, 2015, Koza and Dant, 2007).

**Conceptual Background**

Despite the repeated acknowledgement of the importance of effective conflict resolution in buyer-supplier relationships, there has been limited study of the details of conflict resolution (Lumineau et al., 2015). First, conflict is not a binary construct and yet relative intensity has received limited attention (Ellegaard and Andersen, 2015). Second, although the appropriateness and effectiveness of conflict resolution approaches varies as a function of conflict intensity levels (Andrews and Tjosvold, 1983), previous studies considered only static levels of conflict and no assessments have been made of the contingent effectiveness of various mechanisms according to conflict intensities. Finally, although conflict is a dynamic process most research presents exchange conflict resolution as a ‘one-off’ event, meaning there is a need for investigation of concurrent and sequential resolution strategies.

In order to better conceptualise exchange conflict intensity, we propose that – as other exchange conflict researchers have noted - conflict reflect buyers and suppliers differences in expectations or actual performance (Emiliani, 2003). Specifically, conflict will exist as long as there is a gap between the initiating (supply failure event) issue and perceived efficacy of the resolution intervention and, further, the extent of this misalignment determines the level of perceived conflict intensity (O’Neill et al., 2015). Salient or large discrepancies will generate high conflict levels, whereas minor discrepancies will result in low conflict. This means our model is essentially independent of the type and scale of the causal event. A simple concern that is poorly managed can engender higher levels of conflict, just as a major concern that is well handled can minimize conflict.
Conflict Intensity
Conflict intensity is an important dimension of a conflict episode. In the broader organisational behaviour literature, conflict intensity has been characterised by two constructs (Tsai and Bendersky, 2016), oppositional intensity and emotionality. For instance, a conflict may be expressed in variety of ways, from "tongue-in-cheek" comments to verbal abuse or even physical violence (Brown and Day, 1981). Emotionality refers to the degree of negative emotionality exhibited and felt during the conflict including annoyance, irritation, anger, rage, resentment, and dislike (Jehn, 1997). Different exchange conflict intensities are likely to exhibit different dynamics e.g., conflict spirals: (Emiliani, 2003) and therefore require different resolution mechanisms (Barker et al., 1988).

Conflict Resolution
Conflict resolution is defined as “strategies oriented toward the resolution of the tension” (De Dreu et al., 1999, p. 371). Researchers have classified these strategies and hence various models have emerged. These frameworks differ in the terms used to describe the strategies but their classifications are broadly based on two dimensions reflecting people's concerns for their interests and their concerns for the other party. Generally, five conflict resolution strategies were derived: (a) Collaborating is oriented towards achieving maximum satisfaction of both parties’ concerns through high cooperation; (b) accommodating implies offering help and giving in to the desires of the other party; (c) forcing involves imposing one’s will on others; (d) avoiding involves ignoring all concerns and reducing the importance of the issue; and (e) compromising presumes a mutual give and take so as to gain partial fulfilment of one’s desires (Blake and Mouton, 1964). Essentially, the focus of this literature has been on examining conflict resolution strategies at an aggregate level, and not on the complexities and details that need to be addressed when resolving conflict episodes. Therefore, this research provides little guidance on how to apply these strategies in (supply) practice. Specifically, there is a need to move beyond generalized resolution strategies so far proposed in the conflict literature (Ellegaard and Andersen, 2015). There is some relevant research (Champenois et al., 2016) and, albeit to a lesser extent, in a buyer-supplier relationships. For instance, Ellegaard and Andersen (2015) suggested that inter-organisational communication by non-actors, inter-organisational communication by higher ranking executives, and the replacement of the core actor in the buyer-supplier exchange are effective interventions to resolve severely conflicting relationships.

Conflict resolution in Context
Finally, exchange processes between buyers and suppliers do not exist in a vacuum (Leonidou et al., 2002), the context in which issues emerge, conflict develops and resolution mechanisms are (successfully/unsuccessfully) applied plays a role in the severity and dynamics of conflict. Previous research has highlighted the impact of few variables that could potentially impact the choice of partners’ strategies when resolving conflict including for instance communication strategy (Koza and Dant, 2007). However, to the best of the authors’ knowledge, factors and contextual conditions that impact recipient’s reaction (conflict intensity as experienced by buyers) to resolution tactics (provided by the supplier) have not been delineated in the literature.

Methodology
In this paper we use a multiple case study method and look at supplier-induced conflicts. We focused on a single industry – the Moroccan automotive industry – to
control for industry specific contingencies and minimize extraneous variation (Eisenhardt, 1989) that might be derived from industry characteristics. A theoretical sampling providing distinct contrasts along two dimensions of relationship quality pre-conflict episode (low vs. high) and conflict duration (short vs. long) has been used. This sampling frame enabled us to identify cases of different intensities and different dynamics and resulted in four matched dyads (Table 1). These four cases were enough to reach a satisfactory level of theoretical saturation (Pagell and Wu, 2009). Figure 3 summarises the data collection process.

Interview recordings resulted in more than 500 pages of textual material. Once this process was accomplished, the write-ups were then translated into English and imported into the qualitative data analysis tool QSR NVivo 10 for systematic coding and cross-case comparisons.
Cross-Case Findings

Resolution Misalignment - Conflict Intensities

The data revealed that misalignments in conflict resolution impacted changes in conflict intensity. Misalignments manifested either in the resolution tactics provided (a mismatch between the tactic and issue resolution) or the resolution time (a delay in response). Findings indicate that a gap existed between the requirement of issue resolution and the provided response. For instance, it was apparent from case 1 that when buyers expressed their concern over the conflict issue, they were expecting the supplier to deliver the product following their complaint. However, the supplier only promised that the product would be delivered before the production line stoppage date. Hence, while buyers were focused on a tangible delivery of products, suppliers only offered an explanation of the issue and a promise of issue resolution. A manager mentioned “there was a lack of reactivity from the supplier, they did not provide any containment actions (...) and this got on our nerves” (C3B- Quality Manager). Similar to a misalignment in tactics, cases also highlighted that a misalignment manifested in a delay of response. An interviewee echoed how the time taken to resolve the conflict impacted conflict intensity "we had not received the goods on time, it is true that there was an effort from their side, but it was not timely, it was very irritating (...) and so it was a pure confrontation, the subject was escalated" (C4B-Logistics Manager). Thus, across all cases, buyers seem to have come to view misalignment as impacting conflict intensity.

Buyers’ Resources, Relationship Quality, and Conflict Intensities

Across the four cases, we observed the differential impact of the availability of buyers’ resources and relationship quality as contingency factors that impact changes in conflict intensity. Consistent with Größler and Grübner (2006, p. 460), resources are defined as “something a firm possesses or has access to (...) resources can be tangible, for example, specialized production systems, and intangible, for example, level of training of workers”. In cases 1 and 2, when conflict occurred, possessing resources buffered escalation resulting from misalignment because buyers mobilised resources to reduce the discrepancy “at the beginning, everything was fine [with the supplier]. Although the supplier couldn’t replace the material, on our side we used the stock from the cables we used to buy from the former supplier (...) and that’s how we unblocked the situation and carried out production activities” (C2B-Supplier Quality Engineer). However, in cases 3 and 4, possessing resources escalated conflict “unbeknownst to the supplier of course, we had some room for manoeuvre (...) So not only we were having problems because of their inappropriate reaction, but we also had to deploy extra resources (Deep breath), it was frustrating” (C4B-Purchasing Manager). Respondents’ also provided clear descriptions of how the quality of the relationship prior to the conflict episode impacted conflict resolution dynamics. In cases of low relationship quality (case 3 and 4), conflict rapidly escalated “(...) So when the supplier rejected our claim, and our relationship with them was already very strained, there was no room for discussion, and this increased friction and animosity towards them” (C3B-Operations Director North Africa, SeatCo). Conversely, in cases 1 and 2, relationship quality has both suppressed and activated conflict escalation. As the Purchasing Director from AutoElecCo explained “[CableCo] were very helpful previously, they accommodated our orders’ fluctuations, they satisfied our requests, (...) we don’t forget that when they have a problem, and so we decided to solve the issue” (C1B-Country Purchasing Director). On the other hand, the interviews revealed that although when relationship quality was high, conflict escalated and this was explained by reference to resources availability.
One manager emphasized “(...) we could not work on a stressful mode until the issue is resolved. We didn’t want to have issues with our customer (...) So we were putting pressure on them, pushing our requirements regardless of what they were going through” (C1B-Purchasing Manager).

**Conflict Dynamics and Sequence of Tactics**
A mild conflict situation involved discussing the conflict issue as a debate, and was characterized by low entrenchment in the buyers’ position. Supplier offered an apology, an explanation, and a promise to resolve the issue, and these tactics laid down positive expectations, and confirmed buyer’s thoughts about the supplier’s integrity and their ability to alleviate conflict. One manager recalled “the supplier justified why this happened and informed us that they would deliver this quantity with the next scheduled delivery. So we let it go, we knew that the supplier did not have bad intentions...” (C1B-Purchasing Manager). As conflict unfolded, buyers built expectations with regards to future behaviour in the next micro-episode. However, as a misalignment occurred, the dyad moved to moderate levels of conflict “we actually discussed the issue with the supplier, we listened to the supplier, and we shared our concerns. It happened in a very friendly atmosphere. However, when it happened that the supplier did not respect what he has communicated to us, and the risk was increasing, tension and aggressiveness increased, we had to be firm, we had to make a point” (C1B-Purchasing Manager). At this point, suppliers attempted to cover for all the potential losses generated by the conflict situation to prevent further escalation. This suggests that explaining the conflict issue or making promises lost credibility “the supplier insisted and promised that they would solve the issue shortly (...) but this was not enough (...) So most importantly, in the meantime, they proposed that we could continue supplying from the previous supplier and they would continue to pay all the charges generated from this quality issue until the issue is completely resolved” (C2B-Purchasing Director). Finally, our data also showed that high levels of conflict intensity represented cases where the misalignment was persistent that it impinged on the buyers’ ability to continue the relationship. Therefore, tactics only targeting the resolution of the current issue were no longer sufficient. Suppliers deployed further actions that showed their commitment to the relationship “so we had to invest in new equipment (...) it was a duplication of the production chains” (C1S-North Africa Sales Manager).

**Discussion and Implications for Theory**
In examining the four cases, we have presented evidence for the dynamics of conflict resolution. Building on these findings, we offer a model in Figure 2 with the concepts of resolution misalignment, relationship quality, and buyers’ resources at its centre.

**Resolution Tactics**
Tactics Bundles: The findings from the field interviews suggest that resolution tactics can be classified along two dimensions - content and temporal orientation. With regards to content, these tactics can be classified by whether they are psychological or tangible fixes. Psychological tactic conveys politeness, concern, effort, and empathy to buyers (Hart et al., 1990). In contrast to psychological tactics, tangible fixes refer to actions that the supplier deploy to resolve the task issue at the essence of the conflict (Miller et al., 2000). The data suggest furthermore that these two categories of actions can have a different temporal orientation. We distinguish “Reactive curative” tactics, wherein the focus is present-oriented, i.e. resolution of the immediate issue, and “prospective preventive” tactics, wherein the focus is oriented towards the prevention of conflict...
reoccurrence in the future. Each of these tactic bundles could be employed separately or in combination depending on conflict intensity and contextual conditions.

**Resolution Misalignment and Conflict Intensity**

Our model shows that resolution misalignment is central to conflict escalation. Tactic misalignment generates feelings of frustration and dissatisfaction (Chen et al., 2018) thereby leading to increased conflict intensity. Similarly, the speed of suppliers’ resolution efforts is equally critical as it tracks how the dyad is moving towards conflict resolution. A tardy response triggers negative emotionality, whereas a prompt resolution prevents further frustration and conflict escalation. Essentially, when there is a misalignment in conflict issue resolution, buyers fail to obtain the expected outcomes (Smith et al., 1999), lose resource, and therefore experience increased conflict.

**The Interaction Effect of Buyers’ Resources Availability and Relationship Quality**

Our model in figure 2 positions buyers’ resources in combination with relationship quality, wherein both interact in impacting conflict resolution dynamics. Four combinations have been derived:

- **Complete buffer:** A “complete buffer” situation is characterized by high resources availability and high relationship quality. Possessing resources enabled buyers to absorb the lack of supplier’s responsiveness to conflict (misalignment), and this was enabled by the relationship quality, which provided a psychological safety atmosphere where risk-taking was safe (Edmondson, 2002). Specifically, when relationship quality is high, buyers perceive misalignment as less threatening, and deploy more resources to reduce the discrepancy. Buyers who have a strong existing relationship with their suppliers as well as high resources availability would express low valence emotions; they would have a behaviour that supports the business relationship and would be more tolerant of the conflict situation.

- **Rapid escalation:** Low resources lead to poorer conflict tolerance even though relationship quality is high. In the case of low resources availability, conflict escalates wherein buyers display a defensive and hostile stance to avoid further losses (Lam et al., 2017). Essentially, even though buyers and suppliers enjoy a strong relationship, in instances of low resources, a misalignment in conflict resolution is considered as a suppliers’ failure to fulfil their obligations in the relationship, and thus generates negative feelings and doubt about suppliers’ reliability (Grégoire et al., 2009). Accordingly, when resources are low, the quality of the relationship may backfire and intensify conflict in the exchange dyad, rather than buffer against conflict escalation.
**Conflict persistence**: When the relationship is weak, the possession of resources does not dampen the effects of resolution discrepancy, as the state of the relationship does not motivate buyers to mobilise resources and adjust to the situation (Ellegaard et al., 2003). In this case, buyers are obliged to resolve the issue unilaterally, and this further heightens conflict. Consequently, although buyers’ activities secure fulfilment of their performance goals, it further contributes to the escalation of conflict with suppliers (Reimann et al., 2017) because the unilateral deployment of resources increased buyers’ perception of resource loss. Additionally, the lack of responsiveness from the supplier further confirms buyers’ beliefs about the exchange relationship, i.e. suppliers are misguided and are acting opportunistically.

**Complete activation**: A complete activation situation is characterized by low relationship quality, and low resources availability. Therefore, a resolution discrepancy is chaotic as the contextual conditions are not sufficient for absorbing any misalignments. Any misalignment is perceived with suspicion because relational ties are not sufficiently strong, and buyers are attempting to avoid further resources losses. Under such conditions, doubts linger close to the surface, and this could be costly and damaging to the buyer-supplier relationship (Emiliani, 2003). As such, conflict escalates steeply as buyers have an aggressive and a hostile behaviour.

**Conflict Intensities and Resolution Tactics**
In the case of a “complete buffer” situation, conflict is mild and psychological tactics are sufficient to resolve conflict. In such situations, offering a psychological response is completely effective, and this hold even though no tangible fixes are offered. This finding is consistent with the fair process effect (Collie et al., 2000), and also with Tomlinson et al. (2004) evidence of the strength, for instance of an apology, in buyer-supplier exchanges. In “rapid escalation”, the use of psychological actions alone loses effectiveness because more resources have been lost or were being threatened. A number of examples in the cases showed that the endurance time of a psychological tactic is short and tappers off quickly because it is not sufficient to compensate for the continuous resources loss. Therefore, tangible fixes are deployed to complement the decay in the effect of psychological tactics, and are therefore more reliable when buyers make their judgments about the conflicting situation (Leventhal, 1980). In cases of “conflict persistence” exchanges are characterized by profit-seeking motives rather than social obligations (Robinson et al., 1994), and hence the deployment of well-targeted tangible fixes is effective in resolving the conflict. Finally, in cases of “complete activation”, the deployment of prospective tactics that act as “prophylactic” measures against future conflict occurrence is necessary.

**Conclusion**
In this research, we provide an empirically grounded taxonomy of conflict resolution tactics beyond the conventional categorisation of aggregate resolution strategies (Blake and Mouton, 1964). Based on two characteristics, content and temporal orientation, we proposed four categories representing the range of resolution tactics suppliers have at their disposal including reactive psychological, reactive tangible fixes, prospective psychological, and prospective tangible fixes. As a second contribution, we introduced “resources availability” as a factor unrecognized in conflict research. Our findings add to the conflict literature that organisational constraints (Janowicz - Panjaitan and Krishnan, 2009), in the form of firm’s tangible and intangible resources, influence buyers’ adaptability to and tolerance of conflict. We also contributed to the literature by highlighting the strength of a multi-level view (Klassen and Menor, 2007) as the
interaction between buyers’ resources and relationship quality explained more fully the impact on conflict intensity than each separately. Finally, our research sheds light on the effectiveness of conflict resolution tactics over time, paving the way for scholars to understand the pitfalls of certain tactics and the untapped potential of others as the conflict episode evolves.

**Limitations and Future Research Directions**

The findings of the current research should be viewed in light of the study’s limitations, which provide avenues for further research investigations. First, we limited our study to supplier-induced conflicts. As such, we did not examine instances of conflicts emanating from the buyer (Johnson and Sohi, 2016). Future research should adopt such approach to understand whether different or similar dynamics occur. Moreover, another limitation of our study is related to our data collection approach. We have chosen to collect data on a limited number of cases and this may limit the generalizability of our findings. However, focusing on four cases gave us the opportunity to gain deep understanding of the conflict from both sides of the dyad.

Abstract

The aim of this paper is to investigate the role of supply chain collaboration between buyers and suppliers in the reverse flow of a system of circular supply chains. The empirical context is Swedish unalloyed steel recycling, i.e. recycling of steel with a low proportion of additional components. The paper applies a framework on mechanisms of coordination and supply chain flows to discuss the underlying rationale for how the Swedish steel recycling industry organizes coordination. At the activity level, it is shown how the inherent uncertainty of reverse flows is handled through voluntary cross-industrial cooperation and standardization.

Keywords: Supply chain collaboration, circular supply chain, steel recycling

Introduction

In recent years, a number of studies in different research fields have identified underutilized value in the materials of end-of-life products (see e.g. waste electric and electronic equipment (Cucchiella et al., 2015), spent lithium-ion batteries (Ku et al., 2016), and textile waste (Leal Filho et al., 2019). A recurring problem with utilizing the material value in these end-of-life products is to get the right material to the right place at the right volume in an efficient way, as exemplified by plastic waste (Geyer et al., 2017).

The end-of-life product domain is a complex issue involving a plethora of actors who collaborate outside typical supply chain boundaries (De Angelis et al., 2018). As discussed by Batista et al. (2018) and De Angelis et al. (2018) this kind of flow can be termed as circular supply chains, that is, a circular economy approach applied to supply chain operations. Conversely, a circular supply chain is similar to a closed-loop supply chain.
Chain (Guide and van Wassenhove, 2009) with focus on coordination of forward and reverse supply chain flows. On the other hand, the circular supply chain takes a more holistic approach to value creation with focus on the triple bottom line rather than the financial bottom line. The integration of the supply chain is commonly recognized as positively and directly linked to supply chain performance (Prajogo and Olhager, 2012). Although this link is questioned by Fabbe-Costes and Jahre (2007) at a general level, it is confirmed by Gimenez et al. (2012) for buyer-supplier relationships and the forward flow of the supply chain when characterized by high supply complexity.

Today, the comprehensive approach to sustainability expands the scope of circular supply chain operations with added supply complexity of circular supply chains (Batista et al., 2018). A particular characteristic of this is that supply complexity and uncertainty in the reverse flow is inherently higher than in the forward flow. The supply complexity is due partly to the additional activities in reverse flows compared to forward flows, e.g. acquisition, reverse logistics, sorting, and testing (Guide et al., 2003), and partly related to various differences between reverse and forward flows, e.g. difficulties in forecasting, transport from several different locations to one, and variations in quality of supply (Tibben-Lembke & Rogers, 2002).

While there is agreement in the literature on the importance of supply chain collaboration in circular supply chains amongst many actors across several industries, there is limited empirical evidence on the nature of these collaborations. So far research on coordination mechanisms in reverse flows has been focusing on contracts (Guo et al., 2017) even though mathematical models of contract arrangements do not fully capture the evident complexities and uncertainties. However, the interest in social capital theory in operations and supply chain management literature has enriched our understanding (e.g. Min et al. (2008), and Matthews and Marzec (2012)). Especially of micro-processes as drivers for relationship building to uncover the informal dimension of buyer-supplier relationships. Regardless, it may still be argued that there are limitations to the literature and that the existence of complexities and uncertainties in regards to the organization of coordination activities has not been fully grasped.

Against this background, the aim of this paper is to analyze the role of supply chain collaboration between buyers and suppliers in the reverse flow of a system of circular supply chains. Building on the definition by Tsou (2013) on supply chain collaboration and applying a conceptual framework on the mechanisms of coordination (Martinez and Jarillo, 1990), and supply chain flows (Mentzer et al., 2001), we empirically investigate coordination at the activity level between buyers and suppliers involved in Swedish unalloyed steel recycling. This industry is global and an example of an integrated system of supply chains working circular for a long time, which has also succeeded in reaching high supply chain performance. The use rate of recycled steel is close to 90% (Material Economics, 2018) because of the ability to satisfy special requirements applying to high quality steel production. Thus, this industry provides a good illustration of supply complexity and uncertainty of the reverse flow in circular supply chains.

**Research design and framework**

This study is phenomenon-driven (Eisenhardt & Graebner, 2007) since the research question has a broad scope and is motivated by a lack of previous empirical studies of the phenomenon of circular supply chains applying supply chain collaboration. We use an explorative qualitative case study method to capture the complexity of the reverse flow for the context of Swedish unalloyed steel recycling. Thus, we strive to develop theory on supply chain collaboration through studies of coordination at the activity-level.
between buyers and suppliers in the reverse flow of circular supply chains. The case study design is holistic, in accordance with Yin (2009), examining the global nature of organization within the context of Swedish unalloyed steel recycling. In addition, the procurement intermediary is of particular focus in this study, since it is the central node for coordination in Swedish unalloyed steel recycling. Thus, in this study we start with the procurement intermediary and continue with studies of the other parts of the system. Figure 1 shows a simplified system schematic and the delimitation of this study to exclude small scrap dealers. The organizations involved in the studied system are five Swedish steel producers, a procurement intermediary, and eight scrap dealers.

![Figure 1 – Simplified system schematic of flows in Swedish unalloyed steel recycling and the scope of this study. Note: SSDs – small scrap dealers; LSDs – large scrap dealers; PI – procurement intermediary; and SPs - steel producers.](image)

**Data collection**
The primary data source is semi-structured interviews with company representatives from the Swedish steel industry, scrap dealers and the procurement intermediary. We chose the interviewees with knowledge of the organization of the studied activities with support of previous interviewees. In addition, we use secondary data such as company and industry reports, company webpages, and observations (see Table 1). Furthermore, experts with long experience from working in or with the system provide data for the study and check the study’s rigor.

**Framework**
The Swedish steel industry is global, competitive and has a long history. In the Swedish recycling sector for unalloyed steel there are five steel producers, one procurement
intermediary, and eight scrap dealers. Consequently, there exist supply chain flows and supply chain coordination mechanisms. Since the section of the circular supply chains in this study bears more resemblance with a network than a chain, we conceptually build on the framework by Martinez and Jarillo (1990). Especially, the framework is more comprehensive with regards to informal mechanisms than e.g., Arshinder et al. (2008) who specifically identifies coordination mechanisms within the supply chain, or the strategic elements of supply chain collaboration (Barrat, 2004). Indeed, Martinez and Jarillo (1990) divide the coordination mechanisms into structural and informal coordination mechanisms. The structural mechanisms include departmentalization, centralization or decentralization, formalization and standardization, planning, and output and behavioral control (see Table 2). Informal mechanisms consist of lateral relations, informal communication, and socialization. The second dimension of the framework is supply chain flows (Mentzer et al., 2001). Information includes demand and forecasts, which are separate in the original work of Mentzer et al. (2001). Further, products and services merge into one, since they follow the same pattern. The final framework thus includes the three main flows information, products and services, and financial resources.

Findings
In the organization of Swedish unalloyed steel recycling we identify a central node for coordination in the system, the procurement intermediary. The first part introduces this organization. In the second part, we analyze the findings from our empirical study at the activity-level with our framework.

The procurement intermediary
The procurement intermediary is a small organization with a long history of being a vital node in the recycling of Swedish unalloyed steel that was established over a century ago. The procurement intermediary is owned by some of the largest steel producers in Sweden and its goal is to provide the sector with unalloyed steel scrap. Further, the scrap procurement involves optimization of logistics to minimize transport expenses for the owners. Since actors in the Swedish steel industry compete on different niche markets, with high costs associated to a switch between niches, there is limited or no competition between the owners of the procurement intermediary. The limited competition and the small size of the procurement intermediary exempts the organization from EU-regulation on cartels, while increasing the national competitiveness of Sweden and in particular the competitiveness of the entire Swedish steel industry. From its establishment in 1917 and until Sweden became a member of the European Union in 1994, sourcing of unalloyed steel scrap was national. When Sweden joined the European Union export of unalloyed steel scrap became accepted, thus enabling the current practice of international sourcing of unalloyed steel scrap.

The procurement intermediary sets the price for unalloyed steel scrap on the last day of each month for the following month. However, prior to the price decision, steel producers capture the market trends from scrap dealers, use international contacts for information, and read trade publications to align with the international market price for unalloyed steel scrap. It is important for the steel producers that the assigned price is acceptable also for scrap dealers, since they will not sell nationally otherwise and the price then will need to be adjusted. However, some unusual circumstances still occur that the steel producers and scrap dealers agree require price revisions. An example is sudden market disruptions causing the international price to increase or decrease by 8 percent or more from the procurement intermediary’s assigned price calls for a revised price mid-month. The Swedish monthly unalloyed steel scrap price is unusual in Europe where a combination of a monthly average and a specific price for a specific deal is most common. The ultimate goal of this is for the procurement intermediary’s owners to procure national unalloyed steel scrap at a lower price than international unalloyed steel scrap. In this, they succeed through coordination of logistics among steel producers.

Analysis
We discuss the findings from our case study with our conceptual framework. The analysis follows the structure of the framework. In other words, the ‘structural and formal mechanisms’ comes first and ‘informal mechanisms’ thereafter.

Structural and formal mechanisms
The five structural and formal mechanisms of coordination are ‘departmentalization’, ‘centralization or decentralization’, ‘formalization and standardization’, ‘planning’, and ‘output and behavioral control’. We structure the analysis accordingly and include the three supply chain flows ‘information’, ‘products and services’, and ‘financial resources’, for each coordination mechanism.
Departmentalization
The organizations involved in the studied system are five Swedish steel producers, a procurement intermediary, and eight scrap dealers. These actors handle unalloyed steel scrap sourcing activities both among themselves and externally. For information flows in the system, a procurer at the procurement intermediary is central to the everyday contact with both steel producers and scrap dealers. The procurer collects information on the desired upcoming monthly demand for unalloyed steel scrap from steel producers in the middle of each month. Thereafter, the procurer asks the scrap dealers how much unalloyed steel scrap is available in the upcoming month. The procurer with knowledge of both aggregate demand for and supply of unalloyed steel scrap then prepares a recommendation for how the unalloyed steel scrap should be divided among the steel producers in the upcoming month. Further, the procurer completes the recommendation with planning of logistics to minimize transport costs before presenting it for the procurement committee for final decision around the 22nd each month (see ‘centralization or decentralization’ below). After a final decision on unalloyed steel scrap allocation among steel producers is taken, the procurer informs a third party logistician on what unalloyed steel scrap goes from where to where. The third party logistician is thus responsible for material flows in the system. Financial resources flow in the system directly between steel producers and scrap dealers. However, the procurement intermediary has an online portal for all bills of lading and thus support the scrap dealers with invoice data on a daily basis.

Centralization or decentralization
The central decision-making entity is the procurement committee. The committee consists of three representatives from the steel producer buying most unalloyed steel scrap, two representatives from the steel producer buying second most unalloyed steel scrap, and one representative each from the other three steel producers buying unalloyed steel scrap. Based on the procurement intermediary recommendation on allocation of unalloyed steel scrap among the steel producers, negotiations take place in a monthly meeting. Even though the unalloyed steel scrap demand is rather static, the supply of unalloyed steel scrap never perfectly matches the demand. Eventually the procurement committee decides whether unalloyed steel scrap needs to be imported by the procurement intermediary or not. However, this is both more timely and costly than national unalloyed steel scrap procurement due to longer transportation and a weaker bargaining position towards international scrap dealers. Further, since the unalloyed steel scrap demand remains the same, the transport flows are also predefined with preferred routes. Even so these transport flows are subject to disruptions by e.g. weather, which requires the procurement committee to decide if an increase in logistics cost is preferable to an increase in time for delivery. In essence, the central decision-making lies with the procurement committee where mutual decisions are taken. However, the procurement intermediary’s board of directors set the goals for the procurement intermediary, which the procurement committee work to fulfil.

Formalization and standardization
Documentation is essential to unalloyed steel scrap procurement in Sweden. ‘The Swedish Scrap Book 2012’ specifies unalloyed steel scrap grades and delivery conditions for the Swedish market. Published first in 1951, and updated regularly and jointly by the Swedish steel producers and scrap dealers together with the procurement intermediary, it currently contains 27 classification of different types of unalloyed steel
scrap, each of a volume which is considered satisfactory enough to be included. The procurement intermediary publishes ‘The Swedish Scrap Book’, which involves publication of revisions on their website. This is of importance since this is a kind of standard classification for sorting of unalloyed steel scrap in Sweden. Accordingly, the use of the document is widespread. Firstly, for financial resource flows in the system the document is the foundation. The monthly price of unalloyed steel scrap is assigned for each class separately. As previously mentioned, these prices apply for actors in the studied system. However, national actors outside the studied system use the same unalloyed steel scrap classifications and monthly prices for each class. Consequently, ‘The Swedish Scrap Book’ is the price setter for Swedish unalloyed steel recycling both inside and outside of the studied system. Secondly, for material flows in the system the document is central in unalloyed steel scrap operations both for scrap dealers and for steel producers. ‘The Swedish Scrap Book’ states what steel producers permit and what they cannot allow for each class of unalloyed steel scrap and thus, everyone working in the scrapyard has a copy. Likewise, workers in the steel producers’ scrapyards control the incoming material to ensure its quality. If the quality is poor, the document also specifies repercussions for the scrap dealers. With this in mind, the procurement intermediary educates scrap dealers in unalloyed steel scrap classification for different mixed metal scrap.

Planning
The previously mentioned purchasing committee (see ‘centralization or decentralization above) plan allocation of unalloyed steel scrap for the upcoming month and if import of unalloyed steel scrap is necessary. Based on the procurement committee’s decisions, the procurer at the procurement intermediary (see ‘departmentalization above) finalizes logistics planning. Prior to allocation, each steel producer decides their need for unalloyed steel scrap. E.g., for one steel producer the logistics department is responsible for demand forecasting since it possesses knowledge of the current unalloyed steel scrap stock and planned production. The decision is then communicated to the purchasing manager who represents the organization in the procurement committee.

Output and behavioral control
Swedish scrap dealers have a historical legacy of scams and fraud, which has earned them the title of ‘dirty businesses’. In light of this, the consolidation of scrap dealers into large entities and thus creating a serious industry aligns well with increased transparency throughout the industry. Today the scrap dealers perform quality controls before transport of unalloyed steel scrap to avoid issues downstream and allow site audits from the procurement intermediary several times per year. ‘The Swedish Scrap Book’ (see ‘formalization and standardization above) is the foundation for the quality audit at the scrapyard of the steel producer. Operators check the alloy grade, contamination, and radiation for the different classes of unalloyed steel scrap. Further, the steel producers perform rigorous quality controls in several steps of the steel production process.

Informal mechanisms
The three other informal mechanisms of coordination are ‘lateral relations’, informal communication’, and ‘socialization’. We structure the analysis accordingly and include the three supply chain flows, ‘information’, ‘products and services’, and ‘financial resources’, for each coordination mechanism.
Lateral relations
The procurement committee (see ‘centralization or decentralization’ above) gathers primarily purchasing managers from the Swedish steel producers in a monthly meeting at the head office of the procurement agent. The meeting enables direct contact among managers who all represent their organization’s demand for unalloyed steel scrap, without any direct competition between the organizations in their final markets but with direct competition for the unalloyed steel scrap. Further, the procurement committee consists of sub-groups for supplier evaluation, for supplier site audits, and for unalloyed steel scrap quality through which these purchasing managers also meet. While the procurement intermediary and steel producer representatives meet on a monthly basis through the procurement committee, there is no such recurring meeting also including the scrap dealers. However, a temporary task force that includes the scrap dealers is the project team for development of ‘The Swedish Scrap Book’ (see ‘formalization and standardization’ above). In addition, the radiac collaboration includes both the Swedish steel industry and scrap dealers under the procurement intermediary’s leadership.

Informal communication
The procurement intermediary collaborates with the recycling industry and the steel industry in general. In addition, the procurement intermediary takes part in research activities for the Swedish steel producers’ association. Further, the current CEO of the procurement intermediary was previously employed by the steel producer that purchases most unalloyed steel scrap of all steel producers in Sweden. This has provided the CEO with a large number of informal and personal contacts within the main buyer of unalloyed steel scrap in Sweden. In addition, the procurement intermediary is located in the same building as both the steel producer’s head office and the Swedish steel producers’ association.

Socialization
The CEO of the procurement intermediary brings experiences from his previous employer (see ‘informal communication’ above). With the significant influence of the steel producer on the procurement intermediary in mind, we see this as training for the position of CEO for the procurement intermediary.

Discussion and conclusions
This paper has empirically shown how coordination is organized in the Swedish unalloyed steel recycling. The analysis has been done at the activity-level with a conceptual framework on the mechanisms of coordination (Martinez and Jarillo, 1990), and on supply chain flows (Mentzer et al., 2001). However, the underlying rationale for how the coordination is organized has not yet been answered and is thus in this part the main point of discussion.

The system of circular supply chains in this study involves five steel producers, one procurement intermediary, and eight scrap dealers. A primary reason for the organization of Swedish unalloyed steel recycling with a procurement intermediary as a central node for coordination is efficiency. Firstly, flows of information and financial resources are either steel producer to/from procurement intermediary or scrap dealer to/from procurement intermediary. Thus, the number of flows are lower than in a situation where each actor interacts with others individually. In Swedish unalloyed steel recycling, interaction between one steel producer and one scrap dealer is not sufficient due to limitations in available unalloyed steel scrap. Secondly, a monthly meeting...
among steel producers is enough to decide on unalloyed steel scrap allocation for the upcoming month. Since the procurement intermediary acts upon what is decided in this meeting, the steel producers can dedicate little resources to procurement of unalloyed steel scrap. For instance the procurement intermediary arranges logistics for material transport from scrap dealers to the steel producers. Thirdly, the recurring monthly procedure of pricing and allocation of unalloyed steel scrap is efficient since it is well established. This brings stability to the system that the actors also work jointly to preserve. All in all, these three efficiency improvements align with Williamson’s transaction cost approach (1981).

A different reason for why Swedish unalloyed steel recycling is close to circular is the continuous support from formalization and standardization. The five steel producers and eight scrap dealers join in voluntary cooperation for standardization with ‘The Swedish Scrap Book’ to handle the issue of economies of scale in unalloyed steel recycling, precisely as De Angelis et al. (2018, p. 433) suggests. The effects of an agreed standard on the system of circular supply chains exceed the system boundaries, e.g. classification and price used by other actors. Within the system boundaries, the standard creates formalization, e.g. use of ‘The Swedish Scrap Book’ in operations. In addition, the common standard enables lateral cross-industrial relations through recurring revision of the standard.

In spite of the close connections cross-industry and among the Swedish steel producers through the procurement intermediary, the system of circular supply chains acts according to EU-regulation on cartel formation. There are three main reasons for why this specific supply chain collaboration between buyers and suppliers in the reverse flow of a system of circular supply chains is legal. First, the limited competition among the Swedish steel producers in their final markets. Second, discussions in the procurement committee only relate to allocation and not to price. Third, the small size of the procurement intermediary.

To our knowledge, this study is one of the first to introduce the phenomenon of an existing system of circular supply chains applying supply chain collaboration. By studying how coordination is organized between buyers and suppliers involved in the reverse flow of the circular supply chain we systematically uncover the formal and informal mechanisms of coordination underlying supply chain collaboration.

Abstract

This study investigates the supply chain sustainability from a network perspective. To do so, a systematic literature review is conducted to find the relevant academic articles. Drawing on the evidence from the selected conceptual and empirical articles, the study distinguishes two prevailing network properties in driving sustainability in supply chains. Following the analysis, the study presents a conceptual model in form of a set of propositions linking various network properties to the sustainability performance of firms and networks. This study is one of the first attempt towards synthesizing dominant scholarly discourses and, thereby provides an organising lens for future scholarship in this area.

Keywords: Network perspective, Supply chain sustainability, Systematic literature review

Introduction

Supply chain sustainability is the management of environment, social and economic impacts throughout the life cycles of products and services. Specifically, it involves the "management of material, information and capital flow as well as cooperation among companies along the supply chain taking goals from the three dimensions of environmental, social and economic into account” (Seuring and Müller, 2008, p. 1700). Given the ever-increasing number of actors involved in the design, production and delivery of products and services, firms more and more engage and invest in developing and maintaining relationships with external upstream and downstream actors to achieve sustainability goals (Chen et al., 2017). The role of supply chain collaboration in general (Vachon and Klassen, 2008) and the specific aspects of supply chain relationships (Cheng et al., 2008) in driving supply chain sustainability has been extensively studied in the literature. While the focus has been largely on the dyadic perspective giving little attention to the broader network of supply chain relationships in which firms are
embedded, in recent years, a growing number of articles has begun to highlight the importance of adopting a network lens in supply chain management in general (e.g., Borgatti and Li, 2009) and in explaining and investigating supply chain sustainability in particular (Tate et al., 2013). For instance, Hartmann and Moeller (2014) suggest that although a focal firm has little control over its suppliers’ unsustainable behaviour when the suppliers are beyond the first tier, these indirect relationships can negatively affect the sustainability performance of the focal firm. Because external stakeholders (i.e., consumers, non-business actors) often hold a focal firm to account for the sustainability impact of its internal operations and operations of its. For instance, consumers still attribute responsibility to the focal firm for the non-compliant products (Hartmann and Moeller, 2014); NGOs still put more scrutiny on the focal firm regarding ethical issues (Saunders et al., 2017); government still requires the focal firm to disclose relevant information concerning the sustainability misconduct (Airike et al., 2016).

Thus, it is stated that the achievement of sustainability requires the engagement of actors from multiple tiers where often conflicting sustainability ambitions, objectives, and capabilities prevail (Villena and Gioia, 2018). Comparing to tier-one suppliers, lower-tier suppliers may exhibit more passivity in addressing sustainability issues because not all of them feel connected to the sustainability standard (Prajogo et al., 2014) and they perceive a very low risk of being penalized for not doing so. Furthermore, even though Global 250 companies have established a supply chain code of conduct towards the sustainability, half of these do not disclose the detailed information of the process and mechanisms by which they activate and monitor these sustainability standards across the supply chain. These may inhibit the organization acquiring information, resources and knowledge by combining direct or indirect network interactions and implementing supply chain sustainability effectively (Hung et al., 2014).

Focusing on the patterns of connectivity in supply chain networks, recent research also suggest that firms are more likely to adopt environmental standards or comply with the ethical codes of conduct in the process of sourcing and production when they are embedded in highly dense supply networks (i.e., they receive more monitoring from multiple actors in the supply chain) (e.g., Beckman et al., 2009; Vurro et al., 2009). Therefore, the dyadic level does not capture the essence of a network and the adoption of network lens provides an opportunity to deeply address the supply chain sustainability management.

Whilst the notion of network is a common underpinning theme, connecting these findings, the scholarly literature lacks a synthesis of major findings and a reflection of the current development of this area. Specifically, a more systematic, theoretical articulation of how different properties of networks connecting firms in supply chains reinforce the sustainability performance of embedded firms and network is still absent. Yet many articles have begun to concentrate on issues of non-economic dimension, still very few articles have systematically addressed the environmental and social dimensions from the network lens. Therefore, it is crucial to undertake in-depth analysis in terms of this research area to date. Thus, the purpose of this study is to systematically review and assess the current status of research on supply chain sustainability from a network perspective and provides an organising lens for future scholarship in this area.

To address the above issues, this study aims to conduct a systematic literature review (SLR) approach and selects 54 articles from 17 peer-reviewed international journals. Further to that, this study also develops a novel conceptual framework regarding supply chain sustainability in relation to different network properties (i.e. relational properties, structural properties). This study seeks to address the following review questions:

RQ1. What network properties are examined in relation to supply chain sustainability?
RQ2. How do the network properties (i.e., relational properties, structural properties) of supply networks affect sustainability performance at focal firm, dyadic and network levels?

This study contributes to the existing literature in several ways. First, our study extends the understanding of network perspective by highlighting and explaining the inconsistencies in the literatures. This study is the first attempt towards synthesizing dominant scholarly discourses on supply chain sustainability from a network perspective and provides an evaluation of the scientific status of the field. By synthesising the current conceptual and empirical literatures, this study provides an original and better understanding of the phenomenon.

Methodology
In order to address the research questions, this study adopts an SLR approach in terms of a comprehensive synthesis of academic literatures (Tranfield et al., 2003). Unlike the traditional review approach, this approach allows researchers to explore the knowledge base systematically, collect the relevant information and represent them properly. As described by Tranfield et al. (2003), the SLR approach includes four below steps: (1) searching (2) screening (3) extraction and (4) synthesis.

Searching
Following the systematic process, this study searches from peer-reviewed articles in relevant research area. The initial scoping of the relevant articles contains identifying the relevant keywords and constructing the search strings (shown in Table 1). The search string included is to answer the research questions and obtain the relevant information in terms of three key subjects. Three electronic databases (i.e., Scopus, EBSCO, and ABI/INFORM) are selected to collect the articles regarding titles and abstracts included at least one of the search terms from all three themes.

Screening
This process screens the articles’ titles and abstracts informed by the inclusion and exclusion criteria. In accordance with that, these selected articles were assessed against the inclusion and exclusion criteria to test their relevance in terms of research questions. After screening the titles and abstracts of these articles, 1605 articles are rejected because
they do not focus on the required area and most of them are discussed about inter-firm or inter-organisational performance at dyadic relationships. After that, the remaining 406 articles are considered to be valid for full-text screening. Following that, a further 352 articles are rejected because they did not clearly identify the network perspective in supply chain sustainability. In the end, 50 articles are selected and 4 additional articles are added from cross-referencing to the review list for further in-depth analysis.

Data extraction and synthesis
It is identified that dataset from the selected articles was heterogeneous and from multiple contexts, with empirical, e.g., majority of them are qualitative and only a few are quantitative, and theoretical articles included. The content of selected 54 articles are recorded and summarized in Excel spreadsheets for descriptive analysis and findings. Based on the findings and discussions, the propositions and a novel conceptual framework is then developed. Additionally, the synthesis of different information are cross-validated by the authors before it reached an agreement.

Descriptive analysis
This study provides brief description of the selected articles and assess the descriptive findings by the different nature of information (i.e., journal and rankings distribution, underpinning theories, sustainability dimensions, and unit of analysis).

Journal and rankings
In line with the SLR results, the reviewed articles are situated widely across the different journals in different rankings. It is identified that majority of them come from journals rank 3 (e.g. 30 out of 54 articles), while only 6 out of 54 articles rank 4 and 4 articles rank 4*. To be more specific, Journal of Cleaner Production have the highest numbers of articles, followed by Journal of Business Ethics, International Journal of Operations and Production Management, Supply Chain Management: An International Journal and Journal of Supply Chain Management. Additionally, these results imply a stable growth in the publication regarding this area is growing, with 41 articles published in recent 5 years from 2014 and onwards.

Underpinning Theories
Underpinning theories offer a theoretical understanding of how the questions in a scholarly study are examined. It is identified that network theory was the most frequently cited theory, which provides a broader lens to understand the role of network actors in achieving sustainability in supply network beyond the dyadic lens. In light of the growing concerns of sustainability issues, stakeholder priorities and pressures are increasingly influential to the organisations’ sustainable practices. Stakeholder theory is also frequently cited followed by the network theory.

Supply chain sustainability performance: Definitions and conceptualizations
Organisational sustainability performance is usually assessed from three dimensions, i.e. economic, social, and environment. However, this study aims to focus on social and environmental dimensions in supply networks. In reviewing these selected articles, it is identified that the majority of them examine the sustainability performance in environmental dimensions. Furthermore, although social dimension is still in lack, the research interests have gradually expanded to social dimension over time.

Unit of analysis
In terms of network perspective, the unit of analysis is another important basic element to describe and explain constructs, that is, the level to which generalizations is appropriate. Three types of unit of analysis are categorised, i.e. focal firm, dyad, and network levels. It is identified that articles analysing the sustainability performance of the focal firm as the unit of analysis are still in majority, while the dyad level is very rare. Furthermore, there is a growing trend to adopt whole supply network as the unit of analysis in recent years. The network unit may generate a better understanding of relationships among organisations. The choice of unit of analysis has implications for the relevance of supply chain sustainability measurement and increase researchers and practitioners’ awareness of this issue.

Findings and discussion
This study distinguishes two prevailing network properties in driving sustainability in supply chains. The two properties: relational (i.e., the attributes and quality of network relationships as well as the governance mechanisms supporting and sustaining interactions among participating actors to enhance the likelihood of achieving sustainability goals) and structural (i.e. the architecture or patterns of supply chain relationships) are conjectured to affect both the environmental and social aspects of sustainability.

Network-level collaboration in supply network
The notion of “embeddedness”, referring to the contextualisation of actors (e.g. individuals, firms) within the patterns of inter-organisational relations and the consequent behavioural and performance implications. Relational embeddedness has been also referred to as the strength of inter-organisational relationships or ties (Granovetter, 1973). Different from the dyadic-level collaboration, network-level collaboration for sustainability (more than two actors) provides a broader lens of the interconnected relations of the whole network and explains how information and resources could be disseminated among the extended relationships

It is identified that collaborative relationships in supply network mostly occurs in for-profit organizations in implementing effective sustainability strategy. Those types of collaborations in business communities have different dimensions, i.e. horizontal, or vertical. For instance, Fontana and Egels-Zandén (2018) examined that interlinked suppliers use horizontal collaborative approach (i.e., collective behaviour) to improve the whole network’s CSR engagements, e.g. labour conditions. Soundararajan and Brammer (2018) supported that viewpoint by taking the intermediary (first-tier suppliers)-sub suppliers dyads as the unit of analysis in their study. They argued that a collaborative approach, such as knowledge sharing related to working conditions, leads to the enhanced social sustainability management. Vertically, collaboration among focal buying firms, suppliers and sub-suppliers, usually trigger the transformation of embedded CSR values from focal firms to their multi-tier suppliers, leading to an ethical commitment to CSR, clear addressment on CSR theme regarding the focal firm’s sustainability codes of conduct (Lim and Phillips, 2008).

In addition to that, actors embedded in the for-profit organisations network also seek for complementary resources (i.e., capabilities, process, knowledge, and information) from non-business sectors, e.g. NGO, government. It is suggested that the network-level collaboration among NGOs and business firms enable the creation of social value and help business firms learn about the origin of issue of sustainable practices. Additionally, the development of focal firm’s sustainability initiative also relies on the involvement of government. On the other hand, government involvement gives credibility to the
sustainability initiatives of the focal firm. Furthermore, Meehan and Bryde (2015) highlighted that co-opetition with network actors also becomes a way to achieve sustainability in the field. The main reason behind this is due to the lacking in abundant resources and skills, dyadic partnership alone is difficult to get a governmental-funded capital program. For instance, they found that companies competing for the governmental contracts are more likely to form the procurement consortia in that individual housing associations lack the resources and skills to manage contracts. Thus, this study proposes:

**Proposition 1.** Network-level collaboration positively affect sustainability performance at focal firm, dyad, and network levels.

**Network governance mechanisms in supply network**

To support and sustain collaboration among participating actors to enhance the likelihood of achieving goals, a set of governance mechanisms is needed. Network governance (more than two actors in network) is to manage the whole network involving all the interconnected actors rather than interdependent actors who interact with each other. Also, given the properties of network structure and relationships embedded, network governance provides a theoretical lens to investigate how the actual mechanisms are used to manage the network-level collaborations.

Formal network governance mechanisms refer to “an explicit way by using structural arrangements to affect the network actors’ behaviour” (Tachizawa and Wong, 2015). They can include command structures, incentive systems, standard operating procedures, and documented dispute resolution procedures (Alvarez et al., 2010). To be more specific, formalisation of sustainable supply chain management activities can be realized through a set of corporate codes of conduct, criteria/standards and contracts. A few authors have investigated the impact of formal mechanisms on sustainability performance in terms of different unit of analysis. For instance, at a focal firm level, Wong (2013) observed that formal mechanisms can act as a driver for focal companies quickly adapt to new markets demand for developing new environmental-friendly products or services. In social dimensions, formal mechanism, e.g. labour regulation, or setting sustainability expectations in contracts, also help focal buying firms reduce the riskiness of managing the lower-tier suppliers. This can act as a normative pressure in the supply network and drive lead firms to monitor their lower-tier suppliers for the compliance of sustainability requirement and the non-compliant suppliers would be removed. At supply network level, Tachizawa and Wong (2015) also observed that complying with a set of corporate codes of conduct and international environmental standards, e.g. ISO 14001 enables network actors to implement sustainability (i.e. reduce waste).

Informal network governance mechanisms, in contrast, govern the networks through social forms of control and focus on the soft issues, e.g. trust, power, culture and values, social norms and relationships (Alvarez et al., 2010). In reviewing literatures, this study identifies some informal mechanisms (i.e., trust, power, cultural contents) contribute to sustainability performance. Extant articles state that a trusting relationship can lead to a quicker information and knowledge sharing in that suppliers would be more willing to accept the green practices from focal companies and provide support to the lower-tier suppliers (Dou et al., 2018; Lu et al., 2018). Additionally, Van Bommel (2011) has also investigated the use of power is beneficial for the diffusion of environmental practices. With power, e.g. non-coercive power, focal companies can exert more moral influence and put pressure on their suppliers when requesting implementation of environmental programs. Additionally, cultural contents, e.g. values and perceptions of fairness, also serve as social forms of control. Actors in supply network are actually the carriers of their
own values or culture (Wu and Pullman, 2015). This culture embeddedness may serve as an underlying motive for actors to implement focal firm’s sustainability initiatives.

More importantly, a plural form of governance mechanisms (i.e., a mixture of formal and informal governance mechanisms) is also suggested to effectuate supply chain sustainability. Tachizawa and Wong (2015) stated that relational cooperation may compensate the inflexibility of contractual governance. For instance, governments and citizens have paid increasing attention to the environmental protection and sustainable production in the palm oil sector. Solely relying on the international standards cannot guarantee the activities of production would not harm the planet. Practitioners and researchers suggest that palm oil stakeholders should share their perspectives with small holding, or increase their awareness on certification standards, along with formal mechanisms can effectuate the sustainable cooperation for palm oil. Therefore, this study proposes:

Proposition 2. Network governance mechanisms including formal, informal and plural forms affect sustainability performance at focal firm, dyad, and network levels.

**Supply network structural properties**

Structural properties of the supply network refers to the patterns and connectivity of supply network actors’ embedded in the network context. Drawing upon the “embeddedness” concept, structural embeddedness, which is the focus of our study, encompasses the quality of dyadic relations in which the actors are embedded (Gulati et al., 2000). Structural embeddedness could be seen as a conduit for diffusing information and knowledge about embedded actors strategy and behaviours which affect sustainability performance in supply network (Tate et al., 2013).

Firms embedded in supply networks are not equally affected by the level of sustainability issues due to the specified position of a focal node. Accordingly, firms’ unique network positions such as centrality and structural hole as well as whole network-level connectivity patterns such as density and complexity. For instance, Vurro et al. (2009) identified that both network density and node-level centrality of the focal organisation are likely determinants of central actor’s responsiveness to sustainability implementation in that it affects the ease of communication and efficiency of information flow across actors in the supply network. The central actor receives increased monitoring from other actors when the density increases. On the other hand, it also becomes easier for focal firm to transfer the knowledge which facilitates the sharing of sustainability-related activities when density increases. In line with this, network density interacted with node-level centrality largely determine the ways a focal firm react to its stakeholders regarding implementation of sustainability practice (e.g. authentic CSR efforts). Focal firms with high centrality will use power and influence to encourage other actors, e.g. suppliers, to adopt more responsible practices.

Additionally, other articles (i.e., Wilhelm, 2014; Meinlschmidt et al., 2018) highlight the importance of supply network complexity on focal firm’s sustainability performance. A high structural supply chain complexity may indicate the probability that buying firms lack sufficient knowledge of their lower tier suppliers is also high. Consequently, focal firms need more efforts to generate transparency to those undirected (lower-tier and beyond) actors.

Considering the linkages among focal firm and its undirected actors (i.e., lower-tier suppliers and beyond), the concept of structural hole proposed by Burt (1992) help explain how the information is passed across the supply network. A bridging tie links two nodes whose respective contacts are not linked and by definition a weak tie. Applying these concepts, Roscoe et al. (2016) suggested that focal firm should build weak ties with
suppliers that bridge structural holes in supply network. Bridging weak ties may help facilitate greater information access and enable focal firms to tap into the resource base of an entirely different network. This also indicates that focal firms may benefit from new knowledge and opportunities for finding innovations to enhance sustainability performance (i.e., discover radical eco-innovations under the conditions of technological uncertainty). Hence, this study proposes:

Proposition 3. Supply network structural properties including density, centrality, complexity and structural hole, affect the sustainability performance at focal firm level.

Based on the findings and discussion above, a conceptual framework is established in Figure 1 below:

Figure 1 Conceptual framework

Conclusions and future research
Given the network perspective proposed by Grannovetter (1973) and Burt (1992), this study analysed the influence of network on supply chain sustainability. This study examines the existing literatures focusing on the relationships that occur among three actors and beyond in the supply network. This study provides the insights of current state of the art in the role of network in managing supply chain sustainability. Additionally, this study specifically differentiates the sustainability performance at different unit of analysis. In accordance with this, this study generates 3 theoretical propositions and a conceptual framework for understanding the supply chain sustainability that goes beyond the dyadic relationship, contributing to the future research.

From the managerial perspective, this study synthesizes the various viewpoints of the importance of network perspective on supply chain sustainability. It shed light on the importance of considering the perspectives of sub-suppliers as the management of them are often neglected. Their perceptions/understanding towards sustainability will greatly
affect sustainability implementation and also influence the way they behave in the process of supply chain, e.g. sourcing ethically, compliance to sustainability standards, etc.

After reviewing the relevant findings, this study found out some gaps and suggest some avenues for future research. The overview of them is briefly outlined in Table 2.

Green initiatives in supply chain inter-organisation relationship governance

**Keywords**: supply chain relationship, green collaboration, the automotive industry, governance mechanism

**Topics**: Managing Inter-firm Relationships in Supply Chains, Supply Chain Management, Behavioural Operations

**Word count**: 1000

**Purpose**
Supply chain inter-organisation relationship between supply chain partners developed over some time to push their boundaries and make them collaborate with their partners to assess and ensure they are socially responsible. Latest trends of green supply chain collaboration refer to the responsibility of partners to coordinate their procedures, processes and decisions to comply with social, environmental and ethical standards (Gunasekaran et al., 2015). The benefits of green collaboration result in less waste, a reduction in environmental damage, improve market and financial performance, streamline manufacturing, enhance the company's public image and reputation, and have a positive impact on the costs associated with the supply chain (Dangelico and Pontrandolfo, 2015).

Hence, the challenging question that lies among researchers and practitioners is how supply chain members should collaborate greenness. Furthermore, it is not clear how buyers and suppliers are going to be benefited through green initiatives governance. This gap was noted by Gunasekaran et al. (2015), that how should buyers and suppliers design incentive structures for green initiatives and how should they appropriately reward members across the supply chain.

The relationship is the essential aspect of achieving collaboration. Sheu (2014) discussed in the green supply chain collaboration context it differs where the buyers and suppliers have to strengthen the engagement based on certain long-term agreements, goodwill and trust. Two variables, certainty and dependency, can be used to define these relationships. Researchers can gain a perspective on green collaboration by viewing it from the economic, technological and social standpoints (Sheu, 2014; Green et al., 2012).

For a green supply chain to emerge and be implemented effectively, the relationships, such as buyer-supplier, which form part of the chain are key to success (Gunasekaran et al., 2015). The study by Luo et al. (2015) assessed Guanxi's role between buyer and supplier, and the effect it had on green performance in China, analysing how cultural factors, and the interpersonal relationships between suppliers and manufacturers, impacted on overall green performance. The observation-based research considered the effects of asset specificity, volume certainty, the frequency of transactions and the competition, on collaborative performance in the green supply chain. Above all, this research plan to explore How do green initiatives governance mechanic supply chain inter-organisational relationship, example as Chinese automotive groupings.

**Design/methodology/approach**
Investigate and build theories addressing the interrelated inter-organisational relationships, initiatives such as trust, goodwill, inter-personal relationships as mentioned in the research questions, a multi-case study approach is employed in the study to collect empirical evidence that is sufficiently cover a variety number of suppliers and manufacturers within the Chinese automotive industry. Through a comprehensive review and analysis of the literature regarding the inter-organisational relationship, a proposition of multi-level relationships management is developed. The proposition is then engaged with the empirical evidence that is classified by the dimension, supply chain green collaboration, and trust context within the multi-level relationship. The classification has been considered as an effective configuration method to build theories (Bailey, 1994). The case study evidence is collected through in-depth interviews with four to six senior directors and supply chain managers from each case.

Findings
The analysis of the data provides a deeper understanding of the Chinese automotive industry conditions and confirms the manufacturers and suppliers as ‘an activity system’ when renewing the supply chains in relationship developing stage. The supply chain inter-organisational relationships facilitate the ongoing status of green initiatives. The long-term relationship it is, the competitive environment relationship it is, meaning there is a higher degree of trust and relationship satisfaction between partners, and reduce the uncertainties. Methodical and effective knowledge sharing cannot only assist partners in governance roles but contribute positively to the greener of supply chain inter-organisation relationship. While the overall development of the inter-organisation relationship, all our cases use governance mechanisms initiatives which increase the confidence of manufacturers and suppliers in a long-term relationship.

Relevance/contribution
This study expressed in the form of the effective inter-organisational relationship governance mechanism and green supply chain collaboration ‘knowledge’. Based on data analysis, the best universal practices of governance mechanism initiatives in supply chain relationships are discussed and offered that will reflect exploration as far as monitoring and control of green supply chain relationship tasks. This study reconfigured and developed governance mechanism initiatives within the supply chain inter-organisation relationships (RQ). One of the key factors in bridging the gap between the literature on the green supply chain collaboration in theory and the limited case study is the study insights into the effects of manufacturers and suppliers’ behaviour. The governance initiatives of green supply chain inter-organisation relationship can be considered to be the point at which theory meets practice. By providing an in-depth case study account in which SCC criteria of particular relevance in multicultural collaborators are both identified and addressed, the research provides an original and much-needed contribution to knowledge.

Abstract

Industry 4.0 implies a future digitalized and interconnected industrial value creation and has the potential to transform buyer-supplier relationships. These relationships differ among industry sectors because of industry-specific circumstances. This paper sheds light on future buyer-supplier relationships in the context of Industry 4.0 focusing on industry differences. Qualitative semi-structured expert interviews with 65 experts from German industrial enterprises serve as empirical basis of the exploratory multiple case study. The results reveal how future buyer-supplier relationships differ among various industries. The paper contributes to the current state of research from a management perspective triggering further research in this area.

Keywords: Industry 4.0, Buyer-Supplier Relationships, Industry-comparison

Introduction

“Industry 4.0”, also known as the “Industrial Internet of Things”, indicates a de novo change in industrial value creation based on digitalization and interconnection (Kagermann et al., 2013). People, machines, objects, and information and communication technology systems get intelligently, horizontally, and vertically interconnected (Schneider, 2018). Given its far-reaching technological developments along with its revolutionary character for value creation, Industry 4.0 provides numerous opportunities and potentials, e.g., efficiency, quality, and flexibility improvements (Kagermann et al., 2013).

Industry 4.0 implies a digitized, real-time capable, and intelligent interconnection of value creation chains, networks, and ecosystems (Bienhaus and Haddud, 2018; Kiel et al., 2017; Tu, 2018; Wang et al., 2006). Technological developments enable collecting, processing, analyzing, and sharing data (Thun, 2010; Wang et al., 2006). In this context,
digital technologies may create new forms of collaboration, cooperation, and integration and change buyer-supplier relationships (Obal and Lancioni, 2013). A more intense collaboration, further integration of partners, usage of platforms, and cross-company systems transform the shape of future competition. Given substantial industry specific differences in terms of value creation, analyzing buyer-supplier relationships requires a separate consideration.

Buyer-supplier relationships in the context of Industry 4.0 have scarcely been analyzed so far and consequently little is known about particular differences in various industry sectors (Haddud et al., 2017). However, analyzing the interconnection of companies, cross-company cooperation, and shared value creation is relevant for several reasons. Firstly, analyzing these aspects is vital to unveil how to further develop and improve industrial value creation (Vanpoucke et al., 2013). Secondly, buyer-supplier relationships represent a great source of competitive advantage, e.g., reducing sourcing costs, especially against the backdrop of decreasing value creation depth (Tan et al., 2002; Wang et al., 2006). Thirdly, cross-company interconnection represents a central element of Industry 4.0 and thus asks for an investigation (Büyüközkan and Göçer, 2018).

Whereas it is expected that companies cooperate and interact more closely in the future (Vanpoucke et al., 2013; Wang et al., 2006), it is unknown how buyer-supplier relationships are characterized in the context of Industry 4.0. Both research and practice show great interest in discovering setting levers for future buyer-supplier relationships (Schneider, 2018; Tu, 2018).

For this reason, the study addresses the following research questions:

RQ 1. How are present buyer-supplier relationships characterized in various industry sectors?

RQ 2. What are the distinct characteristics of future buyer-supplier relationships in the context of Industry 4.0 dependent on companies’ industry sectors?

RQ 3. What drivers and causes can be identified why buyer-supplier relationships are transformed in the context of Industry 4.0?

The study sheds light on industry-specific differences in buyer-supplier relationships in the context of Industry 4.0 and indicates areas for future research. Aside from contributing to research, the derived recommendations and implications serve managers and corporate practice, which in turn ensures the study’s practical relevance.

**Theory**

*Industry 4.0*

Based on an ongoing digitalization and interconnection, Industry 4.0 implies a new paradigm shift of industrial value creation. Cyber-Physical Systems and the Internet of Things form its technical basis. Cyber-Physical Systems are characterized by physical objects being complimented with communication systems and technologies that exchange digital data and allow an autonomous and independent coordination (Blau, 2014; Kagermann et al., 2013; Lasi et al., 2014). By means of information and communication technologies, the Internet of Things interconnects physical and virtual objects and systems alike, and in so doing, enables comprehensive communication and vast interactions (Kagermann et al., 2013; Lasi et al., 2014). Applying these technologies paves the way to merge and interconnect the physical and virtual world in industrial value creation. The inclusion of Internet of Things solutions and applications in industrial value creation...
creation is also referred to as Industrial Internet of Things, why this term can synonymously be used to Industry 4.0.

Given its far-reaching implications for industrial value creation, Industry 4.0 provides both strategical and operational potentials for individual companies. First, it paves the way for new, data-driven business models, e.g., platforms, and it may also transform existing business models (Kiel et al., 2017). Second, modular product designs and flexible production processes help to produce individual products nearly in a similar quantity and efficiency like mass production (“mass customization”) (Kiel et al., 2017). Third, value creation efficiency and productivity can be improved, for instance via optimizing capacity utilization and turnaround time. Fourth, Industry 4.0 can decrease overall risks by increasing transparency of the value creation process and fasten responsiveness to adapt to changes (Rong et al., 2015).

Aside from affecting individual companies, Industry 4.0 has the potential to reshape entire value creation processes forming integrated cross-company value creation chains and networks (Hofmann and Rüsch, 2017; Kiel et al., 2017; Vanpoucke et al., 2013). Against this backdrop, a broad and comprehensive horizontal and vertical interconnection represents a key to tap Industry 4.0’s full potential (Kagermann et al., 2013; Müller et al., 2018a).

**Industry 4.0 in Supply Chain Management**

Supply Chain Management aims at optimizing the performance of the value creation process, for instance improving quality, time, and cost, and building up competitive advantages (Tan et al., 2002; Vanpoucke et al., 2017). Supplier Management’s objective is to create, manage, and develop buyer-supplier relationships in order to efficiently organize and manage value creation (Choy and Lee, 2003). Being a central element, supplier integration represents a form of vertical cooperation. It is a set of strategies to design buyer-supplier relationships in a collaborative and cooperative manner, combining resources and capabilities to conduct common activities (Bienhaus and Haddud, 2018; Schoenherr and Swink, 2012; Tan et al., 2002; Thun, 2010; Vanpoucke et al., 2013).

Buyers and suppliers alike benefit from collaboration, cooperation and integration (Bienhaus and Haddud, 2018; Haddud et al., 2017; Tan et al., 2002; Vanpoucke et al., 2017). Intensifying cooperation allows conducting joint activities, for instance, carrying out common research and development projects (Bienhaus and Haddud, 2018; Tan et al., 2002; Thun, 2010; Vanpoucke et al., 2013). Integrating new or unrelated partners ensures access to further resources and expertise (Rong et al., 2015; Vanpoucke et al., 2013). On an operational level, closely working together reduces costs of value creation. First, it decreases process complexities and in turn increases process efficiency, e.g., via lower coordination efforts and less manual reworking. Second, it reduces inventory levels following greater information transparency. On an output level, it increases flexibility, agility, and responsiveness of value creation chains. Further, cooperation helps to address customers’ demand providing individual solutions and services (Bienhaus and Haddud, 2018; Dweekat et al., 2017; Vanpoucke et al., 2017; Wang et al., 2006).

Industry 4.0 affects Supply Chain Management and transforms buyer-supplier-relationships intensifying the interconnection of value creation chains. Technologies, such as the Internet of Things, Big Data, and Cloud Computing, enable real-time data analysis and data management across company boarders (Bienhaus and Haddud, 2018; Büyükökşan and Göçer, 2018; Dweekat et al., 2017; Thun, 2010; Wang et al., 2006). Thus, Industry 4.0 increases information transparency improving efficiency of Supply Chain Management functions, decision-making, and overall business performance (Bienhaus and Haddud, 2018; Dweekat et al., 2017; Vanpoucke et al., 2017; Wang et al., 2006).
In addition, the supply chain is improved as for robustness, flexibility, responsiveness, and agility, for instance, using smart products that advance traceability and further automating processes (Wang et al., 2006). Furthermore, digital technologies pave the way to create new forms of collaboration, cooperation, and integration, for instance transferring value creation to digital platforms, and subsequently change buyer-supplier relationships (Obal and Lancioni, 2013). Intense vertical integration and ongoing collaboration does not only apply for first-tier suppliers, but includes suppliers of further value creation stages (Dweekat et al., 2017; Müller et al., 2017). Consequently, future competition will no longer be amongst individual companies, but between corporate network structures and ecosystems (Kiel et al., 2017).

Methodology
Using a qualitative explorative empirical research design and applying a multiple case study approach, the study analyses how buyer-supplier relationships differ in various industries in the context of Industry 4.0 (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007). Exploratory case studies are used to investigate complex, novel, and evolving phenomena (Yin, 2009). Multiple cases increase the results’ accuracy, reliability, generalizability, and robustness (Eisenhardt and Graebner, 2007; Yin, 2009).

The empirical data comprises semi-structured interviews with 65 experts from German and Austrian companies of heterogeneous firm sizes and different industry sectors conducted between August 2018 and March 2019 (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007). The companies’ characteristics vary in sales volume (av. = 29,200 million EUR) and number of employees (av. = 83,000). They were analyzed in their role as buyers and stem from the automotive (n = 8), automotive suppliers (n = 15), consumer goods (n = 4), electronic and electrical engineering (n = 13), mechanical engineering (n = 13), and raw materials processing (n = 12) industries. All experts hold management positions with an average company tenure of 8.55 years and they are involved in or responsible for Industry 4.0-projects. The experts’ names and companies are anonymized for confidentiality reasons. The sample’s heterogeneity enables generalizing results and counteracts potential negative effects of sample biases (Yin, 2009). Selecting competent and knowledgeable experts strengthens the findings’ reliability (Huber and Power, 1985).

The interview guideline was informed by literature but followed the principles of openness and flexibility. The first part deals with questions about personal facts and company contexts. The second part focuses on current buyer-supplier relationships and the third part deals with future buyer-supplier relationships. To concretize some aspects and to reveal further information, individual questions slightly deviated from the original guideline. All interviews were audio recorded and transcribed which reveals more than 820 pages of text material. Whenever possible, secondary data was used to verify the experts’ statements for triangulation purposes, which increases validity and reliability (Eisenhardt and Graebner, 2007; Yin, 2009).

In order to answer the research questions, a qualitative content analysis was used to identify pattern, themes, and categories in the empirical material (Miles and Huberman, 1994). The study follows an inductive coding procedure that facilitates theory building but the categories were partly informed by literature to allow new aspects to emerge (Edmondson and McManus, 2007; Eisenhardt and Graebner, 2007; Krippendorff, 2013). In a first step, first-order (informant-centric) categories were developed. Second, the categories were synthesized into second-order themes. Third, the themes were distilled into general dimensions. The process was conducted in a research team consisting of three authors to ensure validity and objectivity of the coding procedure (Weston et al., 2001).
Results
The results are divided into three subsections addressing the paper’s research questions in a buyer-to-supplier perspective: First, it is described how present buyer-supplier relationships are characterized in differing industry sectors. Second, we describe to what extent buyer-supplier relationships change in the context of Industry 4.0 and how future relationships vary in several industries. Third, drivers and causes are presented why buyer-supplier relationship are transformed. Given the limited space of the paper, the chapter does only present and discuss those categories that are predominantly named to be relevant for the industries regarded in the sample. Table 1 depicts the results differentiated by industry sectors:

</tbody>
</table>
Present buyer-supplier relationships
Interviewees from the automotive industry state that automated data exchange is how they share data with suppliers. Interestingly, automotive suppliers predominantly use non-automated data exchange with their respective suppliers in contrast.

Automotive suppliers and companies from the consumer goods industry indicate that personal and direct contact to their suppliers is of utmost importance in the present. In the automotive supplier industry, however, the frequency of direct contact with their suppliers is largely dependent on the respective suppliers’ importance.

For mechanical engineering companies, in the present long-term relationships with their suppliers play a crucial role. Those relationships are of close nature, for instance integrating suppliers in innovation and product development processes from early on.

As far as level of trust is concerned, especially representatives from the automotive industry and from automotive suppliers perceive a rather low level of trust in their present buyer-supplier relationships. In contrast, representatives from mechanical engineering and electronic and electrical industries predominantly describe their current buyer-supplier relationships to be positive and well established.

Future buyer-supplier relationships
Automotive suppliers and raw materials processing companies name digital and automated data exchange to be part of their future buyer-supplier relationships. Foremost companies from electronic and electrical engineering state that the importance of platforms and cloud computing increases. In contrast, automotive suppliers indicate that direct and personal contact still remains important in the future, which is also true for the consumer goods industry. In the automotive industry, real-time data exchange is a central characteristic of future buyer-supplier relations. Representatives of raw materials processing enterprises name an enhanced traceability as crucial for future collaboration in their industry. In the electronic and electrical engineering and raw material processing industry major manual activities, e.g., procurement processes, are automated in the future.

Mechanical engineering enterprises predominantly focus on strategic suppliers and companies from consumer goods industry keep a smaller supplier base in the future. Mechanical engineering enterprises and companies from raw materials processing aim at further integrating external knowledge, especially IT-related expertise. Representatives from automotive suppliers as well as raw materials processing companies apply different selection criteria to choose suppliers in the future.

Companies from the automotive industry and automotive suppliers predominantly aim at intensifying buyer-supplier relationships in the future. In addition, automotive suppliers try to intensify and broaden cooperation with start-ups. Companies from raw materials processing intend to cooperate more closely with their suppliers when it comes to new product development. Representatives from the mechanical engineering industry state that they prospectively integrate their suppliers at an earlier stage compared to the present.

Drivers and causes for transformation
Industry 4.0 and accompanying technological developments play a central role in the transformation of buyer-supplier relationships according to all interviewees’ statements. Various interviewees express that well-established and smooth buyer-supplier relationships are required to successfully implement Industry 4.0 across companies and subsequently profit from its entire set of potentials.

Several drivers can be observed why buyer-supplier relationships are transformed that differ in various industry sectors. First, companies from mechanical engineering, electronic and electrical engineering, and automotive suppliers see potential for
optimization in reshaping buyer-supplier relationships. In addition, competitiveness, both on an individual and a supply chain level, is strengthened through enhanced buyer-supplier relationships foremost for companies from the automotive and consumer goods industry. Apart from this, representatives from the automotive industry and automotive suppliers indicate that demands from their customers, e.g., higher flexibility, reliability, and product availability, drives changes in their buyer-supplier relationships. Transforming future buyer-supplier relationships enables companies from those industries to create new forms of value offerings for their respective customers. Data exchange across the supply chain, for instance via platform solutions and horizontal and vertical data exchange, requires new relationships between buyers and suppliers. Especially interviewees from automotive suppliers and consumer goods industry state that the possibility to share information and to increase transparency drives the transformation of their future buyer-supplier relationships.

External causes why buyer-supplier relationships are transformed can be found manifold as well. Representatives of automotive, automotive suppliers and raw materials processing companies name an increased market dynamic and volatility as well as an increasing competition as influence factors for a transformation of buyer-supplier relationships. Especially companies from mechanical engineering face increasing cost pressure they address with transforming their buyer-supplier relationships. Technological changes, e.g., digital technologies for digital data exchange and analysis, pave the way for future transformations, mainly in the industries of mechanical engineering and electronic and electrical engineering.

Discussion
As far as present relationships are concerned, the study uncovers that significant industry differences in buyer-supplier relationships can be observed. Among others, the results show that present buyer-supplier relationships in the automotive industry and automotive suppliers are built upon rather low levels of trust. In contrast, buyer-supplier relationships in the mechanical engineering and electronic and electric engineering industries are characterized by higher levels of trust. For the majority of industry sectors, present buyer-supplier transactions and information sharing are mostly conducted via non-automated, analogue, and manual processes. In this context, personal and direct contact are frequently used and are very important in present buyer-supplier relationships.

Our study reveals that buyer-supplier relationships are transformed in the context of Industry 4.0, but the extent of transformation varies among industry sectors, given differing status quos and intensities of changes. The automotive industry and their suppliers prospectively aim for improving current rather mediocre relationships with suppliers, whereas other industries aim at deepening and intensifying already well-established relationships, for instance, further integrating suppliers. In this regard, the paper contributes to the current state of literature emphasizing that well-established relationships are a prerequisite for successful supplier integration. Further, the paper confirms that intense buyer-supplier relationships pave the way to streamline value creation and to provide a superior value proposition that is aligned on end customers’ demand which in turn serve to build up a competitive advantage (Schoenherr and Swink, 2012; Tan et al., 2002; Thun, 2010).

Extant research has shown that the automotive industry and its suppliers perceive Industry 4.0 rather from an operational, than from a strategic perspective, in contrast to, for instance, mechanical engineering and electrical and electronic engineering companies (Kiel et al., 2017; Müller et al., 2018b). Our paper partly confirms these results revealing that for instance, companies from mechanical engineering and raw materials processing
concentrate on strategical aspects of buyer-supplier relationships, e.g., integration of partners in product development.

The results show that prospectively information sharing will increasingly be conducted via digital and automated processes in all regarded industry sectors. However, the extent and the forms differ as indicated by the results. For instance, in the automotive and automotive supplier industry, especially real-time data plays a crucial role. Digital platforms become relevant predominantly in the electronic and electrical engineering and automotive supplier industry. Sharing information increases productivity and decreases inventory levels, maintenance efforts, and value creation costs (Vanpoucke et al., 2017; Wang et al., 2006). Whereas on an operational level, information sharing might increasingly be conducted digitally (Hofmann and Rüsch, 2017; Müller et al., 2018a), the results indicate that on a strategic level, personal communication remains important in the future. The paper extends literature in adding that direct personal contact will remain of high importance in buyer-supplier relationships in the context of Industry 4.0.

Responsible for a great proportion of value creation, small and medium sized firms keep on working with manual and semi-digitized solutions in many cases for technical and financial reasons. Subsequently, this requires a strategy that both strives for digital data exchange and develops buyer-supplier relationships on a personal level to unfold the entire potential (Dweekat et al., 2017; Müller et al., 2018a).

Changes in future buyer-supplier relationships can be referred back to several drivers and external causes. Literature has revealed that collaboration, cooperation and integration provide several benefits (Bienhaus and Haddud, 2018; Haddud et al., 2017; Tan et al., 2002; Vanpoucke et al., 2017). Our study adds to the current state of research differentiating between industries and providing an industry comparison.

Our paper extends studies that highlight the importance of buyer-supplier relationships for smooth supply chains in the digital era (Tu, 2018; Wang et al., 2006). Information and communication technologies and digital supplier integration efforts pave the way to establish digital value creation networks in the context of Industry 4.0 (Vanpoucke et al., 2017; Thun, 2010).

Conclusion
Industry 4.0 has the potential to transform future buyer-supplier relationships. Despite its importance for research and corporate practice, there is still little research about Industry 4.0 from a Supply Chain Management perspective. Using a unique sample of empirical data comprising interviews with 65 experts from German industrial companies, the study analyzes how buyer-supplier relationships in the context of Industry 4.0 differ in various industry sectors.

The study entails some limitations as for the data sample and its method that are worth to discuss. First, the data sample exclusively includes German companies that may limit the results’ generalizability. Second, the study focuses on selected industry sectors, which must be kept in mind when transferring its implications to other contexts. Third, the study does neither differentiate between different levels of value chain stages, e.g., first-tier versus second-tier suppliers, nor does it analyze differences that stem from various company sizes, e.g., small and medium sized versus large companies. Fourth, the study solely analyzes buyer-supplier-relationships from buyers’ perspectives. As far as methodical limitations are concerned, developing solid theoretical implications from explorative, qualitative research is rather difficult. However, the study consolidates empirical data from individual cases while keeping relevant content, and in so doing, is able to work out theoretical contributions. In addition, various biases, e.g., key informant...
and retrospective bias, are addressed by our methodological approach and discussed along with measures to reduce their impact.

In the course of the analysis, the study uncovers space for future research. Given the study’s limitations and contributions, further research could shed light on the following aspects. Quantitative research may complement the study and, for instance, may quantify and statistically prove the discussed effects. Future research can add the supplier’s perspective to analyze buyer-supplier-relationships, focus on small and medium sized firms, and differentiate between levels of value chain stages. Going beyond the study’s scope, research could focus on the following further aspects. Research could investigate the incentives to integrate suppliers and incentives to intensify cooperation and collaboration. Future research studies are ought to analyze how supplier integration is to be conducted operatively, what efficiency gains and economical outputs can be expected, and which implications for future value creation can be derived. In addition, platforms possess the potential to revolutionize buyer-supplier-relationships and therefore call for special attention leaving great space for future investigations.

The study and its findings reveal several implications for management and corporate practice. First, well-established buyer-supplier relationships can be regarded as a prerequisite for close cooperation and supplier integration in the digital era, which is why establishing such relationships, is of utmost importance. Second, cooperating and collaborating is crucial in the context of Industry 4.0 to acquire knowledge about IT-processes, especially for traditional industry sectors, such as mechanical engineering. Third, companies are advised to consider present relationships with suppliers and to harmonize digital information sharing and transactions across the supply chain. Fourth, the role of digital data exchange across a supply chain, particularly by using digital platforms, must be supported in future buyer-supplier relationships, given their potential for value creation. Keeping these aspects in mind, may help to prepare companies for future challenges and unfold the potential Industry 4.0 poses for industrial value creation and Supply Chain Management.

Abstract

Two organizations with a mutual interest frequently form an inter-organizational relationship (IOR) to gain operational synergies. Despite an inherent pursuit of cooperation, IORs are subject to agency problems caused by residual self-interest and information asymmetry between the independent organizations. The first steps towards a mid-range theory of agency in IORs are taken through a review of literature in operations management, general management, marketing, and economics. Identified similarities (e.g., explicit focus on information asymmetry) and differences (e.g., assumptions about self-interest and opportunism) between the four disciplines form a conceptual basis for further theorizing on governance of agency problems in IORs.

Keywords: Principal-agent theory, Agency problem, Buyer-supplier relationships

Introduction

Organizations increasingly engage in collaboration with one another in order to gain access to resources and new markets. Such relationships are labelled as inter-organizational relationships (IORs) in which two independent organizations engage in collaboration and cooperation to pursue a mutual interest, hence, going beyond purely transactional exchange (Cropper et al., 2006). Despite the inherent ideal to go beyond arm’s length transactions, IORs as social interactions are still subject to agency issues when the independent organizations have their own goals to pursue and private information about their capabilities and actions, leading to challenges such as risk sharing and incentive design (Lassar & Kerr, 1996).

Whilst principal-agent theory specifically focuses on incentive design, it has remained a surprisingly underutilized lens for IORs in operations management when compared to other mainstream theories such as transaction cost economics or the resource-based view (Walker et al., 2015). Instead, empirical agency theory has predominantly focused on a
specific case of corporate governance or how owners should incentivise managers to work towards the owners’ best interests (Dalton et al., 2007). Quite the contrary, economic contract theory has adopted a highly general, yet mathematical, treatment to define the most optimal contract (i.e. an incentive game) to govern agency relations (Gibbons, 2005). We argue that in addition to these aforementioned extremes, there is a need for a mid-range theory that is more cognisant of specific dilemmas in various IOR forms, which are set up to increase collaboration but are typically plagued by asymmetric information leading to risk of agency problems. In addition, given the cross-disciplinary nature of IOR studies, such mid-range theory should resonate across multiple disciplines. Hence, the aim of this study is to 1) provide a systematic review of the use of agency theory in studying IORs and 2) to provide the first steps towards a mid-range theory by reconciling potentially discrepant views of the four disciplines.

Method

We systematically reviewed 26 leading journals in the disciplines of operations management (7 journals), general management (8 journals), marketing (6 journals), and economics (5 journals), to identify articles specifically examining agency theory in IORs. The standard in review methods among management scholars has been to include only the highest ranked journals (see e.g. Bergh et al., 2019). This is particularly suitable when seeking to control for research quality in epistemologically diverse management research as compared to, for example, medicine with its clearer hierarchy of evidence (Tranfield et al., 2003). Therefore, with two exceptions, all journals selected were ranked as 4* and 4 journals according to Chartered Association of Business School’s Academic Journal Guide (AJG) 2018. Two operations management journals were ranked on AJG level 3 but still considered as top journals due to inclusion in the UT Dallas ranking (Manufacturing and Service Operations Management) and due to a substantially high impact factor (Journal of Supply Chain Management). Despite such purposefully induced limitations, we obtained a large enough, yet focused and high quality baseline sample giving us the sufficiently reliable and profound account on the usage of agency theory in the IOR domain.

We conducted title-keyword-abstract searches from four major databases (Web of Science, EBSCO Business Source Complete, ABI/INFORM, and Scopus) by using a generic agency theory search string (“agency theory” OR “principal agent” OR “agent* problem” OR “agent* relation*”) in order to retrieve all agency theory articles from the selected journals. Some databases utilize advanced search algorithms using special keywords created according to article’s bibliographical details (e.g. Web of Science’s Keywords plus). We did not switch off such features.

After merging the results and removing duplicates, we were left with 1192 articles for abstract screening. We aimed to include only articles explicitly discussing agency theory in IORs (e.g. corporate governance articles were excluded). Two independent evaluators conducted the screening utilizing a traffic light approach (red = excluded, yellow = unsure, green = included). All articles receiving a disputed decision were discussed ex post between the evaluators to reach a unanimous decision. This resulted in 70 articles being accepted (green), 961 articles being rejected (red), and 161 articles (yellow) for a further full text review as the abstracts did not provide clear enough details. The same two evaluators then re-evaluated the yellow cases based on the full texts and evaluated potential mixed decisions. Through these steps, we ended up with 100 articles but during the review we decided to discard a further 15 articles as “false positives” not meeting the criteria leaving the final synthesis sample of 85 articles. At this stage of the research, we analysed the sample by coding the epistemological and ontological stance of each article.
together with methodological choices as well as identified the IOR type, empirical context and application domains, roles of principal and agent, and any supporting theories used. These constructs then formed the conceptual basis for our mid-range theory. The complete list of the full synthesis sample is not presented here due to space constraints but is available from the authors. For the same reason, the articles discussed in the following synthesis section and its four sub-sections are not listed in the reference list since all cited articles belong to the synthesis sample (i.e. treated similarly as data).

**Descriptive statistics of the synthesis sample**

Articles in our sample were clearly divided into empirical and non-empirical papers (44 and 41 papers respectively). Empirical papers predominantly relied on theory testing using quantitative methods, either through surveys (20 papers) or secondary data (17 papers). The sample also included four qualitative case studies, one mixed-methods paper, and two papers combining modelling with empirical methods (an experiment and secondary data analysis). The predominant design in non-empirical papers (as well as in the whole sample) was mathematical modelling (32 papers). We also included 9 review papers which clearly developed agency theory in the specific domain of IORs.

The distribution of articles per discipline varied considerably (economics 10, general management 20, marketing 14, and operations management 41). Operations management dominance is explained by the high number of articles appearing in Management Science, (15 articles in total) which we counted into the OM discipline but which appeared to share more intellectual legacy with the economics discipline. Interestingly, out of 26 journals only 22 appeared in our final sample, mainly due to their non-IOR focus. The distribution of articles per journal is illustrated in Figure 1.

![Figure 1 - Number of articles per journal](image)

**Agency theoretic approach on IORs in the four disciplines**

In the following sub-sections, we will summarize the key themes of each four disciplines.

**Operations management**

Within the operations management sub-set of data, we distinguish between two streams: empirical operations management (discussed in the beginning of this sub-section) and more mathematical modelling-based operations research (discussed in the latter part of the sub-section). The former is in line with positive agency theory used more widely in general management and marketing disciplines while the latter clearly shares intellectual legacy with economic contract theory or principal-agent research.
Overall, as Zu and Kaynak (2012) note, agency theory has so far seen relatively minor use, and its constructs little operationalization in empirical operations management. Within this literature, applications of agency theory seem to be a rather recent phenomenon, with most of the articles published post 2010. The most common research approach is theory testing, with surveys as the dominant method. The research is focused on buyer-supplier relationships as the IOR type, with several application domains. In particular, agency perspective is used to study monitoring issues in supply chains such as in domains of quality management (e.g. Zu and Kaynak, 2012; Handley and Gray, 2016) and risk management (e.g. Shafiq et al. 2017; Hajmohammad and Vachon, 2016; Zsidisin and Ellram, 2003).

However, with the notable exception of Handley and Gray (2016), agency theory is typically not accompanied with a clear articulation of the agency problem studied in the context nor an explanation of how the problem is caused by the opportunism of the supplier (rather than contextual issues). Such omissions may suggest it is used more as a governance mechanism to solve a risk-sharing problem rather than an agency problem in supply chains.

Only very few articles use another named theory to support or complement their analysis, though different streams of OM/SCM literature (e.g. supply risk management, forecast sharing, sustainable supply chain management and quality management) are often discussed extensively in the papers. Perhaps as a result, the contributions of the studies are typically not discussed in relation to agency theory, i.e. how the research enhances our understanding of agency problems and their governance in buyer-supplier relationships, but rather in relation to the operations management issue examined using an agency perspective. Notable exceptions to this are for example Broekhuis and Scholten (2018), who demonstrate that behavioural standards established ex ante the formal contract are important pre-requisites for the appropriate creation and management of said formal contract. Handley and Gray (2013) also note how their findings on the substitute nature of contractual penalties and monitoring are not in line with most of the principal-agent literature. Steinbach et al. (2006) provide potentially the strongest of agency theory critiques in our sample. They argue that in focusing on the ‘flawless principal’ and the ‘malicious agent’, prior contracting research has neglected the customer (principal) behaviour and customer role in outsourced service co-production in relation to outcome-oriented contracting. Finally, Wilhelm et al. (2016) introduce an interesting addition to agency theory in the form of the double agency role of the agent in long supply chains, i.e. “first-tier suppliers will act as agents who fulfil the lead firm’s […] requirements (i.e., the primary agency role) and implement these requirements in their suppliers’ operations (i.e., the secondary agency role)” (p. 42).

Two articles raise power issues as important contingencies in the use of agency-based governance mechanisms in supply chains. Hajmohammad and Vachon (2016) develop a framework that suggests buyer power and dependence on the supplier has an impact on the monitoring mechanisms used for risk management in supply chains, while Wilhelm et al. (2016) note that a powerful buyer enforcing requirements to its lead supplier is at risk of decoupling in relation to the double agency role of the supplier.

Operations research deviates from empirical OM by relying almost exclusively on mathematical modelling. As shown earlier, articles published in Management Science comprise the majority of the articles in our set and nearly all (12 out of 15) of them utilized economic models in general and principal-agent framework in particular as a research design. Similarly, all 8 articles included from Operations Research used modelling as well as 4 out of 6 articles in Production and Operations Management.
Indeed, operations research seems to give slightly more ecological validity to rather generic economist treatment of principal-agent problems (see further discussion in the Economics sub-section). Typically, operations researchers focus on buyer-supplier relationships and are interested in modelling actual supply chain management problems as a principal-agent situation. Supply chain topics include inventory management (e.g., Corbett, 2001; Gilbert & Weng, 1998) technology licensing (Crama et al., 2008), outsourcing of services (Jain et al., 2013; Kalkanci & Erhun, 2012; Kim et al., 2007) and organization of health care services (Fuloria & Zenios, 2001) to mention a few. Another IOR type is franchising involving some empirical work (e.g. Fladmoe-Lindquist & Jacque, 1995; Kosova & Sertsios, 2018).

Many papers utilize the standard economics models of adverse selection and moral hazard. Interestingly, two papers (Jain et al., 2013; Roels et al., 2010) focus on double moral hazard indicating that it is not always the principal who suffers from lack of information concerning the agent’s actions. The agent’s welfare is equally compromised when she does not know the principal’s actions. Roels et al. (2010) emphasize co-production of value in consultancy, where performance of the consultant is significantly affected by the efforts of the client. Finally, some papers claimed to go even beyond the classical economics models and adopt more dynamic modelling in order to build more real-life type of models (e.g., Feng et al., 2015; Fuloria & Zenios, 2003).

**General Management**

Within the general management journals, four types of IORs feature most frequently: franchisor-franchisee relationships (6 articles), buyer-supplier relationships (6 articles), joint ventures / syndicates / partnerships (3 articles), and manufacturer-distributor/retailer relationships (2 articles). These IOR forms are explored in a wide variety of application domains and empirical contexts. These include mergers, where the bidding firm or target firm acts as a principal and the investment bank representing one of these firms in negotiations act as the agent (Kesner et al., 1994); professional service agency, where a client firm hires a professional service organisation (agent) to perform knowledge-intensive tasks (Sharma, 1997; Dawson et al. 2014); partner selection (Meuleman et al., 2010; Obloj & Zemsky, 2015; Ruer & Ragazzino, 2006) and evolution of inter-firm collaborations (Argyres, 1999; Ring & Van De Ven, 1994) such as strategic alliances, partnerships, coalitions, joint ventures, collaborative new product franchises, research consortia, and various forms of network organizations; supply chain risk (Camuffo et al., 2007), performance (Lado et al., 2008), and alignment with firm strategy (Lassar & Kerr, 1996); and franchising (e.g. Combs & Ketchen, 1999; Perryman & Combs, 2012; Combs & Ketchen, 2003; Combs et al., 2004; Shane, 1998a and 1998b).

Two research strategies and associated designs dominate. Theory testing papers use secondary data and more limitedly surveys to test hypotheses. In some cases, secondary data is combined with other sources such as structured interviews (Camuffo et al., 2007) or surveys (Combs & Ketchen 1999). In contrast, theory elaboration papers are largely conceptual and typically present propositions for future testing. Illustrative of this approach are Sharma (1998), who develops a framework and associated propositions outlining four types of restraints to professional service agent opportunism, and Ring and Van De Ven (1994), who focus on the evolution of cooperative IORs. Modelling is used in two theory elaboration papers. For example, Makadok and Coff (2009) seek to model the conditions under which different hybrid governance mechanisms are most suitable, with particular attention on the importance of cross-task synergies as a selection factor. Finally, just one paper in this sub-set adopts a case study research design to examine issues of agency. Argyres (1999) elaborates agency theory, transaction cost economics,
and information processing theory using qualitative interview data from partners involved in the B-2 Stealth Bomber project.

Interestingly, a significant number of studies highlight the limitations of agency theory in explaining various IOR phenomena. For example, Meuleman et al. (2010) note that “given the complexity of partner selection […] a single theory approach may be unsuitable for understanding complex phenomena” (p. 995). This perspective has resulted in many proposing extensions to standard agency perspectives or using supplementary theories to improve explanatory power. For instance (perhaps unsurprisingly), transaction cost economics features alongside agency theory in a number of reviewed studies (e.g. Ring & Van De Ven, 1994; Mahoney, 1992; Argyres, 1999; Lassar & Kerr, 1996; Lado et al., 2008). For example, Lassar and Kerr (1996) combine the two to examine the influence of competitive strategy on the nature of agent controls used by manufacturers within their distribution networks. Ring and Van De Ven (1994) also combine these theories to make propositions on the process of IOR emergence, growth, and dissolution.

In a different direction, Combs and Ketchen (1999, 2003) demonstrate how a resource (capital) scarcity perspective can provide additional explanatory power in firm decisions to expand via franchising as opposed to hierarchy ownership models. In later work, Combs et al. (2004) highlight the limitations of both agency theory and resource scarcity theory in understanding why firm initiate franchising and its performance effects. They argue for greater theoretical diversity through use of upper echelons theory, resource-based theory, and institutional theory in this application domain.

In a professional service context, Sharma (1997) challenges some of the key assumptions of agency theory such as those concerning power asymmetry and the emergence of knowledge asymmetry effects. Sharma draws on ideas from sociology of work in the professions’ literature to propose self-control, community control, bureaucratic control, and client control as important restraints to potential opportunistic behaviour by professional agents. Finally, using secondary data of syndicate collaboration in buyouts, Meuleman et al. (2010) combine agency theory with relational network theory to test hypotheses concerning the boundary conditions to the embeddedness approach to partner selection. They find that, when agency risks are low, relational embeddedness is less critical in partner selection, and that relational embeddedness can be partially substituted for reputational capital.

The use of supporting theories perhaps highlights the relative maturity of the general management discipline in using (positive) agency theory. In effect, as studies have moved away from the more transactional principal-agent relationships, upon which many of the assumptions of agency theory are arguably based, and towards the more cooperative end of the relational spectrum (i.e. towards IORs) that characterise many of the application domains seen in these papers many researchers have appreciated the need to supplement the mainstream theory. And yet, conversely, the sheer variety of additional theories adopted points to a relative lack of maturity, in so much as little consensus exits on how best to deal with the deficiencies of standard agency theory.

**Marketing**

Four IOR types feature in the marketing subset: franchisor-franchisee relationships (6), manufacturer-distributor/retailer relationships (3), manufacturer-supplier relationships (3) and a licensor-licensee relationship (1). The twelve empirical papers are all theory testing papers. Concerning research design, survey (7) and secondary data (5) dominate, with one remaining paper using a non-empirical modelling approach. The final paper in the sub-set is a review paper (Bergen et al., 1992) which is considered a landmark conceptual paper on agency theory in marketing.
The twelve empirical papers cover a diverse set of empirical contexts and application domains with varying definitions of the principal and the agent. Grünhagen et al. (2017) study business format franchising across the US, and define franchisor and franchisee as both principal and agent since both have access to private information (a so-called model of dual agency). The other five empirical papers on franchising define the franchisor as the principal and the franchisee as the agent. Dahlstrom & Nygaard (1994) study the governance modes (franchising vs. corporate owned outlet) in the Norwegian oil industry. Antia et al. (2013, 2017) use court records to study franchise relationships across the US. Kashyap et al. (2012) analyse survey responses and contracts to study franchise relationships in the US automotive industry. Three papers (Celly & Frazier, 1996; Gilliland & Kim, 2014; Israeli et al., 2016) study relationships between manufacturers (as principals) and their downstream channel partners (as agents). In contrast, three papers studying upstream buyer-supplier relations (Heide, 2003; Heide et al., 2017; Stump & Heide, 1996) treat a buyer as a principal and a supplier (i.e. a manufacturer) as an agent. Finally, Jayachandran et al. (2013), study license agreements between US or Canadian firms (as the principals) with their contract partners all over the world (as agents). From these studies, it is interesting to glean that any party in the supply chain can be defined as the principal or the agent. Almost all papers make a choice whether to call the upstream partner in the supply chain the principal or the agent; only Grünhagen et al. (2017), as one of the most recent papers in this subset, uses a model of dual agency.

The majority of papers rely on single-sided data. For studies that measure opportunism this raises the interesting question of who reports on assumed opportunistic behaviour? Similarly, do principals report what governance mechanisms they use, or do agents report what governance mechanisms they experience? Such choices vary per publication. For survey studies, two rely on principals reporting on the governance mechanism they use (Stump & Heide, 1996; Heide, 2003), one study relies on agents reporting on the governance mechanisms they experience (Celly & Frazier, 1996), and three studies rely on agents reporting on their own levels of opportunistic behaviour as well as the governance mechanisms they experienced (Kashyap et al., 2012; Gilliland & Kim, 2014; Heide et al., 2017). Agents reporting on their own opportunism raises potential issues of social desirability bias in the data.

Most papers combine agency theory with other theories or literatures. The most frequently used theory as support is transaction cost economics. Literatures on organizational control, contracting or franchising are also regularly used. Gilliland & Kim (2014) use stewardship theory on equal footing with agency theory to build hypotheses about how agents perceive incentives, and to add non-traditional governance mechanisms to their conceptual model. The authors suggest that a reseller may simultaneously play the roles of both steward and agent.

A number of interesting contributions to “traditional” conceptualizations were found. First, Celly et al. (1996) note that unlike for intra-organizational principal-agent relationships, formal authority relationships are not nearly as strong between independent organizations, making monitoring and evaluating distributor behaviours and specifying desirable behaviours relatively difficult. Stump & Heide (1996) present a non-traditional type of incentive. Whereas incentives are generally thought of as rewards from the principal to the agent, they operationalize incentives as specific investments made by the supplier that function as a hostage. Heide (2003) formalizes and tests “plural governance” (i.e. make and buy as simultaneous sourcing options) as a governance mechanism in a principal-agent relationship. Heide et al. (2007) add another governance mechanism: microlevel social contracts, i.e. informal agreements between parties on either output of behaviours. Antia et al. (2017) propose qualification (of suppliers, franchisees) as an ex
ante governance mechanism, as do Stump & Heide (1996). Moreover, Antia et al. (2017) also propose socialization as an ex post governance mechanism, although the bankruptcy-reducing effect of socialization in franchising relationships appeared weak in their study.

Kashyap et al. (2012) propose two additions to agency theory: first, that monitoring should be separated from enforcement (as discovered deviances do not always lead to enforcement), and second, that compliance should be separated from opportunism as “[f]ranchisees may fail to comply for a variety of reasons, such as a lack of resources, a poor understanding of the desired behavior, or a belief that the particular obligation is not appropriate to the local operating conditions” (p265). Both Jayachandran et al. (2013) and Grünhagen et al. (2017) discuss “dual agency”, with risk of pre-contractual and post-contractual opportunism on both sides and agency costs on both sides. Finally, various papers emphasize the effect of legal and regulatory context on governance decisions (Antia et al., 2013; Jayachandran et al., 2013; Grünhagen et al., 2017).

Economics

We use the term contract theory to describe this specific branch of information economics focusing on principal-agent relations. As with economics in general, contract theory is purely based on mathematical modelling. However, it is not just the notation and design which distinguishes contract theory from the positivist approach dominating management research – there are also differences in the key theoretical focus areas. The positivist stream focuses on different formal and informal governance mechanisms to curb opportunism. It seems surprising that contract theory actually pays rather limited attention to opportunism per se and simply emphasizes the value of information. In the economists’ world, every social actor is a self-interested utility maximiser but not a single economics paper in our sample explicitly mentions opportunism or self-interest with guile (Williamson, 1985). In addition, no paper focuses on any other governance mechanism than a contract between the parties. To contract theorists, a contract does not equal a legal contract but instead can be seen as a game between two or more players (i.e. principal[s] and agent[s]), which defines their action structure.

Hence, from an economist’s perspective the aim is to optimize (or minimize) the compensation that the principal pays to the agent while simultaneously ensuring the agent’s highest possible level of effort. Actual payment schemes (i.e. game structures) may vary substantially in terms such as duration (short-term vs. long-term, see e.g. Hart & Tirole, 1988), the contract menus offered to an agent (e.g. fixed-price vs. fixed price cost reimbursement, Rogerson, 2003) as well as opportunities to renegotiate (Gagnepain et al., 2013). Therefore, the models very quickly become extremely complicated mathematical optimization problems. Arguably, too complicated which is why Rogerson (2003) in his classic paper argues that simple contract menus can attain three quarters of gains achievable by the fully optimal complex menu.

Contract theorists are therefore not deeply interested in whether an agent is opportunistic but simply focus on minimizing information rent which the principal needs to yield up to the agent while not knowing the agent’s type ex ante (i.e. an adverse selection model) or not being able to monitor her actual effort ex post (i.e. a moral hazard model). Hence, it is relevant to consider possible goal incongruence (or reasons behind it) since incongruence always exists when the agent’s compensation does not equal the principal’s welfare. Such generic information-focused approach has its benefits. For instance, the difference between an adverse selection and a moral hazard problem is simply timing (i.e. the game structure). In adverse selection, the agent possess private information about her intended effort level before the principal offers the contract and in a moral hazard model the agent’s private information about her induced effort becomes
valuable after signing the contract (Lewis & Bajari, 2014). Naturally, the solutions to these problems differ since finding the optimal solution (i.e. equilibrium) depends on the game structure. Another clear benefit is that contract theory is indifferent who is the principal and who is the agent since the agent is always the one who possesses private information. Therefore, as our sample shows, the principal can be the buyer not knowing the intended effort of its suppliers (Arve & Martimort, 2016) but also the supplier not knowing the demand of the buyer (Kalkanci & Erhun, 2012).

Unfortunately, this is also the clear limitation of the highly generic treatment of the problem since the economic theory of agency becomes nearly indifferent to the actual type of the social actors (e.g. individual vs. organization), which may lead to loss of ecological validity since the specific context of IORs affects the very nature of information and its communication between parties. Therefore, for our IOR focused purpose the most relevant articles in this sub-set are the econometric papers, which were unfortunately a clear minority in our sample (3 out of 10 articles). These papers provide slightly more empirically sound notions such as that renegotiation improves commitment of agents in outsourcing public transport services (Gagnepain et al., 2013), the role of deadlines as governance mechanisms in procurement of highway projects (Lewis & Bajari., 2014) and the importance of the financial health of agent to the welfare of the principal (Fan et al., 2017). Despite their importance, these papers still adopt relatively partial perspective, in favour of the principal, and do not treat IORs as collaborative structures providing benefits to both parties.

The final clear challenge of contract theory towards ecological validity is that it very often assumes that the agent knows her type (e.g. cost structure to undertake the principal’s desired effort) before accepting the contract (in adverse selection models) or learns it while the game progresses (moral hazard models). Crémer and Khalil (1992) provide an important exception by focusing on cost of gathering information. However, they conclude that the high cost of acquisition of information ex ante for the agent is always more feasible to the principal since it decreases information asymmetry and thus information rents given to the agent. In real life this sound bizarre since it would mean that the principal should favour agents who do not know their cost structures potentially leading to disastrous outcomes and even bankruptcy of the agent!

**Concluding remarks**

Based on our review, information asymmetry appears to be the key concept and common denominator between the disciplines forming a basis for IOR agency problems. As collaborative structures between two organizations with mutual interests, IORs are in fact set up to gain access to specific information or knowledge (Barringer & Harrison, 2000) i.e. to decrease information asymmetry between two organizations for example by engaging into collaborative practices or forming a joint venture or other cooperative structures (Parmigiani & River-Santos, 2012). However, we accept the notion that whilst IORs decrease information asymmetry when compared to purely transactional relations, there will always exist residual information asymmetry in IORs, which is contingent to various factors and can still cause agency problems. For instance, the type of IOR affects the extent to which information asymmetry may realistically be lowered. In franchising for example, the principal (franchisor) may have direct access to inventory and sales data of the agent (franchisee), while in collaborative buyer-supplier relationships these may still be private information of the two parties who may share information in other fronts (e.g. technical specifications, process control etc.). In similar vein, joint ventures may be particularly effective in decreasing information asymmetry, as both organizations have legal decision-making right and access to confidential information of the jointly owned
company/operation. Naturally, there also exists variation within each IOR category, when two organizations engage into collaboration and develop more situated practices and governance mechanisms to coordinate their interaction.

The assumption remaining contested between the four fields is the assumption on self-interested or even opportunistic behaviour of the principal and the agent. For economists, self-interest of economic actors is “just” a standard assumption not the core focus. Instead, empirical operations management strongly emphasizes opportunism (self-interest with guile) and has focused on finding the best remedies to extirpate it. Interestingly, general management has taken a leap (and marketing is following the lead) towards repairing and expanding the assumptions of agency theory by incorporating thoughts from other theories. Such an approach has its virtues but may also lead to too strong theoretical pluralism compromising the parsimonious ideal of agency theory.

Based on our review, we conclude that agency theory can be a viable lens to IORs but is not sufficient to fully explain the complex nature of IORs. Instead, it is at its best explaining the problems arising from (residual) information asymmetry between the two parties. The clear room for further elaboration lies in the adoption of more equal stance taking into account two-way information asymmetry (e.g. double moral hazard/dual agency) as well as empirically more fine-grained explanations behind information asymmetries (e.g. failure in communicating vs. deliberately concealing information). We argue that developing these ideas further will take us closer to a mid-range theory of agency in IORs, which should be the focus of future work.

Abstract

The present research investigates the relevance of the relational view enablers and barriers in temporal supply chain contexts. Applying a multiple case study approach situated in industrial projects environment in Italy, this paper develops a relational framework for supplier horizontal collaboration. The findings reveal that, in temporal contexts, the most adopted enabler to co-generate competitive advantage is investing in partnership-exclusive assets whilst other enablers have less importance. Asset interconnectedness and resource indivisibility are two barriers found to be insignificant to co-generation of competitive advantage in temporal contexts, whilst partner scarcity and governance institutional environment can greatly deter horizontal collaboration efforts.

Keywords: Supply Chain Collaboration, Relational View, Temporal Contexts

Introduction

Supply chain collaboration is established in literature as an enabler of value co-creation that couldn’t be otherwise generated (Lamming, 1993; Simatupang and Sridharan, 2002). Collaboration in a supply chain setting comes in different forms, among which; trust, information sharing, managing change, joint conflict resolution and forming joint cross-functional teams (Barratt, 2004). As such, the main challenge becomes how to alienate organisational boundaries between different supply chain actors to enable sharing of risks and benefits so as to enhance the incentives of collaboration (Frohlich and Westbrook, 2001). Successful collaborative initiatives between supply chains members could lead to sustained differentiated performance, yet inter-firm collaboration often fails due to
misalignment of incentives and strategies (Fawcett et al., 2008). Collaboration can be vertical (i.e., across the members of the same supply chain), horizontal (between the members who provide similar activity in the supply chain or competitors) or lateral (Barratt, 2004).

Collaboration has been addressed in supply chain literature using a number of theoretical lenses; as a dynamic capability that needs competence development using the resources based view, as a property of the network and the relationship using the relational view (Fawcett et al., 2012). The relational view (RV) (Dyer and Singh, 1998) provides beneficial insights on co-generation of competitive advantage among different actors in networked environments, in which the unit of analysis is the relationship rather than an individual firm. The central theory of RV suggests that performance could be bolstered through the exploitation of resources that belong to the inter-organisational relationships. Such supernormal profit is jointly generated and becomes a property of the relationship (Dyer and Singh, 1998).

Such theoretical perspective is usually adopted and examined in alliances and long-term vertical inter-organisational relationships, little is known on its appropriateness to temporal contexts (Sabri et al., 2017). Whilst literature has explored supply chain vertical collaboration in continuous transactional supply chain relationships, however, establishing horizontal collaborations in temporal contexts, such as projects environment, is yet an unexplored topic that needs further research. Projects environment usually involves a large number of suppliers and a general contractor where contractors often squeeze suppliers to get lowest prices (Sabri et al., 2017). The situation for these suppliers becomes more challenging in countries like Italy, the second exporter of such products to industrial projects after China, where many of the suppliers are small and medium (SME) and often family owned. The context of this research is supply chain in industrial projects environment, where firms form a temporary networked organisation dealing with non-repetitive activities (Turner and Muller, 2003) with high complexity and uncertainty (Fearne and Fowler, 2006) due to supply chain fragmentation and rivalry.

To this end, this research investigates the readiness of small and medium suppliers to establish horizontal collaboration in the energy projects’ sector in Italy. The present research examines the level of horizontal supply chain collaboration by reflecting on the four mechanisms and four challenges of RV. This study contributes to supply chain literature by testing and reporting on the applicability of the RV in a rarely explored context.

**Supply Chain Horizontal Collaboration in Temporal Contexts**

Supply Chain Collaboration is defined as “the ability to work across organizational boundaries to build and manage unique value-adding processes to better meet customer needs” (Fawcett et al., 2008; p.93). That entails establishing high levels of openness and trust, where firms can co-develop sustainable competitive advantages, achieve scale of economies, process improvements, information and risk sharing (Soosay et al., 2008; Walker et al., 2013). Projects require multiple resources and are composed of many activities performed by a temporary coalition of firms; each one with a well-defined role (design, engineering, procurement, manufacturing, assembly, commissioning and decommissioning) (Hicks et al., 2000). Projects are non-repetitive and have limited time extension, which are reasons for a strong focus on time and costs. Large complex project environments is characterised by iterative flows in transitory networks where main actors are customers, consultants, contractors and suppliers (Gosling and Naim, 2009; Pryke, 2009). In projects environment, to determine if a relationship is worthy of the time and
resources needed to fully develop into a partnership, it’s advisable to rely on a structured multi-criteria partner selection (Eriksson, 2015), that also considers the features of the projects portfolio.

Considering all involved actors as a single entity, supply chain horizontal collaboration can be a tool to break the isolation of small suppliers, overcome dynamic market challenges, pursue technological innovation and face global competition (Gnyawali and Park, 2009; Kumar and Singh, 2017). SME suppliers adopt customer-oriented strategies to meet customers’ needs (Kumar et al., 2014), but they are usually in an unfavourable position against bigger competitors. They suffer many market pressures, deal with resources and organizational constraints, and are strongly exposed to market risks (Kumar and Singh, 2017) and may face difficulties in getting certified and appear on customers’ vendors lists. In such context horizontal collaboration could be beneficial, leading to a development of suppliers (Simatupang and Sridharan, 2002).

The Relational View

It is well established in literature that a firm’s critical resources and capabilities may go far beyond their boundaries. Dyer and Singh developed the Relational View (RV), focusing on the relationship/network routines and processes as an important unit of analysis. According to RV, firms can establish idiosyncratic inter-firm linkages, making relation-specific investments and combining resources in unique ways, co-generating competitive advantage by collaboration (Dyer, 1996a; Dyer and Singh, 1998). In contrast to the resources-based view of the firm, the resources and capabilities in the relational view become a property of a network of interconnected firms (Dyer and Singh, 1998), hence beyond the control of, and can’t be duplicated by, an individual firm. They identify four enablers and four barriers for co-generation of competitive advantage through collaboration. First, Enablers. These are the mechanisms if jointly-leveraged on by partners, can lead to generate sustainable competitive advantages:

*Exchange and investment in partnership-exclusive assets;* these can be physical, human or site specific assets. Specialized assets represent a conjunction between partners’ assets that is fundamental for collaboration purposes (Amit and Shoemaker, 1993). Length of safeguards, volume of transactions and trust influence partners’ decision to joint invest (Dyer and Singh, 1998; Walker et al., 2013)

*Knowledge and information sharing that boosts joint-learning* helps partners in cogenenerating new ideas and innovating (Dyer and Singh, 1998). Establishing inter-firm knowledge-sharing routines facilitates transferring, recombining or creating specialized knowledge (Grant, 1996). But firms need also absorptive capacity, “the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends” (Cohen and Levinthal, 1990, p.128).

*Combining of scarce resources and capabilities results in joint creation of unique new products, services and technologies,* but also in economies of scale/scope thanks to inter-firm procurement procedures or reduced bureaucracy (Walker et al, 2013). Generally, firms can share equipment, facilities, warehouses and know-how resources. The greater is resources complementary, the greater are the synergistic effects coming from their combination (Dyer and Singh, 1998).

*Governance mechanisms* that yield to lower transactional costs generates relational rents improving efficiency and influencing the willingness to engage in value-creation initiatives (Dyer and Singh, 1998; Walker et al., 2013). Dyer and Singh (1998) identified three types of agreement that can be enforced by third parties or not, if not, they can be
formal or informal. The latter are the most effective and least costly safeguards but require
time and trust to be established.

Second, Barriers to co-generation of competitive advantage are the challenges
towards relational rents development, or isolating mechanisms:

Inter-firm asset interconnectedness is based on cumulative bundles of joint investment
decisions, where initial partnership-specific investments put premises for future ones that
wouldn’t be profitable alone (Dyer and Singh, 1998). Bundles creation represent a barrier
because it requires much time and money, and growing interdependence is difficult to
manage (Touboullic and Walker, 2015).

Partner scarcity may lie in the easiness of finding a partner or partner willingness and
collaboration experiences (Dyer and Singh, 1998). It may be necessary to find partners
having local market knowledge, contacts and a widespread distribution network to entry
foreign markets (Dyer and Singh, 1998).

Resources Indivisibility, Idiosyncratic combination and coevolution of resources and
capabilities lead over time to resource indivisibility; making resources and capabilities
increasingly hard to imitate. This leads to loss of flexibility, difficulty in redeploying
resources and loss of control over resources and capabilities (Dyer and Singh, 1998).

Institutional environment may obstruct cooperation and raise transaction costs (Walker
et al., 2013). Matters influencing relational rents go far beyond firm boundaries,
expanding to a broader, country level (Dyer and Singh, 1998). Main barriers in an
institutional environment can be legal, organizational and country-specific (cultural)
restrictions, since geographically dispersed firms may have different legislations,
cultures, conflicting local politics and different priorities (Walker et al., 2013).

Methodology

The literature search was performed using Scopus and Science Direct databases. To avoid
the fragmentation in supply chain collaboration literature, we used the following keyword
combinations to capture all relevant studies; “supply chain*” AND “collaborati*” OR
collaboration”, “lateral collaboration”, “inter-organizational”. The final pool of selected
papers was selected following a two-steps approach. First, the search results were
narrowed down by performing a preliminary qualitative content analysis of abstracts.
Second, the contents of the selected papers have then been analysed and classified to find
common topics and properly conduct literature review.

The empirical settings of this research is a multiple case study methodology; with its
focus on contextualisation (Yin, 2014), it becomes best suited to address the objectives
of this research. The respondents are managers of 14 suppliers of valves and boilers.
This supply network is located in Lombardia region northern Italy, and is composed of
mostly SME suppliers for the energy projects sector. The motivation behind this
selection is in the high competitiveness and temporality of this supply base.

Semi-structured interviews are applied to collect data, we developed a questionnaire
with 36 mixed queries (open/closed ended, and 5-point Likert scale questions). The
questions have been devised to cover the RV concepts, enablers and barriers, as well as
firms’ characteristics and their approach to the market. In particular, we carefully
designed the questionnaire to address the four RV mechanisms and four barriers above-
outlined in the literature review section.

Interviews were audio recorded and then transcribed. Thematic coding analysis was
performed, in which the responses are coded, aggregated and reorganized in themes in
order to obtain significant information to explain the overall collaborative phenomena (or lack of it), considering potential trends and correlations.

**Findings**

*Supply Chain Management in Temporal Contexts: Projects Environment in Italy*

When a project owner (i.e., end-user) decides to develop a new project, they prepare a call for tenders, and contractor offering the best solution/price trade-off wins the bid. Contractor breaks the project into several activities and identifies the needed products and/or services. Together with the project owner, the contractor defines vendor lists for each category to approve qualified suppliers. In this context “*Qualification is a very complex process*” for suppliers, but fundamental to participate in tenders. Qualified suppliers can participate tendering to access the short vendor list. In this phase it is impossible to collaborate as a manager notes “[contractors] put suppliers against each other”. The main discriminant is price, but local content and presence in relevant markets contribute in defining a supplier’s tendering score. Italian suppliers are considered leaders in supplying high-quality components and products for the construction of extraction platforms, pipelines, refineries, and others. Since technology is in a mature phase, the few innovations occur mostly on material. Small and medium suppliers need contractors to outreach larger markets, to win the bid, suppliers need to obtain certifications required by contractors. As a result of the global financial crisis, fluctuating oil prices, and changing global economic/geopolitical relationships, with strong repercussions on oil&gas (O&G) sector. Profit margins along the supply chain are reduced, facilitating the entry of suppliers from lower-cost countries. To overcome such situation, a group of suppliers started to foster lighter versions of collaborations, as one manager notes “[we] developed a network of firms specialized in different O&G sector activities” (e.g., painting, welding, heat treatment). Moreover, a new big challenge for Italian suppliers in this context is the local content clauses in project contracts “Local content will be a strategic discriminating factor for O&G supplies over the next 15-20 years”. Governments, especially in Middle East, want that contractors buy locally rather than importing from Europe. This leads suppliers to change their ‘business as usual’ approach and to initiate collaborations with local partners, both suppliers and agents, yet they “cannot open their own facilities everywhere”.

*Supply Chain Collaboration in Temporal Contexts*

The findings reveal that horizontal supplier collaboration, in projects environment, is heterogeneous. The strongest, most collaborative relationships are maintained with lower-tier suppliers. Among the different Italian lower-tier suppliers there are ongoing informal relationships from many years that allowed to simplify communication, reduce transaction costs, lead time and from time to time make innovations. These are tacit collaborations, without written rules, and often there are no common strategies or goals. Anyway, it’s fundamental to keep doors open to everyone, since contractors may impose other supply chain participants, and this translates in many one-time collaborations. Among competitors delivering the same product/service range, there is little evidence of horizontal collaboration, as one respondent notes “You cannot [fight] every day your competitors and then make the agreement”; even if sometimes contractors push suppliers to work together. Yet not all contractors will be happy having horizontal collaboration in their supply base “contractors understand if there are any set-ups”, as collaborations and mergers threaten competitiveness and may increase final costs endured by contractors. Further, several Italian suppliers tried horizontal collaboration with competitors
“horizontal expansion of multinational groups through acquisitions pushes Italian suppliers towards collaboration with adjacent suppliers”, but rarely with success. The major obstacle is probably a cultural barrier, since they are territorial of their know-how.

There are few interesting collaborations between complementary products suppliers, such as valves and actuators, boilers and gas turbines. These collaborations may occur to enhance competitiveness of the offering “to offer packages technically and commercially competitive for customers”. In this case, supply chain collaboration can help expanding the product portfolio or to approach markets requiring local content. Hence, few long-term horizontal collaborations between complementary products suppliers diffused over time. With local agents or service providers there is horizontal collaboration since it’s often mandatory to have local partners in foreign countries in order to properly serve local customers and meet local content requirements. These can be local agents, distributors or other service providers and actors that, when required, may also help in having local content production. Most of these agents provide commission-based commercial services. They can represent different suppliers, but not competitors (i.e. those proving the same product/service range). Local agents and distributors often provide technical support, assistance, installation and maintenance in reference countries. It’s impossible to have facilities everywhere, so manufacturers tend to use existing local agents/partners’ structures without major investments.

With contractors there is little evidence on establishing collaboration. Respondents agree that having long-term relationships with contractors isn’t feasible, because the contractor’s priority is to have competition in vendor lists to lower prices and maximize profit. Hence, suppliers become defensive to protect their know-how, but sometimes cooperate with them to engineer alternative solutions, solve technical problems and properly deliver the project.

With end-users there may be good relationships that however can be considered more as marketing strategies rather than collaborations. Tailor-made strategies are necessary to establish exclusive long-term relationships, but “it’s difficult to have written contracts where end-users commit to buy a certain amount”. Some manufacturers have regular meetings with end-users, and larger ones may also have dedicated staff “to few trusted end-users”. They may also decide to invest abroad to fulfill local content requirements or to be more responsive towards important end-users. Overall, tendency to have informal approaches, making themselves flexible and available, isn’t collaboration but marketing strategy, because there aren’t joint objectives.

Discussion
In this section we analyse the findings using the RV theoretical lens, to understand which enablers and/or are most relevant in temporal contexts.

Enablers of Competitive Advantage Co-generation in Temporal Contexts
As depicted in Figure1. Six suppliers out of the 14 have invested in partnership-exclusive assets. Several of them would like to invest in site-specific assets, mainly for the localization of production facilities abroad. These investments are usually undertaken with local partners in order to offer local content production. And many of the investments in equipment and tools or human resources are needed to complement such investments in production facilities abroad. Italian suppliers share knowledge and information on an occasional basis rather than implementing structured mechanisms and routines. Further, respondents perceive the combination of scarce resources and capabilities doesn’t lead to value cogeneration. Sharing of facilities, warehouses,
equipment and tools, of course, occur as a consequence of investments in partnership-exclusive assets. While know-how sharing occurs in the ways previously described. Hence, *exchange and investment in partnership-exclusive assets* for geographical approximation is found to be the most adopted enabler to gain a competitive advantage against competitors. Italian suppliers often use this tactic when they want to target a particular foreign market and find they have to collaborate with a partner to penetrate the market (e.g. competitor, complementary products’ Italian manufacturer, local supplier or agent), which leads to enhancing competitive advantage. There is a tendency to include a percentage of local content in many developing countries, further, suppliers who have local facilities are in an advantaged position in tenders.

Italian suppliers need to carefully weigh opportunities to understand which countries are most beneficial, where contractors can guarantee higher revenues prospects. If a supplier has high sales levels with a contractor or in a specific country, this encourages the adoption of partnership-exclusive assets with local commercial agents or branches; which can even be extended to owning spare parts warehouses and provide prompt assistance and maintenance services. At this point, the wisest move is to co-invest locally together with current local partners (e.g. commercial agents, suppliers) or complementary products’ manufacturers, to offer contractors and project owners a wider product portfolio.

Italian suppliers prefer to avoid investments in tangible assets (e.g., equipment and tools), leasing the burden to local partners and only sharing know-how strictly necessary to collaborate. This situation inevitably doesn’t enhance the availability of scarce resources or capabilities needed to collaborate in a given project. In particular, Italian suppliers share part of technical know-how (which they are very reluctant to share) to train local employees, while local partners support by sharing their commercial know-how. This, over time, leads to a human asset specificity increase without monetary investments. Usually, however, no routines are defined for knowledge and information sharing that boosts joint-learning. This is because Italian suppliers are reluctant to share their know-how, and try to only share essential layers of information without delving deeper and usually on occasional basis.

There are no particular governance mechanisms that can be used to effectively protect partners against possible opportunistic behaviours. The respondents perceived contracts as less protective to all involved partners, indeed contracts can be formalized fairly, without placing too many constraints on partners. When suppliers decide to collaborate with a partner in Italy, instead, the exchange and investment in partnership-exclusive assets don’t appear particularly effective. Co-investment in partnership-specific equipment and tools with suppliers can reduce outsourced processes’ costs, but there aren’t many examples of co-investments in such physical assets. With some suppliers there is high human asset specificity, which isn’t the result of monetary investments, but of a long series of interactions that took place for many years between Italian firms. This led to the development of the precious know-how of Italian manufacturers and firms working closely to them. However, neither in this case there are real structured mechanisms for knowledge and information sharing that boosts joint-learning. Rather, there are several examples of occasional know-how sharing among Italian actors.

*Barriers to Competitive Advantage Co-generation in Temporal Contexts*

Respondents weren’t particularly concerned about barriers like asset interconnectedness or resource indivisibility. Certainly, creating cumulative bundles of joint investment decisions in some countries may be difficult for legal or bureaucratic issues, while sharing resources may result in loss of flexibility due to long-term collaboration; but Italian
suppliers think these are situations still manageable and not really problematic. This also could be because their collaborations are still in its infancy, so they haven’t reached critical levels of asset-interconnectedness or resources indivisibility.

As depicted in Figure 2. Partner scarcity has instead turned out being a real barrier. In Italy, apparently there are few possibilities to find new partners, because Italian firms have known each other for decades, relationships are informal and well established, and newcomers are rare or unwelcomed. Abroad, instead, candidate partners abound, but suitable candidates are scarce, for different reasons; i) they offer lower quality products/services, ii) inconsistency of their leadership and business culture, collaboration usually stems from the will of few people in the firm, who, if they trust each other and agree, can lay the foundations for future collaboration development. iii) cultural barriers, as italian suppliers often find it difficult to trust foreign partners, and iv) unwillingness of SME suppliers, especially those who still a family business, as they prefer to remain small and flexible, without ceding part of their decision-making power.

Another great barrier is represented by restrictions imposed by institutional environment. There are legal restrictions mainly linked to the presence of local content requirements and embargoes in some countries, which are induced by political restrictions. There are legal restrictions from competition point of view, not so much because of possible antitrust authorities’ interventions, but because of contrast actions that contractors can undertake to punish and hinder horizontal collaboration among the competitors in their supply base. Furthermore, there may be patent issues, or various specific restrictions in different countries.

The Competitiveness of SME Suppliers in Temporal Contexts

Whenever an opportunity arises for cogeneration of innovation, or when there is need to solve any problem to satisfy a customer, Italian suppliers don’t hesitate to consult Italian universities or lower-tiers suppliers of materials, components and outsourced processes. These, however, are occasional technical discussions, which do not follow well-defined procedures and are possible only between firms having good relationships for a long time. The real enabler that guarantees shared competitive advantages to these Italian SME suppliers is represented by governance mechanisms managing their relationships. Indeed, the high level of trust, respect and mutual esteem present between many Italian firms, as well as the string of inter-firm relationships that characterized their history, have led to an informal management of relationships between manufacturers and suppliers of different tiers. This constitutes an enormous competitive advantage which, in addition to a transaction costs reduction, allows continuous improvement, albeit marginal, of Italian firms’ know-how. Among Italian SME suppliers, however, there are still cultural barriers that must be demolished to collaborate, but there is a noticeable change with new generations of the families are becoming in charge.

Further, there are some organisational challenges, for example it’s very challenging for SME suppliers, who have extremely flexible management, to collaborate with multinationals, who can be rigid and bureaucratic. Moreover, there may also be organizational restrictions induced by cultural differences existing between Italian and foreigner firms, precisely at the level of conception of the way of working itself. In a global market, such as the O&G, it is assumed that firms shall deal daily with various political and cultural restrictions. So, no matter how much obstructing these restrictions could be, Italian SME suppliers have learned to develop capabilities to manage them. On the national dimensions, respondents perceive significant cultural restrictions in Italy. These are mainly given by Italian SMEs’ strong entrepreneurial spirit. Many Italian SME suppliers still have a family ownership managing the business in more of an ‘emotional way’, which leads to avoiding collaboration all together. This to avoid sharing their know-how and leaving part of decision-making power they have on their firm. On the contrary, managers usually manage firms in a more detached and impartial way.

Conclusion

Italian SME suppliers for the energy projects suffer market pressures, and have to deal with constraints pertaining to resource availability and their maturing organisational settings. They are exposed to market risks and face difficulties in the qualification process or in appearing on the preferred vendors list.

The present research investigates the appropriateness of applying the relational view in such temporal projects contexts, with a focus on horizontal collaborative activities. The findings reveal that Relational View theory can be applicable in temporal contexts, but within certain limits. Thus we propose extend the applicability of the relational view to temporal environments by considering the context of the business and market environment. The complete lack of collaboration leads to suggest that RV theory becomes less effective as we move away from the ideal context for which it was designed (e.g., long-lasting alliances).

This study makes several contributions to supply chain theory and practice. First, to the authors’ knowledge, this is one of the first studies to empirically investigate the appropriateness of the RV theoretical perspective in a temporal supply chain context. Such investigation helps identifying which mechanisms to leverage on, and how to be better prepared to the challenges of supply chain collaboration.
The findings guide supply chain managers on how to exploit the benefits of horizontal collaboration to avoid SME suppliers isolation, and overcome dynamic market challenges. Several topics for future research are identified. One main avenue to consider is a cross-case analysis for supply base of private projects versus those of governmental projects, where the relationship dynamics can significantly vary. Another avenue for future research is to complement this study by analysis through the Resource Based View lens. By doing so, it would be possible to understand if there is a correlation between private resources of partners and their ability to collaborate sharing such resources to co-generate value. As such, it would be possible to identify the most important resources to be owned or researched in partners, to successfully establish collaboration.

Abstract

The main objective of this study is investigate how the new model of coffee trade, known as Direct Trade Coffee has increased worldwide and how it has changed the supply chain in coffee trade. Through interviews by multiple-case method, the agents of supply chain coffee as producers, roasters and cafeterias demonstrated your perceptions in trade production, distribution and selling specialty coffee. The Transition Cost theory was used to understand how large the asymmetric information, opportunism and limited rationality impacts the supply chain value overall. This study is value to support the understanding of short and more fair coffee negotiate.

Keywords: Supply Chain; Direct Trade Coffee; International Trade

Introduction

In an increasingly dynamic and integrated economy, which information is constantly permeability in the agro-industry sectors, the informational symmetry and economic development of both producers and roasters are put in the agenda, requiring a rational and behavioral analysis of their agents. Factors such as negotiation, contracts and mutual relationship between sellers and buyers, begin to reconfigure the coffee production chain, peculiarly the specialty coffees (special or gourmet ones).
This article aims to demonstrate the new trend that has grown worldwide in the supply chain of specialty coffee market known as Direct Trade. This new model aims not only to shorten the supply chain’s coffee, but also seeks to increase the relationships between the agents since the coffee producer to the final consumer changing, in this way, the traditional supply chain’s coffee. Although studies about Direct Trade in coffee agribusiness have grown in the last decades, especially in the last few years linked to research on the Third Wave of Coffee, which is focused on specialty coffees, there are still, few studies that try to understand the supply chain of Direct Trade at coffee trade as a whole.

Therefore, this article sought to deepen an understanding the impression of this theme through face-to-face interviews with the agents involved in the coffee supply chain as producer and roasters and/or cafeterias in Brazil and abroad. It was evident through this research that Direct Trade is a trend in the specialty coffee market, but its similarity with the principles of coffee certification and requires further studies would be developed to consolidate the shortening of the coffee supply chain and optimize the aggregation of value of all links in the coffee chain.

**Literature Review**

*Theoretical Background*

Global coffee consumption has increased considerably in recent years. Brazil is the largest producer of coffee in the world and the second in consumption. A range of coffee varieties arises dynamically, requiring the coffee sector methods and actions aimed not only at increasing production but also at analysing the impacts these increases have on the environment, people and the economy (Silva, 2006).

The coffee certifications as FairTrade, UTZ Certified, RainForest Alliance Certified appear with the objective to certifying producers that, throughout the production, have to fulfil environmental and social standards, characterizing to be a specialty coffee, although this is not an affirmative condition that they will be able to obtain a quality coffee (Pinheiro, Nagai, 2014).

On the other hand, the demand for specialty coffees has altered the dynamics of the global market, as buyers are investing directly in coffee growers, taking risk instead of facing future market price volatility. Certified coffees have been a trend in recent decades and the causes of their growth are the benefits that certifications bring. High prices paid to coffee growers, openings to new markets, maximization of production longevity and valorization of labor routines are the “flagship” of Certifications (Guimaraes, 2016).

In order to optimize the process between growers and roasters, a new model of coffee bargaining arises, with the objective of paying a "real fair price" to the coffee grower in the acquisition of a higher quality coffee. Direct Trade is a business model that aims at a direct trade relationship between the coffee grower and / or roasters, eliminating the so-called "negotiators", reducing operating costs and retaining the coffee farmer to the buyer (Counterculture Coffee, 2015).

Thus, in the coffee market, paradoxically, there is a great demand for the consumption of specialty coffees, but the supply of quality grains which are produced in a sustainable manner is below the conventional market, despite its consumption of rapid growth, especially in developed countries.

*The Waves Coffee*

Direct Trade is most faced to specialty(and gourmet) coffees and also, presents in part, as an extension of coffee certification as FairTrade, RainForest and UTZ Certified, etc. but
works in a short supply chain and more direct relationship between agents, as it is concerned with offering superior quality coffees, unique and exclusive, with the characteristic soft drink with high added value, with ‘traceability’ and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization local infrastructure and the community as a whole, with school construction, support for workers, empowerment of coffee growers, gender equality, among other actions that make up the premises of certifications. To clarify further the results, Borrella, Mataix and Carrasco-Gallego (2015) and Guimarães (2016), explain the Waves Coffee.

The first wave of coffee is attributed to the expressive increase and worldwide dissemination of beverage consumption, especially in the late nineteenth and early twentieth centuries. More specifically in the United States of America, this movement gained momentum with the Great Depression and World War II, requiring minimal time and effort in its preparation. (Reis, 2018; Guimarães, 2016).

The second wave arises when, introducing the new concepts of roasting, in order to reach certain beverage profiles and the consistency of the supply, as well as new notions of origin, recognizing that this, at country level, influenced the quality and some characteristics of the grains (Andrade et al., 2015; Guimarães, 2016).

The third wave appeared in the mid-90s, when only specialty coffees and grains of the Arabica species were used, as well as the vaporization of its numerous aromatic and flavor notes, highly influenced by its origin of production, Thus, coffee goes through a process of total “decommoditization”, being considered as a complex, exclusive and seasonal product and compared to other specialty products (Reis, 2018).

The Direct Trade as the State of the Art of Supply Chain Coffee

The traditional Supply Chain Management (SCM) has many agents which are linked each other in the whole chain. Mentzer et al. (2001), infers that SCM can be understand as “the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole” Mentzer et al. (2001).

Overview of Supply Chain

SUPPLIER ↔ INTERMEDIARY ↔ ORGANIZATION ↔ CUSTOMER

Figure 1 – The Supply Chain – Mentzer et al (2001), adapted.

Below, the figure 1 shows the complexity of SCM as a pipeline, proposed by Mentzer (2001). At this model it is clear that there are innumerable intermediary agents and in the coffee chain it is not different, being these intermediaries: cooperatives, associations, brokers, exporters, roasters and coffee shops.
Severins (2015) infers that the traditional supply chain of coffee typically contains seven levels: growing, harvesting, hulling, drying and packing, bulking, blending and roasting. The entire SCM coffee is further extended by several intermediaries, including global transporters as well as exporters and retailers.

The State of the Art of Direct Trade is how the whole chain is shorter and with this, the considerable reduction of costs with the intermediaries along the whole chain, which in turn, allows higher financial gains for the producers and coffee shops. For Badiyan-Eyford (2013), Direct Trade arises because of a strong tendency to offer quality coffees to the market with a close relationship between producers. For this type of trading, there are no pre-designed templates, nor standard terminology.

Direct Trade presents itself as a relationship of stability, trust and equality between the roaster / cafeteria and the producer (Brown, 2012), which is increasingly valued and highlighted in the marketing of the final product. The actors in this chain would thus share their knowledge and work together in a coordinated way in order to optimize the supply chain, increase the quality and supply of specialty grains or beans, as well as "empower" coffee growers and, above all, reduce costs along the chain.

Assumptions of Transaction Cost Economics
In order to obtain an analysis of transactions between agents within a business network, or more specifically, in order to develop this research on coffee agribusiness, we have the Transaction Cost Economics. Transaction Cost Economics, also known as ECT, was developed by Ronald Coase in 1937, when it was published in The Nature of the Firm (Langlois, Foss, 1999, Thielmann, 2013).

Silva Filho (2006) highlights the main factors in the transactions: (i) the limited rationality of agents, which prevents them from taking, over time, decisions that maximize well-being; (ii) the opportunistic behavior of the agents, which motivates them to act in order to obtain benefits at the expense of other agents with which they are related; (iii) the asymmetry of information, which implies unequal access of the agents to the information pertinent to the exchange made by them, preventing it from being given in the most advantageous manner from the point of view of society.

Methodology
For this research, it was characterized as qualitative with a descriptive-exploratory character and it was adopted the study of multiple cases, to understand the behaviors of the coffee agents that act in the direct form of commercialization and to explore what the risks and advantages in the relations between the agents (Labuschagne, 2003; Yin, 2014). In this way, an attempt was made to offer a description of the environment in which the agents are inserted and how their behaviors affect the structure of the chain of acquisition of coffee and the relationships with the coffee growers.

**Case selection**

Agents were chosen that act directly in the direct trade of coffee in each chain link. For this, a non-probabilistic sample was used as sampling (Yin, 2001). Sample convenience was used because, for Miles, Huberman and Saldãa (2013), such sampling is only targeted to agents that meet the requirements of the study in question. As this research aims to understand how agents act to reduce costs between buyers and sellers of coffees, known as chain intermediaries, seven agents in total were interviewed.

As it assumes that each agent via Direct Trade has a mutual relationship between each link in the chain, the focus on each was delimited in the search for possible asymmetries of information, opportunism of some agent or limited rationality of one or several agents. If any of these actions prevails between the negotiations, it will modify the structure and dynamics of direct trade, weaken mutual trust between the parties and strengthen opportunism.

**Interviews**

The interviews were semi-structured and have basic questions that are supported by theories and hypotheses that are interrelated to the research theme (Triviños, 1987, p.146). The interviews took place in Brazil and in the United States, among producers of specialty coffees, roasters and coffee shops.

The choice of the seven interviewees is justified by the following considerations: a) search of the perspectives of the agents participating in the governance structures in the coffee chain; b) the need to understand the practices of international agents; c) to confront or find "gaps" between what is said and practiced among the agents; d) the search for the design of a non-active agent in the direct trade of coffee. These interviews allowed the agents' visions to be intercalated, generating results (or lack thereof) that could respond to the research objective in line with the theory of transaction costs.

**Data collect**

In this stage, Yin's (2001, p. 81) propositions that highlight how the interviewing skills for case studies: 21 questions were followed; knowing how to listen to the interviewee's positions, identifying the interviewee's keywords and effective components; to be flexible and make adaptations to better enjoy the moments of the interview; have extensive knowledge of the issues contained in the interview script and seek to be impartial during their performance.

Initially, contact was established with some coffee shops, roasters, both in Brazil and abroad, and coffee growers from the southern region of the State of Minas Gerais, in order to conduct the interviews. The interviews were recorded and later transcribed in the data analysis stage. In addition to the recordings, annotations of topics considered were taken, and the reductions were made from larger sentences to smaller sentences until reaching the main points of the research (Miles, Huberman and Saldãa, 2013).

There were seven interviews in all, with the managers, directors and coffee growers involved in the practice of Direct Trade Coffee. This stage was based on an elaborate
interview script, considering the theoretical propositions of the Transaction Cost Economy and its impacts within the coffee supply chain.

Data analysis
For the analysis of the interviews, content analysis was used. Bardin (1977) defines content analysis as being a cluster of interlocution analysis techniques, aiming to obtain, through systematic and objective techniques of exposing the content of the messages, the inference of knowledge regarding the conditions of production or receptivity of such messages.

This systematic should follow a sequence of procedures that cover pre-analysis, coding, categorization and inference. Thus, the data were compiled as follows: (i) Pre-analysis: Separation and identification of the interviewees; Separation by topic / subject from interviews; Capture of legend to identify the interviewees; (ii) Transcript of interviews; (iii) Encoding and categorization of interviewed agents: Organize and separate according to the subject of each respondent's related response - (Coffee producer = P; Roaster = T and C = Cafeteria <P1, P2, P4, T1, C1, C2>); (v) Inference of the Thematic Analysis: Analyse the responses of the groups (intensity, frequency and meanings of the pertinent themes; (vi) Realization of the discussion of the results.

Findings
This research has revealed a number of important points about the relationships between agents in the supply chain via Direct Trade. Access to information and transparency in negotiations and contracts are vital for reducing information asymmetry and the opportunistic actions of agents outside of Direct Trade.

Another very important point is the need to demystify that Direct Trade is a direct purchase and sale action between producer and cafeteria (or roaster). There will always be an intermediary within the chain, whether it is an exporter for buyers from other countries or an internal transport company sale made within the producing country. Thus, the structure of Direct Trade is lean (figure 3), but does not completely eliminate the intermediates of the chain.
**The Institutional Environment, of the transactions and the behaviors of the agents**

It was observed that the transactions between the agents are not clear when asked about the expectations advocated by agents. While coffee shops have argued that coffee growers receive direct attention from their sponsors, such as trainings, support and/or technical visits on their farms, whether semi-annually or annually, coffee growers, in turn, have explained that obtaining the quality of their coffees is an action derived from its own dedications and the correct management of the coffee, without, necessarily, the intervention of some agent of the roaster or cafeteria.

**Limited Rationale**

It was observed that all Direct Trade agents interviewed are intended to be rational about their assignments within the specialty coffee chain; but it was noted that this rationality is achieved in a non-integral way, that is, it proves to be a limited rationality, which for Williamson (1989), such rationality is an intrinsic behavior to agents. The rationality of the interviewee P2 demonstrates the limitation on the possibilities or perspectives proposed by the Interviewee T1. Although they seem simplistic perspectives on the same theme, they generate asymmetries of information in the structure of governance and loopholes so that opportunism arises and modifies the entire organizational environment.

**Opportunism**

It can be explained that the main opportunistic behaviors reported among coffee growers were: restriction of information, concentration of access to new markets (for coffee resale); high rates of logistic payment for the outflow of production (paid more, besides the necessary, for not having competition) and mystification of the export processes.

**Asymmetry of Information**

It was unanimous among the interviewees P1, P2, P3 and P4 that they were unaware of the practices adopted by the roasters or coffee shops, regarding technical visits and support in the production processes of the specialty coffees to be sold to them. This is due to the fact that, while roasters and international coffee shops are proposing to offer support (in different ways) to their peers, one can see how many coffee growers do not even know of the possibility of winning an extra prize in their coffees and, above all, increase the networks of transactions between people who offer assistance to the coffee management and the more widespread, increase the transactions with the agents of the post-harvest, which, in turn, increase the risks of opportunism in the relations.

**Discussion**

This research has brought significant contributions regarding the direct trade model of the direct trade model, which, in the coffee agribusiness, focused almost exclusively on the commercialization of specialty coffees, is still incipient its performance in the traditional market (commodity) or certified coffee, but in turn have shown an exponential growth in the last decades, requiring special attention to their growth.

Thus, this research identified by the theory of Transaction Cost Economics (ECT) the existing gaps, in this almost unprecedented chain of direct coffee trade, in whose organizational environment the coffee grower and roaster, because they are distinct, either in the rational model, in the geographic environment, lead to a discrepant informational asymmetry between these agents, making it clear that, while coffee shops focus on the quality of their coffees sold, coffee growers do not demonstrate knowledge about the various 'resources' made available by roasters in this segment.
The small coffee growers producing specialty coffees do not have certain information that would generate market advantages, since their rationalities are directed to the traditional coffee marketing model: 1) it produces; 2) benefits; 3) stock; 4) seeks buyers in the coffee market or sell to cooperatives; 5) sell coffee; 6) It pays the bills and what about is profit. This attitude offers the possibility of intermediaries accessing the chain and reselling specialty coffees to specific markets with a higher premium, but that is not (re) passed to the coffee grower, maintaining the same chain structure.

As for the increase in sales in the international market, it should be pointed out that in view of the difficulties reported by coffee growers in reaching the external market by themselves, as a small-medium producer, it is believed that in the domestic market, it is easier to negotiate prices, etc., for two reasons: (1) the ease of language (communication); (2) the growing public interest in higher quality coffees (or better sensitization). The rationale for coffee export processes, as previously reported, corroborated (or corroborated), to a certain extent, the growth of the domestic market in the consumption of specialty coffees.

Conclusions
Although studies on Direct Trade in coffee agribusiness have grown in recent decades, especially in the last few years linked to research on the Third Wave, which is focused on specialty coffees, there are few studies that seek to understand this chain of direct trade as a whole.

In this way, it is possible to infer, albeit prematurely, that Direct Trade is an extension of certification, concerned with offering superior, unique and exclusive quality coffees with the characteristic soft drink with high added value, traceability and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization of local infrastructure and the community as a whole, building schools, support workers, empowering coffee farmers, equality between genders, among other.

In this way, this work can be glimpsed by the theory of the Economy of the Costs of Transaction in which Direct Trade allows a structure of governance leaner than the traditional coffee agribusiness chain; reduces opportunistic actions when the information asymmetry is small, that is, when there is an efficient bilateral relationship and broadening the rationality of the agents regarding the possibilities of gains among the agents.

Abstract

The main objective of this study is investigate how the new model of coffee trade, known as Direct Trade Coffee has increased worldwide and how it has changed the supply chain in coffee trade. Through interviews by multiple-case method, the agents of supply chain coffee as producers, roasters and cafeterias demonstrated your perceptions in trade production, distribution and selling specialty coffee. The Transition Cost theory was used to understand how large the asymmetric information, opportunism and limited rationality impacts the supply chain value overall. This study is value to support the understanding of short and more fair coffee negotiate.

Keywords: Supply Chain; Direct Trade Coffee; International Trade

Introduction

In an increasingly dynamic and integrated economy, which information is constantly permeability in the agro-industry sectors, the informational symmetry and economic development of both producers and roasters are put in the agenda, requiring a rational and behavioral analysis of their agents. Factors such as negotiation, contracts and mutual relationship between sellers and buyers, begin to reconfigure the coffee production chain, peculiarly the specialty coffees (special or gourmet ones).
This article aims to demonstrate the new trend that has grown worldwide in the supply chain of specialty coffee market known as Direct Trade. This new model aims not only to shorten the supply chain’s coffee, but also seeks to increase the relationships between the agents since the coffee producer to the final consumer changing, in this way, the traditional supply chain’s coffee. Although studies about Direct Trade in coffee agribusiness have grown in the last decades, especially in the last few years linked to research on the Third Wave of Coffee, which is focused on specialty coffees, there are still, few studies that try to understand the supply chain of Direct Trade at coffee trade as a whole.

Therefore, this article sought to deepen an understanding of this theme through face-to-face interviews with the agents involved in the coffee supply chain as producer and roasters and/or cafeterias in Brazil and abroad. It was evident through this research that Direct Trade is a trend in the specialty coffee market, but its similarity with the principles of coffee certification and requires further studies would be developed to consolidate the shortening of the coffee supply chain and optimize the aggregation of value of all links in the coffee chain.

**Literature Review**

*Theoretical Background*

Global coffee consumption has increased considerably in recent years. Brazil is the largest producer of coffee in the world and the second in consumption. A range of coffee varieties arises dynamically, requiring the coffee sector methods and actions aimed not only at increasing production but also at analysing the impacts these increases have on the environment, people and the economy (Silva, 2006).

The coffee certifications as FairTrade, UTZ Certified, RainForest Alliance Certified appear with the objective to certifying producers that, throughout the production, have to fulfil environmental and social standards, characterizing to be a specialty coffee, although this is not an affirmative condition that they will be able to obtain a quality coffee (Pinheiro, Nagai, 2014).

On the other hand, the demand for specialty coffees has altered the dynamics of the global market, as buyers are investing directly in coffee growers, taking risk instead of facing future market price volatility. Certified coffees have been a trend in recent decades and the causes of their growth are the benefits that certifications bring. High prices paid to coffee growers, openings to new markets, maximization of production longevity and valorization of labor routines are the "flagship" of Certifications (Guimarães, 2016).

In order to optimize the process between growers and roasters, a new model of coffee bargaining arises, with the objective of paying a "real fair price" to the coffee grower in the acquisition of a higher quality coffee. Direct Trade is a business model that aims at a direct trade relationship between the coffee grower and / or roasters, eliminating the so-called "negotiators", reducing operating costs and retaining the coffee farmer to the buyer (Counterculture Coffee, 2015).

Thus, in the coffee market, paradoxically, there is a great demand for the consumption of specialty coffees, but the supply of quality grains which are produced in a sustainable manner is below the conventional market, despite its consumption of rapid growth, especially in developed countries.

*The Waves Coffee*

Direct Trade is most faced to specialty(and gourmet) coffees and also, presents in part, as an extension of coffee certification as FairTrade, RainForest and UTZ Certified, etc. but
works in a short supply chain and more direct relationship between agents, as it is concerned with offering superior quality coffees, unique and exclusive, with the characteristic soft drink with high added value, with ‘traceability’ and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization local infrastructure and the community as a whole, with school construction, support for workers, empowerment of coffee growers, gender equality, among other actions that make up the premises of certifications. To clarify further the results, Borrella, Mataix and Carrasco-Gallego (2015) and Guimarães (2016), explain the Waves Coffee.

The first wave of coffee is attributed to the expressive increase and worldwide dissemination of beverage consumption, especially in the late nineteenth and early twentieth centuries. More specifically in the United States of America, this movement gained momentum with the Great Depression and World War II, requiring minimal time and effort in its preparation. (Reis, 2018; Guimarães, 2016).

The second wave arises when, introducing the new concepts of roasting, in order to reach certain beverage profiles and the consistency of the supply, as well as new notions of origin, recognizing that this, at country level, influenced the quality and some characteristics of the grains (Andrade et al., 2015; Guimarães, 2016).

The third wave appeared in the mid-90s, when only specialty coffees and grains of the Arabica species were used, as well as the vaporization of its numerous aromatic and flavor notes, highly influenced by its origin of production. Thus, coffee goes through a process of total “decommoditization”, being considered as a complex, exclusive and seasonal product and compared to other specialty products (Reis, 2018).

The Direct Trade as the State of the Art of Supply Chain Coffee

The traditional Supply Chain Management (SCM) has many agents which are linked each other in the whole chain. Mentzer et al. (2001), infers that SCM can be understand as “the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole” Mentzer et al. (2001).

=========================================================================
Overview of Supply Chain
=========================================================================

SUPPLIER ↔ INTERMEDIARY ↔ ORGANIZATION ↔ CUSTOMER

=========================================================================

Figure 1 – The Supply Chain – Mentzer et al (2001), adapted.

Below, the figure 1 shows the complexity of SCM as a pipeline, proposed by Mentzer (2001). At this model it is clear that there are innumerable intermediary agents and in the coffee chain it is not different, being these intermediaries: cooperatives, associations, brokers, exporters, roasters and coffee shops.
Severins (2015) infers that the traditional supply chain of coffee typically contains seven levels: growing, harvesting, hulling, drying and packing, bulking, blending and roasting. The entire SCM coffee is further extended by several intermediaries, including global transporters as well as exporters and retailers.

The State of the Art of Direct Trade is how the whole chain is shorter and with this, the considerable reduction of costs with the intermediaries along the whole chain, which in turn, allows higher financial gains for the producers and coffee shops. For Badiyan-Eyford (2013), Direct Trade arises because of a strong tendency to offer quality coffees to the market with a close relationship between producers. For this type of trading, there are no pre-designed templates, nor standard terminology.

Direct Trade presents itself as a relationship of stability, trust and equality between the roaster / cafeteria and the producer (Brown, 2012), which is increasingly valued and highlighted in the marketing of the final product. The actors in this chain would thus share their knowledge and work together in a coordinated way in order to optimize the supply chain, increase the quality and supply of specialty grains or beans, as well as "empower" coffee growers and, above all, reduce costs along the chain.

Assumptions of Transaction Cost Economics
In order to obtain an analysis of transactions between agents within a business network, or more specifically, in order to develop this research on coffee agribusiness, we have the Transaction Cost Economics. Transaction Cost Economics, also known as ECT, was developed by Ronald Coase in 1937, when it was published in The Nature of the Firm (Langlois, Foss, 1999, Thielmann, 2013).

Silva Filho (2006) highlights the main factors in the transactions: (i) the limited rationality of agents, which prevents them from taking, over time, decisions that maximize well-being; (ii) the opportunistic behavior of the agents, which motivates them to act in order to obtain benefits at the expense of other agents with which they are related; (iii) the asymmetry of information, which implies unequal access of the agents to the information pertinent to the exchange made by them, preventing it from being given in the most advantageous manner from the point of view of society.

Methodology
For this research, it was characterized as qualitative with a descriptive-exploratory character and it was adopted the study of multiple cases, to understand the behaviors of the coffee agents that act in the direct form of commercialization and to explore what the risks and advantages in the relations between the agents (Labuschagne, 2003; Yin, 2014). In this way, an attempt was made to offer a description of the environment in which the agents are inserted and how their behaviors affect the structure of the chain of acquisition of coffee and the relationships with the coffee growers.

Case selection
Agents were chosen that act directly in the direct trade of coffee in each chain link. For this, a non-probabilistic sample was used as sampling (Yin, 2001). Sample convenience was used because, for Miles, Huberman and Saldãa (2013), such sampling is only targeted to agents that meet the requirements of the study in question. As this research aims to understand how agents act to reduce costs between buyers and sellers of coffees, known as chain intermediaries, seven agents in total were interviewed.

As it assumes that each agent via Direct Trade has a mutual relationship between each link in the chain, the focus on each was delimited in the search for possible asymmetries of information, opportunism of some agent or limited rationality of one or several agents. If any of these actions prevails between the negotiations, it will modify the structure and dynamics of direct trade, weaken mutual trust between the parties and strengthen opportunism.

Interviews
The interviews were semi-structured and have basic questions that are supported by theories and hypotheses that are interrelated to the research theme (Triviños, 1987, p.146). The interviews took place in Brazil and in the United States, among producers of specialty coffees, roasters and coffee shops.

The choice of the seven interviewees is justified by the following considerations: a) search of the perspectives of the agents participating in the governance structures in the coffee chain; b) the need to understand the practices of international agents; c) to confront or find "gaps" between what is said and practiced among the agents; d) the search for the design of a non-active agent in the direct trade of coffee. These interviews allowed the agents' visions to be intercalated, generating results (or lack thereof) that could respond to the research objective in line with the theory of transaction costs.

Data collect
In this stage, Yin's (2001, p. 81) propositions that highlight how the interviewing skills for case studies: 21 questions were followed; knowing how to listen to the interviewees' positions, identifying the interviewee's keywords and effective components; to be flexible and make adaptations to better enjoy the moments of the interview; have extensive knowledge of the issues contained in the interview script and seek to be impartial during their performance.

Initially, contact was established with some coffee shops, roasters, both in Brazil and abroad, and coffee growers from the southern region of the State of Minas Gerais, in order to conduct the interviews. The interviews were recorded and later transcribed in the data analysis stage. In addition to the recordings, annotations of topics considered were taken, and the reductions were made from larger sentences to smaller sentences until reaching the main points of the research (Miles, Huberman and Saldãa, 2013).

There were seven interviews in all, with the managers, directors and coffee growers involved in the practice of Direct Trade Coffee. This stage was based on an elaborate
interview script, considering the theoretical propositions of the Transaction Cost Economy and its impacts within the coffee supply chain.

Data analysis
For the analysis of the interviews, content analysis was used. Bardin (1977) defines content analysis as being a cluster of interlocution analysis techniques, aiming to obtain, through systematic and objective techniques of exposing the content of the messages, the inference of knowledge regarding the conditions of production or receptivity of such messages.

This systematic should follow a sequence of procedures that cover pre-analysis, coding, categorization and inference. Thus, the data were compiled as follows: (i) Pre-analysis: Separation and identification of the interviewees; Separation by topic/subject from interviews; Capture of legend to identify the interviewees; (ii) Transcript of interviews; (iii) Encoding and categorization of interviewed agents: Organize and separate according to the subject of each respondent's related response - (Coffee producer = P; Roaster = T and C = Cafeteria <P1, P2, P3, P4, T1, C1, C2>); (v) Inference of the Thematic Analysis: Analyse the responses of the groups (intensity, frequency and meanings of the pertinent themes; (vi) Realization of the discussion of the results.

Findings
This research has revealed a number of important points about the relationships between agents in the supply chain via Direct Trade. Access to information and transparency in negotiations and contracts are vital for reducing information asymmetry and the opportunistic actions of agents outside of Direct Trade.

Another very important point is the need to demystify that Direct Trade is a direct purchase and sale action between producer and cafeteria (or roaster). There will always be an intermediary within the chain, whether it is an exporter for buyers from other countries or an internal transport company sale made within the producing country. Thus, the structure of Direct Trade is lean (figure 3), but does not completely eliminate the intermediates of the chain.

Figure 3 – Traditional versus Direct Trade Coffee Supply Chain - By Authors
The Institutional Environment, of the transactions and the behaviors of the agents

It was observed that the transactions between the agents are not clear when asked about the expectations advocated by agents. While coffee shops have argued that coffee growers receive direct attention from their sponsors, such as trainings, support and / or technical visits on their farms, whether semi-annually or annually, coffee growers, in turn, have explained that obtaining the quality of their coffees is an action derived from its own dedications and the correct management of the coffee, without, necessarily, the intervention of some agent of the roaster or cafeteria.

Limited Rationale

It was observed that all Direct Trade agents interviewed are intended to be rational about their assignments within the specialty coffee chain; but it was noted that this rationality is achieved in a non-integral way, that is, it proves to be a limited rationality, which for Williamson (1989), such rationality is an intrinsic behavior to agents. The rationality of the interviewee P2 demonstrates the limitation on the possibilities or perspectives proposed by the Interviewee T1. Although they seem simplistic perspectives on the same theme, they generate asymmetries of information in the structure of governance and loopholes so that opportunism arises and modifies the entire organizational environment.

Opportunism

It can be explained that the main opportunistic behaviors reported among coffee growers were: restriction of information, concentration of access to new markets (for coffee resale); high rates of logistic payment for the outflow of production (paid more, besides the necessary, for not having competition) and mystification of the export processes.

Asymmetry of Information

It was unanimous among the interviewees P1, P2, P3 and P4 that they were unaware of the practices adopted by the roasters or coffee shops, regarding technical visits and support in the production processes of the specialty coffees to be sold to them. This is due to the fact that, while roasters and international coffee shops are proposing to offer support (in different ways) to their peers, one can see how many coffee growers do not even know of the possibility of winning an extra prize in their coffees and, above all, increase the networks of transactions between people who offer assistance to the coffee management and the more widespread, increase the transactions with the agents of the post-harvest, which, in turn, increase the risks of opportunism in the relations.

Discussion

This research has brought significant contributions regarding the direct trade model of the direct trade model, which, in the coffee agribusiness, focused almost exclusively on the commercialization of specialty coffees, is still incipient its performance in the traditional market (commodity) or certified coffee, but in turn have shown an exponential growth in the last decades, requiring special attention to their growth.

Thus, this research identified by the theory of Transaction Cost Economics (ECT) the existing gaps, in this almost unprecedented chain of direct coffee trade, in whose organizational environment the coffee grower and roaster, because they are distinct, either in the rational model, in the geographic environment, lead to a discrepant informational asymmetry between these agents, making it clear that, while coffee shops focus on the quality of their coffees sold, coffee growers do not demonstrate knowledge about the various 'resources' made available by roasters in this segment.
The small coffee growers producing specialty coffees do not have certain information that would generate market advantages, since their rationalities are directed to the traditional coffee marketing model: 1) it produces; 2) benefits; 3) stock; 4) seeks buyers in the coffee market or sell to cooperatives; 5) sell coffee; 6) It pays the bills and what about is profit. This attitude offers the possibility of intermediaries accessing the chain and reselling specialty coffees to specific markets with a higher premium, but that is not (re) passed to the coffee grower, maintaining the same chain structure.

As for the increase in sales in the international market, it should be pointed out that in view of the difficulties reported by coffee growers in reaching the external market by themselves, as a small-medium producer, it is believed that in the domestic market, it is easier to negotiate prices, , etc., for two reasons: (1) the ease of language (communication); (2) the growing public interest in higher quality coffees (or better sensitization). The rationale for coffee export processes, as previously reported, corroborated (or corroborated), to a certain extent, the growth of the domestic market in the consumption of specialty coffees.

**Conclusions**

Although studies on Direct Trade in coffee agribusiness have grown in recent decades, especially in the last few years linked to research on the Third Wave, which is focused on specialty coffees, there are few studies that seek to understand this chain of direct trade as a whole.

In this way, it is possible to infer, albeit prematurely, that Direct Trade is an extension of certification, concerned with offering superior, unique and exclusive quality coffees with the characteristic soft drink with high added value, traceability and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization of local infrastructure and the community as a whole, building schools, support workers, empowering coffee farmers, equality between genders, among other. In this way, this work can be glimpsed by the theory of the Economy of the Costs of Transaction in which Direct Trade allows a structure of governance leaner than the traditional coffee agribusiness chain; reduces opportunistic actions when the information asymmetry is small, that is, when there is an efficient bilateral relationship and broadening the rationality of the agents regarding the possibilities of gains among the agents.

Abstract

This paper exploits secondary data provided by a large database of IoT projects and applies hierarchical cluster analysis to classify projects into homogeneous groups by technological novelty, complexity of competences, functional areas of applications, expected impacts and realized benefits, and firm size. The clusters allowed identifying different “developmental stages” firms go through in building their competences in IoT.

Keywords: Internet of Things, Innovation, Digitalization

Introduction

The Internet of Things (IoT) is one of the pillars of the Industry 4.0 (I4.0) paradigm. IoT envisages a network of machines and devices connected and interacting with each other. Within firms, connectivity can greatly improve specific value chain activities ranging from inventory systems, to production, and customer support systems. In addition, some applications are overturning the way in which business is conducted (Rymaszewska et al., 2017). Although the literature on IoT is blooming, most contributions in the area of OM focus on defining and explaining technologies belonging to the IoT family, on identifying areas of applications within the firm and the supply chain (Lee and Lee, 2015), and on understanding risks and challenges (Birkel, et al., 2019; Kamble et al., 2018).

Little empirical evidence exists about the characteristics of IoT projects currently adopted by firms, in terms of novelty and complexity (Henderson and Clark, 1990). This analysis may not only provide a description of what firms are currently doing in terms of IoT but they may also throw light on the dynamic capabilities (Teece et al., 1997) required to develop and implement IoT projects.

To address these issues, this research exploits the information provided by an extensive database of IoT business cases, and applies cluster analysis to identify homogenous groups of projects, in terms of technological complexity, novelty, and functional areas of applications.
**IoT literature background**

The term “Internet of Things” (IoT) came into existence for the first time to represent the globally emerging Internet-based information service architecture (Ashton, 2009). Weber (2009) defined IoT as “an emerging global, Internet-based information service architecture facilitating the exchange of goods in global supply chain networks”.

IoT technologies include network, software and algorithms, hardware, and data processing (Wu et al., 2016). The network is the backbone of the IoT, as it refers to uniquely identifiable objects (things) and their virtual representations in an Internet-like structure. Objects rely on software to communicate effectively with each other and to deliver enhanced functionality and connectivity. Hardware is driven by the customised IoT devices, which generate enormous quantities of data that need to be aggregated and analyzed in real time to provide information regarding status, location, functionality, and environment of the devices. The optimization of data processing is critical to timely processing of the continuous stream of massive amounts of data. In recent years, research has followed the state of the art of IoT solutions in order to facilitate their definition and identify future trajectories (Da Xu et al., 2014).

Lu et al. (2018) provide a systematic review of the business literature on IoT, from the user and organizational perspectives, while Mishra et al. (2016) performed a bibliometric analysis to identify the research networks and the main contributors from an academic point of view. Ben-Daya et al. (2017) explore the role of IoT and its impact on supply chain management through an extensive literature review, finding that most studies have focused on conceptualizing the impact of IoT with limited analytical models and empirical studies.

Incorporating new technologies into existent business environments, structures, and models has always been a challenge. This also remains the case when the IoT is implemented (Pfisterer et al., 2016). However, while there are fine-grained analyses of IoT technical aspects (Whitmore et al., 2015), there is still a paucity of studies on IoT adoption in different businesses and on its impact (Haddud et al., 2017). Despite the importance for social and economic growth, the development of IoT technologies has not yet received a thoughtful examination from a managerial perspective (Ardito et al., 2018).

**Research strategy**

In order to identify the main types of IoT projects, we exploit secondary data obtained from an extensive publicly available database (IoT ONE, https://www.iotone.com) that contains over 1000 cases of organizations in a variety of industries that have adopted IoT technologies all over the world. The database provides information on technological maturity of the project (mature technology, emerging, cutting-edge), required capabilities in hardware and software (measured on a 1-5 scale), areas of impact within the firm, key types of expected impacts and realized benefits, and a description of the IoT solution adopted. In addition, the research team collected information on the adopting firm’s industry and size. Finally, scope of project, whether narrow (i.e. affecting less than three functional areas) or broad, was assessed through the reading of the case.

The dataset was consulted in May 2018 and cases for this study were selected on the base of the possession of all the information listed above. The final number of projects included in this study was 583.

The first step for the analysis of the case studies required to extrapolate the main information and transform it in numerical values. In particular, since information on the project expected impacts and realized benefits was in narrative form, its transformation to allow a quantitative analysis required coding. This was done through Nvivo 11.0. Initial analysis consisted in creating nodes for Nvivo corresponding to aggregations of keywords.
used to identify impacts and benefits. Nodes were then further aggregated using exploratory factor analysis. Appropriate steps for exploratory factor analysis were followed (Hinkin, 1998). First, principal component analysis was used to extract factors, and Kaiser criterion was applied to select factors with eigenvalues above one. Nine factors satisfying this condition were identified for expected impacts, explaining 60% of variance, a percentage considered acceptable (Hinkin, 1998). Seven factors were identified for realized benefits, explaining 56% of variance. Next, varimax rotation was applied to the data. Nearly all items exhibited loadings above 0.6 and all clearly mapped onto one factor. Uniqueness in the final solution was also calculated, with the aim to assess the proportion of factor variance explained by each item.

Hierarchical cluster analysis using Ward method was applied to identify groups of homogeneous projects by functional area of impact within the firm, project scope (narrow vs. broad), novelty of the technology (measured by three degrees of technological maturity), hardware and software capabilities required, expected impacts and realized benefits. Firm size and industry were also added to the clustering variables. The results of the cluster analysis suggest that a five-cluster solution best fits the data. This conclusion was reached by checking dendrograms that show distance between different cluster solutions and by examining changes in the squared Euclidean distance. The significance of inter-cluster differences along the various variables and dimensions included in the cluster analysis was tested through the “test value” criterion (Lebart, 2000).

Results

Table 1 below summarises the key characteristics of the five clusters. Frequency for the characteristics that are statistically more frequent in the cluster than in the sample overall are shown, whereas the other characteristics of the cluster are shown in italics if they are not statistically more frequent than in the other clusters. The table provides insights on the size of the companies involved in the projects assigned to each cluster, on the degree of novelty of the technologies used, and on the complexity in terms of hardware and software capabilities required. With respect to project scope, four clusters out of five include predominantly narrow scope projects, while broad scope projects are grouped in Cluster 4. SMEs tend to implement narrow scope projects either using mature technologies (Cluster 1) or emerging ones (Cluster 3). As for expected impacts, improving efficiency through data collection and management seems to be the most common goal (Cluster 2, 4, 5), while the need to monitor and control systems appears to characterise Cluster 1 and 3.

Figure 1 positions the clusters in terms of degree of novelty of the technology used in the IoT project (X axis) and of the level of capabilities the project required for Hardware and Software, used as a proxy of the project complexity (Y axis). The figure also shows the scope of the project using the colour code (green = broad scope). Some specific observations emerge. First, Cluster 1 is the sole cluster with low degrees of both complexity and novelty. This finding positions the typical Cluster 1 project as an easy “entry” project that can be handled by any company without encountering significant challenges. Not surprisingly, this is the most frequently encountered type of project. Next, Cluster 4 is the sole cluster in which projects have a broad scope and exhibits relatively higher software and hardware capabilities with respect to the overall sample of projects. This characteristic positions Cluster 4 as a cluster of strategic projects that build on a mixture of mature-emerging-cutting-edge technologies to transform a firm and its operations. Cluster 5 groups projects with the highest degree of ambition in terms of technology innovation. Emerging and cutting edge technologies are applied to narrow

Figure 1 - Positioning of the IoT Project Clusters in a Complexity/Novelty Matrix

Scope projects which require relatively more advanced hardware capabilities. These characteristics suggest Cluster 5 include projects undertaken by companies that use IoT strategically and experiment with new solutions. Finally, Cluster 2 and Cluster 3 appear to encompass more software intensive projects with diverse degree of technology novelty (mature for Cluster 2 and emerging for Cluster 3).

Analysis of selected case studies
In the second stage of the analysis, a few case studies in the IoT database were selected and analysed in greater depth. The selection criterion was the following: for each cluster, cases were searched that exhibited the highest number of characteristics distinctive of the cluster. Among cases selected, preference was then given to those for which supplementary information from press sources or company’s reports was available. Three cases were selected for each cluster. Combining the results of cluster analysis with an in-depth reading of individual case studies allows arriving at a more articulate description of the five clusters that includes information not only on the structural characteristics of the IoT projects (maturity, complexity, scope) but also on the specific technologies used and capabilities deployed.

Cluster 1: IoT beginners
This cluster includes organisations, most of which SMEs, which used IoT to monitor a single critical asset. Technologies used in such projects are mature, their prices have gone down over the years and their performance is reliable. They allow monitoring specific assets in order to eliminate very specific risks and issues that can have significant impact for the firms. This cluster includes many projects that tackle security, quality, health and safety matters. Such projects require limited investment, while offering significant and immediate benefits. Common expected impacts were compliance with safety and security regulations and achieving better control of the specific object/asset. In terms of capabilities, this kind of projects requires slightly higher than average hardware competences, given that the project often involves the installation of monitoring devices. On the other hand, software capabilities required are low, as the company performs very elementary data analysis tasks at this stage. These projects are easy to implement and help to demystify the technology, thus providing an entry experience to IoT.

Cluster 2: Using data management to enhance access to information
In this cluster, we have large organisations that used mature data management technologies to enable, simplify and accelerate access to information. Such projects
aggregate data from multiple sources, radically simplify the access to large amount of information and allow to produce valuable reports that support decision making. The most immediate benefit of such projects is to establish a rapid and user-friendly access to all relevant information. Consistently, the expected impact of many of these projects was to exploit data collection and management to improve operational efficiency, a benefit that accrues to 47% of the projects in this cluster. In terms of capabilities, a significant leap in software capabilities is required, since the firm has to make itself acquainted with real time data analysis tools. In turn, the firm has to develop capabilities for turning real-time information into fast decisions. These projects are still narrow scope and frequently introduce smart maintenance.

Cluster 3: Using emerging software technologies to control operations

In this cluster, we have both SMEs and large organisations that used emerging software technologies to control and manage their operations. Industrial operations generate data which is injected in the software developed as part of such project. This is used to regulate and support operations. As the applications are very specific to the activities of the organisation, emerging technology is used. When applied to a technically complex production process, such projects require an advanced understanding of what happens at physical level in order to use data effectively. Therefore, companies who design the machines and equipment are best placed to support their client on such projects.

Cluster 4: Using IoT to bring the power of software to new fields of activity

This cluster includes predominantly large organisations that deploy IoT to bring the power of software to new fields of activities. Example of industries impacted by such projects include agriculture, energy distribution, or public transportation. Such fields are characterised by dispersed and sometime mobile assets that were not previously connected to an information system. These projects bring the power of data management and software technology to the clients of the firm that undertake them. They are complex, broad scope projects that offer a wide range of functionalities and significant benefits for the firm implementing them. Some of them can be considered radical innovations. Such projects can lead to the development of new competitive advantages, but they require significant strategic support and development. The cases fully illustrate the scale of the projects implemented. They connect a broad number of assets using a mixture of newer and mature hardware technologies, and they leverage the data collected through the development of specific software applications. Even if some of the technologies are well established and therefore affordable, such projects require significant investment due to their scale. Such projects are often undertaken progressively. They can be divided in sub-projects that can build on each other over time. While some benefits can accrue right from the earlier investment, a critical mass of assets and data sources needs to be connected in order to realise the full benefits of such projects. This nevertheless requires a broad vision on the full programme, as specific investments might not be justified if they are undertaken independently of the whole programme.

Cluster 5: Leveraging on new generation technology

In this cluster, large organisations take advantage of emerging and cutting-edge technologies in software intensive fields of activities. These projects typically focus on a critical sub-system, but they often enhance the performance of the broader system. This cluster contains strategic projects for the firms that have undertaken them, leading to significant benefits. Firms with significant prior experience in electronics and software undertook most of the projects in this cluster. Combining different technology and different sources of data into one technical system can require working on the projects with suppliers who have very different knowledge base and culture. This is something that needs to be managed adequately to reach success.

Discussion
The cluster analysis has allowed identifying five main types of IoT projects, differing by scope, novelty, technological capabilities required, operational impacts and firm characteristics. In addition, looking at specific case studies has allowed shedding light on the possible relations among the different clusters and on the importance of integration and network capabilities for the successful implementation of the more challenging projects. In what follows, we elaborate on these two aspects with the aim to suggest future directions for operations and business research on IoT.

Concerning the relation among different project types, clusters suggest a possible path of development that links firms’ capabilities with types of projects undertaken and impacts sought (Utterback and Abernathy, 1975). The clusters also suggest a trajectory (Patel and Pavitt, 1997) whereby firms start with Cluster 1 type of projects. Such projects can be performed with a limited investment and offer an immediate and high return. Then, as more objects are connected, Cluster 2 or Cluster 3 projects can be implemented to generate data driven efficiency improvements. These projects allow collecting and aggregating a large amount of data across similar or interconnected assets and produce timely data visualisation and reports. In some circumstances, achieving higher levels of performance requires the integration of multiple novel technologies together (Cluster 3). Here, the higher degree of technological novelty requires not only to invent new components but also to explore what type of architectures allow achieving the desired performance and handling key constraints. Finally, Cluster 5 projects allow generating higher order benefits for firms with ample experience in digital technologies, who transfer some of these benefits to customers by harnessing the power of the most advanced technologies (e.g. the vehicle manufacturer infotainment project).

The sequence of cluster 1-2-3-5 projects lends itself to be interpreted as a cumulative innovation process, offering non-linear levels of performance while firms progress towards more novel and more complex technological capabilities. This development path appears to suit also SMEs, for which cluster 1 and 3 are characteristic. A SME can gain new competitive advantages from Cluster 3 projects, as the case of the bottling company illustrates. Figure 2 illustrates this cumulative innovation process.

On the other hand, Cluster 4 suggests the co-existence of an alternative trajectory whereby firms can “leapfrog” to more novel technologies and more complex capabilities (Lee and Lim, 2001), and use them in large-scale projects. This seems to be true especially for industries that have not been software-intensive in the past. In our case examples, innovative development and benefits accrued to firms whose activities were characterised by dispersed and mobile assets (e.g. the agricultural project). Connecting these assets to a single data management system was, in the past, either unreliable, too expensive or technically challenging. However, such developments require a business vision and a clear system architecture to anticipate key implementation steps. Understanding the broader system, its goals and architecture is essential to take the right decisions related to technology adoption, timing of different sub-project, feasibility and management of changes.
Our results also suggest that more “developed” stages of IoT implementation, characterised by more novel technologies and/or more complex technical capabilities, may only be achieved by firms that possess “second order” or dynamic capabilities (DCs) (Teece et al., 1997). These DCs allow to constantly re-assess, re-deploy and re-configure resources as is required in periods in which the industry business model and/or the dominant technological paradigm is being overturned. In an area close to IoT, Wamba et al. (2017) underlined that the effective use of big data analytics requires process-oriented DCs, defined as the extent to which a firm can develop competences to change business processes in a more robust way than its competitors.

In addition to firm level DCs, Rothaermel and Hess (2007) show that a firm’s innovation is a positive function of its network of new technology providers, a finding that points to effectively orchestrating the network of actors who play a role in implementing innovation projects (Eisenhardt and Martin, 2000) as one possible manifestation of a DCs. These DCs are crucial when the firm has to manage the most challenging and strategic IoT projects, which require mobilising diverse individuals and teams within an organisation and across a network of suppliers and partners. Such projects require managing effectively loosely coupled networks (Orton and Weick, 1990). Projects using mature technology will tend to build on pre-existing and standard interfaces that allow a modular design process while projects that integrate within a dedicated architecture cutting edge technologies, require designing the architecture and the components concurrently. When standard interfaces exist, projects can be coordinated by providing the different teams with interfaces; changes are permitted only within a predefined range. In this context, IoT projects can be coordinated across different teams through information and knowledge sharing activities. Challenges arise from the many variables at stake and the potential divergence of interpretation across the teams involved in such projects. Such projects require an ability to learn and react rapidly through the active management of the relationships across teams. Each team can work on specific independent components and as challenges arise, they can be brought together to share information, to learn and to react rapidly together. A clear example of this type of
DC is the implementation of a connectivity solution for public buses, enabling user-friendly payment, route scheduling capabilities and Wi-Fi.

However, without standard interfaces, a more active design and management will be required to integrate diverse objects and sources of data together using diverse technologies. The need will arise to coordinate the resolution of ill-defined problems through the exploration of multiple solutions by an intellectually diverse yet cohesive group of individuals (Brusoni and Prencipe 2013). As technologies are mostly emerging and cutting edge, they need to be integrated into a coherent architecture often imbedded in a broader system which is also imposing a set of constraints on them. To manage such projects, organizations need to bring together at an early stage teams with very distinct knowledge bases. They will have to explore multiple solutions in order to integrate technologies, components and sources of data. These integrative DC underscore the development by an automotive company of a secure solution for infotainment, advanced driver assistance and in-car time sensitive application (Cluster 5).

Finally, several of the cases have brought to our attention that projects in clusters characterised by more novel technologies or engendering a more strategic orientation (3-4-5) are undertaken in close partnership with providers of new technologies, who, in many cases, co-develop solutions with the user firm and accompany the firm’s future IoT developments. This finding is in line with past research on the importance of network level DC for innovation processes (Rothaermel and Hess, 2007), and on the role of networks in providing access to knowledge not readily available via market exchanges (Gulati, 1998).

Conclusions
This paper has built on secondary sources of information on IoT adoption to try to identify a typology of IoT projects. This is an area of investigation where seldom empirical evidence exists on a large scale. The analysis led to identify five clusters of projects positioned along varying degrees of complexity, novelty and scope. The clustering of projects also allowed shedding light on patterns of involvement of firms of different size (e.g. large firms vs. SMEs) in IoT projects. These findings are particularly relevant to understand what firms currently do with IoT.

Our discussion has tried to elaborate on the existence of possible development paths or trajectories in IoT project implementation and on the dynamic capabilities enabling adoption and success of different project types. This analysis is eminently data-driven and should be considered suggestive of future research directions. Therefore, a more precise understanding of the dynamics of IoT adoption and of enabling capabilities is necessary. In particular, longitudinal analyses of firm-specific and sector-specific trajectories from infancy to higher order achievements should be undertaken. For instance, projects in fields such as agriculture should be studied to develop a grounded theory of leapfrogging in IoT. Finally, future research can be carried out to further explore the dynamic capabilities identified as critical in this paper. In this direction, primary case-based research could throw light on how diverse knowledge bases are mobilised to develop and implement IoT project and on how external partners are integrated in such activities. To conclude, a broad range of research activities is still required in this emergent field of investigation.

Abstract

The intensified digitalization efforts of recent years enable companies to put emphasis on designing and developing innovative management approaches. This leads to the implementation of improved operational processes and to superior decision making in operations management. The Electronic Components and Systems industry (ECS) and corresponding suppliers from other industries represent the main study context. The implementation of smart factory systems provide a new perspective on key drivers for competitive sustainable manufacturing. In order to model these dependencies, a discrete event simulation model (DES) has been developed that supports analysis how the effects of fast-paced technology can influence industrial operations.

Keywords: Digital Transformation, Process Improvement, Simulation Modeling

Introduction

The Electronic Components and Systems industry (ECS) is characterized by long lead times and high market volatility. Aside from this, fast technological developments within this industry and cyclic market up- and downturns are influencing the market (Mönch et al., 2011). Furthermore, too low inventory of required products can cause a loss of opportunity costs by not reaching customer satisfaction, service level and product availability. Therefore, investments into process and quality improvements are key success factors for companies to survive (May and Spanos, 2006). This paper proposes a model based on a single manufacturing process to assess the value of process quality
improvement. The implementation of additional sensors and intelligent software applications for improved quality inspection of production processes supports the detailed analysis presented in this paper. In addition, we analyze the impact on manufacturing performance, i.e., costs (operating costs), productivity (cycle time, utilization and variability) and quality (process and product quality). The benefit of process improvement for operations management is based on understanding the costs and advantages of collecting and analyzing new insights from process and product data. Finally, value is generated from existing data by exploiting specified key findings within defined data sources (Sjödin et al., 2018). Manufacturing processes must be designed in a way to reach an optimum between quality, productivity and costs (Plunkett and Dale, 1988). This leads to the following research questions:

- **RQ1:** How can manufacturing companies improve operational performance through digitalization?
- **RQ2:** What is the impact of digitalized manufacturing processes on costs, productivity and quality, and how can this impact be evaluated?

**Theoretical foundations**

For the purpose of this study we apply queuing network theory in combination with simulation modelling. With this we aim at explaining the impacts of the solution developed in one industrial case from an ECS supplier on process quality, product quality and overall production effectiveness and efficiency. In general, the increase in process variability negatively impacts process performance. Therefore, our main investigation subject is to evaluate how digital process improvement can reduce variability in production processes within plants (Hopp and Spearman, 2001). Analytical approaches based on queuing theory serve as a fundamental instrument to explore what-if questions. Queuing models make cycle time estimation based on the assumption of stochastic arrival and service processes possible. In typical queuing models as given in the so-called G/G/1 model in Figure 1, the arrivals (i.e. demand) of a product at the workstation are often modelled as a stochastic process where inter-arrival times are random variables following specific (unknown) distributions. Based on machine configuration and process requirements, processing times are prone to be stochastic as well. Products that arrive but cannot be processed directly are placed in the waiting queue. The stochastic components are represented by their first two moments what is explained in detail below, i.e. mean and coefficient of variability (Hopp and Spearman 2001).

![Figure 1: Simplified process model](image)

Little’s law can describe a simple and stable process, where the inflow and outflow rates are identical (Little, 1961). However, the analysis of complex processes, requires more than the long-run average values set by Little’s law. For example, Wu (2005) applied Little’s law and the G/G/1 queueing formula to estimate the variance of a simple factory with single toolsets. He identified certain basic properties that provide managerial insights on how variability affects the production performances. Furthermore, the author pointed...
out that the variability of bottleneck toolsets should be reduced to achieve fast cycle time. The following conditions apply for a stable process:

\[ \rho = \frac{\lambda}{\mu} < 1, \]  

where \( \rho \) is the utilization, \( \lambda \) is the unit arrival rate and \( \mu \) is the service rate. \( \lambda \) and \( \mu \) are defined by

\[ \lambda = \frac{1}{t_a}, \]  
\[ \mu = \frac{1}{t_e}, \]  

where \( t_a \) denotes the inter-arrival time of units and \( t_e \) the effective process time. The approximation for waiting time (\( CT_q \)) of a single process, is given by

\[ CT_q = \frac{\rho}{(1-\rho)} \left( \frac{c_a^2 + c_e^2}{2} \right) t_e, \]  

where \( c_a^2 \) is the squared-coefficient-of-variation (SCV) of the inter-arrival time (\( t_a \)), and \( c_e^2 \) is the SCV of the effective process time (\( t_e \)). The effective process time includes the raw process time (\( t_s \)) and all time losses due to setup, breakdown, unavailability of operator, and any other source of variability (Wu, 2005). The throughput rate of a single server is defined by

\[ r = \frac{\rho}{t_e}, \]  

and the cycle time is defined by

\[ CT = CT_q + t_s. \]  

The raw process time represents the sum of times a unit spends on a server, such as load/unload and processing. It is to be noted that the internal service (\( c_{a,i} \); \( c_{s,i} \)) as well as the external arrivals and demand for sub sequential stations (\( \lambda_i; c_{d,i} \)) variability of the system have effects on the waiting time (\( CT_q \)). Additionally, this performance measure is strongly linked to the utilization of the system which is in turn determined by the arrival and the service rates (\( \mu_j; c_{s,j} \)). In this regard, waiting times and service times are both significant parts of the cycle time (see Figure 2) where the former is a non-productive component and must be reduced to a minimum.

![Figure 2: Cycle Time of a single server process](image-url)
Variations within the defined processing limits cause variation in the final product, visible e.g. in quality inspections after the process. The compilation of individual process variations may increase the product scatter and lead to yield losses, long cycle times, high costs and low service levels. The improvement of manufacturing processes has a direct impact on the overall cycle time reduction, especially for products on the critical path. In an industrial environment, most operational processes are characterized by dynamic operating conditions and complex interrelationships that cause changes in inputs, operations and outputs. Variability results in non-conformities that have a negative impact on operations processes. Product characteristics and product quality, as well as process attributes (e.g., process time, set-up time, process quality, equipment breakdowns and repairs) are subject to non-conformance (Klassen and Menor, 2007). Thus, the reduction of variability improves operational performance, such as throughput, lead-time, customer service, quality, etc. (Hopp and Spearman, 2001). The effect of variability reduction on the cycle time and capacity utilization lead to the following results:

a) Lower variability leads to a reduced cycle time at unchanged capacity utilization.

b) Lower variability enables higher capacity utilization and therefore a higher throughput rate.

These insights serve as fundamental basics for our proposed simulation model which is outlined in the next section and forms the basis for the further quantitative impact evaluation.

**Methodology**

This article is based on single case study research including one industrial case which serves as data source for the developed simulation model. The case focuses on the integrated analysis and optimization of the internal processes of heating and hot rolling of molybdenum plates for the production of sputtering targets. The main objective is to increase the proportion of sputtering targets complying with the quality required for the semiconductor industry and thus, to improve process efficiency. From a methodological viewpoint, case study research is an appropriate method for answering the research question of this paper. It serves as a promising methodology for defining propositions and describing upcoming phenomenon within its real-life context – here return on quality through digitalization (Yin, 2003, Voss et al., 2002, McCutcheon and Meredith, 1993). The fundamental process improvement here is covered by the implementation of a model based control tool. Our study connects the competitive value of data analytics and performance measures to enhance manufacturing excellence. When disruptions within a system occur, these methods enable the development of scenarios and recommendations that facilitate instant managerial support. For our process modelling and evaluation we have mapped the process in a discrete event simulation (DES) model. The modelling software is Anylogic 8.2. DES models are networks of queues and activities with coupled resources. This means that units that are called agents in the model language move between different stations during the process time (Banks, 2010). Performance measures are for instance the utilization of resources, the processing times of the target variable, waiting times, the length of queues, the system throughput or bottlenecks (Borshchev, 2013, Buzacott and Shanthikumar, 1993).

**Case Introduction**

**Initial situation**

The production of sputtering targets is a powder metallurgical process, which has lot of critical production steps and tight requirements. The sputtering targets were treated in
production lots of up to 10 pieces each. Only a few process parameters were recorded along the supply chain, and merging of this data with the production lots was a manual task. The main production step “hot deformation” was planned manually and the heating times were estimated. The challenge is to bring a single piece traceability into the whole production chain and enhance accuracy in the main production process step.

**New technical solution**

Single piece traceability was realized by a unified unit number (UUN), which was implemented in the ERP/MES and on each single material ingot. With tailored process models and advanced model-based control tools, the production step deformation is now controlled in a more efficient and accurate way. In the final production steps, single piece production together with almost paperless production was installed. The UUN was implemented which can handle each individual piece of sputtering target along the production chain. A 2-D barcode is graved on each piece and tracked along the production steps. ERP/MES systems were adapted to process this number and all order information is stored including process data. In the main process step new control and optimization tools were developed by extending established methods with tailored mathematical process models. This requires mathematical modelling, parameter identification and model validation, advanced nonlinear process control, and combinatorial optimization like timetabling algorithms or flexible job-shop scheduling (Aschauer et al, 2018; Roetzer et al. 2018). On production level, the process steps from a pressed and sintered plate to a hot-rolled sheet of molybdenum is affected. Rather than focusing exclusively on maximizing the throughput of sputtering targets, the targets for the desired quality have been expanded to include less waste and the energy efficiency of the production plant. Another target was to decrease the work in process in order to reduce the lead time of the manufacturing process.

The case was driven by following challenges:

- **Increased quality:** The temperature control of the plates has a decisive influence on the product quality. In order to achieve here an optimum temperature, a "virtual sensor" is implemented, acting as an estimator for the temperature development of the plates.
- **Process improvement:** The focus on a zero-defect strategy requires the cooperation of the operator and a corresponding focus on quality. For this purpose, the optimization algorithm should provide recommendations to the operator in terms of which products are when, where and how produced.
- **Increase of energy efficiency:** Since the heating of the furnaces is the main energy factor, the optimal use of heated furnaces and the potential decommissioning of unused furnaces strongly contribute to energy efficiency.
- **Reduction of lead time:** The pool of orders that can be optimized by bundling products with similar process steps leading to increased efficiency was remarkably reduced. The order optimization period was limited by two days.

**The Process Model**

In the following section, we outline the process model development. We use some elements of queuing theory to show how an improvement of a single process step can have several impacts on the production system as well as on the whole value and supply chain of an organization. We further illustrate that decision-making at this particular step must consider the overall impact, i.e., improvements made at particular stages do not necessarily generate value for the whole system and can sometimes be detrimental to
overall performance. Please note that due to reasons of confidentiality exact operational numbers as well as process details (which are unimportant for the study) are omitted.

**Heating time estimation**

Since the plate cools down during the rolling and handling process, the optimum reheating time is calculated based on the processing time and waiting times of the rolling and handling processes. In the static calculation (earlier) it was therefore not possible to determine the exact temperature of the plate and therefore a safety time had to be taken into account in order to produce a quality plate. This leads to additional process times and thus to an increase in resource utilization and a reduction in throughputs. By using modern sensor technology and UUN, it is now possible to determine the temperature of the plate in real time and thus determine the optimum reheating times of the plates in the furnaces. This has the effect that the times can be optimally adjusted and thus resources and energy can be saved. Another effect is represented by improved cycle times and throughput. In addition, the quality of the product can be determined at an early stage, since temperature variations can be tracked earlier and in real time. Early detection of deficient quality has the effect that an additional unit can be launched at an early stage and thus costs, resources and energy can be saved.

![Figure 3: Heating time based on intermediate heating sequences](image)

Here, Figure 3 shows an estimation of the relationship between heating times and the composition of time between rolling and handling. Detailed calculations including a specific temperature model showed a potential decrease of cycle time and therefore, decrease of utilization, of about 8-10%, and a potential throughput increase of about 3-5%. The optimization algorithm is based on a material stock of two to three daily quantities and production orders for the next 24 hours. This facilitates a switch from manual scheduling to semi-automated decision-support system. Figure 4 illustrates the entire process of transforming raw materials to finished plates.

![Figure 4: Process Flow Model](image)
Due to our objective to analyze the heating process in detail and as the sub-process forms a natural unit in operations, we focus on processes within the green box highlighted in Figure 4. This flow chart served as initial starting point for the model description and was used to analyze and discuss the process and to build the simulation model based on it.

Development of simulation scenarios
Several simulation scenarios are considered, which combine different furnace settings, heating configurations and heating times as well as other parameters, such as different arrival distributions, various arrival rates, and variability levels. The main process is that the plates are heated to a specific rolling temperature – what takes x minutes depending on the initial temperature – and afterwards rolled; this process is repeated several times. The x min. are estimated based on the cool down time during the rolling process (as given in Figure 3). In some scenarios, an additional safety time is added to ensure that the core temperature of the plate reaches the desired temperature. Please note that due to confidentiality the number of furnaces for initial heating/reheating (IRF) and final treatment (FT) is shown as a ratio.

The following scenarios and sub policies were used for evaluation, whereby all three scenarios in Table 1. are based on two configurations with a static heating time of 20 min and 25 min (P_20 and P_25), and one dynamic configuration where heating time is based on the actual rolling and handling time (P_Opt):

• **Scenario 1** shows the basic furnace setting within the case company where the relation between the number of initial heating/reheating furnaces and final heat treatment furnaces equals to 1:1.

• **Scenario 2** shows the furnace setting where the relation between the number of initial heating/reheating furnaces and final heat treatment furnaces equals to 1:0.5.

• **Scenario 3** shows the furnace setting where the relation between the number of initial heating/reheating furnaces and final heat treatment furnaces equals to 1:0.33.

Findings
Basically, the evaluation focuses on various performance measures such as utilization, throughput rate and work in progress (WIP). Another important indicator is the determination of the optimal processing time and its impact on the overall performance of the system.

Impact on Capacity Utilization
In general, it is desirable to achieve a high capacity utilization in production system. However, too high workload can lead to instability and infinite waiting times. In this model it can be observed that the use of a higher number of initial heaters (S1/S2) leads...
to relatively high and stable utilization (~96%) in both scenarios (see Figure 5). In S3, the utilization decreases by about one third (65-70%), since the ratio favors IRF:

![Figure 5: Capacity utilization of initial heaters](image)

The average utilization is not depending on the static or variable dynamics of the heating times. The initial heater in this system represents the bottleneck. The use of a higher number of initial heaters leads to a high capacity utilization. If a greater number of IRF is used, the load is reduced by approximately one third. Regarding the capacity utilization of the initial heaters, S1 and S2 achieve the same results. The closedown of a FT (S2) leads to an improved utilization. The use of a higher number of heaters would be inefficient if the cost factor of energy was also taken into account, since a FT can achieve between 60 and 70 percent capacity utilization. Thus, the system remains stable and no bottlenecks arise.

**Impact on Throughput Rate**

The throughput rates in S1 and S2 do not differ at all. This is interesting, because in the second scenario a heater is switched off. This means that additional heaters in the final heating phase do not affect the throughput rate. However, the main focus should be on the differences between static and dynamic policies.

![Figure 6: Impact on Throughput Rate](image)

Moreover, the throughput rate from P_20 to P_Opt can be increased by ~3% and that from P_25 to P_Opt by ~10%. Additional data/information to determine the exact heating times have direct influences on the throughput rate (in all scenarios). With reference to the bottleneck of the initial heaters, it can be demonstrated that the throughput rate is limited by the number of initial heaters. In each scenario the dynamic heating configuration achieves the best result.
Impact on Work in Progress (WIP)
The WIP generally represents stocks in the current system and also tied capital. A high WIP means that the system is running at high capacity and can lead to unstable processes. This effect is clearly visible under S1 and S2 in the static area.

![Figure 7: Impact on Work in Progress](image)

Due to the improved process times under consideration of additional information for the initial heating, the number of waiting jobs under P_Opt is lowest at simultaneous high utilization. Based on the high capacity utilization in S1 and S2, policy P_25 shows that inventories are increasing to an equal degree. The simulation showed that the static configuration (P_25) is unstable. The capacity utilization is directly related to the WIP (S1 + S2 vs. S3). Additionally, exact information of plate temperatures have a direct influence on the WIP (P_Opt). The use of a higher number of initial heaters (S3) leads to a low utilization of the system and consequently to a very low or even inexistant WIP.

Impact on total processing time
Here, the process time of the initial heaters is documented. Since the process time is independent of the load and the resources made available, similar results exist in all three scenarios (see Figure 8).

![Figure 8: Impact on total processing time](image)

An improved information acquisition, ensured by the developed and implemented algorithms and sensor technologies, leads to faster processing times. This effect is illustrated in Policy P_Opt. This shows that a reduced process time leads to lower inventories and improved throughput rates.
Conclusion
Different real scenarios were simulated over a period of several months. The generated simulation results underline the qualitative statements given in the introduction of the paper. The case shows that the throughput rate was increased due to the improved process times of the furnaces. A direct connection with the technologies developed in and their influence on the production environment can therefore be proven and validated. In particular, we illustrate the influences of improved data acquisition, digitization efforts and new software solutions (algorithms/sensors) on the production area. However, the collection and analysis of manufacturing information for evaluating potential impact factors is cost-intensive. Based on such a procedure, costly further steps can be avoided if a fail regarding quality requirements can be detected. Furthermore, insights of the effect of learning from data over time reveals important potentials for future developments in Industry 4.0 development projects. In order to provide reliable results from collected and analyzed data, further scenarios have to be tested. Evaluations with the recently installed measuring system lead to higher accuracy in the temperature measurement of plates. Overall, this results in improved manufacturing performance, which is nothing more than increased productivity, quality and costs.

Acknowledgement
This work has been carried out within the scope of the project Power Semiconductor and Electronics Manufacturing 4.0 - (Semi40), under grant agreement No 962466. The project is funded by grants from Austria, Germany, Italy, France, Portugal and ECSEL JU. The overall support of Michael Eidenberger-Schober is gratefully acknowledged.

Abstract

The construction industry competitive environment has been demanding buildings conforming with the dynamic customer/owner requirements put together with the procurement of adequate personalised natural materials made to order in integrated value networks. But, the technological push has introduced BIM procurement as a mandatory industry best practice that demands standard mass produced materials (made to stock) to be introduced in IFC e-libraries ahead of their selection by technical specialists, not the owner. A three experts focus group generated an innovative Cyber Physical System conceptual model (research contribution) to solve this apparent paradox arising from an in depth literature review (theoretical contribution).

Keywords: Customer Relationship Management and BIM procurement, Ornamental Stones under Industry 4.0; IFC libraries and personalised smart materials.
Introduction
This paper will focus on the relationship with the built asset customers (building owners) to define and offer adequate and conforming personalized natural materials for the buildings, such as the Ornamental Stones. The study of this relationship will provide further insights to the replacement of the traditional procurement processes in the Architecture, Engineering and Construction (AEC) sector (Marinho, 2014). So, the overall research exercise will explore new forms of generating sustainable value supported by Digital Business Platforms, under a Building Information Modeling (BIM) approach for construction, design and operations in the AEC.

A framework supported by Service Science Theory (Vargo and Lusch, 2016) that promotes a customer-centric approach (Rajah et al., 2008), will accommodate the positive impact of the I4.0 production control model in transforming the threats resulting from BIM procurement, in the AEC industry, into opportunities. However, this is possible, if materials suppliers firms have a flexible manufacturing system supporting the dynamic offer of new customized materials or objects, by quickly redesigning them and being able to fully adjust the supporting processes (Zawadzki and Żywicki, 2016) to sustain the evolving customer (owner) requirements/expectations within the scope of a co-creative participation (Rajah, et. al, 2008). On the other hand, products/materials in the emerging BIM procurement context must be expressed in a standard format (e.g. Industry Foundation Class - IFC) and so, commercially available in the BIM-web-libraries, ahead of their choice. Only then, customers can choose them, which currently occurs under a traditional push approach that makes to stock (MTS) standard products in high volumes. However, if one follows a pull approach, materials should be first customized in conformance to their specification, aligned with the building one and, only then, made electronically available for selection from e-libraries. In addition, nowadays, this spec is mostly expressed as the material being "mouldable" to the area to be clad (i.e. the built asset geometry), including a certain type of holding system and, also surface texture, everything according to the architect’s (or building technical team) creativity. There is no objective link with the requirements/expectations of the building owner.

Thus, there is a conceptual conflict (paradox), because a major advantage of BIM usage concerns the standardization of the virtual objects to be part of the building, in order to bring in more stability to the construction business by a more transparent and stable procurement process itself. Therefore, the main objective of this paper concerns the introduction and operationalization of a dynamic “virtual element” designated as a [quasi-] Smart Object (Motamedi et al., 2016), co-created with the customer. This should be made available in a IFC standard (ISO16739:2013), on small enough time gap to be competitive with the standard materials, despite being personalized and made to order (MTO). So, this paper starts by establishing the type of customer relationship that should be specified, adopted and operationalized to target Sustainable networked Value Co-creation by pursuing a Service Science approach enabling a significant Strategic Business Positioning to accommodate the response of the Portuguese OS SME to the threats resulting from BIM procurement.

The chosen path to address the previously expressed paradox is, as follows: (i) firstly, by objectively recognizing that there is an increasing and unstoppable trend towards not only customization but personalization, not compatible with mass production products; (ii) secondly, by defining a role for the new digital technologies in the business change process; (iii) thirdly, by identifying new business models and processes aligned with the competitive context progress; (iv) fourthly, by proposing a much more effective support to the MTO option, supported by digital technologies and coming from an accepted
internal change dynamics that might not be objectively dismissed and also, from focusing the customer relationship on the customer/owner interest.

Next sections of this paper are, as follows: 1) the Literature Review, where topics (i), (ii), (iii) are covered; 2) the Methodology, where an exploratory abductive approach based on a focus group is explained; 3) the Empirical Findings, where the topic (iv) is addressed. So, in this section it is put together a conceptual proposal for a Cyber Physical system that enables to introduce a «quasi-smart» personalized material in the IFC library to cope with the challenging initial paradox; and, 4) the conclusions.

**Literature Review**

*The competitive context progress and new business models*

World population will increase 2 billion in the next 20-30 years, most of it concentrated in urban areas. As the Construction Industry (CI) is one of the largest consumers of raw materials and energy (Perspectives and Economics, 2015), it is imperative to find new solutions and innovative products that can contribute to the construction of sustainable cities, since along with sectors such as transport, the planet’s sustainability (Gao et al., 2015) will depend on the CI. Moreover, the Portuguese Ornamental Stones as a subsector of the Construction Industry also shows a significant national importance deserving to be investigated in line with the pursued record of research in the cluster (e.g. Peres and Costa, 2006; Frazão, 2016).

On the other hand, several researchers have argued that the firms’ competitiveness will progress across new management models concerning the integration of their operations in value networks (Lusch et al., 2009). However, in most cases, the customer is still seen as a strange element, independent and far away from the production sites (Lusch and Nambisan, 2015). So, a strategic business operations model promoting inter-organisational collaboration is definitely a solution to be seriously taken into account (Silva et al., 2016). For instance, in the Mass Personalization Paradigm (MPP) customers are intensively integrated into the production process (Wang et al., 2017). MPP requires product fulfillment to be changeable, adaptable, and configurable. In addition to the final product, the basic design and product structure must be able to differentiate at the module and parameter level to meet individual unique needs. Thus, for I4.0 to involve customers in products’ co-creation, the customer must be considered an indispensable actor (Vargo and Lusch, 2016), a situation still not very common, as several Service Science authors were considering. Nevertheless, Camarinha-Matos et al. (2017) confirm that the customers involvement in product design as well as close interaction among engineers of different nodes along the value chain require effective collaboration between manufacturers and customers, and so, it is argued that new sustainable Customer Relationship Management (CRM) models are on high demand. However, Forgues and Koskela (2009) made explicit the nature and fragmentation of procurement within the “design-bid-build” process and the client’s lack of understanding of its role in a new integrated design process, in the AEC sector. So, the role of the built asset owner within the construction networks should change and become clearer, in addition to the building technical team, i.e. architects, engineers and other specialists. An opener network interaction is required, where specialised and integrated agents increase end-user interactions with users, flexibility and iterative facilities design (Grilo et al., 2013).

Naoum and Egbu (2015) still argue for the need to break the fragmented approach of the traditional route and to encourage cooperation through an integrated method of procurement, communication and ideas able to be shared. This means that the construction industry’s poor performance with adversarial procurement practices causing high fragmentation, lack of quality outputs, and low productivity were still going on, as
Latham (1994) and Egan (1998) have reported 20 years earlier. In between this time gap many other researchers have considered that new procurement modes were required to transform the relationships dynamics between the client and the members of the supply chain, improving performance (e.g. Forgues and Koskela, 2009). It should be noted that any construction project involves several stakeholders like client, architects/engineers, developers, manufacturer, general contractors, subcontractors, suppliers and consultants. Moreover, construction material information systems are isolated, with no interaction between them (Kong et al., 2004). In general, it is difficult for a contractor to find all the information using one system and, even more difficult, to do a comparison of the products supplied by different suppliers based on criteria such as product specification, cost, availability, and delivery time (Empirica GmbH, 2007). According to Al-Bizri and Gray (2010), procurement approaches were not creating an organizational framework to deal with fragmentation of the building process and with the cultural issue. One of the biggest problems is the difficulty in implementing widespread team working and collaboration, primarily due to cultural barriers – something that BIM boasts as one of its main attributes (Naoum and Egub, 2015). Some authors also pointed out specific consequences of unclear and performed ad hoc partner responsibilities, in construction networks, such as conflict of resources and coordination efforts (Legner and Wende, 2006; Magdaleno et al., 2007). Therefore, an end-to-end Supply Chain (SC) approach appears to be needed at the AEC sector. However, besides the problem of aligning business processes from different organisations there is the problem of lack of transparency. Even minimal process visibility in BIM-based projects often provides business benefits to business partners, e.g. regarding technical and managerial decision-making (Grilo et al., 2013). In addition, Forgues and Koskela (2009) have identified another gap concerning the absence of recognized code of practice or Body of Knowledge (BoK) to support the new form of collaborative work inherent to that SC streamline approach. So, the BoK related to collaborative networks should be considered in this assignment.

In addition, Bullen and Davis (2003) highlight that the use of the traditional procurement process creates a professional barrier to innovative changes that is required by sustainability. Furthermore, Hamza and Greenwood (2007) added that under the traditional design and build procurement arrangements it may prove to be a very challenging task to design environmentally sensitive buildings as the iterations required are at odds with the contractor’s incentive to avoid delays and extra cost.

The role of new business platforms such as Building Information Modeling
BIM can support project collaborative working environments for enabling: (i) the built asset owner to develop an accurate understanding of the nature and needs of the purpose for the project; (ii) the design, development and analysis of the project; (iii) the management of the construction of the project and (iv) the management of the operations of the project during its operation and decommissioning (Grilo et al., 2013). BIM is an extension to CAD, as regards its design dimension. New functionalities coming from CAD 4D are mentioned in the literature. For instance, the combination of 3D CAD and 4D animations, e.g. virtual building modelling or energy performance graphics, can dramatically improve communication, coordination, and planning of construction projects while reducing risks and costs (Kymmell, 2015). Other sub-dimensions of design are also found in literature, as such concerning time-programming, costing or sustainability (Redmond et al., 2012). For non-design disciplines, such as contractors and project managers, BIM is more like an intelligent Data Management System (DMS) that can quickly take off data from CAD packages directly (Singh et al., 2011). Oreni et al.
(2014) add up the following functionalities, in both previously defined categories: (i) a single repository including both graphical documents - drawings - and non-graphical documents - specification, schedules, and other data; (e.g. ArchiCAD) (ii) a modeling of both graphical and non-graphical aspect of the entire Building Life cycle in a federated database management system (e.g. Bentley); (iii) a building design and documentation methodology characterized by the creation and use of coordinated, internally consistent computable information about a building project in design and construction (e.g. AutoDesk).

Thus, BIM does impact the business performance, by a technological push resulting into: (i) functional integration along the supply chain (Papadonikolaki et al., 2016); (ii) data standardization that defines the information formats, geometry, behaviour and presentation of BIM objects to maximize consistency, efficiency and interoperability across the construction industry, e.g. IFC (NBS National BIM Library, BIM Object Standard, 2019); (iii) data interoperable usability (Lee et al., 2006); (iv) inclusion of ICT frameworks that support collaboration with stakeholders over projects life-cycle (Motawa and Carter, 2013); (v) cloud-based sharing of the lists of products and materials with Suppliers (BIM Object - BIM Supply, 2019) and, (vi) better materials conformance (NBS National BIM Library - BIM Object Certification, 2019) through adequate procurement. In fact, as more disciplines of the construction industry adopt BIM, integrated design, and delivery work processes, the need for interoperable applications grows clearer (Lipman et al., 2011). So, BIM application may help to leverage construction procurement performance, particularly by emphasizing the role of information throughout the procurement cycle and, mostly, by allowing the automation of several procurement processes, diminishing the probability of errors and processes duration (Costa and Grilo, 2015). As each building/engineering project tends to be unique, it is critical to the success of e-procurement that the BIM approach considers the use of universal interoperability standards for the various dimensions, i.e., not only on the e-Tendering, e-ordering, e-invoicing or e-Catalogues, but also on product and process models (Grilo and Jardim-Goncalves, 2011). Thus, data interoperability and standardization provide sine qua non technical support to the claim that fully integrated procurement methods that include Design, Build and Project Management are most appropriate and significantly contribute to the buildability of the project change (Naoum and Egbu, 2015), i.e. to save time, costs and cost of change (Ma et al., 2013). Through the use of a common standard, the integration of building and materials information and, its effective use becomes possible (NBS National BIM Library, BIM Object Standard, 2019). Electronic integration in heterogeneous, distributed environments, business interoperability research intends to determine how and to what extent the potential of these concepts can be reclaimed for realising seamlessly integrated value chains (Li et al., 2008). In addition, BIM-based e-procurement vision may extend the buying capabilities requirements for procurement, also to design and develop products, manufacturing processes, logistics, and distribution strategies (Presutti, 2003; European Commission, 2010). Enhanced collaboration needs to be developed in the AEC sector and BIM requiring changes not only in the information systems. For example, service-oriented architecture (SOA) based BIM, new business processes and employees and culture, along with new management of business relationships are other major required changes (Grilo et al., 2013).
Role of the new digital technologies in the business change process

The fourth industrial revolution is characterized by an increase in digitalization and interconnectivity of physically separated manufacturing systems (Camarinha-Matos et al., 2017). While the digitalization of the systems of machines is made through the use of Cyber-Physical Systems (CPS), the interconnectivity is enabled by the Internet of Things technology (IoT) (Hermann et al., 2015). The Cyber Physical Production System is application of CPS to traditional manufacturing system with a CPS where Internet, manufacturing and cloud computing work side by side (Singh et al., 2019). So, by integrating CPS with production, logistics and services in Ornamental Stones’ suppliers today’s factories would turn into an Industry 4.0 (Lee et al., 2015) generating “quasi-smart” materials able to dynamically adjust to the building specification and customer/owner requirements. IoT could then communicate data throughout the building value chain (VC) if adequate care is put on data standardization and interoperability. This is the core base to support the implementation of BIM procurement with information flowing seamlessly along the VC to feed both technical and management systems associated with the building specification, design, construction and management.

In this way, the horizontal integration of data flow between partners, suppliers and customers, as well as the vertical integration within the organizational structure, involving factors related to the development of the final product and combining the real world with the virtual world (Abreu, 2018) would enable novel forms of personalization (Wang, et al., 2017; Abreu, 2018). This is the proposed theoretical way to overcome the paradox resulting from the introduction of BIM procurement as highlighted before. Therefore, the real world would be connected with a virtual one, ensuring more efficient use of available information (Zawadzki and Żywicki, 2016) to produce individual products at the cost of the mass production (Wang, et al., 2017) of standard materials. Thus, it is argued for the application of Industry 4.0 as a collective term for technologies and concepts to organize the value chain organization (Wang et al., 2017) by enabling real-time planning of production along with dynamic self-optimization (Abreu, 2018).

Methodology

An exploratory qualitative research was conducted by putting together a focus group of specialists that were carefully chosen and so, by asking about their perceptions, opinions, beliefs, and attitudes towards the presented ideas. Three engineers were participating. Topics were clearly and precisely defined based on the literature and there was a focus on enabling an interactive discussion between participants. The participants had common professional characteristics related to the topic being discussed and they were encouraged to discuss and share their points of view without any pressure to reach a consensus. These discussions were run for several times lasting for a total of 20h (10 sessions X 2hours), with the same participants. Questions to be considered were generated from the literature review. This exploratory assignment was expected to provide enough feedback to help to model the theoretical situation that has been previously described. Data were treated and processed according to adequate techniques that are usually used to process the focus group notes in qualitative analysis, i.e. contents analysis (Bell et al., 2018). Finally, the participants made an effort to put together a conceptual proposal for a CPS that enables to introduce a «quasi-smart» personalized material in the IFC library to cope with the challenging initial paradox. By the end this methodological choice configures the operationalization of an abductive approach.
Empirical Findings
The experts in the focus group agreed that the current trends on the competitive environment of the Construction Industry are requiring new business models for the Ornamental Stones SME to overcome traditional problems of the AEC Sector, such as: (i) disaggregation of the value network; (ii) SC fragmentation originating lack of visibility in operations, lack of transparency in procurement and lack of management of the SC as a whole entity (i.e. an end-to-end approach); (iii) favouring MTS mass production materials, which are not aligned with the competitive requirements that are asking for personalisation; (iv) exclusion of the building owner from the business processes concerning the design and construction of the built asset, excluding him/her from the interaction with the SC members, by promoting the imperative of the technocratic decision making; (v) replacement of the built asset owner by the technical specialists, such as architects and engineers among others, with no formal definition of a role for the building owner; (vi) favouring the minimisation of short term costs over costs discussed under the umbrella of a broader Life Cycle Assessment (LCA); (vii) no formal and explicit linkage to the use of local natural materials (e.g. stone), instead of global ones (e.g. glass, steel and concrete), in the category “sustainable cities and communities” of the UN sustainable development goals; (viii) lack of integrated information systems and data interchangeability.

BIM was praised by the focus group members as a powerful information platform to seamlessly and automatically exchange and share data coming from the strengthened CAD software together with other computer sources. These data might be used for several purposes, as follows: to feed Computer Aided Engineering Systems (CAE), e.g. studying the building envelope; for management and administrative purposes, e.g. the collaborative management of the project or of the SC; for better organisational arrangements, e.g. functional integration, fostering a collaborative culture; for innovative studies by putting together several sources, e.g. following the water pipes inside walls by augmented and virtual reality techniques; for supporting a different collaborative customer (owner) relationship both with the building technical team and with the other partners of the supply chain, e.g. with the help of electronic platforms for exchanging relevant information; and, of course, to foster and support a different type of materials procurement by introducing electronic means and bringing in transparency and visibility.

However, the focus group recognised I4.0 as the missing link to pursue sustainable value creation, in terms of the required updated technology to operationalise the new business processes arising from BIM procurement and a collaborative network. By associating the concept of CPS with the IoT, products and machines interconnect and communicate with each other and with the network they are part of, which also includes the final customer, i.e. the built asset owner. Digital technologies enabling the interconnections between the digital world and physical assets are made possible by sensory technologies for acquiring and exchanging data aiming to develop the “quasi-smart” object to include in the BIM IFC library to satisfy a personalized demand for a material (eventually an ornamental stone) on a MTO base. The experts agreed to fully adapt and renew the concept of Cyber Physical System of Silva (2018) to represent the required innovative CPS. The model mapped in Figure 1 is described, as follows.

Suppliers’ manufacturing data such as material consumptions, workforce situations, machine statuses, and order progress are collected and automatically managed in real-time to answer quotation queries for a «quasi-smart» material defined according to its specifications coming from the material requirements expressed by CAE/engineering applications working on the building specification, the objective engineering criteria. However, a second set of criteria that are qualitative, e.g. the off-line application,
maintenance and demolition issues, will act as moderators of the main engineering criteria (first set) enabling a choice among alternative rival scenarios by the BIM modeler. This is the personalized offer (MTO) to be inserted both in the IFC library and in the ERP system. However, the CPS also operates MTS materials, by directly importing their definitions and standard ordering conditions from the ERP to the IFC libraries. One final remark to say that the above mentioned building specification results from the expression of requirements/expectations for the building by its owner, which are transformed into the spec by the building technical team (engineers, architects, others) through the design process. Finally, the term «quasi-smart» material was coined after the focus group discussions, to define a material of which spec is dynamic, depending on acceptable changes from the stakeholders, i.e. the technical teams, the built asset owner and other stakeholders. Then the CPS should be able to deal with these changes.

Conclusions
This paper introduced an innovative conceptual model of a Cyber Physical System (theoretical and research contributions). It aims at solving the conflict between the administrative requirements for the BIM-web-libraries for standard mass produced industrial materials and the electronic needs of «quasi-smart» personalized natural materials conforming with dynamic specs that connect to the requirements/expectations of the building owner. The CPS should only be a (semi-)automatic way to expedite the administrative process of inserting the personalized materials on the BIM e-library within a sufficient time gap to be competitive with the standard ones. However, it is argued that this initial question is a false question because the authors expect that the personalized material can offer other functionalities that the standard one cannot (practitioner contribution). For instance, it is expected the conformance of the personalized materials with a strict engineering criterion coming from the building specification (not only...
aesthetical issues), or even the ability to adjust to dynamic customer/owner requirements for the building, which impact the materials’ spec. In fact, this is what the construction industry “says it needs” and, also, what is on demand after analyzing the competitive environment of the AEC sector, as well as the flaws detected on the current business models requiring to be fixed. Thus, we conclude that the standard material is not competing with the «quasi-smart» personalised material (term coined on this paper). At most they might complement each other. Anyway, the CPS can cope with both situations. As a recommendation for further work, there is a need to find an engineering criterion strong enough to promote the linkage and conformance between the material to be procured, under a BIM paradigm, the building spec and the building owner requirements.

Abstract

Although, there are conceptual works on key I4.0 technologies and empirical findings about specific I4.0 applications, current literature offers only superficial empirical findings about organisation-wide I4.0 transformations. Our objective is to provide a framework for I4.0 implementation and discuss three case studies based on the framework. Based on our findings, even the large companies struggle with I4.0. Nevertheless, they already have digital strategy, digital transformation plan, and digital governance. But digitalization is still in a separated department. Efforts are usually made internally, in manufacturing. Replacing technologies can provide good, easy to estimate return, but will not lead to breakthrough transformations.

Keywords: Digitalisation, Industry 4.0, Sector

Introduction

Digitalisation has become the most recent buzzword in many field of business and management. Today, the digitalisation trend includes the appearance of Industry 4.0 (I4.0) in the manufacturing context (Valenduc & Vendramin, 2016). However, in practice, I4.0 goes well beyond the adoption of digitally based business innovations; novel and/or renewed physical technologies are also integrated in its core. In its vision, I4.0 exploits cyber-physical technologies to offer customized products with digitally enriched service content that is delivered by a reengineered value chain (horizontal integration) within a restructured supply chain (vertical integration) in which all participants are interconnected and share information (Schlechtendahl et al., 2015).
Although, there are many conceptual works on key I4.0 technologies and well-documented empirical findings about specific I4.0 applications, current literature offers only rather superficial empirical findings about organisation-wide I4.0 transformations. Our objective is to provide a complex framework for I4.0 implementation and discuss three case studies based on the developed framework. Our framework synthesizes the common dimensions of company level I4.0 maturity models (Fettermann, et al., 2018) (Geissbauer, et al., 2016) (Viharos, et al., 2017). It covers strategy formulation and deployment, classification of I4.0 technologies (e.g., maturity, human impact), and touches upon changes in the organisation. Given the current state of knowledge, case-study based research bears the potential of a notable contribution for both researchers and practitioners to better understand the phenomenon.

Industry 4.0 in the digital economy

Technologies in Industry 4.0

The emergence of the I4.0 concept shows that the development and adoption of digital and physical innovations has reached a critical mass. In Table 1 we highlight eight core I4.0 technologies. Table 1 is structured according to Schwab (2016) who has grouped the technologies into digitally and physically dominated categories. As Table 1 indicates, authors with very different backgrounds and target audiences usually refer to the same core I4.0 technologies. In our opinion, these technologies are the building blocks of I4.0 efforts and the practical applications generally implement a specific technology (e.g., 3D printing) and/or the combination of technologies (e.g., digital quality management, predictive maintenance) (Goran, et al., 2017).

Literature review

The literature review is organized around the topics of strategy, technology and organization.

Strategy

Several papers argue that a shift in strategic orientation is required to drive a more effective implementation of new technologies (Lewis and Boyer, 2002), or that at least adoption strategies and firm-level business strategies need to be aligned for the successful implementation of any new technology (Kotha and Swamidass, 2000). Nevertheless,
recent findings suggest that this issue requires further verification, as the link between strategy and technology adoption is not always straightforward (Lucianetti et al., 2018). This is especially true in the case of the newly emerging I4.0 technologies and methods.

When introducing changes on the operational level, especially changes that require the application of new technologies, two important issues are discussed in the literature. The first aspect concerns whether the strategic planning is proactive or reactive (King and Teo, 2000). Proactive strategies imply that the company takes an active role in strategic innovation, seeking to introduce new processes or products ahead of competitors with the aim to seize arising opportunities and obtain a competitive advantage on the market. Reactive strategies mean that a company takes a passive role in strategic innovation, changing its strategic behaviour to comply with external pressures, react to the changes observed in the environment or to respond to challenges posed by its competitors.

Another aspect related to the strategic implications of new technology adoption concerns the extent to which a strategic planning process is formal or informal (O’Regan and Ghobadian, 2002). Formal strategic planning represents an iterative, comprehensive and systemic approach by which the management of the company analytically determines a strategic direction for the organization. On the other hand, informal planning relies only on the past experience and intuition of an organization to make decisions regarding the future. This distinction is closely related to the top-down and the bottom-up nature of operations strategy formulation. While top-down strategies are a result of a formal, hierarchical planning process, bottom-up strategies are a result of the knowledge accumulated with the daily activities of an organization (Slack et al., 2010).

Thus, in order to classify strategic approaches to I4.0 implementation, at least two aspects need to be taken into consideration: (1) the reactive or proactive nature of strategic planning, and (2) the formality of strategic planning which is closely linked to the top-down or bottom-up nature of strategy formation.

**Technology related concepts**

The aim of the use of I4.0 technologies and the focus of I4.0-related company efforts can vary significantly. We introduce three different approaches to classify technologies.

*The maturity of the technologies*

Since sporadic application of I4.0 technologies will not lead to an organisational renewal, it is usually suggested to develop a strategy which builds on the interplay of many core I4.0 technologies (Ghobakhloo, 2018). However, core I4.0 technologies are at different stages of maturity. We assess the maturity of the core technologies based on the hype cycle of emerging technologies by Gartner (Gartner, no date). The annual hype cycle defines the actual stage of many emerging technologies alongside the following phases of a “life cycle”: innovation trigger, peak of inflated expectations, trough of disillusionment, slope of enlightenment, plateau of productivity. Furthermore, the analysis also predicts the time horizon when the specific technology arrives at the plateau of productivity phase. To assess the maturity of the eight I4.0 technologies we have reviewed the Gartner analyses on emerging technologies for three selected years: 2009 (Hutch, 2009), 2013 (Gartner, 2013), and 2018 (Panetta, 2018) (Figure 1).

To assess a specific technology, we have looked at its appearance (yes/no), the date of appearance and the predicted year of arriving at the plateau phase. The eight technologies can be classified into four groups:

1. Long history and well-known technologies: simulation and modelling and sensor technologies were not mentioned on the hype cycle at all. While these
technologies have long history, other I4.0 technologies (e.g. IoT, big data) can leverage the applicability of them.

2. Mature I4.0 technologies have appeared a decade ago and are predicted (by different analyses) to have already arrived at plateau phase. Cloud, 3D and RFID belong to this group.

3. Several well-known technologies (IoT, VAR, smart robots) belong to the emerging group that will arrive at the plateau stage in the long term.

4. Big Data lies between the latter two groups. Despite its shorter history, it is predicted to be productive application at the start of the next decade.

Figure 1 – Maturity of core I4.0 technologies – assessment based on Gartner’s hype cycle

Source: (Hutch, 2009) (Gartner, 2013) (Panetta, 2018)

The implication of technology on work force

Based on the implication of technology on work force Acemoglu (2017) differentiates replacing and enabling technologies. Enabling technologies are conceptualized as “augmenting the capabilities of some workers and enabling them to perform new functions, increasing their productivity” (Acemoglu, 2017, p. 4). Replacing technologies are “explicitly replacing labor in some tasks” (Acemoglu, 2017, p. 5). Robots usually impact repetitive tasks both in manual (industrial robot) and in cognitive (automatic order management) settings. On the long run, the promise of AI is that it might replace creative cognitive tasks.

Type of innovation boosted by I4.0

Different types of innovation can be boosted by I4.0. The most complex change is organised around business model innovation. The business model innovation considerably reshapes the relations with stakeholders, and it can also lead to the development of completely new modus operandi (e.g., new processes, new competitors) in a particular industry. It necessarily relies on smart products or services that we regard as the second type of innovation. Finally, the exploitation of I4.0 in process innovation is also a viable adoption strategy. In this case the main (exclusive) aim is to make, usually internal processes of, the value chain more efficient. Manufacturing companies usually look for internal process integration and better operational performance (López-Gómez, et al., 2018). The process innovation approach is a quite narrow interpretation of I4.0.
**Organisation and new organisational structure**

Successful implementation of I4.0 can contribute to a long-term competitive advantage (Gilchrist, 2016). This is why the technology-organization-environment (TOE) fit of the manufacturing companies is more important today, than ever before. Tornatzky and Fleischer (1990) developed the TOE framework, which explains on the organization-level that three different elements of a firm’s context influence adoption decisions and process. These three elements are the technological context, the organizational context, and the environmental context. All three are posited to influence technological innovation, which impacts directly the long-term profitability of a company.

Operations management (OM) literature has researched both the technological level, and the environmental level, while we have little knowledge on the organizational perspective (Baker, 2012). Andersson and Tuddenham (2014) claim that organizational structures are rigid, therefore cannot change as fast as the digitalization process would make it necessary. They argue that digitalization should be part of a reinvented IT function, as it changes the demands on IT. These changes highlight the need for a new organizational governance in which the digitalization has a greater role. While this has regularly been claimed in the context of discussions on IT’s strategic value in firms, it is seldom achieved (Legner et al., 2017; Andersson & Tuddenham, 2014).

A companywide successful digitalization project is driven by the CEO and business leaders, who consider it as one of their top priorities and not just as an “IT effort” (Andersson & Tuddenham, 2014). However, in order to meet the challenges of digitalization, the IT function must undergo a “change that comprises new models of internal organization as well as new forms of collaboration and alignment with business departments” (Legner et al., 2017, p. 307).

**The research framework**

Based on the literature review we developed a framework to grasp the key issues in an I4.0 transition.

![Figure 2 – The framework of our research](image)

**Research methodology**

We collected data from three companies in Hungary working in the automotive and electronics industry based on a uniform case study protocol. Companies were selected by convenience and based on their commitment to I4.0. Our interviewees were managers (manager of digital department (if applicable), senior manager, project managers) who could provide information on these topics. Interviews were recorded and transcribed. We also processed publicly available information, student works and company documents.

* 5 additional interviews at other subsidiaries of the company.

We apply the developed framework for single cases, and then we synthesize the information in the cross-case analysis to identify the specific characteristics of I4.0.

Case descriptions

Each case units’ main business activity is to assemble electronic parts for the automotive companies in TIER1/2/3 positions. The business measures of the case units have improved considerably in recent years due to: (1) soaring production volumes in the European car markets, (2) accelerating offshoring towards Eastern European countries in the automotive industry, and (3) the increasing share of electronic parts in cars.

Company 1

C1 is part of a market leader global company with American roots, currently headquartered in Switzerland. The global company produces half a million different precision products in approximately 100 plants, with 70,000 employees worldwide. The subsidiary operates with 1500 employees in Hungary in the transportation solution business line that belongs to the automotive division and the EMEA region. The product variety, size differences and volumes are all at high level in the plant.

C1 had its first experiments with I4.0 in 2012 with the lead of its lean department. They placed thousands of sensors in machines to increase the machine connectivity level. Their first projects were the electronic andon and the digital dashboard in the production area. In 2014 the automotive division in the EMEA region had a workshop, where they collected the potential processes to improve, 160 processes altogether. The clear objective was to address process efficiency and costs. The Hungarian subsidiary became one of the two pilot plants due to its ambitious lean manager. They started new projects, such as the operator learning management system (OLMS) for operators’ training, the e-QCPC (electronic quality control process chart) by digitizing and enhancing the existing QCPC system. The lean department has employed some IT experts to support these developments. They also have had pilots in predictive maintenance, understanding big data, but achieved limited progress so far. They received a 3D printer for metal to produce products for the aftermarket on this machine. The company has its own internal cloud. In 2016 the global division decided to organize a 6 weeks strategic meeting with the help of a big consulting company to prepare the digital strategy for the division, with a roadmap and a digital governance model.

In the digital governance model, the global division has a digital leader leading the so-called regional champions. Champions work with regional accelerators, 3 in the EMEA region, each of them is an expert in a specific I4.0 technology. In local I4.0 projects a) a subject matter expert (SME), knowing the area of intervention, b) a local accelerator, familiar with the digital technologies c) a project manager, usually someone from the lean
A local digital champion represents the management and coordinate the work of the three experts. The subsidiary provides data analysis and SCRUM training for experts and project managers.

C1 involve employees into the developments (e.g. they can participate in designing the screen for the dashboards), provide online trainings, give rewards for ideas and contribution. The I4.0 applications support decision making (dashboard, eQCPC) and training (OLMS), increase visibility and transparency (dashboard), and hopefully will reduce costs in the future (predictive maintenance, 3D printing for small batches). All these efforts currently need more employees, especially engineers and IT experts.

**Company 2**

C2 is a Hungarian headquartered electronic manufacturing services (EMS) company, listed on the Manufacturing Market Inside’ (MMI) EMS TOP50 list. Almost half of its turnover comes from the automotive segment. In the last few years, the segment have considerably improved its relative share in the turnover. The company have many subsidiaries. These subsidiaries are run by independent top managers with strong control from the HQ. At the company, we investigated two large subsidiaries (1000+ employees respectively). In this paper we use information from the automotive subsidiary.

Regarding process innovations, C2 is committed to lean management and recently to I4.0. However, given that subsidiaries have high degree of independence, no formal strategy or coordination exists for the deployment process. Until now, one meeting for top managers at the HQ was organized around I4.0 in 2018. The managers at all levels of the company share a “conservative” investment policy. It means that investments are usually triggered by specific customer request and short-term returns are expected.

C2 is in TIER2/3 position. High variety and low volume products give most of the product portfolio. The production processes rely largely on manual work. Only a few products are assembled in large volumes that are produced on automated production lines.

The subsidiary started its traceability system on a specific customer request several years ago. For today, this system has turned into a basic MES system. It’s a monitoring system that covers automated processes and machine-based workstations in the assembly. However, there are still stand-alone stations, not connected. In the future the subsidiary could resolve machines connectivity and the integration of further internal functions (e.g., logistics). The subsidiary has developed the system on its own due to cost and independency/flexibility considerations exploiting internal programming know-how. Although, the initial trigger has come from a buyer, the upgrading of MES has been continuous due to functional managers’ and supervisors’ needs.

A few years ago the subsidiary launched an assembly robot on a high runner work station with the support of an integrator supplier. The robot replaces two operators per shift. Relying on M2M communication the assembly robot arm orders the next robot arm to select the scrap. At C2 this assembly robot is regarded as “automation” not as I4.0.

At C2 level the engineering department manages the I4.0-minded projects. This department is led by the chief engineer and by the head of new product introduction (NPI) group. The installation of the robot has delayed considerably despite having an integrator supplier. The potential installation of further robots is constrained by the product portfolio (low proportion of high runners) and in the case of some product the tolerance levels of input materials and shortcomings of product developments cause also difficulties.

**Company 3**

C3 is a subsidiary of a large automotive supplier, with more than 1000 employees. C3 is in TIER 1/2 position depending on the product. Its short-term plan is to double the
turnover without further increase in the number of employees, so they fully exploit the potential of the digital factory concept. The unit devotes its efforts to process innovation. The company developed a division-wide Industry 4.0 strategy (digital factory concept). The digital factory is embedded into a high-tech IT context and it also assumes experts with proper digital skills. KPIs are developed to motivate and measure the advancement of the I4.0 applications. The strategy differentiates the I4.0 technologies and applications based on the proposed roll-out period. Robots (cobots, AGVs), additive manufacturing, shop floor management and reporting systems have been integral parts of operations for the recent years. C3 has installed dozens of robots. At the beginning it worked with integrator, today C3 has the installation competence. 3D printers (more than 10) are in daily use for non-production materials within the unit. Digital reporting system utilize the data collected by an extended MES system that covers production and logistics and integrates also information of other business functions (e.g., HR, development plans).

The company has several centres of excellence that act as internal consultancy units. These units develop and test specific applications and then help the company-wide roll-out process. Beside the central initiatives there are minor I4.0-minded experimental pilot projects in the preparation phase (e.g., drone, gloves).

The deployment of the central I4.0 strategy is supported by a new department (digital engineering). The department has more than 20 employees and it has integrated the lean group as well. The digital department’s main focus is on robot technology. IT department also has a crucial role in digital transformation, e.g., it has developed the MES system, the basis for reporting and BI.

The widespread impact of digital transformation has necessary influence on employees. The assumption is that successful digitalization strategy relies foremost on people. Training materials have been developed and skill matrix is also extended to digital competences.

Cross-case analysis
In order to compare our cases, we organized the key information into Table 3. Due to space constraints we cannot explain the table here.

### Discussion and conclusions

In our paper we developed a framework to grasp the main features of I4.0 transitions through three case studies. Based on our experiences we can draw some conclusions.

First, we found a limited approach towards I4.0 technologies, focusing only on process development in manufacturing and material flows, similarly to López-Gómez, et al. (2018). Results do not support the predictions made by consultancy reports (e.g. Rüssmann et al., 2015). This fact might be due to the positions of case companies in the supply chain (assemblers).

Second, all the efforts companies make are not about competitive advantage (at least yet) as explained by King and Teo (2000) or Gilchrist (2016). This is more about staying in competition and searching for opportunities for improvement. Even the best companies can only be considered as early adopters. Competitive advantage would be related more to product innovation or new business models, but our case companies serve the low-cost direction. It might be a context specific result though, and Western European companies – even within the network of our case companies – follow different path.

Third, consistently with the second finding, mainly mature technologies are in use, and there are only some limited experiments with others. High runner products are in focus. MES system and IoT could be the basis of Big data analytics serving better decisions, but they aren't yet. The lack of technology standards is a big constraint.

Fourth, digitalisation is “integrated” into business as usual operations, adjustments were made to provide the fit; but it did not transform the culture (Legner, et al, 2017). Companies develop digital governance structures that fits into the existing structure. It does not bring a considerable shift, it is “just” a new department. The level of structural change is made according to the level of changes. Less change (C2) does not require even a new department, bigger change (C1) gradually results in new structures.

Fifth, replacing technologies bring good and easy to estimate returns, while for enabling technologies business cases should be developed. However, enabling technologies bear the potential to transform from reactive to a proactive unit and can provide real productivity increase (Acemoglu, 2016, 2017).

Sixth, our case companies developed cooperation with technology providers and consultancy agencies, acquired start-ups if needed to get access to knowledge and develop their own capabilities. For small companies it is not an option.

Since we are currently in the data collection phase, it is still too early to formulate deeper conclusions.

### Acknowledgment

This research was supported by the project “Aspects on the development of intelligent, sustainable and inclusive society: social, technological, innovation networks in employment and digital economy” (EFOP-3.6.2-16-2017-00007). The project has been supported by the EU, co-financed by the European Social Fund and the budget of Hungary.

Abstract

This paper proposes and validates a data-driven framework for production improvement. We take advantage of the latest developments in machine learning to address the complexity of today’s manufacturing systems. Our approach models data from the entire manufacturing process chain in a factory to get a deeper understanding of how certain production factors affect product quality. We experimentally validate our framework at a semiconductor manufacturer and detect both known and unknown process problems. Our approach significantly reduces the fault detection time and provides insights where traditional methods fail.

Keywords: Data-driven production improvement, machine learning, SHAP value method

Introduction

Due to increasing automation and connectivity, modern production systems generate an enormous amount of data. Creating knowledge from these data assets enables superior decision making and can therefore help to gain a competitive edge (Harding et al., 2006; Tao et al., 2018). However, the vast increase of data complexity in today’s manufacturing systems can be overwhelming and as a result most producers fail to capitalise on their data richness (Kusiak, 2017). Over the past years, companies have invested heavily in their IT infrastructure and adopted statistical process control techniques, leading to improved control and lower process variability (Heim and Peng, 2010). However, in the era of big data, traditional statistical methods are no longer enough to analyse complex production data, which is characterised by high dimensionality, sparsity, and multicollinearity. Guha and Kumar (2018) argued that companies should build profound capabilities in big data analytics to compete effectively in the future.

Data mining can help to address this challenge by identifying valuable information in large datasets. In data mining, algorithms are employed to discover hidden patterns in complicated data structures and to predict future events. Compared to statistical data models, algorithmic models can provide a higher predictive power, allowing for more robust and generaliseable conclusions (cf. Breiman, 2001). Also, predictive analytics can
be essential for building and testing theories (Shmueli and Koppius, 2011). Choi et al. (2018) suggest that algorithmic modelling is one of the most important research developments in the operations management field. However, despite its significance, big data analytics has received too little attention from the operations management society (Feng and Shanthikumar, 2018). Especially in manufacturing, computer scientists and engineers, whose contributions mostly focus on industry-specific applications, have dominated this important area of research.

In order to elucidate how machine learning can aid production improvement, this paper addresses the following research question:

- How can machine learning algorithms identify quality drivers from complex manufacturing data?

Encouraged by Feng and Shanthikumar’s (2018) call for research, we contribute to the literature and practice of operations management by proposing and validating a data-driven framework that exploits untapped potentials for production improvement. The framework can consider data from the entire manufacturing process chain in a factory and implements an explainable machine learning concept to overcome the shortcomings of current methods. The principle of the framework is to model production factors, such as process parameters and sensor measurements, to investigate their impact on product quality. Since the developed approach is generic and flexible, it is applicable in any manufacturing sector with a high degree of automatic data capture (e.g. semiconductor, pharmaceutical, plastics, or metal industries). To validate our approach, we apply it at ABB Semiconductors, a producer of high power semiconductors.

The remainder of this paper is structured as follows. In section 2, we conduct a thorough literature review to answer our research question. Thereafter, we outline our data-driven framework (section 3) and describe the research setting at the case company (section 4). Section 5 presents the obtained model results and identifies quality drivers. In section 6, we discuss the developed approach and elaborate on implications for the future of operations management. Finally, section 7 summarises the main findings and concludes the paper.

**Literature review**

Two different streams of literature are particularly relevant for this paper. Firstly, we study the literature on machine learning applications in operations management to map our research domain and evaluate the current state of knowledge. Secondly, we review the directly related computer science and engineering literature on machine learning in production improvement tasks. As this work focuses on quality driver identification, we do not cover publications on predictive maintenance.

**Operations management literature on machine learning applications**

Operations management research on machine learning applications has been predominantly concerned with demand forecasting. For example, Ferreira et al. (2016) showed that bagged regression trees provide better demand predictions than traditional regression techniques. Also Cui et al. (2018) emphasised on the superior performance of machine learning algorithms, especially when dealing with high-dimensional data. The paper studies the operational value of social media information when predicting the aggregate daily sales of an online retailer. The study showed that social media information can improve sales forecasting and that complex machine learning algorithms, such as random forests and gradient boosting machines, outperform linear regression models.
Similar research was conducted by Lau et al. (2018), who designed a big data analytics methodology using a parallel aspect-orientated sentiment analysis for demand forecasting. The authors improved the overall model performance by mining customer-generated content and applying a co-evolutionary extreme learning machine. Carbonneau et al. (2008) studied the application of machine learning algorithms, including neural networks and support vector machines, to forecast demand in distorted supply chains. Neural networks have also been used by Chong et al. (2017) to predict the sales of electronic products in an online marketplace.

Compared to demand forecasting, other application areas of algorithmic modelling, like manufacturing, have received less attention in the operations management literature. For example, Saraiva and Stephanopoulos (1998) developed an exploratory data analysis approach with an interval-based optimisation framework to improve processes. The authors demonstrated the applicability of their methodology in four industrial case studies. Another example was provided by Ghosh and Maiti (2014), who proposed a machine learning framework based on the Define-Measure-Analyse-Improve-Control (DMAIC) methodology. The concept was applied in a foundry process and revealed significant cost saving potentials. Nevertheless, both of the aforementioned papers apply methods that no longer correspond to the state-of-the-art of machine learning.

Technical literature on machine learning applications in production improvement
Several technical articles apply algorithmic modelling to enhance both product and process quality in manufacturing (cf. Köksal et al., 2011). Li et al. (2017) applied an extreme learning machine to optimise an iron ore sintering process. Ronowicz et al. (2015) implemented a regression tree to understand how different process parameters affect the pellet sphericity of medicinal products. Lian et al. (2002) also used a tree-based algorithm to diagnose variations in sheet metal assembly. Tsai (2012) used a self-organising map, k-means clustering, and a decision tree to infer solder defect patterns and to predict quality at an electronics producer. Ozcelik and Erzurumlu (2006) employed a neural network to model warpage in an injection moulding process.

Also in the semiconductor manufacturing industry, there is a range of papers that apply machine learning to improve manufacturing processes and product quality. Weiss et al. (2016) applied a selection of algorithms (e.g. boosted trees, support vector machine and a hidden-Markov-model-based method with lasso regression) to predict the final speed of microprocessors. The authors conducted an experiment with real-time production data and successfully identified 125 wafers with abnormal speed. Based on the predictions, it was possible to adapt the manufacturing process and to correct 25 wafers to normal operation. Skinner et al. (2002) discussed the advantages of using classification and regression trees to model and analyse wafer probe test data. Chien et al. (2013) proposed a framework based on principle component analysis, clustering, and decision tree algorithms to detect abnormal wafers from process data. A hybrid data mining approach was also employed by Hsu and Chien (2007), who extracted defect patterns from wafer bin maps. Chien et al. (2007) used k-means clustering and a decision tree to infer root causes for process faults from semiconductor manufacturing data.

While all of the listed papers clearly contribute to their respective application area, they tend to focus on specific industry segments. A more generic approach that can be applied in various manufacturing industries was introduced by Chen et al. (2005). The proposed method employs a rule-mining algorithm to analyse correlations between damaged products and the used production equipment. However, the presented approach neglects the fact that also other factors than the machine path can affect product quality. Therefore, critical production factors might remain undiscovered. A machine-learning-
based concept that considers both product characteristics and process parameters was provided by Wuest (2015). The author’s theoretical construct incorporates data from multiple manufacturing processes to identify quality drivers. Nevertheless, the proposed method has a limitation. The applied support vector machine algorithm only determines global variable importance. For this reason, the respective influence of a given production factor on product quality cannot be explained sufficiently.

**Implications for framework development**

The literature review above provides two important implications for the development of our data-driven framework for production improvement. Firstly, it highlights that machine learning algorithms are suitable for identifying critical production factors from complex manufacturing data. Nevertheless, we find that previous research has not managed to handle the trade-off between model performance and explanation sufficiently. Getting a deeper understanding of the underlying variable relationships is a prerequisite for improving both product and process quality. Secondly, we discover that most manufacturing-related papers are published in technical literature and focus on a specific industry. This finding is consistent with the criticism of Feng and Shanthikumar (2018), who state that the big-data-related contribution of the operations management society has been insufficient. With this in view, we identify that there is a need for machine learning methodologies that are both practical in an operations context and independent from a specific industry segment. This work seeks to close this literature gap by developing a generic framework based on state-of-the-art machine learning methods.

**Data-driven framework**

The framework consist of the following three phases: (1) Data preparation, (2) data mining, and (3) in-depth analysis of variable relationships (Figure 1). The first phase provides a guideline on acquiring relevant manufacturing data for the subsequent data mining process. In the second phase, a gradient boosting algorithm is trained to explicitly learn the underlying relationships between production factors and product quality. The third phase assesses these relationships and identifies critical production factors. The derived insights can then be used to initiate production improvement measures.

![Figure 1 – Data-driven framework for production improvement](image-url)
Phase 1: Data preparation
To model the interactions between fabrication processes, it is necessary to analyse manufacturing systems holistically (cf. Wuest, 2015). Figure 2 illustrates an example of a manufacturing system where the production factors are independent variables and the product quality is the dependent variable. Within our framework, we suggest to collect data with regard to the following four categories: (1) Operation history data, (2) environmental measurements, (3) product measurements, and (4) quality data. Operation history data (OH) concerns machine trace data and timestamps. Ideally it can be determined which equipment (EQ) has processed a specific product at a certain time. The corresponding timestamps allow computing the operation duration (OD) and the queue time (QT) between two processes. Product measurements (PM) collected during the manufacturing process describe the corresponding product properties. Environmental measurements (EM) comprise machine measurements and other environmental factors such as temperature. The dependent product quality (Q) can be defined through measurements, yield percentages or categories (e.g. pass and fail). Once the data from the four framework categories has been acquired, it must be merged into a single dataset.

![Figure 2 – Independent variables and dependent variable in a manufacturing system; system view notation adapted from product state concept (Wuest, 2015)](image_url)

Phase 2: Data mining
When modelling the previously acquired manufacturing data to identify potential quality drivers, there is a need for an accurate and explainable model. However, satisfying both conditions is subject to the following conflict: While simple (and interpretable) statistical methods tend to have a poor fit with high-dimensional data (Cui et al., 2018), complex algorithms such as neural networks are black box models (Waldrop, 2019). To overcome this drawback, we integrate an implementation of Friedman’s (2001) gradient boosting framework in combination with the novel SHAP (Shapley Additive Explanations) value method by Lundberg and Lee (2017). Boosting algorithms are known for performing well on complex datasets and have already been employed in other manufacturing-related applications (e.g. Weiss et al., 2016). To prevent overfitting and misleading conclusions, it is required to evaluate the algorithm’s predictive performance. Only if the model performs well on out-of-sample observations, it can be ensured that the learned variable relationships are accurate.

Phase 3: In-depth analysis of variable relationships
As previously mentioned, it is considerably difficult to explain sophisticated models such as gradient boosting machines. The SHAP value method resolves this issue by making use of additive feature attribution. The underlying idea is that a complex model can be approximated by a simple explanation model. SHAP values can be interpreted as the marginal contribution of a variable to the overall model output. As SHAP values are derived for each observation separately, they allow to explain model behaviour on both a global population and the individual observation level. For further details, see Lundberg...
and Lee (2017). Within our framework, we compute SHAP values for each production factor to understand its impact on product quality.

Research setting and data
Our case company belongs to a large conglomerate and is one of the leading producers of high power semiconductors. The proposed machine learning framework is validated by using wafer fabrication data from a complex transistor product. The company collects batch-level data according to all four data dimensions of our data-driven framework. The final dataset contains more than 6,000 independent variables from 191 processes and 1,916 production lots (Table 1). In order to protect confidential company information, the data has been anonymised. The dependent variable is a binary variable, which describes an electric quality parameter that causes more than 20% of all product failures. If a batch exhibits desirable quality properties, it is labelled as 1, otherwise as 0. The aim of our machine-learning-based analysis is to learn which specific production factors cause good (1) and poor (0) product quality. In order to ensure unbiased research, the case company did not disclose known process problems in advance.

Identification of quality drivers
The model’s predictive performance is evaluated with the area under the receiver operating characteristic curve (AUC). The hyperparameters of the algorithm are tuned with Bayesian optimisation and early stopping. To prevent overfitting, which can occur if the same data is used for both model tuning and evaluation (Cawley and Talbot, 2010), we randomly sample 80% of the data for model tuning and training. We perform a 5-fold cross-validation (CV) on the training dataset to select the optimal hyperparameters. Then we train the final model on the entire training data and evaluate it on the holdout dataset. The implemented model performs well on the holdout dataset and no overfitting is detected (Table 2). In order to identify the critical production factors we conduct a SHAP value analysis of the top ten quality drivers (Figure 3). Each SHAP value represents the quality impact of a production factor (see y-axis) corresponding to a specific product observation. Positive SHAP values are associated with good product quality, whereas negatives ones suggest poor quality. The vertical dispersion in the plot indicates the density of product entities with similar SHAP values. We identify that four processes (P5, P159, P180, and P182) drive the product quality.

Process P5 has the largest impact on yield, as five of the ten most important quality drivers are associated with this process. It can be observed that missing values (grey data points; modelled as features) with regard to the P5_PM1, P5_PM2, P5_PM3, and
P5_PM4 measurements have a positive impact on product quality. Four different machines can perform process P5, yet, only three of these machines collect the four measurements of interest. In this particular case, the missing values are an indirect indicator that the machine that is not collecting the measurements has superior performance. Furthermore, high values of P5_PM1, P5_PM2, and P5_PM3 and low values of P5_PM4 affect yield positively.

In process P159, missing values concerning the P159_PM1 measurement have a positive quality impact. Similar to phenomenon in process P5, it can be concluded that machines that do not collect this measurement perform better than the others do. Moreover, high measurement values of P159_PM2 and P159_PM3 have a positive influence.

---

**Figure 3 – SHAP summary plot for top ten quality drivers**

**Figure 4 – SHAP dependence plot of queue time after Process-180**
Another important finding is that long queue times after process P180 have a negative impact on product quality. In order to determine a critical threshold, the corresponding SHAP values are plotted against the observed queue times (Figure 4). The SHAP dependence plot implies that queue times exceeding 17,000 seconds (~4.7 hours) after process P180 decrease yield.

**Discussion**

Within the in-depth analysis of the variable relationships, we identified two dominant processes (P5 and P159) and a critical queue time. As previously stated, the case company did not disclose previously known process problems in order to ensure objective modelling. After the model results were available, the producer confirmed that the algorithm successfully identified two critical processes, where a set of problematic machines cause yield loss. A discussion with the product engineers revealed that three of the four machines in process P5 produce particles that induce chip failures. The damages caused in process P159 can be attributed to the loading mechanism of a specific machine type. According to the case company, the latter problem could not be detected with the company’s current analysis tools and therefore it was undiscovered for a long time. In the end, the engineers recognised the process issue by conducting a time-consuming manual data analysis. Our machine learning framework immediately detected the conspicuous machines without any manual effort.

In addition to the known process issues, we also identified the queue time after process P180 as a quality driver. The critical threshold for this parameter could not have been determined with simple correlation methods. Since this specific problem was previously unknown, the reasons for yield loss are not yet explained. An educated guess is that the wafer surfaces start to oxidise if the waiting time after process P180 is too long. As an improvement measure, we suggest introducing a maximum queue time equal to the determined threshold of 17,000 seconds.

Even though our approach has proven to be both efficient and effective in locating production problems, it does not provide solutions on how to solve them. Additionally, we found that some of the identified quality drivers were only indirect indicators for process issues and the interpretation of the model output required domain knowledge. Therefore, we suggest that the human component remains crucial when using machine-learning-based methods for production improvement.

Since the title of this work is “Using machine learning to improve manufacturing” this work would not be complete without discussing the impact of machine learning on operations management. We believe that due to the drastic increase of data in manufacturing systems, companies must build interdisciplinary competencies. Those producers who leverage both manufacturing and machine learning expertise will gain a competitive advantage. Furthermore, we expect that data-driven approaches, such as the presented framework, will complement established production improvement programmes as well as support and inform the human problem solving process in the future.

**Conclusion**

In this paper, we proposed and validated a data-driven framework to improve product and process quality in manufacturing. The framework consists of three distinct phases: (1) Data preparation, (2) data mining, and (3) in-depth analysis of variable relationships. To overcome the limitations of current methods, our approach incorporates an explainable machine learning concept to model data from the whole manufacturing process chain in a factory. After the theoretical development, we applied the framework at ABB Semiconductors, a leading semiconductor producer, and uncovered several critical
production factors. The case company confirmed that the algorithm successfully identified also previously known process problems. Two of the three most important quality drivers could not have been discovered with the company’s current analytics methods. Additionally, our approach reduced fault detection time and allowed determining threshold values for critical process parameters. Nevertheless, the data preparation and the interpretation of the models required human effort.

The contribution of this work is threefold. Firstly, it adds a flexible and generalisable machine learning framework to operations management literature. Secondly, it incorporates state-of-the-art machine learning methods that handle the complex nature of manufacturing data and allow for model explanation without compromising on model accuracy. Thirdly, it equips manufacturing companies with a framework that complements traditional production improvement programmes.

Acknowledgements
We would like to thank Patric Strasser and Peter Kaspar from ABB Semiconductors for providing us with data and feedback to validate our data-driven framework.

Abstract

Companies fail to leverage the full potential of their intra-company manufacturing network because many neglect the coordination layer. New technologies enable support of coordination activities for network managers. This contribution shows the status quo of technologies deployed in order to improve coordination. The basis is a national survey of the Swiss manufacturing industry. In addition, our research shows differences between companies that operate globally or locally regarding the use of these technologies. These differences relate to the structure of the manufacturing network, collaboration with third parties, customer criteria and innovation drivers. Finally, recommendations for actions are derived.

Keywords: Digital technologies, Coordination of international manufacturing networks, Coordination improvement

Introduction

The management of international manufacturing networks (IMN) is essential for the performance of a company (Cheng et al. 2011; Friedli et al., 2014; Liebetrau, 2015). Coordination is a key element in the management of IMNs (Cheng and Farooq, 2018; Ferdows, 1997a,b; Shi and Gregory, 1998). Coordination makes a significant contribution to increase efficiency and competitiveness (Rudberg and West, 2008; Szwiejczewski et al., 2016; Dasu and de la Torre, 1997). However, despite the obvious advantages, many companies neglect this part of network management (Cheng and Farooq, 2018; Bitran et al., 1985).

The father of coordination, James d. Thompson, speaks of interdependencies between organizational units in complex organizations (1967). In such an environment, coordination serves to concert actions (Thompson, 1967). Generally, three types of coordination are distinguished depending on the degree of interdependence: coordination by standardization, coordination by plan, coordination by mutual adjustment (Thompson, 1967). In the sequence presented, the demands on communication and decision-making are constantly increasing (Thompson, 1967). Martinez and Jarillo (1989) distinguish between structural and formal mechanisms such as more informal and subtle mechanism. Coordination within the framework of the management of international manufacturing
networks includes, on the one hand, the degree of autonomy of the decision-making structure (Hayes et al., 2005; Mengel, 2017). In addition, the exchange of knowledge, information and resources as well as the setting of incentives are important components of coordination (Chew et al., 1990; Friedli et al., 2014).

Researchers have already dealt with the influence of IT on coordination and thus productivity (Sun, 2017; Goodhue and Thompson, 1995). Brynjolfsson and Hitt for example, state that IT can lead to an adjustment of organisational structures and, conversely, increase productivity (2000). In general, IT can be seen as an enabler of digitalisation (Vogel-Heuser et al., 2017). Digitalisation can have effects on the level of autonomy (Albano et al., 2018; Gerten et al., 2018), exchange of information (Treber and Lanza, 2018) and thus coordination (Vogel-Heuser et al., 2017). A multitude of technologies and use cases exist in regards of digitalisation (Huansheng and Sha, 2012; Morone, 1989; Torkkeli and Tuominen, 2001). The vast majority of such technologies are used to increase efficiency (Hooi and Leong, 2017; Lasi et al., 2014). Coordination indirectly increases efficiency at manufacturing network level (Colotla et al., 2003; Friedli et al. 2014).

It therefore appears appropriate to concentrate not only on technologies that directly increase efficiency, but also indirectly by means of supported coordination. Furthermore, there is a gap in research regarding the effects of digitalisation on coordination in the international manufacturing network context (Ferdows, 2018).

With this paper, we would like to contribute to the research of coordination with digital technologies in international manufacturing networks. Within the framework of this contribution, we intend to answer the following questions: Which technologies are used to coordinate manufacturing networks, what is the current implementation status in the industry and what are the prerequisites for successful deployment?

**Method**

The research reported in this contribution divides into three steps. In the first step, a literature review based on the concept of vom Brocke et al. (2009) was carried out. This led to the research gap mentioned in the introduction. Second, data from the Swiss Manufacturing Survey (Friedli et al. 2018) were extracted. It serves as the foundation for further investigations. Third, a comprehensive data evaluation has been conducted in order to analyse the revealed research gap. The chosen approach leads to findings which are of importance for science as well as practice.

The aim of the annual Swiss Manufacturing Survey is to identify the current situation of the Swiss manufacturing industry and to investigate long-term structural changes (Friedli et al., 2018). Within the framework of the survey, the questionnaire methodology is used as a research strategy to systematically quantify empirical facts (De Leeuw et al., 2008). Based on the research objectives (De Leeuw et al., 2008), the study provides information about organisation, employees, markets, customers, technology, innovation, global activities and performance. Observable variables were developed for operationalisation (Brancato et al., 2006). Open-ended questions were largely avoided. The target group consists of managing directors and operations managers of manufacturing companies. All types of manufacturing companies are eligible without size restrictions, but also individual business units or sites. The study cooperates with several associations in order to achieve the broadest possible picture of the Swiss companies that are considered pioneers in their sectors. Due to this cooperation, an unbiased response rate could not be calculated (Dillman et al., 1993).

For further analysis, the question "which digitalisation and Industrie 4.0 technologies have the highest and second highest potential for improving the coordination of sites" was
considered. It was compared with the question "which technologies have the highest and second highest potential for improving efficiency". For both questions and the corresponding technologies, the implementation status was checked. Based on this, the data was divided into two groups: companies with high and low implementation status. "High implementation status" comprises the upper three options on a six-point Likert scale "Working on the implementation", "Already in first use" and "Fully implemented". "Low implementation status" comprises the lower three options "Not relevant", "Observing" and "Researching and developing". Subsequently, based on this distinction, further questions were evaluated on industry, global footprint, manufacturing network, characteristics of Swiss sites, customer criteria, process innovation and digitalisation.

The selection of the technologies took place within the framework of the preparation of the study. Twelve future manufacturing technologies were selected from research in various white papers and trade journals for industry. The selection mainly contains digital technologies. The most striking features of digital technologies are the continuing exponential development of computer technology, large amounts of digital data and innovation through recombination (McAfee and Brynjolfsson, 2018). In addition to digital technologies, the selection also includes hardware-based technologies such as robotics and 3D printing. These technologies are also regarded as important drivers of manufacturing (De Carolis, 2017). Figure 1 and 2 present the entire list of technologies. The selection focuses on technologies that have the potential to improve coordination.

Due to the predominant use of Likert-scales, there are no particular conspicuous features with regard to data quality (De Leeuw, 2008). The numeric question types have no outliers. The data thus serve as a scientifically sound basis for analysis.

Results

Survey Results
The survey of companies took place between October 2017 and March 2018. In the course of 2018, 186 Swiss manufacturing companies participated. The managing directors of the companies mainly provided the information. The mechanical engineering sector accounts for the largest share with 28%, with more than eleven industries represented. 76% fall into the category of small and medium-sized enterprises and 52% are family-run enterprises. 45% of the companies have a global footprint and 37% have made changes to the global footprint in the last three years prior to the survey. In total, 158 companies have provided information on the implementation status of new technologies, which shows that Swiss companies are currently dealing with this issue.

Potential and implementation
The rankings of the most popular technologies to improve coordination and efficiency are shown in Table 1. The answers for the highest and second highest potential were cumulated, with the highest potential being given priority in the ranking.

In total, 91 of the 186 companies responded to the potential of technologies to improve coordination or to increase efficiency. Overall, more statements were made about technologies to increase efficiency. Companies value machine-to-machine communication as the technology with the highest potential for improving coordination. In order to increase efficiency, robotics is assigned the highest potential by a large margin. Three technologies can be found in both rankings, even if they are distributed differently. In general, it can be said that predominantly digital technologies have a potential for improving coordination. Whereas in the case of efficiency increases, technologies based on hardware also emerge.

Figure 1 and 2 show the implementation status of 158 companies regarding selected technologies. The order of the technologies corresponds to the associated potential for improving coordination. Companies that see potential in a certain technology to increase efficiency or to improve coordination generally have a higher implementation status than the average. This does not apply to the robotics area, where the average of the sample has a significantly higher implementation status.

Companies that regard identification/communication technologies, mobile devices, big data analytics and autonomous transport systems as coordination enhancing have a higher implementation status in this respect. The implementation status of digital twin technologies are on the same level, regardless whether it is considered as coordination or efficiency enhancing. Although cloud computing is not in the top five technologies to increase efficiency, the implementation status is higher for companies that consider this technology as efficiency enhancing. However, the highest implementation level, "fully implemented", is only achieved in companies that consider this technology to be coordination enhancing. Based on the findings so far, the next step focuses on those companies in detail that expect high potential in technologies to improve coordination.

Figure 1 – Implementation status of selected technologies (no. 1-6) (N=158)

(a) entire sample
(b) ...to improve coordination | (c) ...to increase efficiency
There are 88 companies that made statements as to which technology has the greatest potential to improve coordination. Those are divided into ten industries, with mechanical engineering being the largest (33%). Compared to the overall sample, the mechanical engineering sector is more strongly represented with a plus of 5 percentage points, the electrical equipment sector with additional 3 percentage points and the automotive sector with additional 3 percentage points.

The following differentiation groups companies that have either a high or low implementation status in the technology that they consider coordination enhancing. Those that have a high implementation status are called pioneers in the following. Those that have a low implementation status are called followers.

Figure 3 shows differences in the global positioning of the companies. Pioneers are clearly more global. This is reflected in three factors: Production and development sites are not exclusively located in Switzerland, adjustments have been made to the global footprint over the past three years and there is a rather high probability that activities will be relocated abroad in the next three years.

---

**Figure 2 - Implementation status of selected technologies (no. 7-12) (N=158)**

---

**Figure 3 - Differences in the global footprint depending on the implementation status (N=88)**
Global Pioneers
Since globally positioned companies tend to have a higher implementation status, it is interesting to analyse them more closely. Globally positioned companies with a high implementation status are referred to as global pioneers in the following. Those that have a low implementation status will be referred to as global followers in the following.

For global pioneers, it is noticeable that the categories “socio-economic factors”, “low-cost labour” and “qualified labour” are particularly important (see Figure 4). The differences are less pronounced in the case of “economies of scale”, “economies of scope” and “production volume”.

Figure 4 - Importance of factors regarding the production network of Swiss global manufacturing companies (N=41)

Another interesting fact is that global pioneers assign less responsibility to Swiss locations. Global pioneers have similar competencies and responsibilities at all sites within the network. This applies to 48% of global pioneers and to only 30% of global followers. The differences are marginal in pilot production and the manufacture of complex and strategic products. E.g., pilot production in Switzerland is conducted by 70% of global followers and by 62% of global pioneers. The differences are more pronounced in global purchasing and the central interface between manufacturing and customers. E.g., in Switzerland, 70% of global followers have allocated global purchasing. In contrast, only 43% of global pioneers have allocated global purchasing to Switzerland.

Specific differences
The following section will focus on all 88 companies that have provided information on technologies with the potential to improve coordination. Consequently, both local and global companies are part of the sample.

It is noticeable that followers almost exclusively have higher customer requirements than pioneers (see Figure 5). Only with regard to service and sustainability are local pioneers exposed to higher customer requirements. Overall, delivery capability is the most important criterion for customers in the entire sample. Flexibility in volume and product design is particularly important for customers of local followers. Customers of global followers require greater geographical proximity.
Most companies develop processes alone at their Swiss sites (see Figure 6). This is especially true for global followers and local pioneers. Local followers have the highest average of processes developed in Switzerland (87% in contrast to 69% of global pioneers). Global pioneers are most likely to work with third parties such as suppliers or competitors. Pioneers, whether global or local, work more likely with consultancies. Local pioneers work most likely with research institutions. The share of revenue invested in R&D is on average 8% for followers and 5% for pioneers.

Increasing production efficiency is the most important justification for digitalisation activities for all companies regardless of their global positioning and degree of implementation (see Figure 7). For global pioneers, it is also particularly important to offer new digital services and create new business models. Local followers agree more with all purposes rather than local pioneers. This phenomenon cannot be observed in global companies.
Discussion

Potential and implementation

Overall, more statements have been made about technologies that have the potential to increase efficiency. This fits in with the statement that many companies tend to neglect coordination (Friedli et al., 2014). In general, companies tend to implement technologies that increase efficiency. Although technologies to improve coordination also indirectly increase efficiency (Colotla, 2003; Liebetrau, 2015), the effects of indirect measures are much more difficult to measure (Sun, 2017).

In contrast to the efficiency-enhancing technologies, exclusively digital technologies are listed in the top five of coordination-enhancing technologies. The digital interconnection of distributed plants in order to be able to control them effectively seems to be the primary driver here.

Global pioneers

Global companies have a higher degree of implementation because they tend to generate higher revenues, employ more people and thus have more resources at their disposal (Vaccaro et al. 2012). These resources are essential to carry out digitalisation projects. Global companies are exposed to international competition, which leads to greater pressure to find new ways to become more efficient. In general, however, globally positioned companies are more complex due to product diversity, number of customers, suppliers and other criteria (Hitt et al., 1997). This alone requires driving digitalisation in order to operate effective management. The result supports the discourse in academia that global companies are more innovative (Damanpour, 1992; Calof, 1993).

A further insight is that global pioneers are giving up responsibility in Switzerland and thus giving more autonomy to the sites distributed around the world. Those companies understand that a decentralised structure leads to higher productivity (Brynjolfsson and Hitt, 2000; Leavitt and Whistler, 1958).

Specific differences

The fact that followers are exposed to higher customer demands can may be explained by the fact that pioneers can better satisfy their customer needs and therefore attend to lower values. A further explanation would be that different levels of customer demands exist, depending on the line of business. Nevertheless, pioneers are exposed to higher customer demands for services and sustainability, as these are issues that have recently emerged.

Local companies benefit from independent development of process innovations at their Swiss locations. This does not apply to global companies. Furthermore, local companies in particular benefit from cooperation with research institutions, consultancies and third parties. Global companies tend to benefit primarily from cooperation with consultancies. Nevertheless, global companies engage in a lively exchange with third parties, this has no impact on the implementation status of new technologies.

In the context of Industrie 4.0, local followers seem to be more euphoric about the benefits of it. Global pioneers more likely expect higher benefits from Industrie 4.0 and digitalisation. However, in the case of pioneers, expectations generally appear to be somewhat more cautious and therefore more realistic with regard to direct effects.

Conclusion

There is a lack of consistent studies on new technologies in the coordination environment of manufacturing companies. At the same time, there is great uncertainty among companies as to the meaningful application of new technologies. The findings in this article are drawn from an exhaustive study of the Swiss manufacturing industry.
Furthermore, a data analysis regarding new technologies to improve the coordination of sites was conducted. Rather digital technologies are being considered to improve coordination than hardware-based technologies. Particularly global companies are working on the implementation of such technologies. However, this raises further questions as to whether global companies are able to demonstrate a higher implementation status due to their idiosyncratic resources or whether other criteria are decisive. An important finding is that global pioneers distribute responsibility within the network and thus assign a higher degree of autonomy to individual sites. This can increase performance per se. Further research must be carried out on digitalisation, autonomy, and its effects on performance.

In summary, the research contributes to reveal the status quo of technologies improving the coordination of sites. Furthermore, it shows differences between local and global acting manufacturing companies and those who have already managed to achieve a high implementation status such as companies with a low implementation status.

Abstract

Despite the increasing amounts of data generated by disruptive technologies, such as smart sensors, the use of this data in condition-based monitoring of critical infrastructural assets is still at its infancy. One main challenge is the exchange of data between owners of critical infrastructures assets, and their maintenance contractors. Our case analyses reveal three root causes of lack of data sharing: 1) a mismatch between contract specification (i.e., provisions) and contract evaluation (i.e., KPIs); 2) ineffective incentive schemes (i.e., tied to the wrong provisions or lacking salience); 3) a lack of contractual flexibility to accommodate and facilitate data sharing.

Keywords: outsourcing, data-driven innovations, condition-based maintenance

Introduction

Neglecting to maintain critical infrastructures (such as roads, railways and waterways) can lead to catastrophic failures with widespread economic and social consequences (Frangopol and Liu, 2007). A recent example is the collapse of the Morandi bridge near Genua, Italy, in 2018 that resulted in 43 deaths and forced around 600 people to leave their demolished homes (Valkenet, 2018). The sheer scale of this disaster caused the Italian government to critically review road owners’ licenses to operate, and to oblige them to make their maintenance regimes available to both the government and the general public. Another less tragic, but nevertheless impactful, example is the partial closing of the Merwede bridge in the Netherlands, in 2016, after visual inspections revealed severe signs of saturation leading to a ban of heavy vehicles on the bridge (Van Baarle, 2016). One of the reasons for lagging maintenance is that information management at most infrastructure works is insufficient to inform the responsible organisation (in time) about the state of its infrastructural works. This critical assessment of maintenance decisions in relation to missing information coincides...
with the introduction of several disruptive technologies. Disruptive technologies, such as Internet of Things (IoT) devices, big data analytics, smart sensors, and cloud computing urges organisations to re-think the management of their supply chains (Harris et al., 2015). Employing these technologies allows for productivity increases, costs reductions, and quality improvements (Bălan, 2018). At the same time, these technologies also result in a massive increase in data from which valuable information can be distilled (Queiroz and Telles, 2018).

Disruptive technologies propel ‘data-driven innovations’ at organisations. According to the OECD, a data-driven innovation (DDI) can be defined as “the significant improvement of existing or development of new products, processes, organisational methods and markets arising from the dynamics generated by the use of big data” (OECD, 2015). In the context of this study, equipping infrastructural assets such as sluices and rail tracks with smart sensors provides asset managers with data that can provide (real-time) insights into the condition of assets and upcoming maintenance needs. Combining such insights with usage data and other relevant data, such as weather conditions, enables asset managers to shift towards more advanced maintenance regimes such as Condition-Based Maintenance and Predictive Maintenance (Akkermans et al., 2016; Sakib and Wuest, 2018). These advanced regimes can ultimately lead to “improved availability of installations, reduction of failure costs and lower costs over the entire life cycle” (Van de Kerkhof et al., 2018).

Asset managers of infrastructural networks have not adopted disruptive technologies in their asset management practices on a large scale yet (Van de Kerkhof et al., 2018). Their effective use is especially complicated due to the fact that public organisations, responsible for infrastructural networks, increasingly outsource maintenance activities to maintenance contractors. Even if asset managers would equip all their assets with disruptive technologies, those investments will not yield any benefits if the contractors fail to act upon the data these technologies generate. On top of that, utilisation of the data will, in many cases, require data from both the asset owners and the contractors. Motivating both parties to transfer data in their buyer-supplier relationship requires appropriate contractual and relational conditions.

A plausible explanation may be that, at the core, asset managers and private maintenance contractors have almost opposing interests. While asset managers aim to minimise maintenance, to lower costs and increase the availability of their assets, private contractors want to perform as much maintenance as possible, to increase their profits. Agency theory identifies this as a ‘goal conflict’ and suggests that goal alignment may be achieved through the use of outcome-based contracts (Eisenhardt, 1989). We build on the premise that under such contracts, suppliers will be stimulated to innovate with the aim of making their service delivery more effective and/or efficient (Sumo et al., 2016). Disruptive technologies provide important means to suppliers to achieve such innovations. Hence, it is counter-intuitive that even with outcome-based contracts, disruptive technologies are only used to a limited extent.

The aim of this paper is to determine appropriate contractual and relational conditions that can stimulate data transfers between asset owners and their contractors, as well as innovation, to enable the use of CBM in an outsourcing situation. To attain our goal, we frame our research in agency theory (Eisenhardt, 1989) and analyse the findings from four cases that involve maintenance outsourcing contracts and the introduction of disruptive technologies. Three cases are taken from an executive agency of the Dutch Ministry for Infrastructure and Water Management, responsible for roads and waterways, and one case comes from an unlisted public limited company responsible for railways.

Our theoretical contributions are twofold. First we add to the literature on performance-based contracting by highlighting how such contracts can stimulate both parties to share and
enrich data, as well as innovative behaviour. We aim to lower potential barriers and (further) enhance potential enablers. Second, studying the impact of increasing information (generated by disruptive technologies) on principal-agent relationships in a supply chain context constitutes an important contribution to the supply chain management literature (Waller and Fawcett, 2013). For managers, this paper enhances their understanding on how the use of data for the purpose of enhanced maintenance can effectively be accounted for in contracts.

The remainder of this paper is organised as follows: in the following section, we briefly review extant literature on maintenance outsourcing, and elaborate on the influence of disruptive technologies. We then turn to the notion of outcome-based contracting to develop a framework on how contractors may be stimulated to share data and to innovate. Next, we explain our research methodology before turning to our findings. This paper ends with conclusions, implications, limitations, and future research opportunities.

**Theoretical background**

*The impact of disruptive technologies on maintenance*

The maintenance literature roughly distinguishes between two types of maintenance policies: corrective and preventive (Irawan et al., 2017; Jardine et al., 2006; Tsang, 1995). A corrective maintenance policy implies that maintenance only commences after a failure occurred and/or an asset broke down (Tsang, 1995). In contrast, under a preventive maintenance policy, maintenance is ideally performed before a failure occurs, thereby preventing unexpected disruptions (Irawan, et al. 2017). Condition-based maintenance (CBM) can be considered as an example of a preventive maintenance policy, where asset managers collect data on the actual condition of assets and perform maintenance only if there is evidence of an impending failure (Jardine et al., 2006). CBM can help asset managers identify imminent problems, their nature, the time until they manifest, and where exactly (i.e.: in which specific component) they are about to occur (Tsang, 1995), thereby significantly reducing maintenance costs while increasing asset availability (Jardine et al., 1995).

The notion of CBM is not new at all. However, this concept regained significant relevance after the 2010s when disruptive technologies emerged that provided asset managers with novel ways to collect, store, analyse, and interpret condition data with respect to their assets (Sakib and Wuest, 2018). Disruptive technologies such as (smart) sensors allow the cost-efficient, real-time collection of condition data, in contrast to more costly and periodic methods such as visual inspections. As such, these technologies can support the elements of a CBM program: data acquisition, data processing and maintenance decision making (Jardine et al., 2006). For example, smart sensors can support the acquisition of condition data, while IoT devices and cloud computing can help speed up processing this data. Finally, (big) data analytics can help asset managers in decision making processes with respect to maintenance activities. Ultimately, big data analytics may increase the transparency and availability of information, enabling a constant monitoring of real-time data on the actual condition of assets and tracking performed maintenance activities (Kache and Seuring, 2017).

*Asset manager-maintenance contractor outsourcing relationships*

Many organisations increasingly outsource maintenance activities to specialist maintenance providers (Ulloa et al., 2018). Implementing disruptive technologies to establish a CBM program hence also concerns maintenance contractors. This implies that contractors are often the ones to leverage available data for the purpose of more effective maintenance. Outcome-based, or performance-based, contracts offer an attractive way to achieve just this, as such
contracts allow for the inclusion of appropriate incentive schemes that will lead agents to pursue the outcomes for which they are rewarded (Eisenhardt, 1989). On top of that, performance-based contracts have been suggested to foster supplier-led innovation: “...partner-initiated, proactive undertakings that take place within the context of a specific inter-organisational relationship, either in collaboration with, but in any case for, a focal organisation, that result in new or improved ways of delivering transactions” (Sumo et al., 2016). Hence, we expect that under performance-based contracts, maintenance contractors are automatically incentivised to leverage data for the purpose of more effective maintenance.

In order to stimulate contractors to act in the best interest of the contracting party, an appropriate incentive scheme must be designed and enforced. The extent to which a scheme is effective is likely to be contingent on the proportionality of bonus and penalty elements (Selviaridis and Van der Valk, 2019), in combination with the specifications these incentives are tied to. In most situations, this will involve a mix of behavioural-based and outcome-based incentives, tailored to a specific situation, motivating the agent to act in the principal’s best interest (Halldorsson et al., 2007). Finally, not only the explicit aspects of the contract, the formal and often legally binding agreements of the contract, should be considered. Also the implicit aspects, the social agreements made between the principal and the agent, should be acknowledged when trying to identify the most appropriate contract design.

Based on the insights we gained from the literature, we defined the following four a-priori constructs (Barratt et al., 2011) to guide our exploratory data collection and analysis: 1) the mix of provisions included in the contract (behaviour-based or outcome-based), 2) the incentive scheme specified in the contract, 3) the degree of data-sharing between asset owner and contractor, and 4) performance outcomes. We consider data sharing to be an intermediate performance outcome that will in turn enhance availability. Hence, we posit data sharing to be a mediator between contractual characteristics and performance. Note that our study is qualitative in nature, and hence can only provide a first validation of this conceptual model.

Research methodology
This study focuses on two organisations that are active in the Dutch public infrastructures sector: Rijkswaterstaat (hereafter: RWS) and ProRail. Both organisations aim to smarten the maintenance of critical assets by introducing disruptive technologies and analysing condition data. Since both organisations outsource their maintenance activities to private maintenance contractors, they need to stimulate their contractors to aim for the same goal. Up until now, four cases, three at RWS and one at ProRail, were mature enough to be analysed in this paper. Refining processes with respect to cases at ProRail are still in progress. Nonetheless we found enough interesting insights to compare a more general case from ProRail with three refined cases from RWS. A short overview of each of the four cases can be found in Table 1.

RWS has a national contract management department, but also strong regional sub departments (responsible for the infrastructural assets in their region), each with their own contracts and their own ideas about (smart) maintenance. In order to align all initiatives and outsourcing contracts, the organisation started the ‘vital’ assets program: a program with several pilots, involving assets that play a pivotal role in either the waterways or flood-preventing water systems, to determine a national standard with respect to how asset management can be smartened. In these pilots, RWS aims to collaborate with the contractors and stimulate them to help realise smart maintenance for the assets they maintain to ensure a higher availability of RWS’ overall network. In consultation with RWS, three pilots have been selected as our research cases, which are denoted by ‘Case E’, ‘Case K’ and ‘Case Y’.
ProRail recently started with a national ‘datalab’ to investigate the possibility of predicting railroad switch failures. Failing switches lead to a lower availability of (a specific part of) their railroad system. Although it was initially intended for their own railroad network control centre, ProRail found that predicting switch failures can also be used by their regional departments and maintenance contractors to predict maintenance needs of these switches more accurately. This in turn helps to plan maintenance activities on the most useful timeslot, just before a failure actually occurs. The current challenge is to find a way to incorporate this innovation in contracts that foster collaboration towards smart maintenance. The ‘general’ case from ProRail is denoted by ‘Case P’.

Data collection so far included 20 interviews (15 at RWS and 5 at ProRail) with employees who are actively involved with the maintenance of critical assets (e.g.: asset managers, incident managers) and/or maintenance-relevant data (e.g.: data managers, data scientists), as well as with the employees that are involved with drawing up the maintenance contracts (e.g.: purchasers, contract managers). Moreover, to date, a total of 20 documents from RWS have been analysed, including excerpts of actual contracts, documents that described RWS’ vision on smart maintenance, project documents, and official press releases. Visiting ‘vital’ assets at RWS enhanced our understanding of maintenance regimes in context. Finally, direct observations were made by the researchers of meetings between RWS and their contractors during which the progress of running projects was discussed. Collecting data from different sources allows us to perform data triangulation in order to enhance the validity of the collected data and the resulting evaluation of cases (Yin, 2013).

The quality and rigour of the case studies was ensured by applying specific criteria and measures that address construct validity, internal validity, external validity and reliability issues (Yin, 2013). Data coding and analysis was conducted manually and much in parallel with data collection following recommendations by Barratt et al. (2011). Data coding initially focussed on key constructs, but increasingly included additional themes and codes as they emerged from the interviews (e.g.: to what extent the case companies should specify and manage ‘desired’ behaviour from their contractors). Initially, open codes (e.g.: “key performance indicator”, “bonus/penalty scheme” and “data sharing”) were assigned to the interview transcripts and collected documents. Next, these were grouped into higher-order
categories (e.g.: “contract type” and “incentive schemes”) using axial coding procedures. Overall, data analysis was an iterative process with codes being refined by moving back and forth between data, the analytical framework and the cross-case analysis.

**Preliminary findings**

As our within-case and our cross-case analyses are still ongoing, this section presents some of our preliminary findings. First, the three cases at RWS are described in terms of the four a-priori constructs identified earlier. Subsequently, also the case from ProRail is described in terms of the same four a-priori constructs. A comparison between the key findings from RWS and the key findings from ProRail can be found in Table 2.

**RWS**

*Contractual provisions* – Analysing the empirical data from all three cases, it became apparent that no standard is being used regarding contracts. Rather, each regional sub department uses its own personalised contracts. In Case E for example, even though they call it a ‘performance-based’ contract, in reality it still contains a lot of prescribed activities: “*We named prior generations performance-based, but they were actually prescriptive and full of obligations*” – Senior Consultant Asset Management. The same is true for the contract in Case K. In contrast, the contract in Case Y has a more balanced mix between performance-based metrics and prescriptions of ‘desired’ behaviour: “*The last couples of years we focus more on performance, but in the beginning we focused more on behaviour. We evaluated the contractors’ behaviour and addressed inconsistencies. Nowadays, we focus more on performance and performance scores*” – Contract Manager. In all three cases, interviewees indicated that currently all contracts lack flexibility: “*If you include broad terms in contracts, there is more room for innovative solutions*” – Senior Consultant Asset Management.

*Incentive schemes* – Our empirical data suggests that there is a discrepancy between the performance as requested in the contract, on which incentives are based, and the performance that RWS actually would like to see from their contractors. For example, in Case E, an interviewee recalled a situation where a contractor was incentivised to stall its response to a failure in order to collect a higher reward: “*What also happens: the contractor should fix minor failures itself, but if the damage is larger, the contractor is paid extra. The contractor is then enticed to wait*” – Senior Consultant Asset Management. Also in the other two cases contractors are incentivised to respond reactively to failures while RWS actually wants that their contractors take preventive measures. On top of that, the height of the penalties, that are intended to prevent undesired outcomes, is not appropriate. Case Y provides a striking example of this: “*We do penalise them [the contractors], but sometimes the amount of the penalty is much lower than the costs that they can save by not performing their task*” – Incident Manager. In some situations it is cheaper for contractors to not spend money on maintaining assets and paying the penalty, than actually perform the maintenance task.

*Data-sharing* – Our empirical data suggests that, in general, it is fairly easy for RWS to share data with its contractors regarding maintenance activities and the actual condition of assets. RWS pays its contractors to collect data for them and share it on fixed intervals: “*That information is simply our property […] It is our property, because we paid for it*” – Contract Manager. However, RWS employees are, on average, not fully satisfied with the way how data is shared. An interviewee from Case Y indicated: “*This is where it goes fundamentally wrong… the contractor sends us a .pdf file with which we cannot do anything. You cannot edit such documents*” – Senior Consultant Asset Management. In addition to this, there is a
big difference between the different regional sub departments with respect to their ability to actually process the data they receive from contractors. While Case K involves a regional sub department that can be seen as a forerunner with respect to processing data, Case E provides an example of a regional sub department where data processing is still in its infancy.

Performance outcomes – In all three cases, the current contract designs do not lead to the desired performance outcomes. The current contracts include extensive descriptions that contractors tend to follow meticulously as evidenced by the following example from Case Y: “And if something needs to be adapted unexpectedly [at an asset], then they check the contract and indicate that it is not prescribed. And if it really needs to be fixed, then they ask prices... if this task was offered on an open market place, it would have been three times as cheap” – Incident Manager. Put differently, contractors mainly focus on tasks that are being prescribed RWS in the contracts and do not display any initiative by themselves. Furthermore, it is fairly difficult for RWS to incorporate new innovations during a contract period. In all three cases, there was a (loud) call for more flexible contracts: “Nowadays, you cannot afford to not be flexible at all. Everything is changing, and changing fast...” – Contract Manager.

ProRail
Contractual provisions – Analysis of the data collected on ‘Case P’ leads us to conclude that ProRail made a conscious choice to move towards performance-based contracts: “Obviously, we switched from prescribing what a contractor should do towards performance-based maintenance” – Project Manager. However, a contract manager at ProRail pointed out that in some cases, prescriptions of ‘desired’ activities are still needed: “If we are dealing with safety for example, we prescribe fairly strictly what a safe railroad switch is.” Even though ProRail aims to evaluate contractors based on their performance, in some specific cases they also prescribe maintenance activities to ensure safety requirements are met. Although ProRail is fairly satisfied with their current contracts, one inhibiting factor is the lack of flexibility. “I think that, currently, we have drawn up reasonably good contracts, but sometimes we do get stuck... since we ask for specific activities in contracts we cannot ask for additional things that fall outside of what has been contracted” – Project Manager. Mainly due to European regulations regarding public procurement, ProRail is not allowed to significantly change the initial outsourcing request based on which the current contractor won the contract.

Incentive schemes – In order to stimulate innovation, one measure that ProRail has taken in its contracts is including a monetary incentive. Before a contract period starts, ProRail and the contractor jointly determine the number of malfunctions that may occur during a specific time period at a specific asset. Each additional malfunction in that time period leads to a financial penalty for the contractor, while each malfunction less than the maximum leads to a financial bonus. According to a contract manager, this financial bonus is high enough to stimulate innovation: “The bonus is high enough to, for example, equip railroad switches with a (new) type of switch counter”. Put differently, the financial bonus is believed to be high enough to cover the investment the contractor needs to make to implement an innovation that can lower the number of malfunctions. Nevertheless, in practice some improvements are still needed: “Sometimes it looks like [in practice] that they [the contractor] already hit the requirements for a bonus at the end of November, for example, and is not further stimulated to further improve performance during the rest of the year” – Project Manager.

Data-sharing – Currently, there is almost no data sharing between ProRail and the current contractors with respect to maintenance and/or condition data. This is mainly due to the fact that they did not include any clauses regarding data (sharing) in the current contracts, making
it difficult to ask for data: “We have asked data regarding 100 railroad switches and in the end we only received data on 15 of them” – Project Manager. For new contracts, ProRail will start with including clauses in which they ask for specific data from contractors: “They made new definitions regarding assets and components, and now they ask in new contracts: you [the contractor] have to provide feedback on whether you performed maintenance activities and on which components these activities have taken place” – Data Scientist.

Performance outcomes – The latest contracts used by ProRail are partially capable of aligning the intended performance and the actual outcome achieved by the contractor: “Since we began with performance-based contracts, you do see a decent increase in innovativeness. [...] The number of railroad switch malfunctions decreased by 2/3s as compared to 10 years ago” – Contract Manager. Since the introduction of financial stimuli in their contracts, ProRail sees increases in innovativeness at their contractors resulting in a steady decline in malfunctions. However, with respect to sharing information regarding the condition of assets, the current contracts do not help a lot yet: “Currently, we say: it [the assets] has to perform! Thus, if it performs, it is good. However, I believe that we are changing our minds with respect to this, because we also want to know what exactly happened” – Project Manager.

Discussion and conclusion
The purpose of this study was to enhance our understanding of how contractual and relational conditions can stimulate data transfers between asset owners and their contractors, as well as innovation, in order to enable CBM. In this paper, we analysed four cases from two Dutch infrastructural organisations to determine how their current contractual and relational conditions can or cannot stimulate data transfers and innovation.

Our preliminary analyses lead to three main findings. First, the rigidity of current contracts seem to inhibit both the introduction of new innovations, as well as making adjustments to specifications regarding data sharing. Both RWS and ProRail are clearly struggling with stimulating the sharing of data by and with contractors, and with stimulating the introduction of new innovations. The problem here does not reside in the willingness of either party to start implementation or sharing, but in the rigid design of the contracts. When new and proven technologies become available, both case companies cannot directly capitalise on these since they are dependent on their contractors. Because current contracts cannot be changed during the contract period, it is fairly expensive to quickly adopt new technologies. Stimulating data sharing by and with contractors is also problematic for both RWS and ProRail: the rigid
contracts do not allow changes to the agreements made in the past, and the clauses that are currently used are either underdeveloped or non-existent. Both case companies need to wait until the next contract period to include new requirements with respect to data sharing. More flexible contracts will facilitate efficient data sharing and can kick start the implementation of proven technologies. This finding resonates with the notion of contracts having a coordination function (Schepker et al., 2014), meaning that the contract is not static, but subject to change following changing requirements and circumstances.

Second, current contract designs do not seem to be conducive to achieve the overall objectives of the contracting party. Especially in the three cases at RWS we see that, on the one hand, they clearly aim to smarten the maintenance of their critical assets, while on the other hand, we see that they are currently utilising contracts, which include both performance-based elements and highly detailed prescriptions that ultimately results in passive behaviour by contractors. Although previous studies have acknowledge that most contracts should contain a mix of performance-based and behaviour-based elements (e.g., Halldorsson et al., 2007), the prescriptive elements in the RWS cases seem to overshadow the performance-based elements, leading contractors to stick to prescriptions to avoid being penalised for deviating behaviour. In contrast, ProRail’s case provided evidence that if you have a good mix of performance-based and behaviour-based elements in your contracts, it can indeed help align the overall objectives of the contracting party and the contractors. This demonstrates the importance of considering the detailed design of contracts in joint with the clarity and overall purpose of the contract (Selviaridis and Van der Valk, 2019).

Third, and related to the point above, also the incentive schemes adopted in contracts do not always have the desired effects. At RWS, contractors are rewarded for meeting specific response times in case of failures. Thus, in order to collect a bonus, an asset must first fail while RWS actually wants to achieve the highest availability possible for its assets. Thus, the incentive schemes are not linked to the objectives RWS ultimately tries to achieve. ProRail, on the other hand, incentivises its contractors in such a way that they get a bonus when they have less failures than a specific base line. Less failures in turn leads to a higher availability of ProRail’s network. The incentive schemes are thus better aligned with the objectives ProRail ultimately aims to achieve. Stimuli in contracts should furthermore be proportional to the efforts required to achieve performance targets (Selviaridis and Van der Valk, 2019). The three cases at RWS show that in the presence of mild penalties, the costs of the efforts required to avoid the penalties outweigh the penalty itself. Hence, contractors will accept the occasional penalty leading to more frequent incidents or lower than desired performance.

The findings discussed here should be interpreted with care, as indeed they are very preliminary in nature. Data collection, as well as analyses, are currently ongoing, and may lead to more nuanced findings regarding how contractors may be incentivised to share data and implement disruptive technologies. The mix of cases from the two case companies is also not ideal yet. Expanding our study with additional cases at ProRail, will further enhance our understanding and provide a stronger basis for a cross-case analysis between the RWS and ProRail. Future studies should also more explicitly address aspects of relational governance. Our preliminary findings suggest that the trust levels between our case companies and their contractors is (extremely) low. Contractors follow contracts meticulously and they are mainly focused on short-term gains. This inhibits the building of trust and leads to inefficiencies during the contract period that are very costly.

This paper presents our first thoughts. We are hopeful that our work will pave the way for further empirical research in this area, by us and by others.

Operations Innovation
Operations innovation adoption within the legal service sector

Abstract
This paper discusses how innovation can be effectively applied into the legal sector for increasing its productivity and performance efficiency. Fifty-three semi-structured interviews were conducted with legal professionals worldwide to explore their day-to-day challenges and identify the barriers that hinder innovation application into the legal sector. This qualitative study identifies six key themes, each with a number of different dimensions and expressions, as the result of a systematic thematic analysis examining the raw interviewees’ responses. Our results suggest that the traditional culture and the resistance to new technology adoption are the primary reasons for slow innovation in the legal sector.

Keywords: Legal firms, Efficiency, Innovation

Introduction
Legal firms face difficulties on how to manage their business model and adapt to the rapidly changing technology and customer expectations (Giannakis et al., 2018). Additionally, the deregulation of the legal service sector in 2007 and the demise of legal aid have been the forces driving many legal firms on the verge of bankruptcy or productivity declines (Susskind, 2017). Similarly, legal firms undergo pressures due to the entrants of new competitive businesses such as the accounting firms and the online based legal suppliers promising for faster and cost-effective legal services (Gottschalk, 2002). In addition, still ongoing discussions about Brexit consequences are preventing mostly large legal firms from expansion opportunities and others by changing their recruitment practices due to uncertainty in the qualifications and overall regulations (Hellwig, 2017).
Nonetheless, the legal industry still makes a vital contribution to the worldwide economy, with the UK legal sector generating around ten percent of the global market for legal services, second only to the USA (The Law Society of England and Wales, 2016; Hellwig, 2017). Actions need to be taken for revitalising the sector that can optimise legal business procedures, which nowadays may be somewhat dysfunctional or unorthodox. The professional service sector is characterised by a high knowledge intensity, a high professionalised workforce and a low capital intensity (Von Nordenflycht, 2010); thus, knowledge transfer from other professional disciplines and innovation implementation can be a way forward for improving the sector.

Innovation as a concept can have multiple meanings across different industries. Slack et al. (2016, p.110) argued that innovation of a product or service is about anything new and unique happening to the company. Rothaermeler (2015) describes innovation as “the successful introduction of a new product, process, or business model that can lead to a powerful driver in the competitive processes”. More specifically, from an operations management perspective innovation is about the transformation of a new idea into practice for the means of creating value for the customer. This paper considers innovation implementation as a process change or modernization of the legal service sector.

**Theoretical perspective**

The resource based view supports the theoretical backbone of the study for developing a framework for legal firms to adopt innovation. Resources that are valuable, unique, and difficult to imitate can provide the basis for firms' competitive advantages (Barney, 2001). For this project the authors adopt the term ‘resources’ as the activities that the senior managers are responsible to manage and control, the operations within the legal firms, but also the lawyers. Tacit knowledge that lies among these resources is the key asset for a firm’s competitive advantage (Michalakopoulou et al., 2017) and it can be transferred through team-work, organisational processes and communication (Fu, 2013).

Stakeholder theory is also being employed to support the theoretical perspective of the study. When there should be a change within a business environment, the views of the company’s stakeholders have to be taken into account. In particular, for performance improvement all the stakeholders of a firm should have the same objectives. Stakeholders are not only the people that are taking the decisions but also the people that they are going to be affected by them (Jensen, 2001). Stakeholders are defined as the “organisations, groups, and individuals that can affect or are affected by a firm’s actions” (Rothaermel, 2015, p. 11). For the legal firms there are internal and external stakeholders that can have an impact on the working environment of the legal professionals. For example, internally these are the legal personnel i.e. the partners, the lawyers at all levels and the IT department; these are considered the most valuable internal stakeholders of a legal firm. Furthermore, the owners and the shareholders of the legal firm are those who are the decision makers and the strategy developers. Externally, the regulatory bodies and the government are the institutions influencing the business model governing the legal firms. Last but not least, the clients are the key external stakeholders to whom legal firms deliver value through their services. Finally, the IT suppliers are providing law firms the merchandise i.e. templates and documents to run their business. All these stakeholders are interconnected as changes in their ‘behaviour’ are direct or indirect affecting the legal firms’ performance.

**Literature review**

Innovation for the professional services can be referred here as the entrance of new technological tools, the effective management of employees and the transformation of
employees’ knowledge into services (Love et al., 2011). From an operations management perspective, the application of those innovative aspects in association with operational management techniques such as Lean thinking may lead to a process change and to a competitive edge in the workplace.

Love et al. (2011) characterised service as a “heterogeneous collection of activities that includes business, professional services and consumer services”. Additionally, service is the “combination of the service delivery and the experiences received by the customer” (Johnston et al., 2012, pp. 15-17). Others (Roper et al., 2016; Desyllas et al., 2018) focusing on innovation in the legal sector stated that innovation is considered when firms employ “a process change” or specifically “improved services or new improved ways of delivering legal services”.

Technology adoption is considered as a key innovation element that can lead firms to a competitive advantage. Firms opt for adopting the newest technologies and products to leverage over the highly competitive market (Zaefarian et al., 2017). Although there is a vast selection of technological tools that can help lawyers optimise their work, most law firms are resistant to innovative ways of working. The reasons behind it, is something that this research study is looking to examine.

The culture of the firm and the management of the human factor play an important role for the encouragement of the adoption of new technological tools and techniques. The human element is considered as an additional factor that needs to be taken into consideration for the decision-making, the design and the implementation of operations and innovative approaches within an organisation. Managers should pay particular attention to nurture social capital as a pathway to realise the true value of technology implementation (Wu et al., 2018). This is line with Chichkanov et al. (2019) research on 519 Russian knowledge-intensive business services. They argued that the human factor has a significant influence on the diffusion of technological innovations. Overall, for the lawyers, it is argued that the term innovation emphasises their continuous journey of adaptation, evolution and improvement (Destefano, 2018).

Lean thinking is a philosophy, originally coming from the Japanese manufacturing industry, which has been employed worldwide in various industries as an apparatus to reduce wastes and improve business operations. Companies in the service sector like the healthcare (D’Andreamatteo, et al., 2015; Burgess and Radnor, 2013) and other knowledge-intensive businesses (Suárez-Barraza et al., 2012) adapted the Lean principles to increase their productivity and performance efficiency. Often, it is argued that for the successful implementation of those operations management techniques, the understanding of the importance of the human element plays a significant role (Hines et al., 2004).

Thus, the aim of this study is to explore how synergies among innovative approaches such as lean and technology practices can be integrated and operationalised within law firms can lead to a competitive advantage in the workplace.

**Methodology**

The work presented in this paper is the qualitative part of a mixed-method study that also includes a legal professional survey. The study reported herein has a primarily exploratory character and is based on a thorough thematic analysis examining raw interview data collected through fifty-three in-depth semi-structured interviews with legal professionals working in legal firms around the world. The sample consists of both law academics and legal practitioners including lawyers and paralegal personnel; all the interviewees had experience in working within a legal firm in the UK or abroad. More specifically the respondents were law academics, firm partners, associate solicitors, attorneys/lawyers,
trainee solicitors, legal IT experts, in-house lawyers, barristers and legal administrators. The academic sample included heads of Law schools, senior lecturers in law and law students. Twelve interviewees of this group had the role of the academic and the qualified but not practicing solicitor at the moment. This twin professional background of these interviewees potentially adds value to the research as they could identify in a broader way the challenges of the legal sector since they have faced these themselves in their previous role; actually for some of them these were some of the reasons that led them to change their career path and pick an academic post.

The analysis of the qualitative phase follows a theory-driven thematic analysis approach as described by Braun and Clarke’s (2006) six-step framework for analysing the qualitative data gathered from the semi-structured interviews. Through thematic analysis the researcher can “identify, organise, analyse and report the finding patterns—the themes” in the data corpus (Braun and Clarke, 2006, p.4).

Findings
The qualitative results of the study were organised, managed and analysed using the NVivo11 software. From the thematic analysis, the researcher extracted six main themes and each of them with a number of different dimensions, based on the patterns of the interviewees’ responses; these are summarised in the table 1 below.

In general, the majority of the participants suggested that there are many problems which mostly arise from the legal profession’s heterogeneous and complicated nature. They also identified that there is a need for operational improvements within their legal firms. Additionally, it seems that the legal service sector lacks innovation contrary to other services sectors like the accounting industry. The resistance of service professionals to adopt innovation might be among the reasons for that. For instance, the poor management of employees and the inherent ‘traditional’ culture of the law sector emerged as key challenges. The slow adoption of the technological advancements and the resistance to change were two other potential reasons for the lack of innovation into the legal sector.

Table 1: Thematic analysis

<table>
<thead>
<tr>
<th>THEMES</th>
<th>Human Factor and Culture</th>
<th>Client and Market</th>
<th>Technology</th>
<th>Organisational Transitions</th>
<th>Legal Processes</th>
<th>Education</th>
</tr>
</thead>
</table>

The first key theme according to the table 1 is the human factor and culture that provides an insight into the barriers that legal professionals are facing within their working environment. It is a common fact that the legal profession has a distinctive and typical culture that someone can find it difficult to easily integrate within. Most interviewees supported that if there is to be change, the profession has to go through a cultural and attitudinal change. “The profession is running historical; the recruitment criteria are often similar as those were in the past rather than adapted to the today’s requirements, because they (senior managers) want to recruit and work with people like them” (barrister in commercial law, 9 years of experience). Another respondent having long experience working as a head manager for a large law firm expressed that law firms are operating conservatively in comparison to other professions like the academic one. Although it is evident that most law firms are embracing the new technological tools focusing on
keeping up with the new trends, their traditional and outdated thinking keeps legal employees in the past.

Technology was also an important theme that legal experts were constantly referring to. For instance, most of the respondents supported the view that although technological tools can help the legal profession with the document and case management, it can also impose security risks. Cybersecurity was identified as a significant theme that all senior professionals are often concerned about as they are dealing with clients’ confidential information and large amount of money. The lawyers’ worries have increased after the 2017 cyber-attack to a global large firm operating in the UK, strict regulations are being in place. For instance, according to another legal professional “with technology in place there is a risk of hacking and security issues; who can ensure specific access to legal document? ” (Solicitor and academic in commercial law, 6 years of experience).

Some of the respondents employed in senior position within the legal firms argued that training of the employees on the new technological developments could potentially tackle the resistance on technology adoption. “Technology for me it has been really, really helpful. I mean I am not an IT freak, so at first it may seem a little bit difficult to, but it is not eventually and you get used to that but since I have trained and learnt how to use these new facilities, it is much better” (in-house lawyer in commercial and litigation law, 14 years of experience).

Moreover, another theme identified were the competitiveness in the market and the clients’ constantly changing needs. Due to the competitive environment and the need to satisfy the customer, lawyers have to work relentlessly to meet their deadlines and achieve a good deal for their firm. “There is a lot of pressure to increase your billable hours. You have targets, and you have got to try to hit those targets and bill a certain amount per year” (in-house lawyer in commercial and litigation law, 10 years of experience). Another consequence of competition in the legal market, is that law firms are hesitant to invest in human resources by recruiting senior law personnel as they used to do in the past. Similarly, the interviewee supported that it is evident that legal firms are in a period of reducing or not increasing their personnel for the means of decreasing their costs. “Some firms have made redundancies and cost cutting for trying to optimise their operations” (in-house lawyer in commercial and litigation law, 10 years of experience). In terms of the customer lawyer interface, clients as part of the market are playing an important role to law firms’ prosperity and it is a factor that can drive change. All respondents working in private legal firms argued that they value their customers, by focusing on satisfying them and respond to their requests. For example, face-to-face interaction is often in forefront. “We are interacting with our clients probably via email or through Skype, or on the telephone. However, we are mostly focusing on whatever method is available and it is convenient to the client” (managing director/sharerholder in family law, 20 years of experience). However, communication between lawyers and customers is not running smoothly with problems arising often due to the lack of understanding of the lawyer’s role. “Clients sometimes do not a full understand of what it is going on and this has to do with the fact that they are not experts, they are not lawyers and we have to explain to them the situation in the simplest way possible” (in-house corporate and commercial lawyer, 10 years of experience).

The fourth theme identified refers to the political implications impacted on the legal profession. As legal multinational companies operate under strict regulations and laws in the UK, a change on them, such as Brexit, can have a considerable impact on them in various ways. The legal professionals’ of this study argued that it is still unknown of what law firms will have to do to comply with the new regulations. “It is still uncertain of what will happen with the Brexit. I believe that people are scared, law firms are trying to move
their head offices in Ireland, a lot of solicitors are trying to qualify in Ireland to keep being a European lawyer” (trainee solicitor and part-time student, 2 years of experience).

Last but not least, the complexity of legal processes were mentioned from the legal specialists as a key challenge of the dearth of efficiency in the legal firms. The efficiency is strongly associated with the complexity nature of each legal transaction. For instance, for long transactions like mergers and acquisitions a team of lawyers is needed to secure the deal; that means more time and effort and resource allocation for the client’s legal case completion. For instance, “on average the time delivery for our corporate transactions it takes from three to four months. So it is quite a long process, but I do not think that it can become shorter and as a matter of fact” (partner/ head in financial law, 14 years of experience).

Finally, academic education was identified as another theme that has an impact on the legal firms’ recruitment policies and performance. Another respondent working as a family attorney in a niche law firm in the USA emphasised the lack of skills of the trainee solicitors entering law firms. “There are a lot of newer attorneys that do not necessarily have the experience and skills to enter the sector. However, most of them know how to use online marketing to appear to be experienced and well regarded” (attorney in family law, 8 years of experience). That means that academic institutions do not necessarily equip their law students with the required skills to enter the workplace as early career lawyers.

To conclude, the thematic analysis provided evidence of the challenges that the legal professionals are facing in their working environment mostly focusing on the highly competitive market and the fast developing technology.

Conclusion

This paper contributes by presenting an in-depth explanation about the challenges that legal professionals are facing within the legal firms and highlighting the lack of empirical research into the investigation of how innovative approaches such as technology and the Based on our findings we strongly recommend that where the legal profession operates in a way not as effective, robust or technologically informed as it should, problems should not be ignored; problems should be solved. Lean thinking is a well-established path to higher quality, improved operational performance, increased timeliness and greater respect for the people who provide the services. It can improve legal processes and result in rigorous corporate legal transactions and to a competitive advantage over their competitors in the workplace. Lean is a tool that could enhance innovation and technology adoption and skill enhancement.

Further research focuses on a quantitative survey examining insights on innovation adoption by legal firms’ professionals by addressing questions highlighted by the qualitative work. This is a complementary research looking to eventually produce results that could be easier to generalise into a wider context.

The role of unmanned aerial vehicles in mapping and search and rescue in response to natural disasters

Amna Furqan (amna.furqan@student.hanken.fi)
Hanken School of Economics

Dr. Wojciech Piotrowicz
Hanken School of Economics

Abstract

This paper intends to present the implications of deploying UAVs in assisting mapping and search and rescue in immediate response to natural disasters. For doing so, empirical data has been collected from three organizations with real deployment experience. Evaluation framework (Piotrowicz & Irani, 2010) have been used to classify the impacts. Findings indicate that on strategic level, intangible and non-financial benefits, challenges and risks dominate whereas on tactical and operational level, tangible and non-financial impacts outnumber. Considering these impacts, the study identifies areas for improvement. Moreover, it modifies and extends the evaluation framework for use in humanitarian sector.

Keywords: Unmanned aerial vehicles, mapping, search and rescue

Introduction

Every year, sudden onset natural disasters cause deaths, causalities and often result in significant economic and financial losses (Shavarani & Vizvari, 2018). For international NGOs and aid organizations, these disasters restrict their ability to access the affected areas and collect up to date information about the situation (Haavisto et al., 2016; Erdelj et al., 2017). Since first 72 hours are crucial for searching victims post disaster, therefore collecting accurate and timely geospatial information becomes critical for coordinating rescue operation and delivering need based response. Several studies indicate the usefulness of mini and micro Unmanned Aerial Vehicles (UAVs) in bridging knowledge gaps in immediate response phase and enhancing data collection and information sharing capabilities of first responders and humanitarian organizations (Sakr et al., 2016). While each methodology has different impacts, this research intends to present the benefits, challenges and risks of the using UAVs in disaster response, particularly in mapping and search and rescue.

Evaluation Framework

Since UAVs can be used to strengthen the capabilities of Geographic Information System (GIS) by collecting and transmitting remotely sensed spatial data, therefore we decided
to use evaluation framework (Piotrowicz & Irani, 2010) to identify and classify implications of the use of UAVs in disaster response. This framework takes into account the technology related flexibility and can be used to present impacts that cannot be measured through conventional evaluation techniques (e.g. cost benefit analysis).

For this research, we have the modified dimensions of framework to incorporate unique characteristics of humanitarian sector and our research aim. The dimensions of this framework are explained below.

**Strategic, tactical and operational impacts**

Strategic impacts are linked with the objectives of organization and represent the long term impacts. They affect performance on tactical and operational levels (Gunasekaran et al., 2001). In case of humanitarian organizations, these impacts can be affected by the time and socio-political and economic conditions of the country in which disaster strikes (Pettit & Beresford, 2009). Tactical impacts are linked with resource, process and task requirements and affect medium (short terms) success of project. Operational impacts represent requirements that must be fulfilled on daily basis for successful completion of a project (Gunasekaran et al., 2001).

**Impact characteristics**

Impacts experienced at each level can be categorized based on the extent to which they can be measured indirectly or directly (Gunasekaran et al., 2001). Tangible (T) impacts can be experienced and measured in a direct manner whereas intangible (INT) impacts cannot be assessed directly (Piotrowicz & Irani, 2010). Tangible and intangible impacts may indicate financial (F), or non-financial (NF) repercussions of innovation decisions (Gunasekaran et al., 2001).

**Balanced Scorecard (BSC) dimensions**

Piotrowicz & Irani (2010) have used BSC dimensions to present distribution of benefits in areas such as financial, internal business processes, customers and learning and growth (Kaplan and Norton, 1996). Due to immense importance of donors and beneficiaries in humanitarian sector, several humanitarian organizations consider them as their customers. Donors provide funds and influence humanitarian decision making (Beamon & Balcik, 2008) therefore, we chose them as customers. As the main objective of humanitarian organizations is to save lives and reduce suffering of victims, their main responsibility is also towards beneficiaries (Beamon & Balcik, 2008). Thus, we also regarded beneficiaries as customers.

**Unmanned aerial vehicles (UAVs)**

UAVs are aerial vehicles without passengers and crew onboard. They can be dispatched autonomously or semi-autonomously to perform sensory operations (Sakr et al., 2016). In this research, we aim to analyze the implications of micro and mini UAVs because they are preferred for use in disaster response from regulatory point of view due to their size and weight (OCHA, 2014). The maximum take-off weight of mini UAV is less than 30 kg whereas that for micro UAV is less than 5 kg (Bendea et al., 2008; Giordan et al., 2018). Several humanitarian organizations and emergency management organizations such as International Organization for Migration (IOM), World Bank and Greater Manchester Fire Rescue Service (GMFRS) have used them (both fixed wing and multi-rotor) for mapping and search and rescue in immediate response to disasters (Soesilo et
Mini and micro UAVs can easily be transported to disaster site and perform challenging tasks such as search and rescue (SAR) (Tanzi et al., 2014; OCHA, 2014). They are more affordable to use for mapping and SAR operations compared to other types such as High Altitude, Long Endurance (HALE) and Medium Altitude, Long Endurance (MALE). Small rotary wing UAVs cost around US$2,000, whereas high endurance fixed wing models costs around US$130,000,000 (Tatham et al., 2017). DJI’s phantom (multi-rotor UAV) costs around €500-€1500 and MikroKopter’s ARF OktoXL 6S12 (multi-rotor UAV) costs approximately €6,500 for mapping. Fixed wing UAVs (for mapping) range from €10,000 (Danoffice IT’s Cumulus 1) to €20,000 (SenseFly’s eBee).

The cost of UAVs for live feeds during SAR can range from €42,000 (Microdrones’ MD4-1000) to €40,000 (Sky-Watch’s Huggin X1). These cost variations are due to brand, type of UAV (fixed wing or multi-rotor) and sensors used (Soesilo et al., 2016).

Limited endurance of mini UAVs (<2 hours) and micro UAVs (around 1 hour) affect their ability to fly longer (Bendea et al., 2008) and support SAR and mapping operations without a charging arrangement or extra capacity. Their limited payload capacity restrict their capacity to carry the number and type of sensors and cameras. However, the development of miniaturized and custom designed thermal sensors as well as multi and hyper spectral cameras have enhanced usefulness of these platforms (Giordan et al., 2018).

**Mapping and SAR challenges in immediate response phase**

Immediate response to disaster involves multi-dimensional activities to reduce disaster impact, save lives and prevent further damage. Despite the critical need to rescue victims and provide relief, humanitarian organizations have to face significant challenges in conducting immediate response activities, particularly with first 72 hours. This is because disasters most often damage physical infrastructure and cut off affected areas (Haavisto et al., 2016). Inaccessibility to affected locations coupled with inaccurate understanding of situation limit the ability of humanitarian organizations and first responders to collect up to date spatial data. Most often in response phase, humanitarian organizations are receiving information from deployed assets and reports from the community. The collected information is sometimes inaccurate or incomplete (Griffin, 2014).

**Benefits of UAV assisted mapping and SAR**

The availability of accurate and up to date information is critical for rescuing victims and providing relief (Griffin, 2014). In this regard, images or live video feeds streamed by mini and micro UAVs from disaster site can improve situational awareness of humanitarian actors (Shakhatreh et al., 2018). These videos can also increase the flexibility of first responders in improvising SAR operation (Tanzi et al., 2014); thereby improving SAR time efficiency (Shakhatreh et al., 2018). Sending data acquisition plan to satellites and collecting data from them takes several days whereas UAVs can be deployed on demand for multiple observations of disaster affected area. Mini and micro UAVs carrying IR camera and LiDAR can be quickly dispatched to scan the disaster affected site and collect data even during night time and adverse weather conditions (Shakhatreh et al., 2018). This can improve mapping time efficiency (Nedjati et al., 2016). UAV based images can be used to create maps and other information products (such as DTM and DSM) which can be used to conduct risk assessment, damage assessment and plan need based relief efforts efficiently (Hashemi-Beni et al., 2018). Their use can also reduce the overall response time (Tanzi et al., 2014). Up to date UAV based spatial data
can strengthen GIS and can be used to improve other immediate response activities (Gomez & Purdie, 2016).

Autonomous mini and micro UAVs can reduce operating costs of UAVs because these vehicles are less costly as compared to helicopters and airplanes (Soesilo et al., 2016). Low cost and off the shelf sensors and cameras have also reduced unit cost of these vehicles (Sakr et al., 2016). Moreover, autonomous systems reduce the need of trained pilots to operate the vehicles and decrease the total manpower required to perform UAV based mapping. Micro and mini UAVs can also enhance victim detection and mapping accuracy. As compared to other remote sensing platforms such as airplanes, helicopters and satellite, mini and micro UAVs can fly at low altitudes (30-150 meters) and capture high resolution images from different angles (Soesilo et al., 2016). Sensors carried by these vehicles allow them to locate and detect victims with accuracy (Tanzi et al., 2014). UAVs as a platform can overcome coverage issues due to atmospheric conditions (such as cloud cover and dust whirls) (Soesilo et al., 2016).

**Deployment risks and challenges in disaster response**

Regulations present a major challenge in deploying UAVs for disaster response (Gomez & Purdie, 2016; Shakhatreh et al., 2018). Every country has different regulations and several countries in which humanitarian organizations operate do not have UAV laws (OCHA, 2014; Tatham et al., 2017). Compliance with local regulations is necessary for operationalizing the technology in a safe manner. However, the lack of UAV laws can raise the level of uncertainty regarding their use in disaster response. Since UAVs can collect, store and transmit significant amount of big data, their use has raised concerns regarding data security and privacy of victims (Tatham et al., 2017). This data upon leaking or hijacking can lead to intrusive monitoring of people and observed areas and can also cause personal harm to people (Erdelj et al., 2017). In addition, UAVs have a negative image due to their prior association with the military and their use in modern warfare. For humanitarian organizations, such an image becomes a critical issue that must be managed to retain their image as an independent and impartial entity (OCHA, 2014).

Mini and micro UAVs are sensitive to heavy rains and strong winds (Shakhatreh et al., 2018). Such weather conditions can change the pre-determined flight path; thereby, affecting the coverage of observation area (Shakhatreh et al., 2018). UAV based operations required highly trained pilots and technical staff available, particularly within first 48 hours (Soesilo et al., 2016). In addition, integrating UAVs as a supplementary tool requires significant costly preparations beforehand to ensure timely results. UAV based operations also demand managing (or overcoming) long data processing and energy constraints (Shakhatreh et al., 2018). In case of UAV based SAR, managing coordination between technical team and first responders or humanitarian staff is critical for ensuring success of operation. Lack of clarity about roles and priorities can reduce the possibility to find victims in time and save lives (Soesilo et al., 2016). While the technology is still evolving, technical risks such as limited communication range, need for robust collision avoidance solutions, use of low cost and risky off the shelf components and unexpected sensor failure present challenges related to public safety (Erdelj et al., 2017).

**Methodology**

Empirical data has been collected from a purposeful sample of three humanitarian organizations (HOA, HOB and HOC) with actual deployment experience in disaster response. HOA and HOC are based in Central and Southern Europe respectively. HOB is based in North America. Multi-case study design has been used to enhance generalizability of findings and compare implications across cases. Constructivism
paradigm have been used to guide research process, data collection and data reporting. Altogether 3 skype based individual interviews have been conducted from 3 respondents in humanitarian industry using an interview guide. All respondents are UAV experts who have used the technology and have participated in real deployment experience of case organizations. Apart from the interviews, written communication in the form of UN reports, documents published on websites of case organizations and previous studies were used for data triangulation.

**Findings**

*Humanitarian Organization A (HOA)*

HOA use UAVs as a supplementary tool for mapping only. It uses satellites, on ground team with COBO (Company Owned/Business Only) phone or tablet with GPS and UAVs for collecting spatial data and supporting GIS analysis. Before implementing UAVs, HOA considered cost comparisons between satellites and UAVs, frequency and resolution of observations required, and finance. In addition, an assessment of best tools in terms of days or duration of project was also made. The report was first submitted to the program manager and then to the mission manager in Haiti. After gaining approval, HOA collaborated with a private company named SenseFly to source micro-UAVs and software. After receiving field validation reports from teams on ground, HOA conducted test flight with UNOSAT in the aftermath of Hurricane Sandy (2012). To make sense of spatial data, HOA collaborated with Pix4D and converted raw data or images into accurate 2D maps (orthomosaic) and 3D models (DEMs). For digitizing images and conducting GIS analysis, HOA hired a specialized team from Open Street Map (OSM). It then reduced the size of each UAV based imagery and maps (<50 Megabytes) and shared this information freely (open source) through humanitarian data exchange (HDX platform) and OSM with relevant stakeholders (volunteers, local government, humanitarian partners and civil protection bodies).

UAVs showed advantages during first deployment as it provided the data faster (29th October) than satellite (2nd November). Cost wise UAVs gave a more detailed overview as compared to satellites on km² basis. Upon realizing benefits from this experience, HOA began developing in house UAV capacity. It sourced more vehicles, servers and formed a specialized team in house. Later it deployed UAVs in response to Hurricane Matthew (2016) to verify satellite data, improve situational awareness, collect baseline data to identify hurricane pattern and support damage assessment and plan response (in terms of NFI and food distribution). The respondent mentioned that UAV based operations are challenging because the technology can be deployed only if the Government requests and allows their use. Their use also requires considering and complying with laws regarding data management (storage, filter information and processing). Moreover, cases in which Government receives reports of misuse of UAV sourced data, improvising the situation becomes problematic.

*Humanitarian Organization B (HOB)*

HOB use UAVs as a complementary tool for mapping only. HOB does not replace satellite, manned aviation assets or ground based surveys with UAVs. It uses them for data triangulation or bridging knowledge gaps. HOB prefers to use UAVs for direct live feeds or improve situational awareness of an area when satellite images are inadequate. UAVs provide high resolution images (1.5 to 10 cm) that are accurately geo-referenced. These vehicles are used when HOB has the capacity to use the technology in terms of...
funds, vehicles and technical staff available. UAV are preferred for small scale (10 km) localized assessments as compared to ground based survey. An aerial image sourced from UAV can be cheap as compared to satellite images. Moreover, UAVs provide flexibility to HOB for on demand and efficient mapping. However, the preparation for UAV based operations can be very costly in terms of acquiring the technology, permits and developing or hiring technical staff. Regulations for UAVs are more restrictive than satellites in terms of data management and use of vehicle. If preparations are not done before deploying UAVs in immediate response then, UAV based response can take long time. Even with preparations done, data processing stage can be significantly time consuming if HOB is covering large areas with UAVs. Thus, with 72 hours, it is hard to conclude that UAVs can be effective in delivering the maps. It can be useful with 72 hours provided the vehicle streams live video feeds to the team. Furthermore, the use of UAVs requires collaborating with the technical team or technology providers on site. Challenges and risks mentioned by the respondent deals with ethical implications (such as privacy of victims, data protection and management), lack of uniform standards, long processing time (e.g. 3-4 days to map 10 square kilometers), harsh weather conditions, overhyped product capabilities, costly preparations, lack of experience of technology providers in emergencies and regulatory restrictions. She mentioned that some countries do not even have UAV regulations and several do not have streamlined processes to gain approval for UAV, pilot and operator. It usually takes several weeks to go through several registration processes and certifications.

Humanitarian Organization C (HOC)
HOC has been using UAVs as a supplementary tool for mapping and improving visibility of national partners at lower costs. However, it has been supporting local Governments, National Disaster Management Organizations (NDMOs) and first responders in SAR by prepositioning lower cost UAVs ($2000/ UAV) and localizing skillsets through training programs. For mapping, HOC has prepositioned equipment at six regional bureaus (Panama, Bangkok, Cairo, Johannesburg, Nairobi and Dubai). It has been conducting capacity building workshops for HOC personnel, cluster partners and the Government. For localizing UAVs, HOC is working with civil aviation authorities to get clearance. Before deployment, HOC defined expectations at programme level in each country of operation. Decision to use the technology was based on the comparative analysis of the end product price vs methodology. End product price was measured on project or unit cost basis. For mapping HOC analyzed cost effectiveness of UAVs i.e. it compared quality and accuracy vs cost per hectare of land.

HOC have used UAVs in Philippines after Typhoon Haiyan (2013) to map out millions of damaged coconut trees and to support efforts to enable reuse of farmer lands. In Columbia, HOC used UAVs to track displaced population in the aftermath of Hurricane Irma (2017). In Mozambique, it mapped 14000 km$^2$ of River Delta (2018) to assess damages in the aftermath of floods (2018). In response to Hurricane Maria (2017) in Dominica, HOC used UAVs to support Government and rescue teams. For map generation, HOC use LiDAR, photogrammetry software and high processing power computers to create orthomosaics, Digital Surface Models (DSMs) and Digital Elevation Models (DEMs). It then freely shares the generated information products with national partners to improve situational awareness. HOC use micro UAVs (less than 1kg) and sensors such as Near Term Digital Radio (NTDR) and Unreal Development Kit (UDK) camera for thermal imagery. For observing large areas (e.g. 500 hectares), HOC use fixed wing UAVs. The benefits reported by the respondent include workload reduction,
improvement in inter-agency coordination and information sharing and strengthening GIS. UAVs improved mapping and SAR accuracy, flexibility and capabilities. The challenges and risks that HOC reported include ensuring the appropriate equipment (UAV) for use, retention of technical knowledge and staff, timely communicating with civil aviation authorities for safe operations and assuring safe operations across the cluster.

**Discussion**

Table 1 & Table 2 presents classification of reported benefits, challenges and risks based on the framework dimensions (Piotrowicz & Irani, 2010). Majority of the reported benefits can be categorized as strategic and operational whereas most of the challenges and risks can be classified as strategic and tactical. On strategic level, UAVs mostly improve: inter-agency coordination and information sharing and other immediate response activities. These findings are in line with previous research (Gomez & Purdue, 2016; Soesilo et al., 2016). On tactical level, UAVs can reduce map procurement costs (HOA, HOB & HOC) and improve GIS data collection and information system (HOA & HOC) on organizational (HOA) and multi-agency level (HOC). These findings are supported by previous studies analyzing the impact on intra organization (Sakr et al., 2016) and inter-organization level (Soesilo et al., 2016). On operational level, UAVs can be used to enhance capabilities and accuracy of mapping (HOA, HOB and HOC) and SAR operation (HOC). All these findings are similar to observations made in previous studies (Nedjati et al., 2016). On strategic level, the main challenges and risks mentioned by all cases include concerns regarding: regulations and data protection. Limited resource capacity, lack of deployment preparedness and data management were found common challenges and risks among several cases on tactical level. On operational level, technical team dependence, long processing time, and weather conditions can be categorized as main challenges and risks. These findings have been confirmed by previous studies (Bendea et al., 2008; Erdelj et al., 2017). We found some new challenges and risks such as retaining technical knowledge and staff, monitoring risk and assuring safety at multi-agency level, dependency on agency request and gaining approval internally. On strategic level, intangible and nonfinancial benefits, challenges and risks were found dominant. Majority of benefits, challenges and risks on tactical and operational levels were identified as tangible and non-financial in nature. We found donor and learn and growth as main improvement areas in all organizations. Moreover, findings revealed learn & growth, internal process and beneficiary as the areas that require the most attention to reduce risks and overcome challenges.

**Conclusion**

Findings have revealed the difficulty in measuring benefits, risks, and challenges for humanitarian organizations on strategic level. Most of the implications on strategic level (such as improvement in inter-agency coordination and information sharing and regulations) are intangible and non-financial in nature. Although their impact is difficult to measure, these outcomes can greatly impact the performance of humanitarian organizations in immediate response. On tactical and operational level, tangible and non-financial impacts dominate tangible and financial as well as intangible and non-financial for all organizations. Evaluation framework enabled us to indicate intangible and non-financial implications of UAV assisted response. These impacts cannot be captured by conventional evaluation techniques (e.g. cost-benefit analysis) and operational measures.

Decision making on risky innovative production investments

Pooja Chaoji (pooja.chaoji@tuni.fi)
Tampere University, Department of Industrial Engineering and Management

Prof. Miia Martinsuo
Tampere University, Department of Industrial Engineering and Management

Abstract
Radical manufacturing technology innovations (RMTI) involve the introduction of new technologies in the firm’s production processes. They represent especially challenging production investment decisions, due to inherent high risks and uncertainties. Firms’ approaches to RMTI decision making are insufficiently understood. We explore the nature of RMTI decision making processes in nine RMTI projects from three manufacturing firms. The findings reveal slight differences compared to typical investment processes and organizations’ different approaches for guiding the decision making.

Keywords: radical innovation, manufacturing technology, investment decision

Introduction
Radical manufacturing technology innovations (RMTI) mean the development of the production process through a radical shift in the core production technology and related practices. They involve the introduction of new-to-the firm production equipment and enable big benefits such as targeting of new markets, creation of new products, and savings (Oke et al., 2007; Reichstein and Salter, 2006; Keupp and Gassmann, 2013; Maine et al., 2014). They require significant investments from the manufacturing firm and can be risky. This study deals with decision making concerning these risky innovative production investments.

The front end process for RMTI includes a search for alternative technologies and suppliers, idea selection, and further investigation to prepare a business case for enabling an informed decision for the investment (Frishammar et al., 2013). As compared to regular equipment investment proposals, decision making on RMTI investment proposals presents a greater challenge due to various risks and uncertainty. Radical innovations are not completely known and well understood in the beginning, and they will require learning and development during the innovation process (Von Hippel and Tyre, 1995). Existing literature does not comprehensively cover decision making in such a context: whether to invest in an RMTI proposal or not, and how to assess the investment options. Manufacturing firms will face various dilemmas concerning the risks and potential benefits from the RMTI, and regarding the internal capabilities and external support available, during their decision making.
Therefore, the purpose of this paper is to explore manufacturing firms’ practices in analyzing and deciding innovative production investments at the front end of RMTI. The main research question is: how do manufacturing firms evaluate and decide RMTI investment proposals? The focus is on radical innovations in the core production process, and incremental and peripheral innovations as well as product innovations are purposely excluded.

**Literature review**

**Radical manufacturing technology innovations as risky production investments**
Radical technological innovations deal with the introduction of a technology that is radically novel and different from the previous technology it may be displacing (Harborne et al., 2007). Radical manufacturing technology innovations (RMTI) cover such innovations within the core production technology and process (Chaoji and Martinsuo, 2016, forthcoming). While discussion on advanced manufacturing technologies typically focuses on the technological innovation itself, RMTI imply changes more broadly including the supply, delivery and manufacturing processes and related ways of working. For example, change from subtractive to additive manufacturing could be considered as RMTI. RMTI do not cover innovations in non-core or peripheral production processes such as production quality control and monitoring (Bessant, 1982), or innovations in other than manufacturing operations such as material purchase processes (Parikh and Joshi, 2005).

Radicalness implies novelty at the level of the adopting manufacturing firm, and in some cases the novelty may be true also for the equipment supplier firm and the industry more broadly (Chaoji and Martinsuo, forthcoming). RMTI may require using non proven equipment and technologies, and therefore have greater uncertainty than other types of innovations. The overall creation process (development and implementation) for RMTI starts with activities related to idea search, selection and refinement (Kurkkio et al., 2011). Following the decision to invest in the development of the actual production equipment and its technology, the back end process involves the detailed engineering, construction, installation and production trials (Lager and Frishammar, 2010). A recent study has mapped the different types of RMTI processes and reveals differences based on the degree of novelty particularly at the front end of RMTI (Chaoji & Martinsuo, forthcoming).

The focus in this paper is on the decision making concerning RMTI as risky production investments at the front end of the innovation. Due to their centrality as part of the firm’s production process, RMTI investments can be considered as strategic and long-term oriented. The objective of the front end of innovation is to reduce uncertainties and unknowns about the RMTI idea to enable ‘informed’ decision making (Frishammar et al., 2013). However, some extent of unknowns are present at the decision making as the innovation is not completely known and well understood until its pilot implementation as part of the project itself.

**Decision making in operations management**
Decision making involves the identification and selection from alternative options, and research on decision making suggests various pathways to choosing among alternative options and their potential impacts (Cook et al., 2007). Decision making can be structured, formal comparison and analysis of the alternatives using, e.g., multiple criteria decision analysis methods (e.g. Ting, 2008). Also, it may be intuitive, unstructured and based on a person’s experiences without systematic analyses of all alternatives (Tello et al., 2010; Kammerlander and Ganter, 2015). Furthermore, decision making in an industrial context
is influenced by organizational processes and contexts, raising questions regarding the role of individuals making decisions versus organizational procedures and contexts influencing their decision making (Tello et al., 2010; Leiblein et al., 2002).

Accordingly, decision making can be perceived as a rational process involving the consideration of all possible alternatives, or it can be considered as boundedly rational where individuals consider such alternatives that are practically feasible (Turpin and Marais, 2004), leading to the selection of one possible best option. Research acknowledges that decision making is a behavioural process, wherein the outcome is considered to be linked with the individual involved, for example their previous experiences, values etc. (Evans et al., 2013). Within studies from the behavioural paradigm, the political view observes decision making as a social process of interactions between individuals from different interest groups, each group trying to maximize their gains and interests from the decision (Turpin and Marais, 2004).

**Decision making on RMTI investments**

There has been considerable research on decision making on selection of advanced manufacturing technologies, and both rational and behavioural paradigms have been covered. A large number of studies have concentrated on decision making support formulae and systems (e.g. Sambasivarao and Deshmukh, 1997; Chan et al., 2006; Osman and Cengiz, 2005). The dominant view perceives decision making on RMTI investment proposals to be a rational team-level decision making process comprising three stages: 1. Search for alternatives, 2. Screening alternatives and collecting facts, and 3. Comparing the alternatives in a team, to prioritize them and choose the best alternative (Baines, 2004; Farooq and O’Brien, 2010; Ordoobadi, 2012).

Manufacturing investment decisions are considered as challenging due to the presence of multiple criteria that need to be optimized in selecting the best technology (e.g. Chan et al., 2006; Iakymenko et al., 2016). In addition to economic criteria, strategic needs and risks have been shown to be important attributes in making the decision to invest (e.g. Chan et al., 2006; Iakymenko et al., 2016; Meredith and Hill, 1987; Farooq and O’Brien, 2010; Kakati, 1997; Stading et al., 2001). Some studies also highlight the role of previous experiences, intuitions in such decision making (e.g. Evans et al., 2013), and have described the challenges related to conflicts in interest groups in multi-department or cross-functional teams involved in investment planning teams (e.g. Ordoobadi, 2012; Choudhury et al., 2006; Lefley, 2018).

**Research method**

A multiple embedded case study has been conducted to identify how RMTI investment proposals are evaluated and decided in practice. The selected three manufacturing firms are active innovators: they have had multiple successful RMTI projects in the past 15 years. The companies are from different industries and portray differences in their strategies for RMTI. Within each firm, three RMTI projects were discussed, totalling 9 projects. 17 expert interviews (totaling 27 hours of recorded interview data) were held with managers involved in the evaluation and decision making processes, covering nine different RMTI projects, three in each firm. Table 1 includes background information on the companies, their RMTI projects, and the interview data.

The interview outline included questions on timeframe, activities, events, people involved, search process, evaluation and selection process in the early period of the RMTI project before the investment decision was made. The interviewees were selected by key informants of the projects, due to their participation in the innovation front end. Interviews were arranged in meeting rooms in company premises, were recorded and transcribed. Separate interviews were arranged with all participants. Promise regarding confidentiality of information regarding names of firms, interviewees and the technology involved or product specific information was given.

We analyze what was known and unknown concerning the RMTI project and the business environment, and what were the key factors for decision makers generally in the firm’s decision making. Also we explore the exceptions concerning the specific RMTI project, compared to regular investment decisions. We analyzed the data for the nature of the decision making process, including its activities, the use of systematic and formal practices versus intuitive and unstructured practices. The data was coded to identify the role of individuals, organizational processes, risks inherent in RMTI investment proposals and the key justification criteria and motivations for the decision. The projects were the unit of analysis, and observations were compared across the 9 projects to arrive at the findings.

**Results**

*RMTI decision making process: Deciding on the technology and implementation concept*

Typical decision making on investment involves: 1. Search for alternatives, 2. Screening them and collecting facts, 3. Comparing alternatives in the team and deciding. According to the interviewees, RMTI decision making goes through these three stages, but actually covers two choices in a sequence: technology choice and implementation concept choice.

Typically, there are no known technology alternatives to an existing process for RMTI. The search for technology alternatives appeared in the interviews often as an ongoing long period when the managers engaged in discussions about the need to find an alternate technology or process. Some interviewees told about specific small exploratory projects
as part of the search, to assess or test any potential technologies. In project A1, the firm made a decision to start a technology survey project to find an alternate technology. Typically, during this long ongoing period of active interest in finding alternate technology, the technology choice became clear. This involved either conclusive validation tests, sample pieces made (e.g. projects A1, A2), or depth of technical expertise that was accumulated during ongoing technological research. Typically, there was often one technology that was clearly selected for further investigation, and one of the reasons for this was lack of any other potential fit. For example, an interviewee explained the technology selection at the end of technology survey project in project A1 as follows: “reasons for the selection were, well quite simple. First of all some of the processes were not capable so they were easy to drop out. Some were horribly expensive, so by order of magnitude too expensive or too low in capacity to be realistically useful. So we had basically two realistic options. And then the manufacturer of that one tool gave us the very clear message that they’re not going to sell tool outside Japan. So that left us with one technology!” Similar clear selection of one potential technology was visible in other projects too. For example, an interviewee explained about project B3: “I think every second year in our company has been some kind of, small studies done how to handle these questions. But in those cases (this idea) has never raised up. ....it was only possible way to handle it. And Mr. (project head) was very eager, to make those studies to final end and then he was very happy that okay now we can handle this, biggest problem what (industry name) mill ever have had”.

Once a technology idea was obtained, the firms began to investigate this specific technology and gather data to understand its fit and feasibility to their unique needs. This largely included a search for possible suppliers and gathering information about their equipment concepts and implementation concepts for the technology in the firm’s process. The facts regarding implementation ideas gathered through implementation plans from suppliers and discussions with suppliers, their previous experiences with the technology and existing industrial users of the technology were then typically evaluated by internal technical experts for evaluating their feasibility and comprehensive impact e.g. on own processes, products and customers’ production processes. Figure 1 illustrates the sequential decision making process for RMTI.

![Figure 1 – Decision making process in case of RMTI ideas](image)

Overall, RMTI investment proposal evaluation and decision making in the studied projects appears as a logical, team-based process involving the search, screening and selection of the production technology solution. A lot of effort had to be put to the early search and screening, due to the lack of existing ready-made technological solutions. Also the evaluation of the appropriateness of the screened new technology for the purpose of the firm appeared as technically demanding. The selection of the technology and/or the implementation concept was experienced by the interviewees as natural, and it emerged to decision makers through the screening process quite clearly. In many projects, there was only one viable alternative in the end since others got eliminated during the review, and the final decision making was therefore very straightforward.
Role of organizational processes versus individuals in the decision making

All three firms had some processes in place, to support the RMTI decision making. The alignment of investments with the firm’s strategic goals was evidently important. Decision making and related evaluations were linked with key customers’ needs, product technology roadmaps, and the procedures for investment projects. The organizations had rather rational team-level mechanisms and processes in place, guiding the search and contacting of suppliers, asking for proposals, discussing the proposals in teams, and evaluating them based on explicit criteria.

Despite the rational decision processes, also individual persons had a clear influence on the decisions. Individuals stood out in their contributions particularly during the search for ideas, moving in the right direction, and selecting the right direction among alternatives. Here the persons’ depth of technical expertise was valuable. As an interviewee summarized: “And we have, lucky to have, quite capable personnel to even have an idea what direction we have to take and what kind of tooling we would need to accomplish”. The suitable technology idea sometimes emerged through serendipity, chance events and conversations with the right people or visiting the right firms, and coming across breakthrough ideas and information in other ongoing research. For example, as the interviewee in project B3 summarized how they came across the technology idea: “In real life there, wasn’t any other possibilities to solve. I was lucky to, meet a, partly retired fellow!”

Risks and managing them in RMTI decision making

RMTI involve piloting of a new technology in the production processes of the firm, and in some projects also piloting prototype equipment and unproven technologies. Thus, technological and commercial risks and uncertainties are inherent to RMTI. We analyzed the reasons for firms to accept technical risks in the RMTI projects. Two primary factors guided the firms’ risk-tolerance toward non-familiar, non-proven technologies: strategic need or target, and the investment project replacing a bad old technology.

Strategic need refers to a burning need for the new technology. For example in one project, the key customer started such a new product development program that required components with much higher accuracy, and this implied shifting to tolerance levels beyond the capacity of the focal firm’s existing processes. Therefore, finding a new technology for the manufacturing process became quite urgent. As the interviewee explained: “Because this customer is identified as one of our key customers and this was clearly a very very important project for them, we saw this that it is not the right time to calculate that well there are big risks...”. Strategic targets stem from strategic goals and development priorities: the firms had annual plans and three to five-year technology roadmaps to renew existing capabilities, meet product roadmaps, anticipate stringent regulations, and finally, expand markets.

Replacing outdated or inefficient technology and renewing production capability was a necessity for firms when there was already a commercial justification available. Managers in the investment planning team of some of the RMTI projects wanted to maximize the return on investment. Either they saw that the current technology would not be sustainable for a longer time, or it was already outdated, compared to competition or customer needs. By elimination, there is just the radical choice of renewing the technology completely, as an interviewee explained: “I think the drive was that the other option was just bad.. we have kind of two options here, the bad old one and the risky new one”. In all projects, the alternatives available were scarce, in terms of how many alternate technologies they knew, and how many alternate suppliers were available. The three firms differed in terms of the business context, and it affected the technology
possibilities. The nature of the product and industry segment implied for some projects the unavailability of any mainstream equipment suppliers for their production, and the need to develop and build the equipment needed.

Risks typically present in RMTI proposals at the time of decision making were technical risks due to equipment being a prototype for the equipment supplier firm and pilot trial in exact industrial context of the manufacturing firm. There was also uncertainty about production economics parameters such as speed of production, anticipated volumes, and therefore unit costs, and other product quality parameters. In some projects where RMTI were linked to launching a new product with better specifications, the demand volumes expected in the near future were uncertain, except for demand from key customers.

The measures that gave confidence in taking the above risks included confidence in technology choice, for example interviewee in project A2 commented “the test runs that were implemented at the supplier side were rather conclusive...we were quite convinced that yes it makes a very nice edge. So it meets our expectation in that regard (performance on the key parameter for switching to new technology)”. Confidence in the equipment supplier firm’s capability and commitment to the needed development work was also an important enabler of accepting the technical risks and uncertainty. The confidence was based on previous successful projects with the supplier, or was based on critical review of the supplier’s technical capabilities and strategic interest in this RMTI project. A related aspect was confidence in the plans for implementation. In project A3, a consultant was employed specially for support in the decision on supplier and implementation concept selection: “we used the services of a former employee who is nowadays a consultant...and he was kind of challenging the suppliers’ designs and calculations and expectations and material selections, if for no other reason then at least for the reason of making them make it double sure that they know what they are saying”. In cases where the RMTI project would impact the quality of product, an important confidence generating factor was involvement and positive feedback of key customer(s).

There were also projects where technical failures occurred eventually after the investment decision was made (projects A2, B2), and these were present where firms went ahead only based on their confidence in the supplier firm, and internally were not sure about the implementation plans specific to this project prepared by the supplier. For example, as interviewee in project B2 reflected: “But now afterwards I have to say that, there was problems in the process because they have not made this kind of project earlier... this valuation and how we are making the decision is very important in these kind of situations that, there is some technological risk and in that case there was the technological risk, but we believe that this equipment supplier it has supplied us many kind of equipment and so on, and they have done then very well. But in this case, there was problems in the project management.”

Investment justification criteria
Strategic needs and targets were drivers of initiating the technology search and evaluation processes in most cases. However, these were not sufficient criteria to justify the decision to invest. As the Sr. VP of products involved in project A1 elaborated: “For in this case we, the strategical drive for the better layer tolerance was clear. It was coming almost by nature from the fact that this was the most important parameter our customers are looking for. That’s what we always talk about with the customers, then we need to move forward. So that was clear. By the time we were narrowing down the technologies and it was clear that there’s not going to be a cheap solution, a cheap solution which we could just adapt for our all production so that our all production could change from .3 to .2. It might have
led to the conclusion that let’s not do it...0.1 would be a product which opens up completely new markets and therefore that was for me and for the decision to seek board’s approval it was very important that this technology actually enabled the jump all the way to .1”. Thus, higher benefit than merely satisfying the strategic targets with which the technology search was begun, such as new product, new markets, added economic savings were needed to justify the decision to invest. There was often need for additional pressure, triggers for starting the investment pre-engineering phase once the technology had been identified, such as scope for an investment project (need for additional capacity) in a production mill (project B1, A2), or pressure from key customer to start the development (project A1). Satisfying regular investment justification criteria, such as payback period, integration with existing processes, economic unit costs of production, were also calculated, and there was thus thorough consideration of the impact of the investment.

Besides enough reasons to invest in new technology, enough confidence in technology, equipment supplier firm were also important for justifying the investment proposal. The risks were present, but there was good confidence in taking them. This also highlights the characteristic of uncertainty that is present to the end in RMTI investment proposal, to the point of making decision. As Sr. VP of business development involved in project B1 explained, “when you have made the research and investigations as long as it’s possible, then you just have to make the business case and then either choose or not so, we looked at far as you can, and we thought that there is more to gain.”

Discussion and conclusions
The present study explored decision making practices in manufacturing firms on RMTI investment proposals. For this purpose, we gathered data on events and activities in the front end of nine RMTI projects from three manufacturing firms. The firms belong to different industries and are of different sizes. In studying three projects per firm we intended to discover if decision making on risky innovative production investments follows typical patterns, for example, in terms of the key enablers for the decision. We further analyzed the nature of decision making process in RMTI, as a type of radical innovation.

The findings reveal that the early phases of technology identification and evaluation were technically demanding, and the final phase of selection of technology was often easier due to lack of many comparable alternatives. This is contrary to the dominant focus in previous studies on the problem of selection from among technology alternatives (e.g. Ordoobadi, 2012; Chan et al., 2006).

Strategic needs and risks were observed to play an important role as motivation and justification for the decision making, thus supporting findings from previous research regarding high relevance of strategic needs in justification of advanced manufacturing technology (e.g. Chan et al., 2006; Iakymenko et al., 2016).

Organizational process for investment projects was utilized in the studied cases, and at times organizational process for new product development projects within product research and development team was also used in the early period. The projects were thus driven by organizational processes and team-based decision making practices were used. However, role of individuals was observed in picking right direction for search for technology solutions. This is in line with observations in previous research focusing on radical technologies, where individuals impact how radical technologies capture attention in organizations (e.g. Kammerlander and Ganter, 2015).

The topic of decision making on radical process innovation ideas has been less understood in previous research, and the study thus contributes to call for further
empirical research in manufacturing firms on processes for developing ideas and concepts for radical process innovations (Kurkkio et al., 2011; Frishammar et al., 2016). This study also expands previous knowledge on the creation of RMTI, from the perspective of manufacturing firms (e.g. Reichstein and Salter, 2006; Keupp and Gassmann, 2013). The findings open up decision making in context of risky innovative production investments and illustrate where RMTI projects are similar to and different from regular investment projects. The results have implications for practice, in terms of providing a framework for supporting management of decision making in these high risk, high benefit investments for manufacturing firms.

Limitations of the research include the small sample of RMTI projects and some topics in decision making research, e.g. political process, are not visible in these projects. Also, the use of decision making systems, e.g. IT based systems, in decision making on RMTI remains a question mark since the projects have not provided any evidence on their use. Further research is encouraged concerning other decisions in the RMTI projects besides the investment decision, including possible cancellations, changes, and reorientations. Also, exploring the prioritization and negotiation processes taking place in firms’ management teams concerning RMTI projects could be an interesting avenue for further research. Furthermore, the managers’ ways to acquire information and, thereby, reduce the uncertainty in RMTI investments could be studied further.

Abstract
The aim of this article is to present the scientific production over the last two decades with regard to the terms Industry 4.0 and Maturity and to introduce a new concept of maturity. A bibliometric study focusing on the key words Industry 4.0 and Maturity is conducted and main journals, authors, countries and trends of maturity models are analysed. Based on the analysis, a new concept for measuring maturity to evaluate a company’s readiness for Industry 4.0 is introduced. The assessment enables companies to systematically increase the quality of their transformation by providing insights about their readiness level.

Keywords: Bibliometric Study, Industry 4.0, Maturity

Introduction
New technologies, the demands of the markets and the emergence of new business models have influenced and transformed production processes since the beginning of the industrialization (Zhong et al., 2017). The Fourth Industrial Revolution establishes a new paradigm for production systems. Central concepts to this new paradigm are among others: Big Data, Cloud Computing, Artificial Intelligence, Industrial Internet of Things (IIoT), and Cyber Security (Jazdi, 2014). The term Industry 4.0, which refers to the Fourth
Industrial Revolution, was derived from the German term “Industrie 4.0” and first presented at the Hannover Fair in 2011. It denotes the high technology project of the Federal Ministry of Education and Research of the German Government, with the aim of increasing the automation of local production systems (Lee, 2015). The number of publications on the Web of Science platform, that used the term Industry 4.0 between 2001 and 2018 increased exponentially in the last years, 98 publications in the year of 2012 for a total of 1389 publications in 2017, a leap of approximately 1417%. There is wide agreement that companies must have a certain degree of maturity in order to engage in an Industry 4.0 environment (Canetta, 2018; Unterhofer, 2018). That is, they must fulfill a set of requirements to be able to apply technologies and skills to further develop towards the vision of Industry 4.0. Maturity models serve scientific and practical purposes. From the scientific point of view, these models help in gathering information about the current state of the company and its strategies for Industry 4.0. From a practical point of view, maturity models enable companies to evaluate themselves within an Industry 4.0 context (Schumacher et al, 2016).

The purpose of this article is to present a bibliometric analysis of scientific publications containing the terms "Industry 4.0" and "Maturity" which were published from 2001 to 2018. Main journals, publications, authors, countries as well as trends of maturity models in the context of Industry 4.0 were identified. Based on the analysis of existing maturity models, a new concept for measuring companies’ Industry 4.0 Readiness is introduced.

Methodology
The methodology used in this study follows protocols for research, classification and bibliometric analysis (Weitzel, 2006). Currently, there are several databases that use bibliometric indicators and provide a bibliometric analysis of scientific production. Two of the most common platforms among them are the Web of Science (WoS) and the Elsevier Scopus (Scopus) platform. The data presented in this study was obtained through a bibliometric research of these two platforms. Table 1 presents the keywords, the number of total publications containing the keywords and the number of publications related to the objective of this article.

Results
The number of publications on the Scopus platform using the term Industry 4.0 in relation to the term Maturity, rose drastically in the last years from 2015 (1 publication) to 2018 (49 publications), as can be seen in Figure 1.

Another highlight is the countries that generated these publications. Leading is Germany with 7 publications in WoS and 12 in Scopus. This aligns with our expectation since Germany is the nation that initially launched the term Industry 4.0. In third place is Brazil with 4 publications in WoS and Scopus. Austria, Sweden, England, China, USA, Finland, France, Ireland, Italy, Spain, Switzerland, Taiwan and Turkey appear in sequence. Brazil stands out in second place in the WoS and third in the Scopus ranking.
This is mainly related to the high degree of industrialization in the central and southern regions of Brazil. These regions are characterized by a large number of German immigrants and researchers who completed part of their studies in Germany. Several researches and studies have been carried out in Brazil in recent years with the objective of evaluating the local productive matrix and looking for ways to make it more efficient by using Industry 4.0 technologies, i.e. the maturity evaluation tool developed by the National Industrial Learning Service - SENAI / CNI (Loureiro, 2016) or the work conducted by the Brazilian Industrial Development Agency – ABDI (Gadelha, 2012).

In Table 2 the main sources of the publications were listed and classified according to their SCImago Journal Rank (SJR) and the H-Index. The SJR evaluates and ranks scientific periodicals according to the quantity of their citations in a three year period after the publication of the editions, to the origin of citations as well as to the logic of citations (Falagas, 2008). The H-Index expresses the journal’s number of articles (h) that have received at least h citations. It quantifies the journal’s scientific productivity and scientific impact and it is also applicable to authors (SCImago, 2007).

In addition to the main sources presented in Table 2, the IEEE 2018 International Conference on Engineering, Technology and Innovation (ICE/ITMC) published four articles. This confirms that the examined topic is currently discussed in the scientific community. The Vienna University of Technology in Austria ranks first regarding the amount of generated publications among institutions (three publications) (see Table 3). Among Brazilian institutions the Federal University of Santa Catarina-UFSC stands out with two publications. It is important to note that different institutions work together through the collaboration of several authors, which leads to differences between the...
number of publications and the respective number of institutions. The WoS and Scopus platform provide the most cited keywords, within the set of analysed papers, after inserting the terms Industry 4.0 and Maturity. As expected, the most frequent keyword is Industry 4.0 with 13 quotes in WoS and 14 quotes in Scopus. The keyword Maturity Model appears in sequence with 7 quotes in WoS and 13 quotes in Scopus. Other keywords cited are Digitization, Digital Transformation, Smart Factory, Internet of Things and Learning Factory, among others.

Seven maturity models, identified in the bibliometric research, were further analysed. Additionally, four other models (PwC, Acatech, IMPULS and Rockwell Automation) were included in the analysis. The results are provided in Table 3.

Rockwell Automation (Automation, 2014), which has partnered with other major technology companies such as Microsoft, Cisco and Panduit, presents a five-stage model of measures and best practices for changing technology and culture with the objective of developing a connected company. In a study commissioned by the IMPULS Foundation of the German Engineering Federation (VDMA) (Lichtblau, 2015), carried out by IW Consult and the Institute for Industrial Management at RWTH Aachen University, a maturity model was developed including six key dimensions, each of which is defined on a six-level scale. Four of the six dimensions presented coincide with the necessary capabilities as required for Industry 4.0: smart factory, smart products, smart operations, and data-driven services. According to the model, the level of maturity of a given dimension is defined by the lower level of maturity of the respective areas of interest that compose it. In addition, according to the level of maturity obtained by the model, organizations can be classified into three types: “Newcomers” (level 0 and 1) companies that have done either nothing or very little to deal with Industry 4.0, “Learners” (level 2) companies that have already taken first steps in implanting Industry 4.0, and “Leaders” (level 3 and up) companies that are already well in the way to implementing Industry 4.0, representing the benchmark group. The PwC Model (Geissbauer, 2016) is based on seven dimensions of digital capabilities, involving business, products and services, value chain integration, data analysis, agile IT architecture, compliance and security, organization and culture. Four levels of maturity are presented: beginner, vertical integrator, horizontal collaborator and digital specialist. Ganzarain (2016) proposes a process model consisting of tool oriented sub-models aiming at vision, strategy and construction of actions. A 5-level scale is defined for each model. The maturity model for System Integration (SIMMI 4.0) by Leyh (2016) allows companies to classify their own IT systems with respect to the Industry 4.0 landscape. It consists of five stages of maturity. Each stage represents a corresponding level of maturity for Industry 4.0 and is divided into four dimensions that represent different areas of the company (vertical, horizontal, digital development and technology crossing). In Schumacher (2016) a model based on 62 items of maturity is developed with respect to technology and organization. These items are grouped into nine company dimensions, each being evaluated within five levels of maturity. The model was then applied in case studies.

According to the ACATECH (German Academy of Science and Engineering), being 4.0 means generating data knowledge to transform the company into an agile, learning organization, allowing rapid decision making and flexible adaptation of processes in all business areas. The ACATECH has developed a maturity model, which includes four key perspectives of an organization: resources, information systems, organizational structure and organizational culture. Each of these perspectives are assessed at six levels of maturity (Schuh, 2017). In the study called DREAMY (De Carolis, 2017), five major areas are initially structured: design and engineering, production management, quality...
management, maintenance management and logistics management. Based on these areas, five levels of maturity are defined: initial, managed, defined, integrated and interoperated as well as digitally oriented. In order to evaluate the digital capacity of an organization, not only technologies in use are considered. Instead, the digital capacity is evaluated by four dimensions: processes, control and monitoring, technology and organization. In Gökalp (2017) a maturity model for Industry 4.0 based on ISO/IEC 15504 is presented (also known as SPICE; Software Process Improvement and Capability Determination). The model is built on five dimensions and six levels of maturity. Canetta (2018) developed a model based on 36 questions divided into five areas: strategy, processes, products and services, technology and human resources. Based on the questions four different levels of maturity are derived: absence, beginner, intermediate, and experienced. As a result, a radar-type graph is generated and the mean of the company's general maturity level, based on the five dimensions, is calculated. In Sjödin (2018) five case studies are analysed and the challenges and key steps required to implement a smart factory are identified. A model is then built based on three principles: people, introduction of agile processes and configuration of modular technologies. These principles are classified into four maturity levels. The benefits of implementing a smart factory are analysed as well, which are the following: greater process efficiency, lower operating costs, higher product quality as well as greater safety and sustainability.

Readiness: A New Concept for Maturity
The previously introduced maturity models imply to get a holistic view of a company by evaluating various dimensions of it (apart from Leyh (2016) which primarily focuses on the IT-Systems of a company). There is a common understanding that maturity regarding Industry 4.0 cannot be based on one dimension alone, hence several dimensions are introduced. Depending on the model, the focus of the dimensions varies. Overall, two main dimensions can be identified, namely an enabler dimension and a technology dimension (see Table 4). Based on the characteristics of these dimensions, the maturity level regarding Industry 4.0 is evaluated. Thus, in current models, maturity appears to be considered as an outcome instead of an independent dimension.

| Table 4 – Enabler dimension and technology dimension in maturity models |
|--------------------------|----------------|-----------------|-----------------|
| **Enabler**               | **Source**       | **Technology**   | **Source**       |
| Organization and Culture  | Geissbauer, 2016 | Data Analysis, Agile IT Infrastructure | Geissbauer, 2016 |
| Processes, Organization   | De Carolis, 2017 | Control and Monitoring, Technology | De Carolis, 2017 |
| Organizational Alignment  | Gökalp, 2017     | Information Systems | Schuh, 2017 |
| Culture, Organizational Structure | Schuh, 2017 | Products and Services, Technology | Canetta, 2018 |
| Strategy, Processes, Human Resources | Canetta, 2018 | Technologies | Sjödin, 2018 |

In our experience, companies often fall short in their Industry 4.0 approach since they may have the necessary enablers and technology but lack in their maturity. Maturity is the necessary path to achieve the improvement of organizational processes, within a set of specific areas (following the Capability Maturity Model (1986)). Enablers of maturity models describe generic dimensions of organizations which are not related to technology. For example, a company can have a culture which is open to change and use new technologies, but is unaware about the improvement path in specific areas of the company and comes short in its Industry 4.0 approach. Therefore, we introduce a new concept for evaluating how prepared a company is to engage in an Industry 4.0 environment. Our
approach follows the idea of Schumacher (2016) who enhanced the technology focus of maturity models with organizational aspects to get a more detailed assessment of a company’s Industry 4.0 maturity. Similar to our concept, augments current maturity models which were focused on enablers and technology with maturity itself. We call this concept Industry 4.0 Readiness. Industry 4.0 Readiness takes into account the dimensions of enablers, technology as well as maturity of a company and shows how ready a company is to engage in an Industry 4.0 environment. For each dimension of the concept four different levels are set. The lowest level refers to a company which is not yet ready with regard to the respective dimension. The highest level implies that a company is fully ready to engage in an Industry 4.0 environment. However, there are no levels to Readiness itself. The different dimensions (enablers, technology and maturity) set up a three-dimensional Industry 4.0-Readiness space in which a company is categorised (see Figure 3).

In the following, the three dimensions and the proposed variables of these dimensions will be presented. The variables were chosen based on their relevance in the scientific literature. Whereas, numerous variables of enablers and technology could be found based on the literature analysis conducted in part III, variables for maturity were elaborated on the basis of the Capability Maturity Model Integration (CMMI).

**Enablers**

Enablers for Readiness are differentiated into the following three variables (following Schumacher, 2016; De Carolis, 2017; Leyh, 2016):

- Organizational Culture
- Business Model
- Human Resources

These variables were chosen based on the enablers mentioned in Table 3. However, the enablers in the maturity models differ in their granularity (i.e. Organizational Alignment (Leyh, 2016) compared to Strategy, Leadership, and Culture (Schumacher, 2016)). Therefore, we aggregated them into variables with a similar level of granularity. Organizational Culture refers to people’s shared basic assumptions about transformation at all levels of the company. How strategy, market perspective and value constellation benefit a company in its readiness will be assessed by the variable Business Model. Lastly, Human Resources point at the digital and data literacy of employees and their strategic development.

**Technology**

The technology dimension is of great importance and at the centre of discussion of the scientific community (Schneider, 2018). Instead of specific technologies Industry 4.0
design principles based on Bücker (2016) and technology components of the aforementioned maturity models were chosen in order to consider ongoing technology developments. Additionally, contributions from the authors’ practical consulting experiences were taken into account. The following variables have been included:

- Interconnection
- Information Transparency
- Decentralized Decisions
- Technical Assistance
- Network-based Production

Interconnection refers to the connection of all members of an organization in the Industry 4.0 era. Objects as well as people are connected. Information Transparency is based on the collection of data from the connected objects and people in real time. Linking this data to digitalized models makes it possible to create a virtual copy of the physical world. Hence, all objects and people have access to all relevant data. Therefore, they are empowered to make informed Decentralized Decisions on their own (with respect to the company’s overall goal) as autonomous as possible. Technical Assistance refers to the idea of supporting humans in accomplishing their increasingly complex work in organizations. The last variable, Network-based Production comprises technologies like additive manufacturing, which enable not only the main manufacturer to produce the whole product or parts of it, but various actors in the value chain as well, even if an actor is the final consumer himself.

**Maturity**

According to Kohlegger, (2009, p. 59), “a maturity model conceptually represents phases of quantitative or qualitative enhancement of the capacity changes of a maturing element to evaluate its advances in relation to defined focus areas”. The capability of a process is defined as competencies, or sets of actions and know-how, applied by an organization, which are subordinated to coordinated activities and make use of the organization’s assets. In the Capability Maturity Model (CMM), a methodology created in 1986 to improve organizational processes and capabilities in managing the development, acquisition and maintenance of software products and services, the maturity concept is classified as the necessary path to achieve the improvement of organizational processes, within a set of areas, called levels of maturity. In Chrissis (2006) the Software Engineering Institute expanded the CMM concept to add hardware integration giving form to CMMI as a guideline for process integration and product improvement. The original proposal of CMMI encompasses four bodies of knowledge: systems engineering, software engineering, integrated product and process development, and supplier sourcing. Our concept adapts this approach to Schuh (2017) and takes into account that new business models are produced under consideration of product-service systems (PSS) (Tukker, 2017). Considering the three-dimensional model presented in Figure 3, the maturity of an organization, as observed in the models presented in Table 3, should be assessed by analysing four areas:

- Product-Service Development
- Production
- Logistics
- Marketing and Sales

Product-service Development addresses the effort to meet customer requirements that
are currently based on customization and product-service systems. Production and Logistics are the main value adding chains in manufacturing companies and must be structured in a systematic way. Marketing and sales have to be integrated into production planning and control as well as sales and distribution planning to realize the potential of technologies and enablers of Industry 4.0.

**Conclusion**

**Summary**
Maturity is a concept, which offers important solutions to companies from a competitive point of view in face of the fast and changing environment of Industry 4.0. This bibliometric study analysed a total of 168 publications on the Web of Science and the Elsevier Scopus platform. Initially, the terms Industry 4.0, Advanced Manufacturing and Digital Transformation were combined with the term Maturity to identify scientific publications ranging from the year 2001 to 2018. A total of 20 publications that deal with the topic of interest were identified. Based on the analysis of these publications, a drastic increase in scientific publications in 2017 could be observed with Germany and Brazil being one of the main contributors. Out of the 20 publications seven publications introduced a maturity model for Industry 4.0. Additionally, four more practice oriented publications covering maturity models were identified. These models evaluate the maturity of a company regarding Industry 4.0 on the basis of different enablers and technology dimensions of a company. They do not target maturity as dimension on its own. Addressing this gap, a new concept for maturity is introduced. The main difference of the concept to previous models and concepts is that maturity is no longer seen as a dependent dimension and, thus, as outcome of a company’s enablers and technologies. Instead, the concept introduces Industry 4.0 Readiness consisting of three different dimensions, namely enablers, technology and maturity itself. The Industry 4.0 Readiness is assessed by diagnosing the level of the company in each of the three dimensions.

**Limitations and Outlook**
The newly introduced concept for maturity still has its limitations. First, despite the fact that the variables and levels of the concept’s dimensions were carefully selected, there is the possibility that they are too generic or not of practical relevance for companies. If a variable is too generic, an accurate assessment of the variable is difficult. If a level is too generic, there is not a clear distinction between the levels of a dimension. Hence, a valid and reliable assessment of the Readiness of a company becomes challenging. Therefore, the variables have to be tested regarding their practicability and level of detail and adjusted accordingly. In order to address this point, a focus group with industry experts is planned. Within the focus group, the dimensions and variables of the concept are discussed, evaluated and updated. Second, the concept lacks operationalisation. For the operationalisation of the concept, a situational judgement test will be developed. Consequently, for each variable a situational description will be defined. Furthermore, the situational descriptions are discussed within a focus group of experts and revised. Third, the concept is based on the existing literature and therefore mainly of theoretical nature. Since maturity models fulfil a practical as well as a scientific purpose, the practical purpose needs to be validated. For the practical validation of the concept, it is intended to pre-test the operationalized concept with Brazilian and German companies to show the practical applicability and possible deficits. The results of the pre-test are used to update the concept and apply it in practice. Based on its application in practice, the model will be evaluated regarding its practical usefulness.

Abstract

Digital process innovation—defined as the use of digital technology for process innovation—has recently become a new orientation of manufacturing companies to solve operational problems; however, the actual impact of digital process innovation is still unclear. In this research, we study the actual effect of digital process innovation on organizational performance. We further examine whether the impact of digital process innovation is strengthened if manufacturing firms increase their absorptive capability and their slack resource. This research provides valuable insights into how to effectively implement the strategy of digital process innovation.

Keywords: Digital process innovation, Absorptive capacity, Slack resource

Introduction

Operational problems, such as high-volume inventory, continuously increasing operational cost, operational inefficiency, are usually the concerns of the conventional manufacturing process (e.g., Boston Consulting Group, 2014; Kearney, 2016). Recently, digital process innovation—defined as the use of digital technology for process innovation—has become a new orientation of manufacturing companies to solve such kind of operational problems and has demonstrated its effectiveness. Taking GE Company (d’Aveni, 2015) as an example, it adopted digital technology in the production mode transformation of an engine from the assembly of twenty separate cast parts into direct production of one piece. This saves 75% of the operational cost. Nevertheless, there are some other concerns towards the effect of digitized operational processes. For instance, more energy is required in three-dimensional printing than in the traditional injection molding (Chen et al., 2015). Thus, the actual impact of digital process innovation is still unclear.
In this research, we study the actual impact of digital process innovation on organizational performance. We further investigate operational factors that may exert significant bearing on digital process innovation to enhance a firm’s performance. Specifically, we examine that the impact of digital process innovation is strengthened if manufacturing firms increase their knowledge absorptive capability and their slack resource.

**Theoretical Background and Hypothesis Development**

Digital process innovation enables firms to promptly and accurately identify customer requirements and preferences and to offer customized even new products that, in turn, better meet customer individual requirements (Armenakis and Harris, 2009; Ye et al., 2007; Judge et al., 2009). This may result in increasing firms’ performance. Hence, we hypothesize that the adoption of digital process innovation can improve a firm’s performance, as shown below.

Hypothesis 1: Digital process innovation enhances organizational performance.

Operational absorptive capacity is referred to the capability of an organization’s operational units to obtain, assimilate and exploit knowledge from external source (Patel et al., 2012). In a company, when its operating unit has absorptive capacity, the unit is more likely to have the ability and flexibility to obtain, assimilate and exploit the information provided by external parties and required for the implementation of digital process innovation, leading to higher organizational performance. Therefore, we hypothesize:

Hypothesis 2: Absorptive capacity of a firm positively moderates the relationship between digital process innovation and organizational performance.

Slack resource is defined as the buffer resource, in excess of the minimum necessary resources for a firm’s daily operation, for coping with environmental uncertainty (Nohria and Gulati 1996). Companies with slack resource are likely to have buffer resource as safeguard to present the risk imposed while implementing digital process innovation, leading to enhanced organizational performance. Thus, we have the following hypothesis.

Hypothesis 3: Slack resource of a firm positively moderates the relationship between digital process innovation and organizational performance.

**Methodology**

We conducted a longitudinal event study to test the effect of digital process innovation on organizational performance. We focus on manufacturing companies that are publicly listed firms in the Mainland China. Driven by the recent China’s policies such as Made in China 2025 and internet plus manufacturing action (China Daily, 2016), many manufacturing companies have gradually adopted and even have fully implemented the strategy of digital process innovation. Hence, manufacturing companies in the Mainland China are the most proper setting to conduct this study.

We consider digital process innovation as a firm’s official launch of digital innovation initiative for its manufacturing process. Accordingly, we collected the
announcements about the adoption of digital process innovation from Factiva and Wisenews using keywords, for example digital platform, digital channel, digital manufacturing, intelligent manufacturing, additive manufacturing, and three-dimensional or 3D printing. Return on asset is regarded as the performance outcome of the firm. R&D intensity as a proxy for absorptive capability while slack resource is based on inventory level.

Finally, we obtained the relevant announcements from a sample of 168 firms. For these sampled firms, we collected data on return on asset, absorptive capacity and slack resource from the China Stock Market and Accounting Research databases.

Data Analysis and Results
We employed the approach of longitudinal event study to test the causal relationship between digital process innovation strategy and organizational performance. The results show that digital process innovation has a long-term effect on the performance of manufacturing companies. Subsequently, we conducted the ordinary least squares regression to examine the potential moderating effects of absorptive capacity and slack resource on the association among digital process innovation strategy and firm performance. The findings demonstrate that absorptive capacity and slack resource strengthen the effect of digital process innovation on firm’s performance.

Discussion and Conclusion
This research reveals the real impact of digital process innovation on organizational performance in the manufacturing domain and explores the factors to enhance such impact. Specifically, it fills up the gap how to effectively implement the strategy of digital process innovation. This research also provides useful guideline for effective implementation of digital process innovation by considering a firm’s internal absorptive capacity and slack resource.

Abstract

Organisations require effective access to disruptive technology management including a generation of a culture of continuous innovation. Therefore, the open innovation paradigm has been established as a theoretical base for managing innovation in the enterprises and public sectors. In order to handle the independent ownership and management of GNSS CORS technology complexity in Thailand at the national level, collaborative innovation has arisen for building and refining the creative ideas and sharing internal resources and external knowledge. Moreover, stakeholder theory is deployed to consider the role-plays and the power of each of the partners over an inter-organisational collaboration.

Keywords: GNSS CORS, Collaborative innovation, Public sector

Introduction

Public and private organisations in sectors such as health care, construction and logistics that require satellite data for ensuring target locations are faced with a proliferation of positioning applications. Continuously Operating Reference Stations (CORS) constitutes one of the technologies designed as a supplement to Global Navigation Satellite System (GNSS) signals to improve positioning precision (GPS.GOV, 2017). Effectively implementing this land-based augmentation system has presented difficulties for countries such as Thailand. In particular, independent ownership and management of the GNSS CORS network has led to problems of duplication and overinvestment and the lack of facility sharing has adverse effects on the budgetary requirements of individual CORS users.

To resolve such complications in the management of GNSS CORS technology in Thailand requires the adoption of technological innovation in the public sector. To this
end, the various Thai government agencies involved have developed a form of collaborative innovation. But this must take account of the different levels of power among the CORS licence holders based on their number of assets and major missions. The present paper analyses key issues surrounding innovation management with respect to GNSS reference networks from the perspective of the open innovation paradigm, with a particular focus on collaborative innovation and stakeholder engagement.

**Theoretical Background**

*Open innovation*

The term ‘open innovation’ was coined in 2003 by Chesbrough in his seminal book, since then open innovation has become a term synonymous with modern approaches to innovation (Cassiman and Valentini, 2016). Essentially open innovation means that the innovation process is permeable, meaning that “there are many ways for ideas to flow into the process, and many ways for it to flow out into the market” (Chesbrough, 2006). This understanding that innovation transpires across the boundaries of individual firms and involves many actors linked together in formal and informal innovation activities has resulted in Chesbrough (2003) distinguishing open innovation from the traditional closed model of innovation. Closed innovation is based on the premise that investment in R&D results in technological discoveries that advance into new products and services, which increase profits that are then reinvested into the development of further new technologies, all in a process controlled and managed by a single firm. Conversely, within open innovation this process is opened up with ideas and technologies being developed externally to the firm. What also occurs is the spinout of ideas, technologies and business models from the open innovation activities to other firms who perhaps create new ventures.

Since 2003 a plethora of studies have emerged on the topic of open innovation. While we agree with Huizingh (2011), who highlights that innovation has very rarely been ‘closed’, there is no denying the increased focus on more complex forms of innovating with multiple actors, across organisational boundaries. What we see in the literature is the use of ‘open innovation’ as an umbrella term, with other forms of innovation such as collaborative innovation, network innovation, co-creation, user-driven innovation, crowdsourcing all falling under the broader term of open innovation. While it is not the purpose of our paper to disentangle the knotty conceptual underpinnings of various types of openness within innovation practices, it is important to recognise the shared dimension of these concepts – namely, that innovation takes place with multiple actors and not within the confines of a single organisation.

*Open innovation in the public sector; collaborative innovation*

While much of the literature in this area has its roots in for-profit organisations there is a growing body of research focusing on the application of these practices of innovation in public sector organisations. There is a recognition that open and collaborative forms of innovation may support an increase in the quality and quantity of innovations in the public sector (Nambisan, 2008; Bommert, 2010), at the same time as helping to remove policy impasses and deadlocks while dealing with ever increasing complex societal problems (Torfing, 2016). It is also known that models of open and collaborative innovation cannot be directly transferred into a public sector setting due to the policy processes and cycles that determine the introduction of new policies (Mergel and Desouza, 2013). However, there is a growing literature on the development of guidelines and frameworks applying
the principles of open and collaborative innovation into the public sector (e.g. Bloch and Bugge, 2013; Brown and Osborne, 2013; Crosby et al., 2016).

In a related field, collaborative governance is defined as the inclusion of government organisations in formal discussion in order to reach agreement with respect to public policy adoption or how government resources or plans are managed (Ansell and Gash, 2008). Networked government engages all types of organisations (for and not-for profit organisations) and citizens in the system to attain relevant public goals. As a result, the concept of collaborative innovation emphasises that resources should be shared over different organisational boundaries (Moore, 2009; Bommert, 2010). Also, a cross-disciplinary approach is proposed to the collaborative work between governments in which the advanced collaborative innovation hierarchies could strengthen public innovation by instigating stable processes (Sørensen and Torfing, 2011).

**Stakeholder management**

A key aspect of open and collaborative innovation is the management of stakeholders to engage with innovation. This appears to be more of a challenge in public sector led collaborative innovation where IP issues are less transparent, knowledge is often more tacit and there are inherently more politics at play (Mergel and Desouza, 2013). Furthermore, the literature identifies a key consideration concerning the management of the open and collaborative innovation, which is ‘who’ takes ownership and responsibility for the innovation. This means that the facilitation of the collaboration is of utmost importance in the success of the collaborative innovation (Sørensen and Torfing, 2011); but there is limited theoretical or practical insight into how this facilitation can be done effectively.

A multi-stakeholder partnership (MSP) is an idea in which stakeholders, both governmental players and non-governmental players, make an effort to do something together under a win-win situation, with each actor given a clearly defined role (Simon et al., 2016). When the stakeholder-based process is applied to local government administration, the decision makers are influenced by the stakeholders who are empowered to deploy the power over their organisation (Gomes, 2006). There appears to be an element of power differential that can impact the success of the collaboration; for example, the individual managers’ consideration of power and power-motivated behaviours can impact the success of the innovation (Cankar and Petkovšek, 2013). This can result in power asymmetries that can risk the operation of the collaborative innovation (Sørensen and Torfing, 2011). In order to overcome these power differentials there are traditionally five elements that underpin the collaboration concept; namely:

1. organisation,
2. associateship,
3. interaction process,
4. objective, and
5. temporal attribute.

The task of exploring the stakeholders’ role needs the comprehension of the distinctiveness, the depth, area of interest, distinct portion and logic deducting of players. The requisite conditions are as follows: to obtain the arrangement of the public value that needed to be co-produced; to gain legitimacy and authorisation over the converging and diverging points: and to create the required capability of co-producing the public value, especially delivery and interconnected system capacity with a close attention to the important route, divergent resourcing, and contrasting time frames (Bryson et al., 2017).

*Initial conceptual framework*
This demonstrates the complexity of the areas to be considered in the setting up and management of a collaborative innovation network. Figure 1 outlines the initial conceptual framework for our study. It illustrates the key areas of importance and will provide guidance as an analytical framework for our empirical data.

![Initial conceptual framework](image)

**Figure 1 - Initial conceptual framework**

Our study into the complexity of managing the GNSS CORS system in Thailand aims to analyse how different government agencies are collaborating in terms of data gathering, data management and service distribution. Our study will also evaluate the roles played by prominent owners of GNSS network infrastructure in this collaboration.

**Research Methodology**

**Outline of the research design**

An earlier case study of interagency cooperation relating to GNSS reference station administration in Australia has shown the need to make proper allowance for the innovation capability of each participating organisation and to assign the separate key roles (Hausler and Philip, 2013; Higgins, 2008; Roberts et al., 2004; Roberts, 2009). Based on the apparent similarities, we seek to build on the Australian research findings in our own study of GNSS CORS management in Thailand. A central feature of the Australian case was the establishment of ANZLIC as the top government body in Australia and New Zealand responsible for the accessibility and usability of spatial information (ANZLIC, 2019). In Thailand, no less than nine organisations are getting involved in GNSS ground infrastructure technology, including six government agencies and three universities (Rizos and Satirapod, 2011).

Our research design is founded on a realist ontology combined with a multi-methodology approach to data gathering, including focus groups, expert interviews and in-depth case studies. In practical terms, this involves focus group interviews with six organisations who own the base stations in Thailand and expert interviews with academics from three universities, supported by simultaneous analysis of the Australian case study documentation. Our approach to data analysis is based on deductive content analysis to derive our research findings. The broad objectives and scope of our study and
somewhat convoluted nature of the research design lead to a large set of multifarious research data (Stewart et al., 1990).

The data collection phase started in the summer of 2018 and is currently ongoing. Following transcription and translation of the focus group and expert interviews, detailed content analysis is applied, and findings are compared.

**Data collection methods**

A focus group is a data collection method that provides large amounts of information on the perspectives and spontaneous body language from a range of individuals about issues raised in the group interaction (Rabiee, 2004). Primary focus group data were collected from six government and public organisations that control GNSS CORS infrastructure in Thailand. The six focus groups respectively comprise the Royal Thai Survey Department (RTSD), the Department of Lands (DOL), the Department of Public Works and Town & Country Planning (DPT), the Hydro and Agro Informatics Institute (HAI, a public organisation), the Geo-Informatics and Space Technology Development Agency (GISTDA, a public organisation), and the National Institute of Metrology, Thailand (NIMT, a public agency).

Each of the focus group interviews lasted between one and three hours. They were conducted internally: the participants were invited to discuss a given topic with three to six government officers who came from the same organisation. The detailed composition of each focus group was determined based on selected criteria covering the purposive specification and multidimensional aptitude of the participants. These criteria included, for example, age range, knowledge of the study area as well as other characteristics, organisational responsibility and decision-making power. As they had been carefully selected based on these criteria, the participants were comfortable expressing their ideas to the group members and researcher (Rabiee, 2004). Additionally, some of the participants were assigned as the representatives of their specific department, in order to substitute for any important decision makers who were unavailable for the focus group interviews.

Expert interviews constituted the second data collection method employed in this study. This particular qualitative technique requires skilful participants with a specific interest and expertise in the relevant area of research. Although a powerful technique if applied in the right manner and circumstances, the choice of experts is subject to a number of constraints; in particular, proficiency in the specialised research questions but also limitations in terms of time, availability and accessibility. Such factors tend to put a strict limit on the number of the potential participants (Baker et al., 2012).

Once selected, experts are requested to attend sessions with an interviewer who raises queries relating to specific topics and records the responses (Muskat et al., 2012). In our research design, the experts were two Professors and a Lecturer from three Thai academic institutions; namely, Chulalongkorn University (CU), King Mongkut’s Institute of Technology Ladkrabang (KMITL) and Kasetsart University. They are all professionals in GNSS technology and related fields of research; and they participated in semi-structured interviews lasting between one and two hours.

**Data analysis methods**

Data collection was immediately followed by the start of the process of data analysis. Summaries and transcriptions of the focus group and expert interviews, including nonverbal communication as well as the way in which participants used words and the tone of their voice, were made in preparations for the next steps in the analysis (Onwuegbuzie et al., 2009; Stewart et al., 1990). In a qualitative research paradigm, the
analysis aims to understand the meaning of a situation, rather than its literal truth, according to the purpose of the study. In the context of focus groups, transcribing interview data could yield many similar instances and phrases. There is then a risk that data selection and evaluation could become highly subjective. Therefore, an in-depth analysis of the interview data should be systematic, sequential, verifiable and continuous. (Krueger and Casey, 2000; Rabiee, 2004).

Content analysis is a flexible approach that can be applied to quantitative data as well as qualitative data, either in an inductive or deductive investigation. Although its very flexibility and lack of straightforward guidelines for use have sometimes caused problems for researchers applying this analysis method, it is very well suited for delicate and multifaceted context analysis. Moreover, a deductive analysis is capable of testing existing assumptions or differentiating between phenomena relating to dissimilar categories and different times (Elo and Kyngäs, 2008).

Based on our prior theoretical knowledge from the literature review, we have used our initial conceptual framework (in Figure 1) to apply deductive content analysis to the massive set of data from both the focus group interviews and expert interviews. This has been done through a systematic process, in which data consisting of the use of words, tone of voice, gestures, facial expressions and body positions have been examined in connection with the research questions. The quotes have been classified into a ‘relevant category’ and ‘not so relevant category’ and duplicate quotes have been grouped as per their similarities. The data preparation step has been repeated until all was in readiness for the data interpretation stage (Rabies, 2004).

Findings

Outline of data analysis

After the preparation stage, we have analysed our data in accordance with the seven criteria of Krueger (1994) and Rabiee (2004); including actual words used and their meaning, context, internal consistency, frequency or extensiveness of comments, intensity of the comments, specificity of responses, and big ideas.

1. Consider the actual words used and their meaning

The word most frequently mentioned in the interviews is ‘business model’, which the participants considered as a framework for the collaboration. The participants seemed to believe that this word constitutes the main guideline for the direction in this collaborative project and that it will influence multifaceted factors of the cooperation, including the policy or regulation that will be adopted accordingly.

2. Consider the context

The researcher did not ask about the importance of the CORS technology. However, the participants expressed that this technology is necessary to ascertain the quality and ease of their work. Thus, the expansion of GNSS network is required. However, they are taking additional technology into account at the same time, in order to prevent obsolescence of traditional technology effect.

3. Consider the internal consistency

The individual participants’ steadiness in viewpoints and position was firmly retained; the viewpoints of others rarely impacted their individual perspectives. Some changes happened solely when new information emerged from trustworthy members who are directly responsible for the matters related to that information.

4. Consider the frequency of and extensiveness of comments

The most frequent words occurred in discussions is ‘who’, with reference to the context, ‘who’ means ‘which organisation’. The questions about ‘who’ arose in many
instances: either who should be the project leader?, who should be the national data centre?, who should manage the central network?, who should process the CORS network?, who should provide the services?, who should take responsible for the marketing strategies?, who should deal with the private sector or foreign countries?, and who else should be able to own the CORS in Thailand?. The participants responded to the question about ‘whether collaboration on GNSS CORS in Thailand should be done’ that ‘everyone (organisations) wants to get involved in this collaboration as it is a great opportunity to gain advantage from the shared infrastructure’. ‘Many of them want to be the leader of an association; however, who is the most appropriate one?’

5. Consider the intensity of the comments
This stage has aimed to perceive the profound feelings of the speakers about their comments. When the directors or managers from the prominent organisations stated that they agreed with the collaboration, it means that their organisations would love to join the created community of CORS as important players and could leave the coordination once the conditions are of no further interest. Conversely, the comments from less-powerful organisations are thereunder. They have more positive feelings about this collaboration than the powerful ones.

6. Consider the specificity of responses
The replies from the members that related to individual experience have been considered as contradictory hypothetical situations. For instance, an officer who graduated from Japan recommended to use the Japanese business model as a guideline of the cooperative project rather than Australian business model; whereas an IT specialist commented about cell-based technology to replace or supplement the CORS technology.

7. Find the big ideas
Making provision for overall discussion matters requires a temporary pause to increase the ability to assess the massive amount of resources thoroughly and go through the variety of information efficiently. As a consequence of this step, the big picture of the discussion would be asserted.

Data interpretation
A preliminary interpretation of the results by manually comparing and contrasting the interview data can be summarised as follows. First, the comments in respect of the given topics reflect a considerable shift in attitudes towards the collaborative project. There are several issues that the interviewees concerned about listed below.

1. Whether public collaborative innovation relating to GNSS technology will come into effect?
The lack of the obliging power of the laws and regulations supporting the actions has decelerated the team forming process. Further, a change of the government could cause unpredictability and uncertainty in the policy of CORS management.

2. Which government agency (between the one who has the maximum number of the assets and the one who has core responsibility for state surveying) should be the project leader?
The Royal Thai Survey Department who is responsible for the national mapping was the most frequent mentioned organisation in this point. Nevertheless, the Department of Lands who have the greatest amount of CORS sites in Thailand was named as well.

3. Which organisation should be the national data centre?
Should the project leader be the national data centre? If yes, they would be the central unit for the CORS management in Thailand. On the other hand, the national data centre should be able to make profit or make the contract with private sector or foreign countries.
Therefore, the Royal Thai Survey Department, which is a Special Services Group of Headquarters, Royal Thai Armed Forces, might not be applicable to this aspect.

4. **What should be the shape of the cooperation design?**

As regards the interests of the structure of the cooperation between government organisations, the regulations or an Act of Parliament to permit government authorities to share internal information with other parties had to be granted beforehand. In addition, the restrictions on resource sharing and the relationship between organisations should be clarified.

5. **What business model should be selected?**

They need to judge between Japanese business model and Australian business model (or other business model) which one is the most pertinent to be followed?

6. **What technology should be installed for the overall network configuration?**

Multiple type of hardware and software have been established, the configuration for the central network need to be chosen in advance. Once the data streaming start, the network setting should be ready to go as well.

Second, the interviewees demonstrated the strong desires for concrete out-turns with respect to rational doubts that are mentioned above. The following are crucial needs they pointed out.

1. **Regulations or policies**

   They greatly desired the effective regulations or policies for inter-organisational cooperation so that each organisation is allocated a suitable role.

2. **Authority**

   An appropriate authority is demanded of each office. In order to the flexibility and possibility in working on this project together, particular authority should be given to specific collaboration members. Therefore, they will know the extent of their legitimate rights in performing tasks or duties and protect them from any charge and trial as the result of proceeding with the plan under the government policies.

**Contribution**

The ultimate goal of our research is to support the adoption of the policy framework for strengthening the GNSS CORS collaborative innovation in Thailand. This will include the development of a viable business model to formulate budgetary guidance and resolve budgetary issues.

From a theoretical perspective, our research contributes to a better understanding of the roles that each of the stakeholders should play in a collaborative innovation effort, taking account of their different levels of power and interest. Collaborative innovation holds considerable promise in breaking individual policy deadlocks, minimising system-wide investment costs and improving public service quality. However, Bommert’s (2010) contention still holds: there is an urgent need for empirical research, typically in the form of in-depth case studies, to substantiate such potential benefits. Our research aims to make an original contribution to fulfilling this need.

**Conclusion**

The study of GNSS CORS technology management in Thailand is now under way to establish a final stage of analysis and interpretation which are an extremely time-consuming process due to a huge amount of data. After that, we will endeavour to adopt the policy framework for this technology management which require a great thoroughness. Therefore, the relation between the cooperative government organisation and the power of stakeholders should be identified precisely prior to the policy adoption. However, the vital role of political leadership, politicians, and politics that influence
public value production in the society are greatly significant to take into account (Bryson et al., 2017). As a result, further study would extend to focus on the political power issues that could impact the GNSS CORS collaboration management in Thailand.

Abstract

Micro and small enterprises in developing countries are a source of employment and poverty alleviation but have low survival rates. This contrasted picture hints to the paramount importance of dynamic capabilities, which enable firms’ sustainable performance. Research on dynamic capabilities, however, is scarce. Because dynamic capabilities depend on managers’ actions, we focus on dynamic managerial capabilities, namely human capital and social capital, and their relationship with financial performance. Using secondary data, we analyzed 2340 Peruvian micro and small enterprises. We found that human capital is positively related to financial performance, and mediates the relationship between social capital and financial performance.

Keywords: Dynamic managerial capabilities, Micro and small enterprises, Developing countries

Introduction

Small-and medium-sized enterprises (SMEs) are key players in the sustainable growth of most economies. In developing countries, SMEs contribute to up to 45% of total employment and 33% of GDP (OECD, 2017). Recent research has contributed to the understanding of SMEs’ efforts to improve their operations and the consequent impact on performance (e.g. Lagacé and Bourgault, 2003, Matthews et al., 2017). However, significantly less attention has been paid to micro and small enterprises (the smallest firms in terms of number of employees and annual turnover). These are especially important for the production ecosystems of developing nations, such as Latin American countries, in which MYPEs (which stands for micro and small enterprises in Spanish) represent the vast majority of firms, and a rich source of employment, poverty alleviation, and economic dynamism (International Labour Organization, 2016, Maksimov et al., 2017).
Unfortunately, many MYPEs struggle to sustain their operations over time. Among the most common reasons for business failure, low profitability occupies the first rank (Global Entrepreneurship Monitor, 2018). This hints to the utmost importance of productivity (Krishnan, 2013). While many micro and small enterprises focus on marketing practices to increase their sales and respond to market needs (Danis et al., 2009), it seems that they pay a lot less attention to the management of their operations. Generally, the development of capabilities is relegated to the background. If existent, this development process is usually unstructured, and sometimes unintentional. However, this view is a rather oversimplification of the MYPE’s potential. It is possible that MYPEs have different capabilities and use different processes to build them compared to large enterprises (Arend, 2014). Yet, we argue that capabilities that are dynamic are important in the sense that they allow MYPEs to deal with the typical constraints of developing countries, also known as institutional voids.

The managerial perspective of dynamic capabilities proposes that these capabilities are driven by top managers (Salvato and Rerup, 2011). Given the small size and entrepreneurial origins of MYPEs, owner-managers are undoubtedly the key actors for capability development (Matthews et al., 2017, Eikelenboom and De Jong, 2018). In line with this managerial perspective, we focus on the study of dynamic managerial capabilities. Dynamic managerial capabilities are “the capabilities with which managers build, integrate, and reconfigure organizational resources and competences” (Adner and Helfat, 2003: 1012, emphasis added), and have been proven to be crucial in large enterprises (Ambrosini and Bowman, 2009, Helfat and Martin, 2015). Thus, our research question is the following: What is the impact of dynamic managerial capabilities on financial performance in MYPEs in emerging economies? To respond to it, we conduct a quantitative study using secondary data from Peruvian MYPEs.

Current research focuses on the role of the environment, e.g. institutional voids and market characteristics, thereby implying a deterministic stand. Our goal is rather to unveil how owner-managers actively and purposefully invest in themselves to develop their MYPE’s dynamic capabilities. We contribute to the literature on dynamic capabilities and society in general by offering a basis to create successful training programs aiming to support MYPE managers’ skills.

**Theoretical background and hypotheses development**

While only a few studies focus on the operational capabilities of SMEs usually in developed countries, a lot fewer on dynamic capabilities of MYPEs in developing countries. The body of literature has focused on the heterogeneity of SME’s operational capabilities and their impact on performance (e.g., Wolff and Pett, 2006). Empirical evidence shows that what works for large companies does not always work for micro and small companies (Cagliano et al., 2001, Arend, 2014). We can translate this argument to the level of dynamic capabilities. Dynamic capabilities are at higher-level of abstraction (Helfat and Winter, 2011) for they allow firms to adapt operational routines and capabilities to the dynamic environment (Eisenhardt and Martin, 2000). It is plausible, for example, that MYPEs are reluctant to invest in continually adapting to the environment since it implies obtaining financing and using resources to perform “less urgent things.” As Krishnan (2013: 1441) points out: “some entrepreneurs even consider ‘process’ a bad word in their companies due to the organizational rigidity, inertia, and bloat associated with them.” Owner-managers that think like this indicates that they lack an operations management (OM) view. A profound negative implication is that these owner-managers would not prioritize the MYPE’s continuous improvement.
infrastructure, and consequently hinder the materialization of a dynamic capability (Matthews et al., 2017, Anand et al., 2009). Furthermore, the environmental characteristics of developing countries shape the need for dynamic capabilities (Meyer and Peng, 2015). Prasad and Tata (2009), for example, argue that a supportive political/legal system, access to financing resources, information management, and establishment of inter-organizational linkages increases the quality levels of Indian micro-enterprises. Yet, managers’ endeavors to make the best use of the available resources and capabilities as well as managers’ interpretations (Adner and Helfat, 2003, Helfat and Martin, 2015) are key enablers of dynamic capabilities.

Thus, due to the key role of managerial intervention for the concretization of dynamic capabilities (Helfat and Martin, 2015), we study dynamic managerial capabilities, “the capabilities with which managers build, integrate, and reconfigure organizational resources and competences” (Adner and Helfat, 2003: 1012). We focus on two core underpinnings of dynamic managerial capabilities: human capital and social capital.

Managerial human capital
Managerial human capital refers to knowledge, education, experience, and skills (Helfat and Martin, 2015). Human capital improves productivity by, first, improving the marginal productivity of other organizational resources, and second, affecting the amount and type of investments in physical and labour resources (Bruhn et al., 2010). Using a meta-analysis, Jiang et al. (2012) confirm the pivotal role of human capital for increasing operational outcomes. However, most of the literature has focused on human capital in large firms in developed countries. Following the framework of Ployhart and Moliterno (2011), we consider two forms of human capital: generic and specific knowledge.

First, generic managerial knowledge is acquired mainly through education. Education fosters managers’ ability to process complex situations and make faster decisions (Wally and Baum, 1994). Education also forms a basis for openness to new experiences and innovation (Barker and Mueller, 2002). This generic knowledge provides the constituent skills that can be applied in different situations, such as problem solving and social intelligence (Ployhart and Moliterno, 2011). Because of their great mobility, managers can transfer them across industries and firms (Bailey and Helfat, 2003).

In the case of MYPEs, they are usually led by entrepreneurs. And entrepreneurs’ education is positively related to business success (Robinson and Sexton, 1994) and profit (Bosma et al., 2004, Honig, 2001). Although Lee and Tsang (2001) found that education only supports venture growth in large enterprises, we argue that in the context of developing economies, the owner-managers’ educational background creates a competitive difference. Our argument follows Unger et al. (2011) in that heterogeneity and scarcity of educational resources in these countries mean that highly educated managers are better prepared to face environmental constraints and identify opportunities.

H1. Managerial generic knowledge is positively associated with financial performance of MYPEs in developing countries.

Second, specific managerial knowledge is the knowledge and skills that are specific to the tasks of the manager (Unger et al., 2011). In that sense, the performance of manufacturing MYPEs is dependent on managers’ skills in OM. Because of our interest in dynamic capabilities related to the MYPE’s OM, we chose to represent managers’ specific knowledge as the aggregate knowledge regarding practices to improve (quality management) and innovate. We also include managers’ knowledge on information and communication technologies (ICT) since small enterprises heavily rely on them to operate efficiently (OECD, 2017). In fact, these three types of specific knowledge encompass the
most commonly reported growth-impeding constraints on the contribution of the operations function in SMEs (Clegg, 2018).

While in developed countries quality management practices are taken for granted, in developing countries, managers may be more skeptical about the benefits of implementing them. Due to lack of information regarding quality along the supply chain and difficult access to economic resources, MYPEs in developing countries may show low levels of quality (Prasad and Tata, 2009). Furthermore, it is possible that owner-managers see quality as a threat. Quality training may be elusive for those with little management background or time. Making operations transparent, through quality management practices, may also frighten owner-managers that rely on informal mechanisms and bureaucratic corruptive influence (Mersha, 1997). The managers who take the big step to acquire knowledge of quality practices are thus creating a source of differentiation (Chandler and McEvoy, 2000), not only supporting better quality products but also developing elaborated and proactive plans, and, consequently, superior performance (Frese et al., 2007).

Knowledge of innovation practices, such as development of new or better products, services, and processes, represents the second type of specific knowledge. Empirical evidence in large firms categorically states that innovation has a positive impact on financial performance. On the one hand, MYPEs have few resources to continuously renovate their products or sustain a large-scale research and development operation. On the other hand, because of their size, inherent flexibility, and less bureaucratic organization, they have an enormous potential to capitalize in innovation practices (Qian, 2002, Honig, 2001). We expect that owner-managers who are highly skilled at innovating can accurately sense new opportunities and reconfigure their MYPE’s resources.

Knowledge of ICT represents a third type of specific knowledge. Although this ICT knowledge may marginally affect the development of dynamic capabilities in large enterprises, they allow MYPE owner-managers to reinforce the corporate image, offer timely information, and assist consumers (Nieto and Fernández, 2005). Many positive outcomes arise from this presence in the virtual world. First, knowledge in ICT simply reduces unnecessary paperwork and presents the MYPE to the world. Second, MYPEs benefit from a constant inflow/outflow of data that may foster formal knowledge storage (e.g. standard operating procedures, sales catalogues, quality reports). Third, MYPEs have direct access to different sources to support timely and informed decision-making (Wales et al., 2013, Agarwal and Selen, 2009). Finally, training in e-commerce allows managers to reduce costs by facilitating the MYPE’s integration with business partners (Wales et al., 2013).

Overall, we posit that the managers’ accumulated capital specific to the management of their MYPEs’ operations shapes how they develop, modify and reconfigure their MYPE’s capabilities.

**H2.** Managerial specific knowledge is positively associated with financial performance of MYPEs in developing countries.

Drawing upon the model of Ployhart and Moliterno (2011), we hypothesize that generic knowledge facilitates the development of specific knowledge. The idea is that other enterprises may copy the owner-manager’s generic knowledge—for example, hiring an equally capable person. Context-generic forms of human capital facilitate the adaptation and assimilation of specific-context forms. Managers with a high level of education may have higher attention capabilities, be more selective in the knowledge to assimilate, and accurately invest in the type of specific knowledge they need. Therefore, managers create a unique distinctive source of capability when they use their general
knowledge to acquire easily and selectively the specific knowledge provided in managerial training. We argue that when specific knowledge, supported by generic knowledge is applied to the particular context of the MYPE, a unique human capital becomes a dynamic capability, which in turn concretizes in financial gains.

\[ H3 \] Managerial specific knowledge mediates the relationship between generic knowledge and financial performance of MYPEs in developing countries.

Managerial social capital
Managerial social capital refers to “goodwill derived from relationships, both formal and informal, that managers have with others and can use to obtain resources and information” (Helfat and Martin, 2015: 1286). Social capital is at the basis of dynamic capabilities (Blyler and Coff, 2003). It fosters the search and acquisition for resources by taking advantage of social ties, for example, in the form of referrals to investors or other stakeholders (Shane and Cable, 2002). In developing countries, informal mechanisms, such as the use of personal networks, are privileged to counterbalance the cumbersome political and economic context. Strong ties help managers to compensate for the lack of governmental support, and access to reliable information (Stam et al., 2014). Also, entrepreneurs belonging to business networks or who are “politically connected” can enhance their performance by seizing capability-building opportunities and accessing public-sector resources (Armanios et al., 2017, Bosma et al., 2004, Acquaah, 2007).

\[ H4 \] Managerial social capital is positively associated with financial performance of MYPEs in developing countries.

We also advance that managerial social capital increases specific knowledge (human capital). Through social networks, owner-managers are influenced by others’ knowledge and experiences (Helfat and Martin, 2015). This may translate in an increased motivation to invest in new knowledge either to deepen what they have learned from their peers or to gain status. Consequently, we expect that specific knowledge mediate the relationship between managerial social capital and financial performance.

\[ H5 \] Managerial specific knowledge mediates the relationship between managerial social capital and financial performance of MYPEs in developing countries.

Method
Research context and sample
Peru is our research setting where MYPEs represent around 99% of companies of which 20.1% are in the manufacturing sector (Global Entrepreneurship Monitor, 2018). Moreover, Peru ranks among the top five economies with the highest “entrepreneurial spirit index,” and 7.4% of Peruvians are owner-managers of established businesses (with more than 3.5 years in operation). In 2008, the Peruvian government enacted a legislative decree approving a law to promote the competitiveness, formalization and development of MYPEs, and the access to decent employment. Other initiatives, such a labour regime for MYPEs and national training programs, and new organizations’ efforts to support the MYPEs’ development, make of Peru an ideal context of study.

We use data from a secondary source comprising results of a survey conducted by the National Institute of Statistics and Information Technology (INEI, 2013). The data was collected through interviews between August and September 2013. The population was composed of MYPEs—according to the definition of local authorities, annual sales between 20 and 1700 tax units (1 tax unit=3650 Peruvian Soles)—in the manufacturing sector. The survey includes 2515 responses (response rate=83.2%). Non-responses originated from buildings not found, activities not studied, rejection, definite closing, or
absence. Additionally, we discarded other responses for two reasons. First, because we focus on managerial capabilities, we discarded responses in which the informant was the accountant or the administrative assistant. Second, we did not include two responses of MYPEs with more than 100 employees because it is not considered a MYPE per the Peruvian definition. We ended up with 2340 usable responses. The MYPEs in the sample represent different manufacturing sectors (apparel=31.4%, metal products except from machinery and equipment=27 %, furniture=15.9 %, leather and related products=15.5 %, wood and cork products including straw and plaiting materials=6.1 %, food (dairy and cacao products)=2.1 %, other manufacturing industries=2 %) and geographic regions (Lima=38.5, Arequipa=22.2%, La Libertad=13.5 %, Lambayeque=6.1 %, Junín=6.0, Cusco=3.5 %, others=10.3 %).

Measures
To measure the dependent variable, financial performance, we use the value added of the MYPE calculated as the costs of inputs to production and the price of output. The respondents provide the main entries of their profit and loss statements for 2012. Regarding the independent variables, we measure the core underpinnings of dynamic managerial capabilities of the respondent, the owner-manager or a top manager. Human capital includes two measures. First, generic managerial knowledge as the last education level attained in a 10-item-scale (from 1=none to 10=completed university education). Second, specific managerial knowledge as a formative index of the total hours of training and mentorship received in 2012, regarding quality management practices (quality management systems, 5S, Kaizen, ISO 9000, and good manufacturing practices), ICT (web design, e-commerce with suppliers and customers, online banking, online transactions with public organizations, social networks, and basic computing skills), and innovation practices (practices to develop new or better products, services, and processes in the firm and the supply chain). We measure social capital as the frequency of participation in meetings of business associations (from 1=weekly to 6=annual). We use the logarithmic transformations due to the right-skewed data distribution.

We include several control variables, including characteristics of the respondent (age and gender), and the enterprise (logarithmic transformation of the MYPE’s years of operation). Given that macro level factors may also affect financial performance, we consider two environmental variables, munificence and dynamism. We use the value added of each industry sector between 2007 and 2011 available in the INEI database. We replicate the calculation as in prior studies using time as the independent variable in the regression of growth (Castrogiovanni, 2002). So, munificence equals to the regression slope coefficient divided by the mean value, and dynamism to the standard error of the regression slope coefficient divided by the mean value. To control for knowledge in the shop floor, we include the natural logarithm of the total hours of technical training received by the employees in 2012.

Results
The means, standard deviations, and correlations are available upon request. We used ordinary least squares regression to test the direct effects proposed in H1, H2, and H4 (Table 1). Human capital, in its two forms was positively associated with financial performance supporting H1 and H2. Social capital, however, was negatively associated with financial performance and the effects were not strong enough to be significant. H4 is not supported.
To test the mediation effects in H3 and H5, in line with Rungtusanatham et al. (2014), we ran Hayes (2013)'s PROCESS model 4 for SPSS with 95% bias-corrected confidence intervals and 10000 bootstrap subsamples. The bootstrapping method has been proven as more reliable than the traditional Baron and Kenny method (Ta et al., 2018). If the confidence intervals do not contain a value of zero, significant mediation is evident (Hayes, 2013). In support of H3, the results confirm that managerial generic knowledge was associated with financial performance, mediated by managerial specific knowledge (indirect effect=2011.7, SE=794.42, 95% CI=605.32 to 3682.39; direct effect=30310.78, SE=3454.21, 95% CI=23537.13 to 37084.43; total effect=32322.48, SE=3419.78, 95% CI=25616.35 to 39028.61). In support of H5, we found that managerial social capital was associated with financial performance mainly through the investment in managerial specific knowledge (indirect effect=11343.2, SE=4675.76, 95% CI=3184.3 to 21418.51; direct effect=-935.05, SE=17494.74, 95% CI=35241.93 to 33371.83; total effect=10408.15, SE=17266.93, 95% CI=23452 to 44268.3).

**Discussion**

We contribute to the literature on OM in micro and small enterprises. Our study attempts to integrate views from OM, Entrepreneurship, and Human Resources Management by using the dynamic capability perspective. Our argument is that in such small firms, functions overlap and the owner-managers are in the spotlight. They decide every step of the MYPE so any heterogeneity in practices, capabilities, and performance depends on their own capabilities. In adopting this “human” angle, we complement prior works that focus on the effect of operational capabilities on performance (e.g., Cagliano et al., 2001). We also contribute to the literature on OM in developing countries that has largely emphasized the role of the environment (e.g., Prasad and Tata, 2009). Our findings show that the individual level that is investments in managerial knowledge of the management of the MYPE’s operations is fundamental. This suggests that the effects of new improvements or innovations at the organizational level (MYPE’s dynamic capabilities) is affected by the capability of the owners or managers to bring the knowledge to the MYPE through their own instruction efforts (dynamic managerial capabilities).

Overall, we contribute by bringing the individual back into the conversation of dynamic capabilities. In that regard, we show that dynamic capabilities could help...
MYPEs to overcome the obstacles along the growth path identified by Clegg (2018). Our results demonstrate that human capital provides the main underpinnings of dynamic managerial capabilities that result in increased financial performance. In that sense, our results echo those in the literature on large firms in which top managers’ capabilities are the key actors. Notably, MYPEs in developing countries highly rely on their owner-managers. A possible explanation is that human capital is scarce in developing countries. The Peruvian index of expenditure on public education (as a percentage of GDP) was 2.6 in 2012—compared to the top country, Norway with an index of 6.9. Knowledge and skills are thus very valuable assets. The significance of human capital in our study, as well as its mediating role, has a profound practical implication for developing countries: a need for both educational policies and training resources to support entrepreneurs to manage their operations. Although many countries are investing strongly in entrepreneurship education and training, which has an effect on starting or growing a business (Martin et al., 2013), this may be not enough. Our results suggest that investing in O&M education and training determines performance of the business in the long term.

Furthermore, our results are congruent with previous literature that highlights the key role of informal mechanisms to counterbalance institutional voids in developing countries (Stam et al., 2014). Although we did not find support for a relationship between managerial social capital and financial performance, we did find that specific human capital mediates this relationship. This implies that personal connections may increase the opportunities to access new knowledge related to the MYPE’s OM, which in turn increases financial performance. In large enterprises, connections with supply chain partners have been proved important; in MYPEs, other types of networks, such as business groups, may matter equally or more. The direct effect of managerial social capital in our sample is, however, negative. Although not strong enough to be significant, this indicates that the sole reliance on associating with peers may not be beneficial for MYPEs likely because of limited resources and time.

Conclusion
We tested the relationship between dynamic managerial capabilities and financial performance of Peruvian MYPEs. The Peruvian context is representative of Latin American countries in terms of entrepreneurial spirit, as well as economical, cultural, and political context. Nonetheless, cross-country research can shed more light into the different successful combinations of dynamic managerial capabilities. We acknowledge that our analysis is limited by the available data. We encourage the study of other variables such as different types of education, training, and social capital. We conclude that MYPEs are key players in developing economies yet neglected so far in the OM research agenda. In this study, we explicitly consider the interconnections of three core underpinnings of dynamic managerial capabilities—human capital, the knowledge of operations management (managerial specific knowledge) and the managerial generic knowledge, and social capital. Our results support the positive impact of dynamic managerial capabilities on financial performance for MYPEs in a developing country.

Abstract
Sustainability concepts inform business considerations of production and procurement in order to satisfy consumer demands for ethical products. Drawing on the Deception Impact Model, the aim is to understand the severity of deception, implementation of socially sustainable practices, and impact on consumers by examining a case in the Indigenous art Australian souvenir industry. It found where a firm decouples from socially sustainable practices the result, a form of deception, negatively impacts ethically motivated consumers. The paper highlights where Indigenous people should be involved in the development chain to avoid infringing on human rights as it relates to commodification of culture.

Keywords: Social Sustainability, Ethical Practice, Deception, Indigenous Art

Introduction
The growing consumer desire to make ethical purchases necessitates firms to become more transparent in their production and procurement processes. Sustainability concepts, which include social, environmental, and economic dimensions, are ways in which business can consider the production and procurement in order to satisfy
consumer demands for ethical products. Likewise, the sustainability dimensions are a lens in which to examine operational processes to understand where practices decouple from what is legally and socially accepted in the provision of goods and services.

Sustainability issues transform the competitive environment for business (Longoni and Cagliano, 2015). There are various reasons for the private sector to demonstrate sustainability practices in their operations and behaviour. For example, the recent shift within the sustainable development paradigm has seen the private sector take a more prominent role alongside civil society and governments in addressing issues facing inclusive global growth and development (Scheyvens et al., 2016). Beyond contributing to global aspirations for sustainable development, economies can be achieved through environmentally sustainable operational practices, such as waste reduction and energy conservation. These savings can be amplified across a supply chain through coordination with upstream and downstream partners (Gupta and Benson, 2011) and assist in achieving a positive long-term performance of individual companies and their supply chain (Ahi and Searcy, 2015).

When considering sustainability within a supply chain context financial returns are not the only benefits for a network of firms working together to compete in the industry. Supply chain partners also have an interest in understanding each other’s processes in order to ensure they are satisfying the needs of stakeholders in both legal and social aspects. The reason is to uphold legal obligations and avoid broader scrutiny by society.

Despite the benefits of practising sustainability in business processes, there are many instances of firms decoupling from strategic sustainability goals during implementation at the operational level. This paper uses the case of the Australian souvenir industry to illustrate where a firm decouples from socially sustainable practices in the production and procurement of low-cost souvenirs featuring stylised designs representative of the culture of Indigenous people. The result of the decoupling, a form of deception, negatively impacts consumers who are motivated to make ethical purchases. In addition to upholding the rights of Aboriginal and Torres Strait Islander people to protect and commodify their culture as a fundamental concept of Indigenous human rights.

This case has been chosen to illustrate deceptive practices as it has been recently highlighted within a Federal Government Inquiry (the Inquiry) and subsequent report (the Report) and legal proceedings brought before the Australian courts prosecuting a well-known souvenir distributor (the Distributor) mislabeling products to deceive consumers who are concerned with making ethical souvenir purchases. Further, this case highlights the role of social sustainability in business to protect human rights as it relates to the cultural dimension. Reasons for this will be outlined.

To understand deception in this context and understand where operational processes decouple from sustainability objectives happen, the Deception Impact Model (DIM) by (Hammadi et al., 2018) is utilised. The DIM connects three dimensions to provide an understanding and positioning of a firm’s practices and impacts regarding severity of deception, implementation of sustainability practices and, impact on customers and other stakeholders.
There are differing attitudes and values towards the commodification of culture to produce souvenir product influencing what is classified as ‘authentic’ or ‘fake’ product. It is not the aim of this paper to classify or debate authenticity concepts, rather demonstrate the implementation (or lack) of social sustainability concepts in the production and sale of souvenir products featuring designs representative of Indigenous culture, and their subsequent impacts on operations management, supply chains, consumers and stakeholders. The term inauthentic will be used in reference to objects or products that do not engage Indigenous people in the design for the purpose of providing clarity and consistency.

The aim of this paper is to highlight where operations management and supply chain concepts can add value to society - particularly with respect to developing Indigenous Australian enterprises which are a valuable mode of sustainable development in remote regions. The paper provides a background to unsustainable practices, then discusses the concept of culture within a human rights framework and how it relates to the social sustainability in the Australian souvenir industry. The legal proceedings brought before the Distributor are examined using the DIM framework to understand the severity of the Distributor’s deception. The Distributor’s development chain is then examined to understand the degree to which the firms are implementing socially sustainable practices from an operations management and supply chain perspective. Finally, the impact of consumers and other stakeholders is considered to position the Distributor in relation to the implementation of social sustainability practices.

Background

Historical factors also demonstrate a lack of internal culture towards social sustainability among distributors and retailers with the issue of deception relating to inauthentic products within the Australian souvenir supply chain having been addressed in 2003 prior to the Distributor case in 2018. The Australian Competition and Consumer Commission brought action against Australian Icon Products Pty Ltd (AIP) for engaging “in conduct likely to mislead or deceive consumers” due to making claims that souvenirs were hand-painted by Indigenous Australians (NSW Government, 2007). Under Australian consumer law, “consumers are entitled to receive goods that match their description”. The ACCC alleged Australian Aboriginal Art Pty Ltd (AAA) mislabelled products claiming they were ‘Australian Aboriginal Art’, ‘Aboriginal Art’ and/or ‘Authentic, made by Aboriginal artists or artists of Aboriginal descent’ despite not employing Indigenous people in the production process (NSW Government, 2007). The 2003 and 2004 cases demonstrate broader public awareness of deceptive practices by souvenir wholesalers in the form of mislabelling products. Despite this awareness, the production and sale of goods to retailers with misleading labels continued.

Recently in Australia, the Arts Law Centre of Australia revealed the widespread use of deception in the souvenir industry through an advocacy campaign. The campaign, known as Fake Art Harms Culture, highlighted the pervasiveness of merchandise available at tourism retailers, which presented as Indigenous cultural souvenirs appeared
ambiguous in provenance (Indigenous Art Code, 2019). One of the aims of the *Fake Art Harms Culture* campaign was to draw awareness to products whereby culture is commodified, often with inappropriate designs and materials, to create a product for a specific market. The advocacy campaign led to the Federal Australian Government undertaking an official *Inquiry into the growing presence of inauthentic Aboriginal and Torres Strait Islander 'style' art and craft products and merchandise for sale across Australia* (Inquiry) and a final report (Report) into the findings was published in 2018 (Australian Government, 2018).

Additionally, in 2018, the Australian Competition and Consumer Commission (ACCC) launched legal proceedings against a souvenir distributor finding the firm in breach of labelling laws (Australian Competition and Consumer Commission, 2018). The ACCC case demonstrates a legal mechanism (i.e. consumer law) in which incorrectly labelled souvenirs representing Indigenous culture assist in protecting consumers from making unethical purchases.

Despite consumer law providing protections for consumers in this context, Australian law does not extend to the “underlying idea or information that is put into a work” or a “style or method of art” such as dot painting techniques synonymous with Indigenous culture. Therefore, there are limited legal mechanisms in place to prevent a product being produced that references an Indigenous story or artistic style associated with a culture or specific nation (Artists in the Black, 2019). The commodification of Indigenous cultures to produce and sell souvenirs, without having an overt connection to an Indigenous person is not legally prohibited, and are termed ‘inauthentic’ for the purposes of clarity. Thus, as evidenced by the 2018 Distributor case, producers, wholesaler, and retailers of souvenirs continue to engage in deception.

**Social sustainability: Culture as an aspect of human rights**

While social sustainability is becoming an increasing concern of business (Mani and Gunasekaran, 2018), there is ambiguity regarding the social sustainability dimension and what it encapsulates (Ajmal et al., 2018). Cultural and ethical issues have been overlooked compared to factors related to legislative compliance, and the hierarchy of factors enabling social sustainability has not been clearly established (Mani et al., 2014).

A dimension of social sustainability is the rights of Indigenous people. The *United Nations Declaration on the Rights of Indigenous Peoples* protects Indigenous people’s “right to maintain, control, protect and develop their cultural heritage” and “to maintain, control, protect and develop their intellectual property over such cultural heritage”; the “right to the dignity and diversity of their cultures”; further advance their economic and social conditions including employment (Australian Human Rights Commission, 2012).

Supply chain management research has been limited in considering the interrelationships between sustainability issues (Gimenez et al., 2012). The three sustainability pillars are ubiquitous in our understanding of sustainability, however, their distinction as separate dimensions is conceptually fuzzy (Kuhlman and Farrington, 2010). There has been a stronger focus on addressing economic and environmental
dimensions of sustainability in business, while the social aspect has not been well developed (Ajmal et al., 2018). As a concept of social sustainability, upholding the rights of Indigenous people demonstrates the convergence of positive social and economic development outcomes.

The Declaration highlights the role of culture, cultural heritage, and intellectual property as fundamental to the rights of Indigenous people. A successful example of Indigenous Australians engaging in enterprise and using culture as a means of advancing economic and social conditions is Indigenous art centres. Art centres have become important institutions in remote Australia as they provide people with access to the mainstream art market where only a limited opportunity for economic inclusion exists, and in some instances, represent the only non-welfare form of income available to Indigenous people (Seet et al., 2018). Art centres are also linked to the overall wellbeing of Indigenous people and broader communities by generating positive psychological and emotional impacts (Allain, 2011).

Despite the success of art centres in facilitating cultural production for the art market, commercialisation of culture can lead to conflicting priorities between producers and consumers within the souvenir industry. Indigenous artisans producing handcrafted goods according to cultural protocols (e.g. use of a specific material or production technique) for tourist markets may not be able to price a product to fit the requirements of consumers seeking a low-cost travel memento (Gutentag, 2009). Thus, non-Indigenous firms with capabilities to produce low-cost products, and without legal obligations to follow cultural protocols, are free to appropriate elements or styles of Indigenous culture to meet consumer demands (Gutentag, 2009). In this instance, the non-Indigenous producers are able to exploit the legal environment and take away opportunities for Indigenous people to advance their economic and social conditions through the commodification of culture and intellectual property. The example of non-Indigenous firms participating in the market under these conditions illustrates how firms can engage in socially unsustainable practices in the production of inauthentic goods within the souvenir industry.

**Severity of the Distributor’s deception**

The relationship between social sustainability and the production of authentic souvenirs has been established as an aspect of human rights. Examining levels of deception is one of the three interrelated factors proposed by DIM to determine the degree to which a business is delivering on sustainability objectives from a supply chain perspective. In the case of the Distributor who was prosecuted by the ACCC, the DIM framework provides a basis for understanding the severity of deception. In a supply chain context, deception can occur between buyer-supplier or organisation-consumer. Deception is the gap between actual claims, practices and outcomes of those practices.

The development of nomenclature for deception relating to sustainability within supply chain literature demonstrates its prevalent in contemporary business. Green-washing and blue-washing (Dadush, 2018) describes the practice of misleading
consumers by misrepresenting the degree to which a product or service is environmentally (green) or socially (blue) sustainable.

The Australian Federal Court found the Distributor in breach of Australian Consumer Law over misrepresenting souvenirs featuring Indigenous style designs as being hand painted by Indigenous people (Australian Competition and Consumer Commission, 2018). The products at the centre of the case were represented to be ‘associated with Australian Aboriginal Art’ and using words in the labels including ‘Aboriginal Art, ‘genuine’, and ‘Australia’ (Australian Competition and Consumer Commission, 2018).

Several products were featured in the case including loose boomerangs, boxed boomerangs, bullroarers, didgeridoos and message stones. Some of the products featured designs licenced by an Indigenous artist. However, the products examined in this case that were in breach of labelling laws were manufactured in Indonesia with designs the firm procured from Internet sources (Federal Court of Australia, 2018).

Blue-washing is applicable to this case as the Distributor made claims on particular products to infer a connection to Indigenous people and local products that do not exist in that form. The deception not only impacts consumers but also the buyers (retailers).

When using the DIM model (Figure 1) to investigate the deception, consider the inauthentic supply chain in the Donald Trump quadrant as the supplier deceives with low sustainable impact yet are liked for the low price. The change to the authentic responsible supply chain can risk failure as consumers may not like the increased price despite having an authentic product and thus have made an ethical purchase. However, it is most likely that it shifts to influencer with an outcome being the partial loss of consumers, triggering a new concept/idea being marketed for its sustainability, with a final shift towards maturity. Note though, Robin Hood is a possibility if both supply chains collaborate and find a solution to be authentic and to keep the price in an acceptable price range.

---

**Figure 1: Deception Impact Model (DIM). See also Hammadi et al. (2018)**
Implementation of sustainability practices

The sustainability orientation of an organisation is significant and is based on sustainability practices to achieve sustainability goals. The DIM proposes a firm’s sustainability orientation on a spectrum between compliance with standards or legal obligations through to internal firm culture. The spectrum has been developed through Goldsmith and Samson’s (2005) four categories of sustainability practices: compliance, conformance, performance, and transformation. Compliance and conformance are on one end of the spectrum, considered a reactive approach to sustainability implementation, and are demonstrated by firms who will only do what is necessary within a particular industry (Goldsmith and Samson, 2005). The DIM proposes the impact of this reactive orientation as an indicator of low implementation of sustainability.

To operationalise this impact in the context of the Australian souvenir market, the Distributor's development chain was examined. A strategic business activity is new product development (Hilletoft and Ericsson, 2010), with the intersection of product development with the supply chain known as the development chain (Primus, 2017). Attributes of products and the supply chain process can be aligned by firms to increase competitiveness (Morita et al., 2018) and thus, influence operations processes.

Two key elements of the development chain are ‘planning and design’ and ‘sourcing’ activities, with product architecture (planning and design phase) connected to the attributes of products. Within souvenir purchasing Revilla and Dodd (2003) found “appearance/utility, traditional characteristics and certification, rarity, local production and low cost” as factors impacting purchases. The Distributor sourced Indigenous symbols from the internet to be incorporated into souvenir products to give the products a particular appearance that would be attractive to customers (e.g. traditional characteristics). Labelling and packaging also inferred local production.

Design sourcing is the primary activity in which the Distributor decouples from human rights within the social sustainability dimension. This represents a key stage during the development chain where a firm can go beyond legal requirements, and ethically source a cultural element which will return positive benefits to Indigenous people, while satisfying product architecture requirements, thus supporting the human rights of Indigenous people to protect, maintain, and control their cultural heritage.

Make or buy decisions is another dimension of the planning and design phase, and supplier selection falls under sourcing activities. A factor influencing souvenir purchases is price. Research has found that price-orientated operations strategy models are less likely to compliment social and environmental sustainability aims (Longoni and Cagliano, 2015). The products considered in this case are at the lower end of the market and there is evidence that the Distributor outsourced production of souvenirs to Indonesia (Federal Court of Australia, 2018). Offshoring production of Indigenous style souvenirs may not result in decoupling from social sustainability as a discrete activity. However, combined with a decision to not include Indigenous people in the design of
the product combined with mislabeling statements on the product’s packaging demonstrates a low commitment to social sustainability.

**Consumers and other stakeholders**

Within souvenir purchasing there are a variety of customer motivations “including workmanship, sensuous appreciation, cultural linkage and ease of handling” (Hu and Hong, 2007, p. 123). As consumers become more aware of products and manufacturing processes, firms are driven to address sustainability concerns (Mani et al., 2014). Despite customer trends, retailers need to consider balancing the demands of customers who are interested in sustainability, while also guarding against potential loss of market share and sales resulting from sustainable practices (Wilson, 2015).

Within the DIM, organisations able to accomplish positive impacts on consumers, despite relying on deception, are considered to be at the high end a deception severity spectrum. Retailers who knowingly procure products such as those discussed in the Distributors development chain, that disregard the cultural aspect of human rights, and are also priced at the lower end of the market, can satisfy price conscious consumers who are not motivated by ethical purchases. Due to the nature of competitive environments, buyers and suppliers on the supply chain may be motivated to align competitive priorities and have a low commitment to social sustainability. A challenge for business in the operationalisation of sustainable practices is reconciling traditional operations management models that focus on price, markets, and capability, to fit sustainability aims (Longoni and Cagliano, 2015). An internal ‘reactive’ culture towards social sustainability, which relies on maintaining minimum compliance with regulatory requirements, demonstrates the low commitment of those Australian souvenir supply chains to address human rights issues.

Conversely, authenticity is also a dimension motivating souvenir purchasing. Authenticity is considered a social construct, and consumer perceptions of authenticity is shaped by the “social and cultural conditions under which the product was produced” (Littrell et al., 1993, p. 200). It is not the aim to classify which product attributes constitute an authentic Indigenous souvenir product. However, this concept is important when souvenir producers mislabel products and engage in blue-washing as consumers seeking authenticity are at a disadvantage when making an ethical purchasing decision. This is also relevant in a buyer-supplier context as retailers may also be deceived if they are seeking to supply ethical products.

**Conclusion ideas**

Applying the DIM, this paper contributes to the understanding of product development and supply chain decisions within the Australian souvenir industry with regards to Indigenous art. When examining the Distributors development chain it was revealed that a critical stage in which a firm decoupled from social sustainability practices occurred in the procurement decision supporting a product’s architecture. The paper highlights where Indigenous people should be involved in the development chain for
other non-Indigenous firms selling like-for-like products so as to avoid infringing on human rights as it relates to commodification of culture.

For Indigenous organisations and individual artists, seeking to enter the souvenir industry as a means of economic participation and inclusion, the paper provides an understanding of why specific techniques (such as offshoring) are used to satisfy customer purchase requirements, conversely impacting social sustainability. Additionally, for existing firms within the souvenir industry seeking to satisfy the market for ethical products, the research highlights where deception and decoupling from social sustainability relating to human rights and the cultural paradigm can occur from a production perspective.

Here, we addressed the gap in supply chain and operations management knowledge Indigenous producers face when participating in souvenir markets as established in the Report. Finally, the research contributes to the understanding of cultural paradigms within commodification contexts, as they relate to social sustainability as a concept.

Acknowledgments
The authors acknowledge Aboriginal and Torres Strait Islander peoples as the traditional owners of Australia, and pay respects to elders past, present, and emerging. The term Indigenous is used in reference to the cultures of both Aboriginal and Torres Strait Islander people throughout this paper.

Abstract

New formats of retail stores continue to emerge, in order to better meet the needs of consumers. In Brazil, the Cash & Carry format occupied a leading position due to the high growth in number of stores and billing volume. This research aimed to characterize the value chain of the Cash & Carry format in Brazil, in comparison to the traditional physical stores in search of the justification for this phenomenon. Through a documentary research, the ten largest retail chains of the country and their brands of physical stores and wholesale stores were analysed, in order to construct the presented models.

Keywords: Supply Chain Management; Cash & Carry; Value Chain

Introduction

Retail organizations are diverse and new forms continue to emerge so that consumers can now buy goods and services in a wide variety of stores (Da Conceição, 2018). The idea of cash & carry, better known as "Cash & Carry" in Brazil, came into being in Europe and was more developed in the United States from 1980 onwards. The idea came from the following understanding: having a store capable of bringing the desired product to small retailers or objective consumers, without offering any services but with a more robust mix of products (Napoleão, 2017).

According to Abad (2016) and Napoleão (2017), Brazilian families has preferred the "Cash & Carry" to the supermarket and hypermarket. This research aims to characterize the chain of values and the format Cash & Carry, demonstrating the main advantages obtained by this business model in comparison to the traditional physical retail that justify its recent rise and its impacts in the retail supply chain in Brazil. The contribution of the results obtained here derives from the example of this operation in an emerging country.
Literature Review

Chain of Values

For an examination of the activities performed and the way they interact, for a broad approach and identification of the main process flows of the company, the chain of values can be introduced as a systematic tool for such an evaluation.

According to Porter (1990: 31): The value chain disaggregates a company into its strategically important activities so that it can understand cost behavior and existing and potential sources of differentiation. A company gains competitive advantage by performing these strategically important activities at a cheaper or better way than the competition.

The performance of the value chain represents a process of differentiation between companies and their processes and the establishment of competitive advantages. Figure 1 illustrates the value chain model proposed by Porter (1990).

![Value Chain Model, Porter (1990)]

Primary activities are those involved in the physical creation of the product and its sale and transfer to the buyer, as well as after-sales service. In any company, primary activities can be divided into five generic categories: (1) internal logistics: the activities associated with the receipt, storage and distribution of inputs in the product, such as material handling, warehousing, inventory control, fleet scheduling, vehicles and return to suppliers; (2) operations: the activities associated with the transformation of the inputs into the final product, such as working with machines, packaging, assembly, equipment maintenance, testing, printing and production operations; (3) external logistics: the activities associated with the collection, storage and physical distribution of the product to buyers, such as storage of finished products, material handling, delivery vehicle operations, order processing and programming; (4) marketing and sales: these are the activities associated with providing a means by which buyers can buy the product and induce them to do so, such as advertising, promotion, sales force, quotation, channel selection, channel relationships and pricing; and (5) technical assistance: these are activities associated with the provision of service to enhance or maintain the value of the product, such as installation, repair, training, parts supply and product adjustment.

Support activities can be divided into four generic categories. Like the primary activities, each category of support activities can be divided into a series of activities of...
value that are distinct and specific to a particular company. The generic categories of support activities are:

1. Acquisition: refers to the function of purchasing inputs used in the company’s value chain, not to the purchased inputs themselves. Inputs purchased include raw materials, supplies and other consumer items, as well as assets such as machinery, laboratory equipment, office equipment and buildings. Although these acquired inputs are commonly associated with primary activities, they are present in each value activity, including supporting activities.

2. Technology development: it consists of several activities that can be broadly grouped together in efforts to perfect the product and process. The development of technology related to the product and its characteristics can support the entire production chain.

3. Human resource management: consists of activities involved in the recruitment, hiring, training, development and compensation of all types of personnel. Human resource management affects competitive advantage in any company, through its role in determining qualifications and the cost of hiring and training; and

4. Company infrastructure: consists of a number of activities, including general management, planning, finance, accounting, legal, government affairs and quality management. Infrastructure, unlike other support activities, generally supports the entire production chain and not just individual activities.

Porter (1990) relates an advantage to value creation, that is, the competitive advantage arises from the value that a company can create for its buyers and that exceeds the cost of manufacturing the company and provides the difference between a firm’s offer and that of others.

From the evolution of Supply Chain to Cash & Carry

When looking to analyse the dynamics and structure of the chain of supermarkets, it is necessary, at first, to understand some basic concepts that guide the actions of the products and services that are in networks. The need to understand the performance scenario is fundamental for assertive and optimized decision making throughout the chain.

By understanding the organizations and the ways that these are instituted, it becomes perceptible to understand the dynamics and structure of the business and therefore outline the strategies needed to gain competitiveness. The understanding of economic reality requires interpretations that are based on a systemic environment, which involves not only the parts, but the whole and their interrelations (Capra & Jakobsen, 2017).

Antonialli et al. (2016) infer that it is emphasized as the importance of studies on productive chains requires evaluations of both economic and technical operations throughout the stages of production and consumption of goods, ranging from (organizational, institutional, consumer) environments that permeate the production chain, essential for the construction of the competitive advantage of the chain (Antonialli et al, 2016).

Although dynamics is different from that of the Supermarket Supply Chain, these studies converge to the same point, being applied to all sectors, which are the structures of their respective chains (Zylbersztajn, 2005). By using the concepts of chains, production systems and coordinated subsystems, the expansion of volumes of empirical research volumes, both national and international, was evident from the 1980s to the present day. Whether in agro-industrial systems or in any other organization, they all employ the concept of continuous production steps, from the raw material to the finished product, in order to guide their analysis (Andrade, 2015).
The supply chain, according to the Supply Chain Council (2002), infers that "the supply chain covers all efforts involved in the production and delivery of an end product from the vendor supplier to the customer's customer" (Machline, 2011). Thus, typical transactions and the influence of institutional and organizational environments (which are defined as determinants of competitiveness) are common to all chains, regardless of the theoretical conceptualization (Zylbersztajn, 2000).

This relationship between supplier, producer and client creates and models the organizational and institutional environment, from which it is intrinsically linked to the cultural environment and the consumer environment, as shown in figure 1. Thus, the Supply Chain can be understood as the "main cell" in all production dynamics of products or services goods, since each chain link is affected, directly or indirectly, by any actions that affect one of its agents.

When we turn the perspective to retailing in the dynamism of information and interpersonal relations, new approaches emerge not only in the academic environment, but also in the commercial relations and the Cash & Carry is one of those results coming from the modifications in the organizational and institutional environments, as mentioned above.

Cash & Carry
According to Oliveira, Lima-Filho and Watanabe (2013), it is understood as Cash & Carry being the format of store known in Brazil for being a mixed operation of wholesale and retail, of which its actions are intended to serve preferentially, purchase (Silva, 2017).

In addition, it is important to note that the quality of the food service is not limited to the food service sector. According to Broud (2016) and Levy (2000), Cash & Carry is understood to be: The "Cash & Carry" is a phenomenon nowadays, mainly in Brazil, this model joins features of wholesale retail and aims to provide products with lower prices to the client to offer good services. This model does not have a refined structure, the design is low cost and its focus is on "pay and carry" (Broud, 2016; Levy, 2000).

Napoleão (2017) advocates that over the years, the development of this type of business has brought from new purchasing systems to adoption of new practices, such as the agglomeration of additional services added to the physical structure of the store, and in this way, it is possible offer not only cheaper products, but also, better quality services whose situation ends up adding more value to the enterprise.

Methodology
This work, in terms of its concept, is characterized as qualitative, through documentary analysis as scientific articles, as well as reports of specialized journals in the field, descriptive-exploratory. This infers that this type of research seeks to understand a reality that has not yet been studied, in which one can describe how the phenomena related to it occur (Gomes, 2006; Reis, 2018).

Pimentel (2001), shows us that studies based on documents as primordial material, be they bibliographic reviews or historiographical research, extract from them all the analysis, organize them and interpret them according to the objectives of the proposed research, giving them the specific treatment in order to corroborate with the object of study (Pimentel, 2001). Garcia Gutierrez (1984) apud Junior, Medeiros & Augusta (2017), reflects on documentary analysis as "all recognition and study that is made of a document, requiring an identification of the physical characteristics, which would be the form, and the intellectuals, the content". These elements corroborate the establishment of the best method to organize all the “information” expressed in the document (JUNIOR, Medeiros & Augusta, 2017).
It was applied in this work the analysis of documents such as scientific articles, books and reports in magazines or nationally recognized electronic sites that dealt with the theme of evolution and modification in the structures and dynamics of the retail chain and seek to understand what the current panorama of the transition traditional market of the hyper and supermarkets for the recent cards.

As a study delimitation, we opted to work on the analysis with the top 10 retail chains in Brazil's supermarket or hypermarket sector, according to the Brazilian Retail and Consumer Society (Sbvc, 2017). From the list obtained, company flags were tabulated in a spreadsheet and classified according to their size and sales format (small retail, super / hypermarkets, cash backs, etc.). In order to obtain a broad analysis specifically of the cash cards, the analysis of the discount cards that make up the Brazilian Association of Wholesale Carriers (Abaas, 2017) was included in the analysis. Below, the table 1 presents the flags chosen for the analysis.

</tbody>
</table>

From the choice of the sample, the electronic websites and news related to the respective flags were searched and the data obtained were classified in a spreadsheet, so that the specific characteristics of each company were allocated according to each activity of the value chain. Then, the data collected and classified were submitted to content analysis according to Bardin (1977), and the content analysis categorization was based on Porter's value chain proposal (1990).

Findings and Discussion
In analyzing the Brazilian retail supply chain over the last decades, it is notorious to realize that there has been a restructuring between distribution channels both among internal and external agents and, therefore, shaping the structure and dynamics of the latter. With this, several consumers have migrated their shopping environment, but mostly inserted in the super / hyper format for the retail and small retail formats.

This fact can be evidenced when it is observed that the largest retail groups operating in Brazil started to enter this market more intensively over the years, especially in the
infrastructure and locality models of their stores. To better elucidate this phenomenon, the section will be presented in three stages. The first presents the comparisons of traditional retail value chains versus the retail value chain. Subsequently, the traditional structure of the Brazilian retail chain is presented, followed by the characterization of the chain after the rise.

The retail versus retail chain of value - Traditional structure of the retail chain in Brazil
The Cash & Carry in Brazil, although recent, presents a highly dynamic and increasingly comprehensive structure. The distribution channels between the suppliers of inputs, products or services to the final customer, generate impacts at all levels of the chain.

The more complex and long the relationships between the agents that feed the chain, the more financial and managerial resources will be needed, and this is the dynamics of the traditional retail model in Brazil, where the acquisition, inventory, distribution and sale management of products of the supermarkets, presents in its great majority, like an extensive and pushed system. Figure 1 summarizes the distribution channels of the products in the traditional retail markets in Brazil.

Retail Chain - Previous View

![Retail Chain - Previous View](image)

In this model, the product manufacturer presents itself not only as the one who produces a particular product, but also becomes a stockist (in this case, stockist would mean the manufacturer as being the maintainer of the products in its own physical structure for later distribution) and sometimes acts as a distributor to the wholesale or traditional retailer. The Wholesale in turn supplies the small retailers that make the products available to customers, replacing them from time to time. The same happens with traditional retail, where the products are stored at the disposal of the final customer. In this model, the interfaces between the links in the supply chain show an increase in the final cost of the product, since each agent must receive a value for transportation, inventory and / or resale of the products to final customers.

Losses, low optimization of inventory management and costs, is recurrent in this type of marketing. Sometimes this commonly used structure has certain barriers that raise costs throughout the chain, as explained above. Linked to this favor, chain coordination
becomes fragile because it has several links between agents, which, due to the complexity of coordination conditioned to the various factors, can generate countless losses due to the organizational environment that this chain is inserted.

In addition, the operational costs of the distribution operations mean that the products that reach the end of the chain have an additional level of intermediation and consequently an added value that ultimately increases the final price of the product to the final consumer.

Current structure of the retail chain in Brazil

At Cash & Carry sector, dynamics and coordination of the chain become leaner, with the optimization of the distribution and storage of products. In the meantime, it is worth stressing with the performance of the chain is more dynamic, both the product outputs and the search for these products by the end customer. This coordination of the chain reinforces the considerations of the Value Chain proposed by Porter (1990) and demonstrate the impacts that the operations both internal and external, modify the organizational and institutional environment of the retail chain as a whole.

Thus, stores denominated Cash & Carry become the link between the manufacturer and final consumer, presenting not only as a retail store, but also as a wholesale center and as a Distribution Center (CD - It would be inferred that it is a warehouse whose purpose is to manage the inventory of goods in the fixed distribution (Abralog, 2016; Do Nascimento et al., 2018).). This changes the whole structure of internal logistics, operations and supplier, vendor and consumer relations. In this sense, Cash & Carry is a protagonist in relation to the position in the supply chain, since it occupies in a concentrated and strategic way, a new location in the structure of the chain. Figure 2 demonstrates the Chain Supply Chain and its structural arrangement differentiated from the traditional chain.

Retail Chain - Current View

![Retail Chain - Current View Diagram](image)

*Figure 1 - Current structure of the retail chain in Brazil – By Authors*

Notorious is the concentration of the agents under a single player that are nets of Cash & Carry. These, in turn, have the following characteristics: 1) attacked; 2) Retail and 3)
Distribution Center for himself as well as the small and medium retailers of the surrounding region. This explains the growth of this type of commercialization in recent years in Brazil, since in addition to reducing the costs of maintenance, personnel and charges with CD's, the cash cards provide a greater mix of products in a single structure and increase the capillarity of distribution of the products.

In addition to providing support to small retailers, the final consumer is also impacted by the quantity / price ratio, where more quantity, lower price than the cash cards provide and corroborates for the maintenance of small retail stores with quick purchases in small quantities and (which does not, on certain occasions, also exempt the consumer from purchasing small quantities in the card in certain situations or preferential).

This new arrangement solidifies the trend of the expansion of the Cash & Carry in Brazil, because it meets the assumptions of the Brazilian consumer (be it the final or internal consumer of the chain), which is the question of price. As the prices are better in the wholesale account, one can then refute, at first, that the card is a fad, but a new business model that emerges to consolidate over time.

**Delimitations and Suggestions**

This research was limited to a brief illustrative analysis of the structure and dynamics of the supply chain in Brazil, since the incipient studies are about this topic in depth and, thus, propose new perspectives and considerations about the Cash & Carry Brazilian. However, the limitation was only limited to some academic articles available and also focused on specialized magazines in Brazilian wholesale and retail.

As a suggestion for future research, it is the search for correlating international and national articles (if there is one) to understand the coordination of this chain and the economic, financial and social impacts that the attack provides to the region in which it is installed, such as employ ability, cost and inventory, logistic cost, among other determinants. Moreover, the authors of this work sought to demonstrate the Cash & Carry chain as a whole in its physical structure, but without neglecting or omitting, as shown in figures 2 and 3, the profound changes that online retailing causes and will cause in retail as a everything.

Thus, it is suggested that further studies are about what impacts online retailing can impact on the retail strategies, as well as, to understand the dynamics of Online Retail Supply Chain in the interfaces between supplier and buyer, restructuring the organizational and institutional environment of retail trade.

**Conclusions**

Cash & Carry, although widespread around the world for more than two decades, presents substantial growth in Brazil only from 2012 to the present day. However, the Brazilian retail sector is not in line with this expansion, since only large groups started to emerge for this new modality that is Cash & Carry. The perception of traditional retailers needs to be reviewed and, above all, studied and disseminated in their planning and management strategies so that there is no disappearance of traditional retails or even the bankruptcy of several of these, due to a strong and massive competition resulting from credit cards.

Since the Brazilian consumer is more closely linked to the prices of the products, the Cash & Carrys appear as an innovative and comprehensive business model, providing a more balanced inventory management between a push-pull management, since the latter occurs more strongly in the traditional retail. This leads to a reduction in the costs and concentration of the products in the own cards that not only replenish their stores in their gondolas, but also have their own stock at the same time, as well as serving as a CD for small retailers, that is, an anchor for other people in the chain.
This all leads to a reduction in costs and optimization of transactions across all interfaces, which today, is a matter of survival of most businesses. Thus, the exponential growth of Brazilian cash loans is more like a market trend than just fad or punctual actions of large corporations. The dynamics of the current relations are getting faster and faster and adapting to the new trends is and will be, in most cases, the threshold between the success or failure of the cash advance in Brazil.

Are Quick and Dirty the Characteristics of Chinese Manufacturing Systems?

Yongjiang Shi (ys@eng.cam.ac.uk)
Institute for Manufacturing, Cambridge University

Abstract

This paper seeks to review the Chinese manufacturing evolutions in the last 40 years and explore what the characteristics of its industrial systems could be. We recognise that the traditional industrialisation model and industrial systems have made China the largest manufacturing country in the world. However it has also brought the nation to the tipping point where its very success could potentially destroy its own and the world. The paper concludes by proposing that the new generation of operations and manufacturing strategies need to learn from the evolution of Chinese manufacturing and explore un-conventional strategic and system solutions.

Keywords: New Manufacturing Strategy, Chinese Industrialisation, and Industrial Systems

Introduction

China started its economic reform by introducing the open-door and market policies in the late 1970s. It has achieved the GDP (Gross Domestic Product) annual growth about 10% continuously in the previous 30 years although it slowed down to 7-8% in the last five years. The industrialisation made China the largest manufacturing nation in the world in 2012, the second largest GDP country in 2013, and possibly the largest GDP PPP (purchasing power parity) country in the last year. However, the dark side of the industrial developments has gradually been exposed and caused global concerns, including environmental pollutions in water, soil, and air; fast increases of CO2 emission speeding up climate changes; all kinds of natural resource limitations potentially constraining manufacturing growth in the future; and social welfare systems lagged behind triggering society unrest risks.

This paper seeks to explore and explain what Chinese manufacturing developments in the last 40 years can inspire and challenge many management disciplines. The paper believes the classical management model and industrial systems have brought China not only to the largest manufacturing nation but also to the tipping point where its success can destroy its achievements and even the world. Therefore, it recognises the new generation of operations and manufacturing strategies have to learn from the Chinese manufacturing experiences and explore new type of strategic and system solutions.

Literature Review

This paper reviews literature in the following three areas: the concept of industrial systems, Production and Operations Management regarding China in relation to design – operations improvement, and how Chinese industrialisation urgently requires an integration of
environmental and social sustainability concerns in the era of Anthropocene. First proposed by Paul Crutzen and Eugene Stoermer (2000) to denote the present time interval in which many important geological processes and conditions have been, and continue to be, profoundly affected by human activities.

**Industrial Systems**

The concept of industrial systems is evolving with the pace of economic, technological and social development. In 1980s-1990s, industrial systems initially refer to networks of relationships among firms (J. Johanson & Mattsson, 1987; Jan Johanson & Mattsson, 1987), when researchers began to realise the importance of viewing business activities from the network perspective since coordination and cooperation becomes very crucial to organizations’ survival in the fierce market competition (J. F. Moore, 1996; J. Moore, 1993).

Later, the concept of industrial systems is further developed by the Royal Academy of Engineering, who defined industrial systems in a report as “the context, resources, activities, processes, actors, and interdependencies that support the creation and delivery of products and services” (The Royal Academy of Engineering, 2012). This report suggests that a system thinking to gain a holistic understanding of industrial systems is of vital importance for different stakeholders within the system to capture value.

Another report contends that, except for the value perspective, sustainable issues should also be among the main concerns towards the research of industrial systems (Institute for Manufacturing, 2009). Despite the fact that there are already several definitions of industrial systems among different researchers, we argue that current concepts are not straightforward and comprehensive enough to capture the essentials of industrial systems. We, therefore, propose the following working definition of industrial systems: “An industrial system refers to a complex input-output transformation process.”

**Production and Operations Management regarding China**

Production and operations management research within the Chinese context has been growing and the topics range from strategy through policy issues to supply chain/network management (Jiang, Frazier, & Heiser, 2007). These China-related research do address the differences from traditional research based on Western countries under the Chinese context, such as how Chinese companies with different ownership structures differ in operations management and technological capabilities (Pyke, Farley, & Robb, 2002), how organizational culture in the east and west differs and its impacts upon organizational performances (Naor, Linderman, & Schroeder, 2010) and how buyer-supplier relationships should be governed through transactional and relational mechanisms (Liu, Luo, & Liu, 2009).

There are also a few researchers investigating how well the Chinese manufacturing system performs when introducing established manufacturing practices such as Kaizen (Aoki, 2008) and Lean operations (Taj & Morosan, 2011), and compare the performance to that of Japanese companies. In general, scholars do agree that operations and supply chain management issues are very important to Chinese companies (Robb, Xie, & Arthanari, 2008).

Despite the fact that researchers have noticed the significant growth of Chinese manufacturing, there are few literatures explicitly investigating the distinctive characteristics and mechanisms of Chinese manufacturing which are potentially very different from that of traditional Western countries or Japan. Also, many researches have been focused on joint-venture activities, which would inevitably be affected by their foreign investors. Supply chain
management issues in China, though quite mature in Western context, still lack comprehensive elaboration and investigation, which is also a growing trend of future research.

Sustainable industrialisation development in China in the era of Anthropocene
In recent years sustainable development has gained increasing attention in the domain of operations management. Scholars called for an integration of environmental and social sustainability priorities in operations strategies (Longoni & Cagliano, 2015). Most notable efforts and suggestions are in the form of “lean sustainability” (Piercy & Rich, 2015) and “environmental management practices” (Simpson and Robert, 2014).

During the recent years as China transformed from a developing economy into the world’s largest manufacturing nation, it has become an important research phenomenon. Alongside the economic growth as the rest of the world comes to terms with China’s increasing political power. When it comes to Chinese industrialisation and its consequences, there is limited research in the POM discipline.

In social science there are some efforts directed to how Chinese innovate. Many refer to innovation in China using the term proposed by Christensen (1997) as “disruptive innovation”. Some also use terms such as “cost innovations” (Williamson 2010), “secondary innovation” (Ni and Wu, 2000) and “frugal innovation” (Economist 2010: Zeschky et. al, 2011). Disruptive innovation allows firms to offer products with superior customer value at low costs (Brown and Hagel 2005; London and Hart 2004: in Zeschky et. al, 2011). Kash (2010) points out that Chinese innovation tends to be more incremental and process driven, as learning usually occurs within the connected network and the hierarchical structure of the society often encumbers product innovation or technology breakthrough.

Yin Yang embodies duality, unity in diversity, change, and harmony, offering a holistic approach to problem-solving (Li, 1998, 2008, 2011: in Fang, 2012). To the best of our knowledge little research has been done to apply Yin Yang thinking to explore Chinese innovation.

Overall there is a gap in consolidating existing knowledge and research to update the POM society about Chinese industrialisation and the environmental and social challenges China face. Therefore we endeavour to start the exploration with this paper, in the hope to stimulate a conversation, and to invite more research into this very timely topic. As we live in a globalised world, China’s concerns will soon become the world’s challenge.

In summary, the following diagram seeks to link the above theoretical reviews with some general understandings about Chinese industrial achievements. The diagram highlights that management research community has not got enough attention and detailed observation in Chinese manufacturing evolutions (Figure 1). Consequently, we need to explore the following three main aspects of Chinese manufacturing.

Research Design and Data Collection
Based on the literature review and research gap analysis in the last section and Figure 1, the fundamental research question can be defined as the following – “Can Chinese new industrial systems cope with the future development requirements?” The research question implies further detailed explorations in three key areas:
1) Understanding Chinese manufacturing developments and the industrial systems in the last 40 years during the economic reforms;
2) Explaining and identifying the characteristics of the Chinese industrial systems and manufacturing evolutionary process – the drivers, triggers, and transformations;
3) Identifying future external requirements and capability gaps of Chinese industrial systems to cope with the future development.

The research question and related exploration areas are massive but timely in order to understanding Chinese manufacturing and its implications to industry and academia, especially for POM society. In order to comprehensively capture the picture of the Chinese manufacturing evolution, the following research design is proposed and discussed as Figure 2 illustrates. Considering 30 years Chinese radical industrialisations, multiple industrial data sources and combined pictures about different levels of Chinese industrial systems are necessary. Besides exhaustive secondary data collection through published academic papers and industrial reports, the first hand longitudinal and accumulative observations from the collaborations with Chinese industry and academic institutions have provided most insightful observations and narratives of Chinese industrial developments. From the middle of 1990s, systematic PhD research projects and theses have been dedicated to Chinese industrialisations and continuously upgrading. The Figure 2 illustrates the research project and its aims, predicted outcomes and research process.
The research process as demonstrated in the above Figure 2 includes three main stages after research design – empirical data collection and mapping; key industrial development explanation and key milestone identifications; and theoretical implication and impact through the key event analysis. Technology roadmap approach developed by Phaar and his colleagues (2011) are adopted in the Research Stage I in order to systematically present the data and identify the linkages between the main events and interacted institutions. Checkland’s soft system think approach (1999) is implemented in key milestone identification and event linkage analysis.

Research Findings
Based on the research data and analysis, three main research findings are identified:

*Chinese manufacturing evolutionary map:* Figure 3 illustrates Chinese manufacturing development in the last 40 years. It seeks to capture the most significant events and driving forces as well as the consequences. According to the data analysis, the Chinese industrialisation can be divided into the following three phases.

1) Up to 1980s - “Accumulation” period
At the time China has just started the Economic Reform, the state controlled planning means there was a shortage of almost all consumer products. State Owned Enterprises (SOEs) reform started during this time to adapt to market demand. With the establishment of special Economic Development Zones, China started to attract foreign investments, particularly into the coastal cities. Economy in townships also started to develop as local private firms in hired “Sunday engineers” who were employees to help with knowledge transfer to gain faster technology dissemination. Zhejiang private firm cluster as well as the Dongguan contractual manufacturing model emerged. It is the period where both knowledge and fixed assets were accumulated in preparation for transforming China’s manufacturing.

2) 1990s – “Transformation” period
SOE reform continues with re-structuring and resources transfer into private enterprises. More and more multinational companies and other foreign investments took place to facilitate the formation of manufacturing bases in Pearl River Delta (PRD), Yangtze River Delta (YRD), Zhujiang River Delta (ZRD), Shandong Peninsula, Beijing (BJ) and Tianjin (TJ) region. Labour intensive and consumer goods industries start to gain momentum.

3) 2000s - “World Factory” period
SOE reform continues across national level while the central government continue to nurture new industries like automobile and telecommunication to fuel further economic growth. Infrastructure projects and Western region development plans also helped with the continued double digits GDP growth.

4) 2010 to present – “Post World’s Financial Crisis” period
China emerged as the world’s largest manufacturing base. Chinese companies start globalisation journey. Central government encourages innovation at the national level in an effort to transform Chinese manufacturing from labour intensive, “catching up” to potentially “overtaking”. Environmental concerns become major challenge of the China model. Globally the so-called “Beijing Consensus” and newly re-emerged powerhouse caused concerns and debates on Chinese development and industrialisation models.

In summary, Chinese manufacturing and its industrial systems have demonstrated “quick and dirty” characteristics in its fast growth. The quick part is the formation and reconfiguration of the resources into new industrial systems while the dirty part is its poor quality and pollutions.
Figure 3. Chinese Manufacturing Developments and Industrial Evolutions
Reasons why Chinese manufacturing can grow so fast
Based on the evolutionary mapping, the paper recognises the following key factors making Chinese manufacturing industry outstanding from an economic standard perspective:
- Good ambidexterity capabilities dealing with the shift between market and planned economies, different requirements of rural and urban markets, complex supply and demand relationships, as well as FDI (foreign direct investment) dependency and indigenous innovation.
- Dynamic balance of industrial systems on all levels from basic work units, factories, enterprises to regions, sectors/industries, and the whole nation. So much has happened that one could say that the only constant is change. Economic reforms and radical transformations are deeply embedded in the majority of Chinese people’s life.
- Pursuing prosperity through hardworking and dedication are deep-rooted Chinese cultural traits. Also they believe in the importance of education, regardless of rural or urban Chinese. This has generated a large number of educated and skilled labours that formed the foundation of the rapid development of Chinese manufacturing. The economic reform policy frees up the long suppressed entrepreneurship and enhances the traditional spirit. It forms a solid foundation for industrialisation.

What are the negative impact of Chinese manufacturing industry
Chinese industrial systems’ problems are mainly caused by its successes:
- The dedication has changed into desperation that single-mindedly pursues economic performance. GDP indicator and material achievements have emerged as the most important driver for growth. Such focus has caused significant environmental and societal issues.
- The dedication has also propelled the whole China to learn from the advanced nations through benchmarking, duplication and imitation. But Chinese manufacturing ignores its own problem solving capabilities, sometimes even fail to acknowledge that there were problems.
- Because of the fast growth and radical changes, Chinese industrial systems lack of systematic review and rationalised redesign. Lack of interactions between industry and academia fail to integrate good practices into systems or processes.

Inspirations from Chinese Industrialisation
We propose that the evolution of Chinese manufacturing can provide inspiration and insights to the POM discipline and community. In particular it highlights the following interesting trends:

New industrial systems:
- Transformation: a major POM task may be to transform from the current “design - operation - improvement” process towards a more radical design and reconfiguration one.
- The boundaries have been changed: it requires not only input-output transformation and value-creation systems, but also industrial ecosystems that enable value-creation system to be easily reconfigured.
- New perspectives: the individualistic corporation/firm view is no longer enough; what we need is a holistic, ecosystem perspective that takes into account of stakeholders in the whole community - clusters, regions, nations, and the whole world.
Can existing thinking cope with the future requirements?
- We need to adopt new industrial design principle: not only competitive advantages but also more “resource based view” orientation – by more appreciating the intrinsic value embedded within the resource and strategically cascading its full potentials – new RBV 2.0.
- Industrial symbiosis and circular economy may provide a better model for POM
- Constructive ambiguity: learning from the Chinese government in how it directed China and Chinese manufacturing, a Yin Yang thinking inspired strategy may enable us to navigate the ever changing and ever complex world of the future.

Inspiration for management discipline may include the following:
- Adopt a holistic/ecosystem perspective when seeking solutions to management current challenges, as the world is becoming more and more connected, a form based individualistic view may no longer be sufficient as manufacturing is becoming ever complex effort of collaboration.
- Strategic ambidexterity: learn to adopt the Yin-Yang thinking, particularly in the form of balancing seemingly opposite forces dynamically can be a very powerful management tool.
- Chinese innovation models, such as Alibaba and Xiaomi, may offer solutions to liberate and leverage current resource constrains and inspire management research community.

Conclusions
It can be recognised the key characteristics of Chinese manufacturing systems and operations management as “Quick and Dirty”. The quick response and fast reconfiguration of social resources into industrial systems are the strengths. But the dirty operations cause serious wastes, pollutions, and damages to the society and the world. For China and the rest of the emerging economies to improve and live the Western way of life is clearly not sustainable. Even though China has achieved incredible growth in its economy, it was primarily based on a low wage, export driven model, at the cost of deprivation and degradation of the environment. Today China stands at a crossroad. To avoid any disasters going forward it needs to change its goal from only seeking short-term economic growth and profit to a more sustainable form.

Chinese manufacturing at a tipping point. Clearly the current Chinese industrial systems cannot cope with the future requirements. The profit driven growth focus needs to be transformed to high value added manufacturing. Besides the manufacturers, all other key stakeholders must also participate to enable the transformation. Government agencies need to support and direct manufacturing towards a sustainable and environmentally friendly system; consumers need to be educated with the awareness and supported by the manufacturers to ensure the products are consumed efficiently throughout its life cycle.

Finding a solution for China may help the rest of the developing nations, as well as helping the entire earth to restore its original balance. As it is no longer a problem that China needs to solve on its own. If the environmental concerns (air pollution, global warming, water supply just to name a few) as well as social issues won’t be given enough attention and addressed effectively in the near future, soon the rest of the world would suffer the dire consequences together with China.

Is the current Chinese industrial systems can cope with the future requirements? No, of course! However, it is no longer a Chinese problem, but it has emerged as the whole human beings’ challenges. We need to face it together.
Acknowledgement
This paper is a long-term research outcome. During the time, we received many supports from both internal research centres and educational programmes at IfM and many collaborators in China, especially Zhejiang University Management School and our joint research centre there. Most recently, our research has also received the European 7th Framework Programme research grant – Europe-China High Value Engineering Network (EC-HVEN 295130). We are also grateful for the great contribution and assistance given to us so generously by our friends from the industry.

Does Logistics Clustering Promote Regional Economic Growth? 
The Case of China’s Yangtze River Economic Belt

Abstract 

This paper analyzes the mechanism of how logistics clustering promotes the regional economic growth in China’s Yangtze River Economic Belt. Based the panel data of 2000-2016, the author empirically studied the spatial heterogeneity of logistics clusters and their positive effects on the regional economic growth by introducing the location entropy index into Cobb-Douglas production function. The results show that logistics clustering can significantly promote the regional economic development, but there is spatial differences between the three sub-regions in the Yangtze River Economic Belt. 

Keywords: Yangtze River Economic Belt, Logistics clusters, Regional economic growth 

Introduction 

In recent years, the importance of clustering of industrial activities to regional economic growth is well recognized by researchers following Marshall’s industrial cluster theory (Chhetri et al., 2014; Rivera et al., 2016; Kumar et al., 2017; Hylton and Ross, 2018). According to Porter (1980), industry cluster is defined as geographic concentrations of interconnected companies and institutions in a particular field, which compete and cooperate. Sheffi (2012) pointed out that logistics cluster is a specific type of industrial cluster, which refers to the geographical concentration of: (i) firms offering logistics services, such as third party logistics service providers (3PLs), transportation carriers, warehousing companies and forwarders, (ii) the logistics functions of manufacturers and retailers, such as the distribution operations of retailers, manufacturers and distributors, and (iii) companies with logistics intensive operations (such as automobile manufacturers or bulk commodities distributors) for whom logistics is a large part of the cost (Sheffi, 2012). 

Both Kadokawa (2011) and Rivera et al. (2014) illustrated the competitive advantage and network benefits of logistics clusters to the regional economic and industrial development. According to Kadokawa (2011), geographic concentration of logistics firms can have benefits through external and internal economies of scale and scope
(Kadokawa, 2011). Other benefits of logistics clusters include natural resource endowment, stable local demand and market size, rent opportunities and other opportunities such as knowledge sharing, greater specialization and supplier competition (Rosenthal and Strange, 2004; Van den Heuvel et al., 2014; Hylton and Ross, 2018).

Despite the positive evidence gained, previous studies lacked detailed examination of the mechanisms through which logistics clusters promote regional economic growth. Moreover, previous studies are largely based on developed countries and lacked enough focus on whether regional economic growth of emerging economies will also benefit from logistics clusters, given that there are major differences between developed countries in terms of infrastructure, technology development, skills level, and policy and regulations.

After 40 years of reform and opening up, China has made significant achievements in its social-economic development. Due to governmental policy support and increasing investment in infrastructures of modern logistics industry, logistics clustering is becoming an emerging phenomenon in China. However, there still a paucity of research examined how logistics clusters will benefit the regional economic growth. Questions remain to be answered: Does logistics clusters promote the regional economic growth? Are there spatial differences in different regions? And what are the possible reasons for these differences? This research attempts to answer the above questions and to provide recommendations to policy-makers and practitioners for better development of logistics cluster.

The main contribution of this paper is to examine the macro level mechanism of logistics clustering in promoting the regional economic growth in China. This finds of this paper will also help future researchers to better understand the logistics clustering in other national contexts.

**Literature review**

Previous research on the formation of logistics clusters is largely carried out on the basis of the framework of industrial cluster theory (1920). For example, Li (2007) emphasized the importance of trust mechanism in promoting logistics clusters. The author suggests that trust mechanism is an important driving force to promote logistics clusters. Chhetri et al. (2014) analyzed the impact of labor factors on the development of logistics clusters. The research shows significant spatial clustering of logistics employment in the western and southern corridors of Melbourne, associated spatially with manufacturing, service industry and retail hubs in those areas.

One of the important focuses of previous research has been the influence of logistics clusters on the economic growth. For instance, Rubbén et al. (2013) analysed the impetus of the logistics cluster on the economic growth of Arogon region in Spain using the input-output method. Rivera et al. (2014) analyzed the impact of logistics cluster on logistics industry development in the US. The study found that the spatial agglomeration of logistics industry in the US had a gradual upward trend, and accompanied with an increase in employment, a decrease in total cost of social logistics, a higher level of logistics services and a faster coordination of supply chains, thus promoting the development of logistics industry in the US. Kumar et al. (2017) studied the marginal contribution of logistics clustering to the regional economic growth in the US by taking advantage of spatial econometric model. The results show that logistics clustering has a positive impact on the regional economic growth and the employment promotion in the US. Hylton and
Ross (2018) further demonstrated the two-way synergistic growth relationship between logistics clustering and the regional economic growth by using data sets at the U.S. Postal Code Level.

There are a rising number of studies examining the characteristics of logistics clustering in China. For instance, Zhong (2011) analysed the logistics cluster degree of 31 provinces and municipalities in China by using the location entropy theory. The results show that there is a strong spatial correlation between China’s logistics clusters in provinces and regions. Similarly, Xie et al. (2015) used the method of location entropy and spatial autocorrelation to analyze the spatial and temporal evolution characteristics of China’s logistics clusters. The results show that China’s logistics industry generally presents a trend of agglomerative development, with strong spatial autocorrelation and obvious spatial heterogeneity. Xu and Fang (2018) empirically tested the spatial spillover effect of logistics clusters on China’s regional economic growth and its spatial difference by using spatial econometric model. The results show that the spillover effect of logistics cluster on the economic development in central China is the greatest, followed by Eastern China, but negative spillover effect was found in Western China.

Despite the research effort in the existing studies there are still major gaps in the literature. First, modern logistics is a productive service industry with high product liquidity, which means that logistics clusters have obvious spatial spillover effect, which is less focused by the previous study. Second, the impact of logistics clustering on the regional economic growth should be reflected by a range of indicators of regional economic growth, but most of the existing studies were carried out from a single indicator, and there are few studies focused on a comprehensive set of indicators of the regional economic growth. Third, the previous research mostly focused on the national or provincial level and there is a lack of research focusing on provinces and cities in a specific region.

Based on the panel data of 11 provinces and cities in China’s Yangtze River Economic Belt (which is one of the most important economic development regions in China) from 2000 to 2016, this paper analyses the promoting role of logistics clusters on the regional economic growth and its spatial differences through econometric modelling.

**Research framework and methods**

*Mechanisms of logistics clustering in promoting the regional economic growth*

Nowadays, logistics industry is an important part of modern supply chains and the regional economy. The operation of logistics is typically cross-region and cross-industry. The development of logistics cluster is influenced by many factors such as resource endowment, geographical location, leading industry, economic structure, economic policy, government support, and logistics infrastructure. Logistics clusters can promote the regional economic growth by improving the efficiency of regional economic operation, promoting the development of related industries, optimizing regional industrial structure, and generating spatial spillover effect. Based on the extant literature review, the potential role of logistics clusters in the regional economic growth is shown in Figure 1.

Previous literatures (e.g., Liang, 2015; Shu, 2014; Tao, 2017; Rivera et al., 2014) found that the economies of scale and cost-saving effects brought about by logistics clustering can drive the micro-indicators (such as, manufacturing value added, regional...
industrial productivity, manufacturing labour productivity, total factor productivity, logistics industry efficiency) of regional economic development into a benign direction, so as to optimize the micro-foundation of the regional economy and improve the efficiency of regional economic activities. In addition, logistics clustering can also promote the effective flow of regional economic resources, and optimize the allocation of regional logistics resources, as well as improve the efficiency of logistics industry (Yu and Wu, 2010; Chen and Zhang, 2018).

Selection of evaluation indicators of logistics clusters

The literature suggests that the most common approaches used to measure the degree of industrial clustering include Industry Concentration Index (ICI), Herfindahl-Hirschman Index (HHI), Location Quotient (LQ), Spatial Gini Coefficient (SGC), Ellison–Glaeser index (EG). These approaches have its advantages and disadvantages (Rivera, 2014; Chhetri, 2014; Cerina and Mureddu, 2014; Cui, 2017; Kumar, 2017; Abushaikha, 2018). In consideration of the characteristics of the logistics cluster, we choose LQ as the indicator to measure the degree of logistics clustering in China’s Yangtze River Economic Belt.

LQ was first proposed and applied to location analysis by Haggett (1965) and was since widely used in economic geography and regional economics. Because LQ is based on administrative units to measure the degree of spatial clustering of industrial development, its method of calculation is simple and the data needed is more available. Therefore, LQ is considered as more suitable to measure the degree of regional logistics clustering. LQ is defined as:

\[ LQ_i = \frac{e_i}{E} \times \frac{E_i}{E} \]  \hspace{2cm} (1)

Where, \( e_i \) is the employment number or the output of the logistics industry in region \( i \), \( e \) is the employment number or the output of all industries in region \( i \), \( E_i \) is the employment number or the output of logistics industry in a reference region (which

Figure 1. Potential role of logistics cluster in the regional economic growth
Econometric model construction

According to the classical economic theory, the influencing factors of total economic output include capital input, labor input, natural resources and technological conditions. Cobb-Douglas production function (expressed as $Y = AK^\alpha L^\beta$) is typically used to measure the total economic output. In order to further investigate the impact of logistics cluster on regional economic growth, we introduce the LQ (degree of logistics clustering) into the Cobb-Douglas production function on the basis of relevant research results (Pang and Liu, 2012; Rivera et al., 2014; Gong and Zhang, 2017). Therefore,

$$Y = AK^\alpha L^\beta LQ^\gamma$$

Where $Y$, $A$, $K$, $L$ and $LQ$ represent the total economic output ($Y$), natural resources and technological conditions ($A$), capital input ($K$), labour input ($L$) and logistics clustering ($LQ$), respectively. The parameters $\alpha$, $\beta$, and $\gamma$ represent the elasticity, so that $0 < \alpha, \beta, \gamma < 1$, $0 < \alpha + \beta + \gamma < 1$. By taking the natural logarithms on both sides of the formula (2), we get the formula (3):

$$\ln Y = \ln A + \alpha \ln K + \beta \ln L + \gamma \ln LQ$$

Assuming that natural resources and technological conditions remain unchanged in a short run, we can obtain the following econometric models:

Model I: $Y_{it} = \beta_0 + \beta_1 K_{it} + \beta_2 L_{it} + \beta_3 LQ_{it} + \varphi_{it}$

Model II: $\ln Y_{it} = \beta_0 + \beta_1 \ln K_{it} + \beta_2 \ln L_{it} + \beta_3 \ln LQ_{it} + \varphi_{it}$

In order to further investigate the difference of the impact of logistics cluster on regional economic growth in different sub-regions in the Yangtze River Economic Belt, we introduce dummy variables $D_1$, $D_2$ and $D_3$ into formula (5) and to obtain model III:

Model III: $\ln Y_{it} = \beta_0 + \beta_1 \ln K_{it} + \beta_2 \ln L_{it} + \beta_3 \ln LQ_{it} + \beta_4 D_1 \ln LQ_{it} + \beta_5 D_2 \ln LQ_{it} + \beta_6 D_3 \ln LQ_{it} + \varphi_{it}$

Where, $i$ denotes the upstream, middle and downstream area of the Yangtze River Economic Belt, $t$ denotes each period, $\beta$ is the coefficient to be estimated, and $\varphi$ is the error term; $D_1$ is the dummy variable, so that $D_1 = 1$ denotes the downstream area, $D_1 = 0$ denotes other areas; $D_2 = 1$ denotes the middle reaches area, $D_2 = 0$ denotes other areas; $D_3 = 1$ denotes the upstream area, $D_3 = 0$ denotes other areas.

Data analysis and results

The case of China’s Yangtze River Economic Belt

As part of China’s regional development strategies, Yangtze River Economic Belt is one of the largest regions needed coordinated development of regional economy, which covers 9 provinces and 2 metropolitans: Shanghai, Jiangsu, Zhejiang, Anhui, Jiangxi, Hubei, Hunan, Chongqing, Sichuan, Yunnan and Guizhou. Total area of the region is about 2.05 million square kilometres, which is more than a fifth of whole China. By the
end of 2016, the region had a population of 591.4 million, which accounted for 42.77% of the total Chinese population. The regional GDP was 3,351 trillion RMB, which accounted for 45.06% of the total Chinese GDP. The added value of logistics industry in the region was 1,366 billion RMB, which accounted for 41.32% of the total national value added of 3,306 billion RMB. The high value added of the logistics industry compared with the national value added suggests that the logistics industry in the region is hugely important.

Data source and data processing
To examine the logistics clustering effect and its impact on the regional economic development, the panel data is collected from the Statistical Yearbook of the 11 provinces and metropolitans in the region over 17 years from 2000 to 2016. The main variables included GDP (Y), total investment in fixed assets (K), total number of employees (L), and location quotient coefficient of logistics industry (LQ). In the analysis, we used employment number as the basis of calculating the LQ value. Moreover, in order to eliminate the influence of price factors, CPI index is used to adjust GDP and total fixed asset investment (see Table 1 for the descriptive statistics main variables).

Test Result
Eviews 9.0 software is used to process the data. F values of model I, model II and model III are tested respectively before choosing fixed-effect model or random-effect model for the panel data. The test results of F statistics of three models are respectively: F1(10, 173)=281.74, F2(10, 173)=309.62, F3(10, 170)=277.44, while the critical value of F statistics is F(10,173/170, 0.05)=6.46. Moreover, the Hausman’s test results show that the P values of the three models are all significant, thus indicating that the original hypothesis that individual effects are not related to explanatory variables is rejected at a significant level of 0.001. Based on the F-statistics and the Hausman’s test results, fixed-effect model was chosen for the parameter estimation. In addition, because the data set contains time and space in dimensions, there is potential problem of heteroscedasticity. Therefore, the White heteroscedasticity correction method is used in the least square regression , the estimated results of the model are shown in Table 2.

It can be seen from Table 2, all variables are significant for all three models, and suggesting there is no spurious regression. Regression results of model I suggest that logistics clustering (LQ) has significant impact on the regional economic growth (Y). Similarly, regression results of model II suggest that there is a significant positive correlation between logistics clustering (LnLQ) and the regional economic growth (LnY).

</tbody>
</table>
The regression results of model III suggests that the effect of logistics clustering on the economic growth of different areas – downstream, middle reaches and upstream – in the Yangtze River Economic Belt is not identical. According to the national statistics of China, downstream areas of Yantze River Economic Belt is economically most developed followed by the middle reaches area and then the upstream area. The results suggest that the differences in economic development of different sub-regions may have impact on the different promotion effects of logistics clustering on the economic development. As shown in Table 2, the regression coefficients of logistics clustering on regional economic growth in downstream, middle and upstream sub-regions are 0.329, 0.546, and -0.072, respectively. The positive regression coefficient of downstream and middle reaches area of the region indicate that logistics clustering in those sub-regions has a positive effect on the regional economic growth. The negative regression coefficient (although small in value) in upstream areas of Yangtze River Economic Belt indicates that logistics clustering in the upstream area did not promote the regional economic growth.

Robustness test
Robustness test was conducted by using the output of logistics industry instead of logistics employments to re-calculate the level of logistics clustering (LQ'), so that to test the stability of the regression results. As shown in Table 3, the regression results suggest that all coefficients are significant although at different significance levels with the original regression models, thus indicating that the results are generally stable. The regression results also shows that the logistics clustering calculated by replacing the number of logistics employments with the output of logistics industry has more significant impact on the regional economic growth (the regression coefficient increased from 0.187 to 0.466). However, there are some differences among sub-regions in terms of levels of significant impact on the regional economic growth.

The robust analysis suggests that due to different levels of economic development in sub-regions of the Yangtze River Economic Belt, the role of logistics clustering in promoting the regional economic growth is not the same. The logistics clustering (LQ') measured by logistics outputs in the developed sub-region (i.e., the downstream area) plays a more important role in promoting the regional economic growth. On the contrary, the logistics clustering measured by logistics outputs in the less developed sub-region (i.e., the middle reaches area) has weaker effects on the regional economic development. Furthermore, there is certain inhibitory effects of the logistics clustering in terms of logistics outputs in the least developed sub-region (i.e., the upstream area) on the regional economic growth.

**Conclusions and implications**
The existing literature lacked the empirical understanding of the relationship between logistics clustering and the regional economic development. In this study, we take China’s Yangtze River Economic Belt as an example to test the promotion effects of logistics clustering on the regional economic growth.

First, logistics clustering has a significant role in promoting the regional economic growth in the Yangtze River Economic Belt. However, there is spatial differences among sub-regions (i.e., upstream, middle reaches and downstream areas), which is consistent with Cerina and Mureddu (2014)’s research. The role of logistics clustering in promoting regional economic growth is not identical among sub-regions. One of the reasons behind such difference is the uneven economic development in those sub-regions. Generally speaking, logistics clustering (in terms of logistics employment) in the middle reaches area followed by the upstream area contribute most significantly to the regional economic growth. Such contributing role is much weaker in less developed sub-regions (i.e., upstream area) and even being negative.

Second, based on the robustness test, the logistics clustering (measured by logistics industry outputs) has shown a more significant impact on the regional economic growth, which indicates that industry clustering on the basis of value added has a greater impact on the regional economic growth than that of the logistics clustering in employment. Again, due to the uneven economic development among sub-regions in the Yangtze River Economic Belt, logistics clustering has shown differences in promoting the economic development of sub-regions. What we found is that logistics clustering in terms of logistics outputs in the less developed sub-region (i.e., the upstream area) has a negative effect on the regional economic growth.

These findings deserve attention from policy makers when promoting logistics clustering in different sub-regions. First, the economic contribution of logistics clustering needs to be recognized. Policy-makers should focus on strengthening clustered development of the logistics industry given that it has significant impact on the integration of economic activities.
and the optimization of logistics resources in the region, and subsequently on the regional economic growth. To enable logistics clustering, the accumulation and the investment in human capital, logistics infrastructure, ICT infrastructure, and improvement of the interconnectedness of roads within the region are essential.

Second, policy makers should also realize that contributions of logistics clustering differs across regions. According to Cerina and Mureddu (2014), industry clustering is not always good for the economic growth. For instance, the regional economic growth will not benefit from the logistics clustering from the upstream area of the Yangtze River Economic Belt. Because although logistics clustering improves sector efficiency and optimization, but it may reduce the total employment numbers and total investment in the wider society in that sub-region. Given this sub-region has lower average skills levels and is more labour intensive, and has a higher need of general investment rather than focused investment, the economic contribution of the logistics clustering will be reduced. Therefore, policy-makers should formulate suitable policies according to local conditions, local economic development levels, status of leading industries, geographical conditions, quality of logistics practitioners, and the technological level in the region.

Third, while providing policy support, the regional government should avoid over-intervention, since the logistics clustering would inevitably be realized by the participation of logistics enterprises. Therefore, direct administrative intervention should be minimized to optimize the business environment and to improve the engagement of logistics enterprises.

Abstract

The main objective of this study is investigate how the new model of coffee trade, known as Direct Trade Coffee has increased worldwide and how it has changed the supply chain in coffee trade. Through interviews by multiple-case method, the agents of supply chain coffee as producers, roasters and cafeterias demonstrated your perceptions in trade production, distribution and selling specialty coffee. The Transition Cost theory was used to understand how large the asymmetric information, opportunism and limited rationality impacts the supply chain value overall. This study is value to support the understanding of short and more fair coffee negotiate.

Keywords: Supply Chain; Direct Trade Coffee; International Trade

Introduction

In an increasingly dynamic and integrated economy, which information is constantly permeability in the agro-industry sectors, the informational symmetry and economic development of both producers and roasters are put in the agenda, requiring a rational and behavioral analysis of their agents. Factors such as negotiation, contracts and mutual relationship between sellers and buyers, begin to reconfigure the coffee production chain, peculiarly the specialty coffees (special or gourmet ones).
This article aims to demonstrate the new trend that has grown worldwide in the supply chain of specialty coffee market known as Direct Trade. This new model aims not only to shorten the supply chain’s coffee, but also seeks to increase the relationships between the agents since the coffee producer to the final consumer changing, in this way, the traditional supply chain’s coffee. Although studies about Direct Trade in coffee agribusiness have grown in the last decades, especially in the last few years linked to research on the Third Wave of Coffee, which is focused on specialty coffees, there are still, few studies that try to understand the supply chain of Direct Trade at coffee trade as a whole.

Therefore, this article sought to deepen an understanding the impression of this theme through face-to-face interviews with the agents involved in the coffee supply chain as producer and roasters and/or cafeterias in Brazil and abroad. It was evident through this research that Direct Trade is a trend in the specialty coffee market, but its similarity with the principles of coffee certification and requires further studies would be developed to consolidate the shortening of the coffee supply chain and optimize the aggregation of value of all links in the coffee chain.

Literature Review

Theoretical Background

Global coffee consumption has increased considerably in recent years. Brazil is the largest producer of coffee in the world and the second in consumption. A range of coffee varieties arises dynamically, requiring the coffee sector methods and actions aimed not only at increasing production but also at analysing the impacts these increases have on the environment, people and the economy (Silva, 2006).

The coffee certifications as FairTrade, UTZ Certified, RainForest Alliance Certified appear with the objective to certifying producers that, throughout the production, have to fulfil environmental and social standards, characterizing to be a specialty coffee, although this is not an affirmative condition that they will be able to obtain a quality coffee (Pinheiro, Nagai, 2014).

On the other hand, the demand for specialty coffees has altered the dynamics of the global market, as buyers are investing directly in coffee growers, taking risk instead of facing future market price volatility. Certified coffees have been a trend in recent decades and the causes of their growth are the benefits that certifications bring. High prices paid to coffee growers, openings to new markets, maximization of production longevity and valorization of labor routines are the "flagship" of Certifications (Guimaraes, 2016).

In order to optimize the process between growers and roasters, a new model of coffee bargaining arises, with the objective of paying a "real fair price" to the coffee grower in the acquisition of a higher quality coffee. Direct Trade is a business model that aims at a direct trade relationship between the coffee grower and / or roasters, eliminating the so-called "negotiators", reducing operating costs and retaining the coffee farmer to the buyer (Counterculture Coffee, 2015).

Thus, in the coffee market, paradoxically, there is a great demand for the consumption of specialty coffees, but the supply of quality grains which are produced in a sustainable manner is below the conventional market, despite its consumption of rapid growth, especially in developed countries.

The Waves Coffee

Direct Trade is most faced to specialty (and gourmet) coffees and also, presents in part, as an extension of coffee certification as FairTrade, RainForest and UTZ Certified, etc. but
works in a short supply chain and more direct relationship between agents, as it is concerned with offering superior quality coffees, unique and exclusive, with the characteristic soft drink with high added value, with ‘traceability’ and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization local infrastructure and the community as a whole, with school construction, support for workers, empowerment of coffee growers, gender equality, among other actions that make up the premises of certifications. To clarify further the results, Borrella, Mataix and Carrasco-Gallego (2015) and Guimarães (2016), explain the Waves Coffee.

The first wave of coffee is attributed to the expressive increase and worldwide dissemination of beverage consumption, especially in the late nineteenth and early twentieth centuries. More specifically in the United States of America, this movement gained momentum with the Great Depression and World War II, requiring minimal time and effort in its preparation. (Reis, 2018; Guimarães, 2016).

The second wave arises when, introducing the new concepts of roasting, in order to reach certain beverage profiles and the consistency of the supply, as well as new notions of origin, recognizing that this, at country level, influenced the quality and some characteristics of the grains (Andrade et al., 2015; Guimarães, 2016).

The third wave appeared in the mid-90s, when only specialty coffees and grains of the Arabica species were used, as well as the vaporization of its numerous aromatic and flavor notes, highly influenced by its origin of production. Thus, coffee goes through a process of total “decommoditization”, being considered as a complex, exclusive and seasonal product and compared to other specialty products (Reis, 2018).

The Direct Trade as the State of the Art of Supply Chain Coffee

The traditional Supply Chain Management (SCM) has many agents which are linked each other in the whole chain. Mentzer et al. (2001), infers that SCM can be understand as “the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole” Mentzer et al. (2001).

Overview of Supply Chain

SUPPLIER ↔ INTERMEDIARY ↔ ORGANIZATION ↔ CUSTOMER

Figure 1 – The Supply Chain – Mentzer et al (2001), adapted.

Below, the figure 1 shows the complexity of SCM as a pipeline, proposed by Mentzer (2001). At this model it is clear that there are innumerable intermediary agents and in the coffee chain it is not different, being these intermediaries: cooperatives, associations, brokers, exporters, roasters and coffee shops.
Severins (2015) infers that the traditional supply chain of coffee typically contains seven levels: growing, harvesting, hulling, drying and packing, bulking, blending and roasting. The entire SCM coffee is further extended by several intermediaries, including global transporters as well as exporters and retailers.

The State of the Art of Direct Trade is how the whole chain is shorter and with this, the considerable reduction of costs with the intermediaries along the whole chain, which in turn, allows higher financial gains for the producers and coffee shops. For Badiyan-Eyford (2013), Direct Trade arises because of a strong tendency to offer quality coffees to the market with a close relationship between producers. For this type of trading, there are no pre-designed templates, nor standard terminology.

Direct Trade presents itself as a relationship of stability, trust and equality between the roaster / cafeteria and the producer (Brown, 2012), which is increasingly valued and highlighted in the marketing of the final product. The actors in this chain would thus share their knowledge and work together in a coordinated way in order to optimize the supply chain, increase the quality and supply of specialty grains or beans, as well as "empower" coffee growers and, above all, reduce costs along the chain.

Assumptions of Transaction Cost Economics
In order to obtain an analysis of transactions between agents within a business network, or more specifically, in order to develop this research on coffee agribusiness, we have the Transaction Cost Economics. Transaction Cost Economics, also known as ECT, was developed by Ronald Coase in 1937, when it was published in The Nature of the Firm (Langlois, Foss, 1999, Thielmann, 2013).

Silva Filho (2006) highlights the main factors in the transactions: (i) the limited rationality of agents, which prevents them from taking, over time, decisions that maximize well-being; (ii) the opportunistic behavior of the agents, which motivates them to act in order to obtain benefits at the expense of other agents with which they are related; (iii) the asymmetry of information, which implies unequal access of the agents to the information pertinent to the exchange made by them, preventing it from being given in the most advantageous manner from the point of view of society.

Methodology
For this research, it was characterized as qualitative with a descriptive-exploratory character and it was adopted the study of multiple cases, to understand the behaviors of the coffee agents that act in the direct form of commercialization and to explore what the risks and advantages in the relations between the agents (Labuschagne, 2003; Yin, 2014). In this way, an attempt was made to offer a description of the environment in which the agents are inserted and how their behaviors affect the structure of the chain of acquisition of coffee and the relationships with the coffee growers.

Case selection
Agents were chosen that act directly in the direct trade of coffee in each chain link. For this, a non-probabilistic sample was used as sampling (Yin, 2001). Sample convenience was used because, for Miles, Huberman and Saldãa (2013), such sampling is only targeted to agents that meet the requirements of the study in question. As this research aims to understand how agents act to reduce costs between buyers and sellers of coffees, known as chain intermediaries, seven agents in total were interviewed.

As it assumes that each agent via Direct Trade has a mutual relationship between each link in the chain, the focus on each was delimited in the search for possible asymmetries of information, opportunism of some agent or limited rationality of one or several agents. If any of these actions prevails between the negotiations, it will modify the structure and dynamics of direct trade, weaken mutual trust between the parties and strengthen opportunism.

Interviews
The interviews were semi-structured and have basic questions that are supported by theories and hypotheses that are interrelated to the research theme (Triviños, 1987, p.146). The interviews took place in Brazil and in the United States, among producers of specialty coffees, roasters and coffee shops.

The choice of the seven interviewees is justified by the following considerations: a) search of the perspectives of the agents participating in the governance structures in the coffee chain; b) the need to understand the practices of international agents; c) to confront or find "gaps" between what is said and practiced among the agents; d) the search for the design of a non-active agent in the direct trade of coffee. These interviews allowed the agents' visions to be intercalated, generating results (or lack thereof) that could correspond to the research objective in line with the theory of transaction costs.

Data collect
In this stage, Yin's (2001, p. 81) propositions that highlight how the interviewing skills for case studies: 21 questions were followed; knowing how to listen to the interviewee's positions, identifying the interviewee's keywords and effective components; to be flexible and make adaptations to better enjoy the moments of the interview; have extensive knowledge of the issues contained in the interview script and seek to be impartial during their performance.

Initially, contact was established with some coffee shops, roasters, both in Brazil and abroad, and coffee growers from the southern region of the State of Minas Gerais, in order to conduct the interviews. The interviews were recorded and later transcribed in the data analysis stage. In addition to the recordings, annotations of topics considered were taken, and the reductions were made from larger sentences to smaller sentences until reaching the main points of the research (Miles, Huberman and Saldãa, 2013).

There were seven interviews in all, with the managers, directors and coffee growers involved in the practice of Direct Trade Coffee. This stage was based on an elaborate
interview script, considering the theoretical propositions of the Transaction Cost Economy and its impacts within the coffee supply chain.

Data analysis
For the analysis of the interviews, content analysis was used. Bardin (1977) defines content analysis as being a cluster of interlocation analysis techniques, aiming to obtain, through systematic and objective techniques of exposing the content of the messages, the inference of knowledge regarding the conditions of production or receptivity of such messages.

This systematic should follow a sequence of procedures that cover pre-analysis, coding, categorization and inference. Thus, the data were compiled as follows: (i) Pre-analysis: Separation and identification of the interviewees; Separation by topic / subject from interviews; Capture of legend to identify the interviewees; (ii) Transcript of interviews; (iii) Encoding and categorization of interviewed agents: Organize and separate according to the subject of each respondent's related response - (Coffee producer = P; Roaster = T and C = Cafeteria <P1, P2, P3, P4, T1, C1, C2>); (v) Inference of the Thematic Analysis: Analyse the responses of the groups (intensity, frequency and meanings of the pertinent themes; (vi) Realization of the discussion of the results.

Findings
This research has revealed a number of important points about the relationships between agents in the supply chain via Direct Trade. Access to information and transparency in negotiations and contracts are vital for reducing information asymmetry and the opportunistic actions of agents outside of Direct Trade.

Another very important point is the need to demystify that Direct Trade is a direct purchase and sale action between producer and cafeteria (or roaster). There will always be an intermediary within the chain, whether it is an exporter for buyers from other countries or an internal transport company sale made within the producing country. Thus, the structure of Direct Trade is lean (figure 3), but does not completely eliminate the intermediates of the chain.

Figure 3 – Traditional versus Direct Trade Coffee Supply Chain - By Authors
The Institutional Environment, of the transactions and the behaviors of the agents
It was observed that the transactions between the agents are not clear when asked about the expectations advocated by agents. While coffee shops have argued that coffee growers receive direct attention from their sponsors, such as trainings, support and / or technical visits on their farms, whether semi-annually or annually, coffee growers, in turn, have explained that obtaining the quality of their coffees is an action derived from its own dedications and the correct management of the coffee, without, necessarily, the intervention of some agent of the roaster or cafeteria.

Limited Rationale
It was observed that all Direct Trade agents interviewed are intended to be rational about their assignments within the specialty coffee chain; but it was noted that this rationality is achieved in a non-integral way, that is, it proves to be a limited rationality, which for Williamson (1989), such rationality is an intrinsic behavior to agents. The rationality of the interviewee P2 demonstrates the limitation on the possibilities or perspectives proposed by the Interviewee T1. Although they seem simplistic perspectives on the same theme, they generate asymmetries of information in the structure of governance and loopholes so that opportunism arises and modifies the entire organizational environment.

Opportunism
It can be explained that the main opportunistic behaviors reported among coffee growers were: restriction of information, concentration of access to new markets (for coffee resale); high rates of logistic payment for the outflow of production (paid more, besides the necessary, for not having competition) and mystification of the export processes.

Asymmetry of Information
It was unanimous among the interviewees P1, P2, P3 and P4 that they were unaware of the practices adopted by the roasters or coffee shops, regarding technical visits and support in the production processes of the specialty coffees to be sold to them. This is due to the fact that, while roasters and international coffee shops are proposing to offer support (in different ways) to their peers, one can see how many coffee growers do not even know of the possibility of winning an extra prize in their coffees and, above all, increase the networks of transactions between people who offer assistance to the coffee management and the more widespread, increase the transactions with the agents of the post-harvest, which, in turn, increase the risks of opportunism in the relations.

Discussion
This research has brought significant contributions regarding the direct trade model of the direct trade model, which, in the coffee agribusiness, focused almost exclusively on the commercialization of specialty coffees, is still incipient its performance in the traditional market (commodity) or certified coffee, but in turn have shown an exponential growth in the last decades, requiring special attention to their growth.

Thus, this research identified by the theory of Transaction Cost Economics (ECT) the existing gaps, in this almost unprecedented chain of direct coffee trade, in whose organizational environment the coffee grower and roaster, because they are distinct, either in the rational model, in the geographic environment, lead to a discrepant informational asymmetry between these agents, making it clear that, while coffee shops focus on the quality of their coffees sold, coffee growers do not demonstrate knowledge about the various 'resources' made available by roasters in this segment.
The small coffee growers producing specialty coffees do not have certain information that would generate market advantages, since their rationalities are directed to the traditional coffee marketing model: 1) it produces; 2) benefits; 3) stock; 4) seeks buyers in the coffee market or sell to cooperatives; 5) sell coffee; 6) It pays the bills and what about is profit. This attitude offers the possibility of intermediaries accessing the chain and reselling specialty coffees to specific markets with a higher premium, but that is not (re) passed to the coffee grower, maintaining the same chain structure.

As for the increase in sales in the international market, it should be pointed out that in view of the difficulties reported by coffee growers in reaching the external market by themselves, as a small-medium producer, it is believed that in the domestic market, it is easier to negotiate prices, , etc., for two reasons: (1) the ease of language (communication); (2) the growing public interest in higher quality coffees (or better sensitization). The rationale for coffee export processes, as previously reported, corroborated (or corroborated), to a certain extent, the growth of the domestic market in the consumption of specialty coffees.

**Conclusions**

Although studies on Direct Trade in coffee agribusiness have grown in recent decades, especially in the last few years linked to research on the Third Wave, which is focused on specialty coffees, there are few studies that seek to understand this chain of direct trade as a whole.

In this way, it is possible to infer, albeit prematurely, that Direct Trade is an extension of certification, concerned with offering superior, unique and exclusive quality coffees with the characteristic soft drink with high added value, traceability and sustainability, while certifications are concerned with numerous facets within the organizational structure of the coffee chain, such as training to improve coffee quality, optimization of local infrastructure and the community as a whole, building schools, support workers, empowering coffee farmers, equality between genders, among other.

In this way, this work can be glimpsed by the theory of the Economy of the Costs of Transaction in which Direct Trade allows a structure of governance leaner than the traditional coffee agribusiness chain; reduces opportunistic actions when the information asymmetry is small, that is, when there is an efficient bilateral relationship and broadening the rationality of the agents regarding the possibilities of gains among the agents.

Operations in the Public Sector
Can lean management practices in the operations of the universities lead to sustainability?

Dr. Niladri Palit (Niladri.Palit@gcu.ac.uk)  
Glasgow School of Business and Society, Glasgow Caledonian University, UK

Abstract

Sustainability in the educational curriculum of the higher education providers like universities has received considerable attention due to its importance in practice in most of the industry sectors. However, when it comes to having a sustainable operation in universities, limited evidence is found in both theory and practice. The few research papers that addressed the issue, did not quite address the underlying barriers by proposing effective solutions. This research aims to propose solutions to this problem by examining if lean practices would be able to facilitate environmental sustainability in the universities’ operation in the UK.

Key Words: Sustainable University, Lean Management, Barriers to Sustainability

Introduction

Sustainability has been a buzzword in practice for the last couple of decades. It has also been a matter of academic interest to most of the universities in modern times. There has been a considerable shift in sustainable development in the last two three decades due to the increasing importance of policies to promote sustainability (Jorge et al., 2015). Yet, the universities often struggle to manage their sustainability targets in their own operations especially in the case of environmental sustainability. This has been documented in several studies from different parts of the world including studies in Portugal (Aleixo et al., 2018), in the UK (Robinson et al., 2018), in Poland (Kogcielniak, 2013), in Lithuania (Dagiliute and Liobikiene, 2015). The present study focuses on the UK higher education providers and to the issues on the environmental sustainability of the triple bottom line framework. The rational for this is the documented concerns regarding the performance of many of the university’s environmental sustainability issues based on People and Planet League table. Following the Data Energy Certificate release in 2017, a study was followed to identify the potential savings opportunities in the UK higher education sector. A potential £15.6 million savings opportunity was identified (Hawkins, 2017). In a report published in the Guardian (2016), only 25% of the UK based university campuses are on course to meet the carbon reduction targets by 2020 (Lightfoot, 2016). The author further mentioned-“UK universities are helping lead the world on environmental research – but when it comes to their own back yard they appear to be falling behind.”
This leads to the question of why the higher education sector falls behind their environmental performance. This has been mentioned in the literature including Disterheft et al. (2012), Netaji and Netaji (2013), Kogcielniak, (2014), Berchin et al. (2017), and Akins et al. (2019) where the authors highlighted the presence of certain challenges/barriers to sustainable approaches in the form some case studies. These studies highlighted the importance of cultural change, but these studies did not highlight the type of change required and the stages involved in operational improvements to achieve those changes. Some authors tried some assessment tools to offer some practical insight regarding assessment and reporting of sustainability performances, but these have limitations in terms of addressing some of the basic barriers including awareness (Lauder et al., 2015). Moreover, there has been limited evidence on how to address those challenges against achieving those sustainability targets in the university set up by improving the universities’ operations. Adoption of some of the continuous improvement techniques from operations management such as lean management has been found to be improving the sustainable operations in practice in many sectors including manufacturing (Piercy and Rich, 2015). Yet, limited evidence is available when it comes to operations in universities. On this backdrop, “this research aims at exploring and examination” if lean management principles can be implemented in universities operations to facilitate the sustainability targets to be achieved by addressing the barriers. This research will focus on the operations of the universities in Scotland in the first phase with an extension to the UK wide research in the subsequent phase. The objectives are

**Objective 1.** To examine the barriers to achieving sustainability goals in universities operations in the UK.

**Objective 2.** To examine if the lean management principles can be applied to address those barriers and improve performance.

**Literature review/Research backdrop**

There is a growing body of literature on sustainability in the universities and other higher education institutions. This section presents an appraisal of extant literature considered relevant to this study, highlighting key themes and theoretical propositions for this research. A conceptual framework is also presented.

**Sustainability Tools**

A literature review shows some of the themes in the research involving sustainability issues such as tools used for sustainability measures (Li et al., 2018; Marrone et al., 2018; Algamdi et al., 2017; Berzosa 2017; Jorge et al., 2015; Lozano, 2011; Lozano, 2006), application of environmental management system (EMS) (Disterheft et al., 2012; Clarke and Kouri, 2009). Research in presenting the tools used for sustainability performance reporting has been considerably popular in the last 10-15 years. Lauder et al. (2015) presented a review of the Green Metric of the university ranking that is used for sustainability reporting in the university. In early research, Lozano (2006) presented a comparative study among the different tools used to assess and report the sustainability efforts by the universities along with some proposed modification in some of the tools such as Global Reporting Initiative (GRI), and Graphical Assessment of Sustainability in Universities (GASU). The author further extended the study to incorporate the GASU to compare the performance of the 12 universities’ sustainability performance (Lozano, 2011). Townsend and Barrett (2015) used Environmentally Extended Input Output Analysis (EEIOA) in their empirical study based on the University of Leeds. The authors found this tool to be allowing the performance
comparison between the universities. Jorge et al. (2015) proposed a multi-item quantitative tool which can be used for cross-university comparison. Alghamdi et al. (2017) examined 12 tools in sustainability in universities. Berzosa et al. (2017) conducted a comparative study with the application and application of multiple tools of sustainability applied for universities. Li et al. (2018) used the Analytical Hierarchy Process approach to propose prioritisation of the sustainability indicators in an Australian University. Marone et al. (2018) analysed and investigated the strengths and weaknesses of one of the popularly used index, the green metric index. Leon (2018) used Neighbourhood Evaluation for Sustainable Territories (NEST) tools for the environmental assessments of the University of the Basque County. Alshuwaikhat et al. (2018) proposed a model using the application of Geographical Information (GIS) tools to evaluate the sustainability related performance at the King Fahd University of Petroleum and Mineral. Alba-Hidalgo et al. (2018) proposed the definition/scope of environmental sustainability in the context of universities. The authors highlighted some of the characteristics of the tools that are used for this purpose such as STARS, SAQ (ULSF), AISHE, GASU, Green Report card, CSAF, AUA, STAUNCH, UI Green Metrics, CRUE, and USAT (MESA).

Alongside the sustainability performance reporting, the research on the application of Environmental Management System (EMS) has also been the topic of discussion in the literature. Clarke and Kouri (2009) discussed different campus EMS frameworks, their characteristics, and the drivers of implementation. Disterheft et al. (2012) conducted an empirical study on EMS development and implementation in universities across Europe. Velazquez et al. (2013) conducted a study on Sustainability Management System (SMS) implementation at the University of Sonora in Mexico to reduce the waste of water. Lo-Iacono-Ferreira et al. (2016) emphasized the importance of having an EMS for Ecological Footprint Assessment using Life Cycle Assessment. In a recent work by Omrecen et al. (2018), the authors presented a case study based on the implementation of climate strategy at the University of Gothenburg by the effective use of EMS. However, a limited insight was offered in these studies on the perceptions of the staffs and students. A study by Sammalisto et al. (2015) addressed this issue in a case study of a Swedish university. The authors addressed the perceptions of the staff members of the university on ISO14001 implementation. Other tools found such as Sustainability Management System.

Perception of Sustainability
Sammalisto et al. (2013) addressed the perceptions of the staff members by proposing a conceptual model. The author concluded with some insightful findings including variety in staff perceptions, and the importance of top management’s encouragement. The importance of top management support was also highlighted in the studies of Wright (2010), Wright and Horst (2013). Nejati and Nejati (2013) proposed a scale for capturing the student perception on sustainability in the universities. Sylvestre et al. (2014) conducted an empirical study to address the perceptions of the professors of Dalhousie University by the implementation of Q-method.

Barriers to Sustainability
Despite a considerable amount of research in sustainability reporting and the tools used for sustainability in the universities, the efforts to achieve sustainability in the universities often fall short. This is mainly due to the existence of some of the barriers. This has been highlighted in few studies including Wright (2009), Wright and Horst (2013), Kogcielniak (2014), Robinson et al. (2015), Disterheft et al. (2015), Dagiliute
and Liobikiene (2015), Leal Filho et al. (2017), Alexio et al. (2018), and Akins et al. (2019). The issues identified as barriers includes financial predicament (Wright, 2009; Wright and Horst, 2013; Aleixo et al., 2018), lack of awareness/weak acknowledgement (Wright, 2009; Dagiliute and Liobikiene, 2015; Leal Filho et al., 2017; Alba-Hidalgo et al., 2018; Akins et al., 2019), resistance to change (Wright, 2009), lack of leadership/management support (Wright and Horst, 2013; Kogcielniak, 2014; Leal Filho et al., 2017), type of approach adopted by policy makers/lack of support from policy makers (including Government) (Kogcielniak, 2014; Dagiliute and Liobikiene, 2015; Robinson et al., 2015; Leal Filho et al., 2017; Aleixo et al., 2018). In addition, authors including Vieira et al. (2018) discussed barriers to the EMS implementation in the university set up. Vieira et al. (2018) conducted the study in the Brazilian higher education sector.

One of the key internal issues has been identified as the barrier was the lack of top management support in some of the above studies in the last paragraph. A top-down approach to entail the goals and objectives of the sustainability has been recommended as a proposed requirement in the studies including Wright and Horst (2009), and Kogcielniak (2014). However, some counterintuitive evidence has also been documented such as Dagiliute and Liobikiene (2015) the existence of a top-down approach in their study in the Lituanian universities. The authors extended this as a possibly due to external barriers including government support and frequent policy changes. This has been highlighted in some other studies such as well to be having a significant impact on the clarity on the sustainability goals at the workplace among the higher education providers (Kogcielniak, 2014; Robinson et al., 2015; Leal Filho et al., 2017; Aleixo et al., 2018). In fact in the study by Robinson et al. (2015), the authors identified a need for setting a realistic and achievable carbon reduction target to be set in place.

There are certain limitations are in existence in the above studies such as:

- Many of the studies were conducted in specific geographic locations such as Canadian universities (Wright, 2009), Portuguese universities (Aleixo et al., 2018), Polish universities (Kogcielniak, 2014), Lithuanian universities (Dagiliute and Liobikiene, 2015), Brazilian universities (Vieira et al., 2018). Li et al. (2018) highlighted the geographical differences may have implications on the results to be changing form case to case.

- A need for a more exploratory investigation with a different group of stakeholders (Wright and Horst, 2013; Disterheft et al., 2015; Leal Filho et al., 2017);

- A need for identifying solutions/ways to overcome the barriers (Filho et al., 2018).

Earlier, this research highlighted the importance of the problems of poor environmental performance and related flak being drawn towards the universities in the UK. This has motivated the present research to aim at conducting an exploratory study and identifying if any proposed solution can be offered to address some of the barriers.

Problems of environmental sustainability can be improved by improving the practices of operations within the organisation. Some well known continuous improvement practices such as Lean operational practices have been identified as one of the key facilitators towards environmental sustainability in manufacturing sector in some early researches by Florida, (1996), and Corbett and Klassen (2005): “lean is green”. In fact, this mantra was the theme of a literature review of Garza-Reyes (2015). Authors including Hughes et al. (2012) highlighted the importance of lean practice with the focus on “doing more with less being used/spent”. Simpson and Power (2005) found the similarity between the practices that support lean manufacturing and environmental performance. This type of overlap between lean and sustainable practices has been
identified in the study of Cabral et al. (2012) where the author found the environmental waste reduction from lean tool implementation. According to Piercy and Rich (2015), one of the key limitations of the majority of these previous research topics was the focus on the relationship between lean practice and environmental sustainability only. In their research, the authors showed far stretching benefits that could be derived from lean practice towards sustainability in the UK based manufacturing sector. In recent research by Halldosson et al. (2018) reiterated the potential for integrating the principles of lean management and sustainability initiatives. The authors further supported the findings of Piercy and Rich (2015) on the need for exploring the potential benefits of lean practices beyond environmental sustainability to other forms of sustainability that can be derived from the triple bottom line.

Despite its proven success in many other sectors including manufacturing, the application of lean management practice in higher education’s own operation has been quite limited. Thomas et al. (2015) argued that higher education institutions (HEI) in the UK are quite slower to adopt the lean practice and derive the necessary benefits. Balzer et al. (2014) highlighted some of the factors as a facilitator including institutional readiness, leadership, awareness, understanding, support, and a favourable culture or the associated changes towards it. Similar was the finding by Anthony et al. (2012) where the authors highlighted some additional critical success factors of successful implementation of lean six-sigma such as support from top management, effective communication, strategic and visionary leadership, and a favourable culture. This research has identified some of the similar key facilitators/success factors in the case of achieving sustainability by the universities. In fact, Balzer et al. (2014) highlighted based on some previous research by Balzer (2010), the amount of paper cost reduction up to 92% in facilities and management work orders in University of Central Oklahoma. Based on these observations and the growing concern in terms of league table performance and the follow up implications, our research focuses on the aim highlighted in the introduction section.

**Design/Methodology/Approach**

The objectives of this research aimed to understand the barriers of sustainability in the operations of the higher education sector in the UK. This was followed with the exploration and examination of some of the solutions using the concept of continuous improvement such as lean management techniques. According to Creswell (1998), when the phenomenon of interest is its early stage with a lack of understanding around the theories, qualitative exploration is more appropriate. On the contrary, the well defined phenomenon may render a need for the quantitative investigation. The research methods adopted in similar research are quite diverse including qualitative methods such as in-depth interviews (Wright, 2009; Wright and Horst, 2013), semi-structured interviews (Disterheft et al. 2015; Aleixo et al., 2018), and qualitative case study (Akins et al., 2019). In the study of Leal Filho et al. (2017) used survey methods to gather qualitative and quantitative data in respective phases to conduct a mixed method research study. Scondaruy data based research was also found in some literature including Robinson et al. (2015). To select an effective methodology for this study, a set of literature on methodological discussion in operations management and related fields such as supply chain management were referred including Meredith et al. (1989), Craighead et al. (2007), Boyer and Swink (2008), and Golicic and Davies (2012). The framework proposed by Meredith et al. (1989) (Please see fig 1.) was found to be the appropriate starting point for this research as it allowed the current research to cater the three elements of research paradigm: Ontology, Epistemology, and Methodology.
(Denzina and Lincon, 1994, Frankel et al., 2005). The vertical dimension of the framework represents the epistemological elements where as the other dimension explains how the reality exists (Meredith et al., 1989).

Although, the concepts of sustainability are not new, given the present research context, the concepts are relatively in its earlyy days (Jorge et al, 2015). The objectives of this research require an understanding of the way people perceive, behave and react to the changes that are brought about by the incorporation of the principles/strategies required to achieve sustainable goals. Thus, this research adopted qualitative methods. The intension of the researcher of the present research is to interpret people’s perception. Considering these elements, this research adopted semi-structured interviews with the university academics/non-academic staff members and the policy makers including the top management. In phase 1 of this study, the interviews will be conducted with the above mentioned participants from Scottish Universities. Then a preliminary analysis will be conducted. This is expected to be followed by the UK wide sampling.

![Figure 1 – Framework for research method (Source: Meredith et al. (1989))](image)

Relevance/Contribution
The literature review section of this research highlighted how the research about sustainability and lean management in the operation of the higher education sector is in
their early stage. Similar is the case in practice as well as highlighted in the form of documented problems with certain league table performance in the UK higher education sector. On this backdrop, the present research is expected to contribute to the theoretical knowledge especially identifying the barriers of achieving environmental sustainability and proposing some conceptual solutions with the help of lean management principles. Recent trends including plastic free society, requirements of less energy consumption in public sector premises, and less consumption of paper are some of the modern day challenges modern day universities face including the Scottish universities. Moreover, wider issues including challenges including a change in geopolitical changes, tighter budget, societal changes including poverty, and increasing tuition fee are also posing challenges in terms of the sustainable performance of the universities in the UK. However, often the universities do struggle to set out an optimal policy with respect to sustainability performance. Hence, the present research is expected to contribute to the generation of ideas to have an effective policy by having a more efficient operation in the universities for Scotland with a further expectation to generate future research ideas for UK wide.

**Discussions and Conclusions**

This research is expecting to find a similar set of barriers including lack of awareness, financial constraints, lack of stakeholder engagement, and resistance to changes. It is expected to be found that the lean management principles to be having a positive impact on achieving the sustainability targets of the university by addressing the barriers. There are some counter-intuitive results were shown in an earlier study by Rothenberg et al. (2001) in manufacturing set up where the authors found some negative relation between the lean practices and sustainability in certain particular cases. However, this research has shown a great deal of literature has found a positive relation between the implementation of lean practices and achieving sustainability in manufacturing. In fact, the authors including Anthony et al. (2012) even argued that the non-applicability of lean practices in a non-manufacturing sector like higher education is a misconception. Thus, this research is expecting to generate new ideas as a solution to overcome some of the barriers toward achieving environmental sustainability in the higher education sector in the UK.

A possible limitation would be some of the barriers of sustainability would be quite external in nature and proposing a solution would either require a longitudinal study over time. Another possible limitation that would emerge would be the applicability within the specific geographical situation. This problem has been highlighted in some of the research papers cited in the literature review. This study is expected to set the basic foundation solution approaches/concepts which could be extended in future research to offer more generalisable solutions. In addition, future research could also take into consideration the other dimensions triple bottom line i.e. social and economical sustainability.

**Acknowledgments**

The author would like to thank the two anonymous EUROMA reviewers of this article. They contributed with valuable feedbacks that are incorporated in this manuscript improving the quality of the final version of this paper. The author would like to thank Glasgow Caledonian University for awarding a research excellence grant which helped conducting this research.

A location model for cultural facilities based on spatial analysis

Abstract

Clusters of cultural facilities such as museums and galleries create synergies with positive results for the public. Public institutions are the main builders and operators of cultural facilities, and equity for residents is a major criterion in site selection. This study proposes to solve the public cultural facilities location problem using a spatial analysis based on the local Moran’s I statistic for efficiency and the gravity model for equity. This model provides an objective method to locate a cultural facility. Local governments can use this model to avoid unnecessary social conflicts that often occur in locating a cultural facility.

Keywords: Location model, Spatial information, Public cultural facilities

General instructions

With the remarkable growth of cultural tourism, cultural facilities have become high added-value assets that attract domestic and foreign tourists to a society. Compared to public service facilities like hospitals and schools, cultural facilities are visited by people of their own independent and free will. In this context, research on the locations of cultural facilities needs to consider different factors than that on general public facilities. Clusters of cultural facilities such as museums, art galleries, and cultural centers create synergies that have a positive effect on the public. Public institutions are the main builders and operators of cultural facilities, and equity for residents is a major criterion in site selection.

Most studies on the location-allocation of cultural facilities have focused on defining the factors that are taken into account (Shim, 2005; Park & Kim, 2009; Markusen & Gadwa, 2010; Kong, 2018). If mathematical modeling is developed on the basis of the factors defined in previous studies, it is possible to identify candidate locations more systematically and objectively. However, it is hard to find such research among the analytical studies on the locations of cultural facilities.

Since Alfred Weber’s study in 1909, a variety of mathematical location models have been developed (Brandeau & Chiu, 1989; Current et al., 1990). Efficiency and equity are the traditional priorities in a location problem for public facilities (McAllister, 1976;
Mayhew & Leonardi, 1982). The objective functions in these prior studies minimize the spatial distribution of facilities for equity and maximize the coverage of service demands for efficiency, under a given budget constraint. Some subsequent studies address the problem using an optimal location model with a minimum travel distance and maximum coverage area (Morrill & Symons, 1977; Smith et al., 2013). Khodaparasti et al. (2016) suggest a more realistic measure of equity based on the Gini coefficient of the Lorenz curve and use data envelopment analysis to find an alternative with high efficiency, small inputs, and great outputs. These previous studies do not consider the complicated interactions between the demand and the candidate locations. Thus, they cannot consider the cluster effect, which greatly increases the efficiency of a new cultural facility.

This study proposes using spatial analysis to solve the cultural facility location problem based on the local Moran’s I statistic for efficiency (Anselin, 1995; Yuan et al., 2018) and the gravity model formula for equity (Guagliardo, 2004; Xing et al., 2018). The local Moran’s I statistic measures the correlations of candidate locations with various demand levels, which are then used to determine their cluster levels with a statistical test. The gravity formula is used to capture the degrees of alienation for candidate locations, which depends on how far away a location is from existing cultural facilities based on accessibility.

When a cultural facility is located in an area in which similar facilities are already situated and there is or will be a strong cultural image, it is reasonable to expect that such a facility leads local culture and produces a neighborhood ripple effect through interaction with the existent facilities. If a P-median model is applied to minimize travel cost, it is possible to define a factory site or a commercial district as a final candidate. In this case, the location of a cultural facility is unlikely to cause any economic or cultural ripple effect. To measure the location equity of cultural facilities, it is possible to use the Coverage model. However, this model fails to provide information on the degree of relative inequality and tries to get closest to the point with the longest demand, meaning that the demanders living in the center can be isolated. Given these aspects, the local Moran’s I (Anselin, 1995; Builes-Jaramillo & Lotero, 2018) and Gravity model (Joseph & Bantock, 1982; Guagliardo, 2004; Kiran et al., 2018), can become good alternatives to classical location models because they enable analyzing spatial information to allocate a cultural facility location.

To identify the optimal location for a cultural facility, this study proposes an optimal location model with a bi-criteria objective function that is capable of measuring facility agglomeration with the use of the local Moran’s I model and regional equity with the use of the Gravity model. The optimal location of this model is drawn by the Pareto optimal set (Kalyanmoy, 2001; Cheaitou et al., 2018) and the Top-K (Chaudhuri & Gravano, 1999) algorithm.

To confirm the effectiveness of the proposed optimal location model, we measured the agglomeration and equity of cultural facilities for 85 public cultural facilities (i.e., museums, art museums, art centers, local culture centers, and culture houses) in 424 districts in Seoul, Korea based on data from the National Culture-based Facility Survey published by the Ministry of Culture, Sports and Tourism in 2017. In our analysis of Seoul’s 424 districts, we found areas where the agglomeration of facilities is valid and quantified the equity between the districts to derive optimal locations for new facilities.

**Literature review**

Most studies on the location of public facilities have focused on location models for hospitals considering efficiency and equity (Wang, 2012; Smith et al., 2013; Khodaparasti et al., 2016; Zhang et al., 2016). Location efficiency was measured with the P-median...
model and equity with the Coverage model. Smith et al. (2013) revealed that two objective functions had a trade-off relation with each other with the use of the P-median model and Coverage model when assessing optimal hospital locations. Based on the relative locations of population centers in any geographical area, some improvement of equity may be achieved with little loss of efficiency. Therefore, it was proved that this model made it possible to identify a point that satisfied both efficiency and equity.

For the efficiency of cultural facilities, influence is more important than size. It is likely that the influence of a cultural facility is connected to its neighboring facilities. A place in which similar facilities are gathered together can experience enhanced differentiation and uniqueness, and thereby find it easy to secure visitors. The local Moran’s I can analyze the agglomeration or distribution of similar facilities in a geographical area. Feng & Ji (2011) classified the commercial facilities located in Shanghai into 16 types and measured the agglomeration and distribution of each facility type with the use of the local Moran’s I. Their results showed that businesses that require interpersonal contact are concentrated in the interior of the city, while businesses that depend on heavy resources like transportation and construction are located at the outskirts. In addition, the local Moran’s I was applied to research on the spatial inconsistency between the distribution and potential demand of public facilities like medical facilities or bicycle facilities (Rybarczyk & Wu, 2010; Yin et al., 2018).

The Gravity model measures the potential accessibility of facilities to the local population in a particular area. To measure the distance between a facility and a demand point, a Euclidean distance is usually employed. However, recent studies introduced models that consider travel distance by vehicle or walking. These models can reflect more realistic accessibility than linear distance-based models (Chang & Liao, 2011). With the use of the Gravity model, the equity of 12 public facilities, including schools and parks, was analyzed. The results showed that public facilities were mainly distributed centrally and had high accessibility. This indicates that a non-central area experiences inequality in its geographical separation level. The analysis results indicate that national policies have paid more attention to the requirements of residents living in central areas and have ignored minor opinions until now (Tsou et al., 2005; Lou & Qi, 2009).

In reality, location-allocation decisions take various objectives including cost, accessibility, and demand into consideration. To design a model, it is possible to give a different weight value to each objective function depending on its significance and thereby produce different optimal locations. These optimal locations of the multi-objective function are identified in the form of a Pareto front. Since this method provides a set of optimal candidates, rather than a single optimal location, a decision-maker is able to select the most proper location according to subjective preference or quantitative decision criteria (Zhang et al., 2016; Neema & Ohgai, 2010).

Methodology
The notations are as follows.

Index

$h, i, j, q$: location units (districts or candidate districts for locating a new facility)

$k$: existing cultural facilities

Data
\( x_i \): number of existing cultural facilities in location \( i \)  
\( \bar{x} \): average number of existing cultural facilities in the area  
\( d_{ik} \): distance from location \( i \) to existing facility \( k \)  
\( v_k \): potential demand for existing facility \( k \)  
\( s_k \): capacity of existing facility \( k \)  
\( n \): number of all locations  
\( w_{ij} = \begin{cases} 1, & \text{if location } i \text{ and location } j \text{ are adjacent} \\ 0, & \text{otherwise} \end{cases} \)

In formula (1) below, \( I_i \) measures the efficiency of location \( i \). The formula is used to measure the proximity tendency of locations with similar cultural facilities. Note that \( w_{ij} \) becomes 1 if location \( i \) and location \( j \) are adjacent, and otherwise 0. In formula (2), \( A_i \) captures the equity of location \( i \). It measures the spatial accessibility of a location based on how closely located all cultural facilities are from the location. In formula (3) as a constraint, \( P_i \) is the p-value of the local Moran’s I of location \( i \). If the value is 0.05 or less, it is interpreted that the agglomeration level of the location is statistically significant at the level of 95\% (Lee et al., 2015). P-values for \( I_i \) statistics are calculated with the use of normal distribution. Formulas (4) and (5) are used to calculate the mean and variance for location \( i \), respectively. \( Z[I_i] \) statistics can be calculated in formula (6) (Anselin, 1995; Lee et al., 2015).

**Decision variables**  
\( I_i \): local Moran’s I index  
\( A_i \): equity level of location \( i \)  
\( P_i \): p-value of the correlation coefficient of location \( i \)

\[
\text{OBJ1: Max. } I_i = \frac{\sum_{j \neq i} w_{ij} (x_j - \bar{x})}{\sqrt{\sum_{j \neq i} (x_j - \bar{x})^2}} \quad \forall i, \quad (1)
\]

\[
\text{OBJ2: Min. } A_i = \sum_k \frac{S_k}{d_{ik} v_k} \quad (2)
\]

s.t.
\[
P_i \leq 0.05 \quad \forall i, \quad (3)
\]

\[
E[I_i] = \frac{\sum_{j \neq i} w_{ij}}{n-1} \quad \forall i, \quad (4)
\]

\[
V[I_i] = \frac{w_{(2)} (n-b^2)}{n-1} + \frac{2w_{kk} (2b^2-n)}{(n-1)(n-2)} - \frac{w_i^2}{(n-1)^2} \quad \forall i, \quad (5)
\]

\[
Z[I_i] = \frac{I_i - E[I_i]}{\sqrt{V[I_i]}} \quad \forall i, \quad (6)
\]
with \( b_2 = m_4 / m_2^2 \), \( m_4 = \sum z_i^4 / n \) as the fourth moment, \( w_{i(2)} = \sum_{j \neq i} w_{ij}^2 \), and
\[
2w_{i(qh)} = \sum_q \sum_{h \neq i} w_{iq}w_{ih}h \neq i, q \neq i.
\]

A solution of a multi-objective model can be drawn with the dominance concept. If the location \( X^{(1)} \) is better for all objective functions than \( X^{(2)} \) or is strictly better for at least one objective function, it is fair to say that \( X^{(1)} \) dominates \( X^{(2)} \). In the multi-objective model, the Top-K selection query is the algorithm that determines the order of priority of the Pareto optimal set. This algorithm makes the Pareto optimal set arrayed by the order of locations closest to the objective function (Chaudhuri & Gravano, 1999).

**Experimental analysis**

The public cultural facilities used in this study are 85 public cultural facilities in Seoul that are listed in the National Culture-based Facility Survey published by the Ministry of Culture, Sports and Tourism in 2017. They consist of museums, art museums, art centers, local culture centers, and culture houses. The types of public cultural facilities in Seoul, their positions, and their sizes, which are all provided by the National Culture-based Facility Survey, were used for the analysis. In Seoul, there are 424 districts of administration. The maps and coordinates of the Seoul administrative districts were offered by Statistics Korea in the format of shapefiles. In terms of the population in each district, the 2018 demographic statistic data of Statistics Korea was used.

For the local Moran’s \( I \) analysis, a neighboring area was defined as an area that shares a boundary at a 2.5 km radius from the center of the administration. Table 1 shows the 18 districts that have a statistically significant agglomeration of cultural facilities among the 424 districts of administration. \( I_i \) statistics are recommended to be analyzed with the result of standardization. This is because it is more accurate to compare relative agglomeration by estimating the \( I_i \) value of frequency distribution, rather than using its absolute value, and because the \( Z[I] \) value makes it possible to make clear interpretations in terms of statistical significance (Lee et al., 2015).

To find optimal locations from the bi-criteria function, this study extracts a Pareto optimal set and uses Top-K to list the locations in the Pareto optimal set by the order of solutions closest to the ideal point. The solution results are presented in Figure 1. As shown in Figure 1, the four solutions identified are placed at the very front of the graph and dominate other solutions.

Figure 2 below illustrates part of the results. The left and right figures show the distribution of existing cultural facilities in Seoul and the four candidate locations color-coded by rank, respectively. The district with ID 1101061 selected as the optimal location has public facilities located far from its center, low equity, and public cultural facilities established in its neighboring districts. Therefore, it is found that the district is the best in terms of residents’ equity and interaction with neighboring facilities.
Conclusion
This study proposed an optimal location model for cultural facilities that addresses their social roles in various fields, including urban regeneration and welfare. Given that recent studies on locations of cultural facilities mostly focused on defining the main factors, this study, which proposed a mathematical model in the consensus of quantitative research results, contributed to widening the range of research on the locations of cultural facilities. A quantitative approach based on a mathematical model can ensure the clarity and objectivity of the analysis and shorten decision-making times. In addition, since it takes the distribution of existing facilities into account, it is likely to complement the administrative system of the present government that focuses on the construction of new
facilities. The location models proposed in previous studies made use of multi-objective functions to find optimal locations and thereby identified a Pareto optimal set to gain a set of flat solutions. The model proposed in this study used Top-K, a type of scoring algorithm, to make the solutions arrayed by the ranking of the solutions close to the objective function, and thereby aimed to provide additional useful information to a final decision-maker.

The location model proposed in this study can be used for the analysis of various kinds of locations other than for cultural facilities. For example, to find a proper agricultural plot, this model can identify a district that has a spatial agglomeration of the same crops and high accessibility to sales districts. It is possible to infer that a place with high agglomeration is equipped with the proper climate and soil conditions for the crops, and high accessibility to sales places can save on the cost of transporting agricultural products.

The proposed model can measure the efficiency of a location and its equity on the basis of accessibility in consideration of facility relations. In follow-up research, land price and proximity to neighboring tourist attractions will be additionally considered. Most public facilities are constructed within limited budgets, meaning that land price can become a critical variable. If there are famous tourist attractions around cultural facilities, it will likely increase visits to the cultural facilities and establish a strategy of urban development in connection with the tourist sites.

Abstract

The digital revolution will significantly transform organisations, their strategies, processes and needed competencies. As the central German provider for e-recruiting in the public sector, the online job portal Interamt provides a unique database that documents the current personnel requirements of public institutions. We summarise a snapshot of current digitalisation-related recruitment in Germany by applying text mining algorithms and statistical analyses to 800 web-crawled job postings. Our results show that public institutions are not recruiting next-generation IT experts but rather focus on current, more modest digitalisation steps. We recommend directions for further research and job market analyses.

Keywords: Job Market, Text Mining, Public Service Operations Management

Introduction

Public sector operations are massively challenged by the digitalisation. New products and services have to be developed and new expectations from citizens and organisations arise (Dunleavy et al., 2006). The management of change and transformation are of major importance, including process management and technological innovation (Benner and Tushman, 2003). Many jobs through all industries will be significantly transformed or replaced by digital technologies soon. Frey and Osborne (2017) did not specifically focus on the public sector, but summarise for the overall economy that 47% of all jobs in the USA could be replaced by intelligent robots or software in the next 10 to 20 years. This development is also rapidly increasing the demand for highly qualified work. But there are also many chances connected to digitalisation. In the past years, especially organisations with in IT-intensive or highly competitive industries could benefit from the adoption of big data and analytics (Müller et al., 2018) as major elements of digitalisation. Digitalisation in the public sector is not only about performance and efficiency. Customer requirements and ways of contact between the citizens/customers and public institutions are also significantly changing (Lindgren et al., 2019).
Most of previous research focuses on the potential of digitalisation and on describing the future. We are taking a closer look on the current situation. The term digitalisation and its idea grew in the last decade (Dunleavy et al., 2006). We are taking a job market perspective to summarise current digitalisation trends and answer the following research question:

*Which conclusions can be drawn from analysing currently advertised positions in German public sector institutions regarding their digitalisation efforts?*

While parts of this article include topics from information systems research, it also contributes to the domain of public service operations management, which is a rather underrepresented research field (Radnor et al., 2016). Text mining as a method for big data analysis also represents an innovative and growing method for operations management research (Cohen, 2018; Guha and Kumar, 2018). We present the first large-scale analysis of public sector digitalisation jobs in Germany and thereby follow the literature about the resource-based view on organisations and their operations strategy (Coates and McDermott, 2002; Paiva et al., 2008). We are building theory about the current personnel management of public organisations and their digital transformation strategies and contribute to current developments of evolving operations research in the era of big data (Feng and Shanthikumar, 2018).

**Research Background**

In public discussions nowadays, digitalisation could be replaced by the term *digital revolution*, comprising all aspects of transforming life and work into a more digital environment. In the academic literature, Legner et al. (2017) define it as follows:

“*While digitisation puts emphasis on digital technologies, the term digitalisation has been coined to describe the manifold sociotechnical phenomena and processes of adopting and using these technologies in broader individual, organisational, and societal contexts.*”

Researchers use various search terms when looking for digitalisation topics. Buer et al. (2018) selected terms like “industry 4.0”, “smart factory”, “cyber physical system”, “big data”. Most of these terms have a manufacturing context and will not be equally useful in the context of public administration.

The analysis of competencies related to information technology (IT) has a long history (Todd et al., 1995; Bassellier et al., 2001; Murawski and Bick, 2017). To use text mining technology though, has only been popular (and technically easier) for the last ten years. In the field of technology and processes, some job mining articles already analysed profiles. Müller et al. (2016) created competency profiles for business process management professionals and Kregel et al. (2019) for lean professionals. Examples for IT-related analyses are the comparison of business intelligence skills with big data skills (Debortoli et al., 2014) and the analysis of digital competencies in lean-related job profiles (Kregel and Ogonek, 2018). As the public sector is known to be text-intensive, research about text mining in this domain is particularly recommended (Hollibaugh, 2019).

Due to the sharp increase of available online data in recent years, the task of extracting the most relevant information has become a novel and evolving process. As a result of this data push, job portals and websites that are very domain-specific, have experienced an increase in scope, quality, and performance. Their advantage for both jobseekers and employers is the concentration of domain-specific jobs. Given the increasing relevance of the topic of digitalisation and respective skill shortages in public sector institutions, these data collections provide a great opportunity to study current digitalisation-related recruiting.
**Research Process and Methodology**

We crawled and analysed job advertisements from the website Interamt, which claims to be the largest job exchange platform for German public services. About 50,000 ads per year come from federal, state or local level institutions. Typical job providers are ministries, state offices, city governments and associations.

We used a Robotic Process Automation (RPA) software bot to crawl the website frequently for several months to receive all job ads matching the search term *digi*°. These search results therefore include words like digital, digitise, and digitalisation in various meanings and contexts. We did not use classical web crawling, as the Interamt website used internal frames and did not provide an individual page address for each job posting. The RPA bot was developed to simulate human access to the websites to avoid being locked out by technical bot detection functionalities. The website’s structure and source code significantly changed several times during the data collection period so that we needed to reconfigure the bot accordingly.

The collection of the raw job posting data was followed by several data processing steps as well as qualitative research workshops where we discussed, categorised and clustered data properties. The following Figure 1 summarises the elements of our research process and is divided into the job analytics flow addressing the data processing, and the researcher workshop flow representing the researchers’ influence on the data analysis and the respective results.

The research workshops were used to set goals and steer the quantitative job analysis. First, the crawled jobs in a raw form were sighted to discuss the general data base and identify typical reoccurring contents. We decided to form four main job categories for a coding of all crawled postings. More details are given in the results section. At the end of the job analytics flow, the researchers again had to sight the processed data especially for the topic modelling to discuss and summarise the main findings of the data-driven research steps.

![Figure 1 – Research process and methodology](image)

The pre-processing of the raw data builds the typical first step of a big data analysis. Here, the categorisation, cleansing and allocation of the individual job advertisements of the data set is a necessary condition for effective use of our data-driven research approach.
Using raw and unedited job ads for modelling could lead to incorrect results. In our research process, an analysis was required to extract structured information from partially structured or unstructured job advertisements. This included the correction of missing values, job advertisement normalisation, and discretisation, and text pre-processing to remove and replace embedded characters that may affect the analysis content.

The elimination of irrelevant stop words also took place in the pre-processing step. We aimed on reducing text corpus of terms that occur frequently but are not adding to the informative value. In the German job advertisements, these are mainly articles, pronouns and some adjectives. For this processing step we created an extensive stop word list containing 897 terms, covering about 40-50% of the total text content.

During a research workshop, we decided to manually categorise all job ads into four disjunct groups. The allocation was executed manually by assistants following a written set of rules. All job information was transformed into the following elements: Job ID, check for duplicates, check for relevance, job posting organisation, job tasks, job requirements, “nice to have” requirements, job title, minimum pay scale group, maximum pay scale group.

We also applied categorisation algorithms. In our research design, we considered the k-nearest neighbours algorithm and Naive-Bayes, which have been intensively discussed in the literature (Smith et al., 2002; Islam et al., 2007). Both variants were examined for their suitability for job classification. The probabilistic classifiers summarise terms of the same frequency, since otherwise inquiries deliver only general results. Due to the summary, the classifier has an average frequency of occurrence and can therefore be regarded as a suitable attribute for the individual class descriptions. In order to use frequently occurring terms for classification, compound terms consisting of several individual terms are formed. This makes them more specific and produces better results. If the words are evenly distributed across the job advertisements, it can be concluded that very frequently occurring words are not suitable for classifying job assignments. This is because they appear in almost every job assignment, making it impossible to distinguish between them. At the same time, some words occur so rarely that they are not certified to be separable. Following these considerations, only words that occur with medium frequency are left for classification. Especially challenging for the classification of job advertisements is to find the correct threshold values for differentiation.

Job similarities were the object of investigation in our next step. We used the clustering of job advertisements to quickly find similar ads and a macrostructure for our job collection. We also used this to detect possible duplicates. In contrast to the previous classification, clustering does not use a predefined set of terms or taxonomies used to group job ads. Instead, groups are created based on job characteristics that are found in the set of documents. We applied hierarchical clustering techniques, which clustering groups of job ads according to a similarity measure in a tree structure. Instead of finding only one cluster that best matches a job advertisement, hierarchical cluster algorithms group the job advertisement iteratively into larger clusters. At the beginning, each job ad is arranged in its own cluster, which represents a leaf in a cluster tree. In the next step, two clusters that are as similar as possible are combined. This process continues until all small clusters are finally assigned to a single large cluster of all job advertisements.

Our next step was topic modelling, a method with rising popularity in research in the last years (Schmiedel et al., 2019). Topic modelling describes a group of statistical procedures which allow conclusions to be drawn about the thematic structure of the individual job advertisement in the collection of advertisements. Algorithms also determine the thematic relevance of the respective job advertisements. In contrast to keyword tools, the topic modelling used does not only reveal keywords and topics that
appear in the job advertisements. Rather, it shows us the semantic relevance and context of words and phrases. In this step, we apply the Latent Dirichlet Allocation (LDA) topic modelling technique (Blei et al., 2003) to domain-centred job data along with other feature engineering methods to define characteristics of a job posting and a requested job profile. We chose the LDA algorithm, because it can generate higher-dimensional topics than other common algorithms (Masada et al., 2008). The algorithm is based on a repeated random selection of text segments, each of which captures the statistical clustering of word groups within these segments. The algorithm thus calculates the topics of the text collection, the topic portions in the individual texts and which words belong to the respective topics. Our design is natural language controlled, enriched with n-grams and latent topics as features. Several techniques such as latent semantic indexing, natural language processing, and semantic matching are performed on the job data.

The similarity value is then calculated and further normalised by min-max transformations. In this way, a similarity matrix is obtained, which determines the proximity of a digit* display to a range of values. The system of job capture and processing mentioned in this paper is therefore inspired by the necessity to use text mining algorithms to explore different needs for personnel within the public administration - by means of job advertisements - through a constructive mechanism on their relevant content contribution to the concept of digitalisation. This not only enables accurate and relevant information filtering, but also reduces time and human effort throughout the process.

**Results**

After a first pre-processing and duplicate removal, we could analyse 800 job ads crawled by the RPA bot from the Interamt website. More than half of them (432) describe jobs far away from shaping digitalisation activities. Instead, those ads only use digit* randomly for describing secondary information technology (IT) aspects of current jobs. Examples for those hits are sentences like: “combine classical marketing activities with digital marketing activities”, “file management of the audit office is completely digitalised, experience in Word and Excel is required”, and “the ability to meet the requirements of modern digitalisation, e.g. become acquainted with new IT systems”. In some cases, the term only described application processing or similar side aspects: “Please note that your application will be digitised for internal processing”.

The content analysis of the remaining hits resulted in three major job categories. Ads could be categorised as addressing IT specialists, IT generalists, and project managers without specific IT skills. A qualitative manual analysis of the job ads showed that IT specialists typically create and implement digitalisation concepts and advise managers and employee regarding new technologies. IT generalists have a stronger focus on maintaining IT infrastructure and systems and to assist employees with digitalisation-related requests. The category of project managers without specific IT skills is needed for the general management of digital transformation, change, and process improvement.

Since we described our method and research path to our findings in the last section in detail, we will focus on five modelled topics identified by the introduced algorithms. The originally German data tables have been translated into English for this article.

The first modelled topic summarises terms related to flexible time management and home office (see Table 1). The effects of digitalisation on work organisation are inconsistent and sometimes contradictory in our data. Overall, it is becoming apparent that digitalisation within the public administration is leading to a disentanglement, more flexible and decentral of work. This results in new demands on the communication, cooperation and management of employees. A distinction can be made between internal and external work flexibility. External flexibility is reflected in the creation of jobs...
outside full-time work for an indefinite period. This includes fixed-term employment contracts (52.70% of all cases) and various forms of part-time work (87.41%). This type of internal project economy is most common in the areas of general local government, construction and housing, transport and economic development. This change has an impact on the qualification requirements, the function-related task structures and activities of the employees as well as the organisation of work, on the one hand as a structuring of tasks and activities based on the division of labour in horizontal and hierarchical terms.

Table 1 – Modelled topic “Flexible Time Management / Home Office”

<td></td>
</tr>
</tbody>
</table>

The future and performance of the public administration therefore do not necessarily require specific expertise. This is because the core competencies of many classic administrative professions are shifting more and more into breadth in the future and are also becoming detached from the classic job profiles. For example, the job advertisements very often demand considerable new- and further- qualification affinity. As the changes in job profiles are assumed to increase in the future, a continuous professional development gains importance (see Table 2).

Table 2 – Modelled topic “Professional Development”

<td></td>
</tr>
</tbody>
</table>

The next modelled topic has a high overlap with the previous topic. Not only technical skills are listed in the job ads, also human abilities are formulated clearly. The ability to guide and coordinate, critical thinking and persuasiveness are just as much in demand as communication skills at various hierarchical levels, resilience, flexibility, problem-solving skills and emotional intelligence. We summarise this topic with “initiative (Table 3), as independency and autonomy of employees are highlighted.

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Communication skills are a standard element in many job ads of different sectors. In the analysed set of digital* jobs though, a focus lies on virtual communication (Table 4). Communication and collaboration systems are a classical element of information systems research for many years and it is not surprising, that they also form a key element of digitalisation-related recruiting. Requirements amongst others list cooperation, leadership, virtual teams, and teamwork as important terms of this topic.

**Table 4 – Modelled topic “Virtual Communication”**

<table>
<thead>

</tr>
</tbody>
</table>

Before starting the data processing and statistical analyses, we discussed which technologies we expected to find in the data. In a literature review about digital technologies affecting the public sector, we identified the following developments amongst others: Artificial intelligence and machine learning specialists (Nam and Pardo, 2011), big data and process automation experts (Kim *et al.*, 2014), user experience and human-machine interaction designers, (Gil-Garcia *et al.*, 2014), information security analysts, robotics engineers and blockchain specialists (Swan, 2015). Our evaluation indicates that there is still no significant demand for many completely new specialist roles. However, employers underscore the importance of skills to understand and analyse problems (Table 5). Combined with professional development (Table 2), this brings the opportunity to develop specialised knowledge after the recruitment.

**Discussion and Conclusion**

According to our analysis, the public administrative culture faces major challenges. The concept of digitalisation is determined above all by the closely interwoven IT investment decisions of the public sector, the amount of available information, the dynamic development of policy fields and technological change. The digitisation requirements of the administration are developing at a rapid pace, making flexibility and lifelong learning the most important factors for its modernisation. Derived from the job advertisements, the personnel policy of the public administration formulates the requirements in this context as efficient processes, networked procedures and proactive behaviour.
Thus, workflows and standards do not change visibly. New IT procedures are taken into account, also in order to make work easier in the future. This not only serves the employees, but also leads to a high communication orientation to external parties. The use of IT procedures, in turn, is intended to influence quantitative and qualitative job planning in many areas through faster and cross-departmental processes. The new employees should support and implement these changes and should therefore be able to implement the new requirements in a targeted manner, usually in a project context. At the same time, it is clear that personnel should participate in and contribute to change. To this end, particularly the intensified personnel development was identified. It includes continuing education, training, supervision and coaching. But there is also a clear need to create an open administrative culture in which staff are encouraged to get involved as their engagement and commitment is wanted and needed.

At the same time, most of the ads can be summarised showing a trend for supporting and accompanying digitalisation. However, the majority of postings does not describe a very concrete or pioneering role or mindset. It could be the case, that the most innovative impulses and changes are given in Germany by expert groups and central agencies. Most of the analysed institutions seem to follow trends, role models / pilot institutions, or simply laws and regulations. In summary, our results leave two major ways for interpretation. The data analysis shows that German public sector institutions either do not actively plan far ahead and do not seem to have a clear vision and strategy for digitalisation-related recruiting. Or they intentionally recruit for a short-term vision and are in an early stage of digitalisation where the identified key developments are known but more modest steps must be taken first.

Limitations and Further Research
Our research of course has its limitations. We only interpreted a snapshot of job postings between November 2018 and March 2019 from one single platform representing public sector jobs in Germany. Also, text mining methods would be more effective, if much more data would be available. Furthermore, more detailed job profiles are possible, if the data set would be more homogenous. These limitations leave a lot of space for future research.

The method and its details leave many possibilities for modifications in the future. Although knowledge discovery was applied quite early in the history of computer science, text mining has received a boost in the era of social networks and employment websites. Job Mining has thus become a central field of research. While studying the related literature, the research challenges such as information overload, correct model choosing to represent the found knowledge, content economy, use of RPA technology, etc. represent an innovation for job mining. As a result of these new developments, topic modelling algorithms were the most interesting research area and especially all application areas led to a mixture of classical data mining and topic modelling algorithms.

No research branch is currently working in this area of public administration with content-based analysis on such data stock. But there is potential for further improvement through machine learning and natural language processing techniques. Kobayashi et al. (2018) suggested LDA as the best decision to use topic modelling, especially when exploring larger text collections in the areas of employee satisfaction, performance motivation, leadership and communication quality, and their interrelationships and possible adjustments. The non-parametric machine learning algorithms proposed by (Rosa and Ebecken, 2003) essentially use genetic algorithms in combination with a k-nearest neighbours approach in the context of the assignment of text content. González-Briones et al. (2019) and some years before Lu et al. (2013) proposed a case-based and
agency-based recommendation system for job seekers and recruiters. It uses a hybrid approach that combines content-based recommendations and machine learning for natural language processing approaches to improve result accuracy and provide a more accurate information extraction. They control two models based on probabilistic hybrid information extraction by combining machine-selected job segments based on latent features of individual preference.

In the future, we could also continue our study by interviewing recruiting specialists of public institutions, discuss our findings and their view on digitalisation-related recruiting. Interesting could also be to narrow the data set down and look for specific job titles like digitalisation project manager or big data analyst do analyse their requirements and remits. Researchers could also take the digitalisation job mining on to other countries. How are the open positions in countries characterised, which are known for their comparably mature digitalisation status? Another intriguing idea could be to transform the Interam analysis into a longitudinal study. This would allow to regularly compare different snapshots e.g. once per year with each other to identify changes and trends in public sector jobs related to digitalisation. Another aspect is the comparison of public sector recruiting with the private sector. Analysing the differences and communalities regarding in their digitalisation efforts leaves many opportunities for future research.

Abstract

The purpose of this research is the clarification of Knowledge Management (KM) definition and the alignment of KM-tools with KM-Processes under the experience of the Greek public sector. The KM-tools emerged from relevant literature and semi-structured interviews were projected into each of the four KM-processes (K-creation, K-storage, K-dissemination, and K-application) in order to map the way they were used in each phase of KM-lifecycle. This research provides: a) novel theoretical insight in combining KM-tools with KM-processes in the public sector and b) a practical “roadmap” of KM for public sector executives.

Keywords: Knowledge Management (KM), KM-Tools, Public Sector
Introduction

We live in a society, where Knowledge is the most important strategic resource for an organization (Drucker, 1993) and its management has become an intriguing, though complex research issue (Allameh et al., 2011), with a variety of KM definitions and KM-processes emerging. Despite that, most researchers and practitioners regard (Anand & Singh, 2011; Alavi & Leidner, 2001) KM as a the process of K-creation, K-storage, K-dissemination, and K-application.

Early KM publications focused mainly in the private sector but in recent years, there is a burgeoning interest in the public sector as well (Seba & Rowley, 2010; Singh Sandhu et al., 2011; Luen & Al-Hawamdeh, 2001), where KM-based actions like benchlearning, aim to modernize and improve public services (Sotirakou & Zeppou, 2004). Aligning with this, the European public sector employs a self-assessment and quality improvement tool, namely the Common Assessment Framework (CAF) (Vakalopoulou et al., 2013), which encompasses the KM process. This implies the production of new knowledge which should be managed for enhancing organizational performance (Linderman et al., 2004). Besides the fact there is a proliferation of such models and a growth of prescriptive publications the practical problem of KM’s effectiveness (Ragab & Arisha, 2013; Massingham, 2014) is yet to be considered. Thus this gap between theoretical and practical endeavours is the motivation for this research which identifies KM-toolkits and studies the way they are used in the Greek public sector.

By drawing on existing literature, KM definition and KM processes are clarified and synthesized, becoming the background for the production of KM-Toolkits which are aligned with KM-processes. The case under study includes team members that applied CAF in the Greek public sector. Specifically, seven public sector executives, from different public sector organizations, accepted our invitation and participated in this research. Data collection tools include: semi-structured interviews, observation and documents, which are analyzed to capture the KM-tools applied at each CAF KM-process. As a result: a) a novel theoretical insight is provided as it the first time that researchers collocate KM-tools with KM-processes in the public sector and b) a basic “roadmap” of CAF KM for engaged public sector executives is developed.

The paper proceeds as follows: synthesis of KM definition and KM processes, presentation of KM-tools, short CAF presentation from a KM view, description of research methodology, presentation of research findings, discussion of findings and conclusion.

Knowledge Management (KM) Definitions & KM-Proceses

Since KM is a complex concept in social science there will be a discussion of several KM definitions in order to synthesize a presentative one, that we will be used in this research. Many authors (Obeidat et al., 2016; Quintas et al., 1997; Bhatt, 2001; Anand & Singh, 2011; Bhatt et al., 2005; Gold et al., 2001) regard KM as: process, activity, set of activities, strategy, knowledge flow, and dimension. Despite, the different terms used, most researchers commit to same conceptualizations. Mishra and Bhaskar (2011) set a logical connection among them, claiming that “existing conceptual research in KM field identifies a dynamic set of activities, called KM processes, which improve organizational knowledge flows”. Besides, the majority of researchers (Obeidat et al., 2016, Quintas et al., 1997; Bhatt, 2001; Anand & Singh, 2011; Bhatt et al., 2005) accept
the term “process” in KM definitions. Therefore, this research employs the term “process”, aligning with the explanation of Mishra and Bhaskar (2011).

The description of the processes characterizes most definitions of KM. Nonaka’s seminal work set the foundations for KM by developing the SECI Model which describes in a spiral way different patterns of interaction between tacit (uncodified) and explicit (codified) knowledge: 1 Socialization (tacit knowledge converts into tacit knowledge), 2. Externalization (tacit knowledge converts into explicit knowledge), 3. Combination (explicit knowledge converts into explicit knowledge), and 4. Internalization (explicit knowledge converts into tacit knowledge) (Nonaka, 1994; Honarpour et al., 2017). Since then several initiatives focus on defining KM. Nonaka and Takeuchi (1995) describe KM as the systematic process of K-creation, K-storing, and K-dissemination, whereas the majority of researchers (Alavi & Leidner, 2001; Mishra & Bhaskar 2011; Gold et al., 2001; Bhatt, 2001) pertain K-application as a generative process to KM. All these processes are parts of a continuous KM-cycle, functioning complementary and/or alternatively and they could be categorized as: K-creation (knowledge identification, capture, acquisition, and creation), K-storage (knowledge in tacit form may be codified in an understandable form to the extent possible), K-dissemination (K-sharing K-transfer both explicit and implicit form), and K-application (application and use of knowledge in the organization value-adding process) (Anand& Singh, 2011).

Besides the description of processes, there are also enablers and results informing the definitions of KM in literature. With respect to enablers thee important resources are widely accepted among various researchers: right knowledge, right people and right time (O’Dell & Grayson, 1998). These critical factors facilitate and enhance the K-flow so as to improve organizational performance (O’Dell & Grayson, 1998; Du Plessis, 2007; Kamara et al., 2002; Martensson, 2000), increase productivity (Eschenfelder et al., 1998), create value for organizations (Yew Wong & Aspinwall, 2004) and enhance innovation (Dayan & Evans, 2006; Martensson, 2000). Combining all the above, KM might be defined as: a continuous cyclical process of K-creation, K-storage, K-dissemination, and K-application, in which right knowledge flows in right people at the right time in order to improve organizational performance (Figure 1).

**KM-Tools**

KM tools are regarded as methods, techniques, and practices, used by organizations in order to manage their knowledge. Merono-Cerdan et al. (2007) divide KM-tools in Technological and Non-Technological. KM Technological Tools are: decision support technologies, groupware, social network services, knowledge bases, digital document management, intranet, wikis (Honarpour et al.,2017; Merono-Cerdan et al., 2007). KM non-Technological tools are: spontaneous knowledge transfer initiative, informal talk room, training, mentoring, learning before doing, teams, community of practice, knowledge café, brainstorming, after action review, storytelling, knowledge repositories (Honarpour et al.,2017; Merono-Cerdan et al., 2007). In addition, leadership, case study and benchmarking methodology could be viewed as IT-free KM-tools. Extant literature is abounding with publications recognizing and describing KM-tools (Merono-Cedan et al., 2007; Massingham, 2014) but limited attempts combine them with KM-processes (Alavi & Leidner, 2001; Alavi & Tiwana, 2003) whereas in the public sector there is a gap of such studies.
Linking the common assessment framework implementation with KM

CAF is a self-assessment tool, which is influenced by European Framework of Quality Management (EFQM) and Speyer Standard, promoting public sector change and improvement of quality and productivity. It was introduced in European organizations in 2000, whereas in Greece applications started from 2007 onwards (Vakalopoulou et al., 2013). This model includes 9 criteria with the 28 sub-criteria. For each criterion and sub-criterion a structured questionnaire is used in a 5-point Likert scale and appropriate documentation is required to justify choices. This phase is followed by an action plan development that aims to improve low scores in criteria by continuously applying the Deming cycle (Plan-Do-Check-Act). Usually, benchmarking facilitates action plan production and the whole CAF process provides learning and innovation feedbacks to organizations.

CAF is strongly connected with KM. Firstly, in this model, there is a sub-criterion referring to KM, which gives the opportunity to organizations to assess their KM-process and develop relevant improvement plans. Secondly, CAF implementation favors the production of new explicit organizational Knowledge, initiating the KM-process. Thirdly, KM like CAF is a continuous process. Moreover, the key methodology (Benchmarking/Benchlearning) used in CAF, is a KM-tool that could create, store, disseminate and leverage knowledge. Furthermore, KM facilitates innovation and learning (Dayan & Evans, 2006; Martensson, 2000), two aspects found also in the CAF model. Therefore, CAF applications are a means for studying KM.
Methodology and methods used
The purpose of this research is the alignment of KM-tools with KM-processes under the experience of the Greek public sector. To achieve our purpose the case in question concerns the CAF public sector community (25 members), which employs the CAF model, as a TQM-KM practice. Therefore, interviewees are Greek public sector executives, members of CAF cross functional teams, who were invited by email to contribute their experience. KM-tools drawn from relevant literature were identified through the use of semi-structured, open-ended interviews, observation, and documents. In addition, the latter methods where employed in order to investigate “What” and “How” KM-tools (namely KM-toolkits) are used in each KM-process.

Specifically, we received ten responses from CAF community members. Three out of ten organizations denied contributing in our research because of time deficit and leadership denial. Presumably, seven Greek public sector organizations participated (referred as organization H, R, D, M, MA, MB and MC). With respect to semi-structured interviews, participants were contacted by emailing them the interview protocol and an informed consent form, which reassured their confidentiality and anonymity. Interviews conducted from September 15 to November 15, 2018, in person (by visiting executives in their workplaces) were tape recorded in Greek. The interview protocol consisted of open-ended questions, mainly because the KM term is not widely known in the Greek public sector. Six questions were asked by interviewers with the same sequence to all respondents, covering the following main topics: a. motives for K-creation (CAF), b. What and How KM tools were used at: K-creation, K-storage, K-dissemination, and K-application, c. Which organizational factors facilitated and procrastinated the KM-process iteration. Besides the interviewer, a second researcher (observer) was listening carefully the interviewee, keeping detailed notices regarding body-language, layout, place, equipment, communication with other staff. Furthermore, participants sent us minutes of meetings, training manuals, presentations and reports produced and used during CAF implementation.

Findings
Motivations for starting the K-creation are different among organizations (see Table 1).

</table>
During CAF implementation, specific KM-tools were applied by project teams at each KM-process. Specifically, during the K-creation process the following tools were employed: Brainstorming, Regular Planned Meetings, IT, Interviews with peers, Training (internal or/and external). Moreover, during the K-storage process Technology Platforms, Data-Bases, and Minutes of meetings were used. The K-dissemination process included the use of Discussion, Data Base, Emails, Teleconferences, face to face planned meetings, Benchmarking, Formal Events and Notifications, and Minutes of meetings (planned). Finally, the K-application process contained the use of IT, After Action Review, and Pilot application.

With reference to the way that the KM-tools were used in CAF KM-process, two dimensions are considered: CAF team formation and activities.

With respect to team formation, all organizations, apart from R and H, developed the CAF team by using a top down process. In this process, Leadership requested from middle managers, through a free participation process, to build a cross functional team. However, two out of seven organizations (R and H) had set specific participation criteria, such as: communication skills, good knowledge of department processes, and IT skills. All CAF cross functional teams consisted of 5-6 members, who were assigned after discussion, roles and duties during the first meeting. Due to daily workload, time restrictions, tiredness, resources deficit and cultural aspects, mainly 2-3 team members were totally engaged in most organizations where as the rest of them were partially involved. Organization MA and MB team members collaborated exceptionally and were fully engaged in the project, regardless of the abovementioned restrictions.

As far as CAF activities are concerned, the following ones took place at CAF teams under study: training, planned and informal meetings, data collection and documentation, benchmarking and after action reviews. Training is a critical first step, in which a team-coordinator was trained from a public sector body responsible for training public employees and then disseminated the knowledge gained to the rest of the team. Then, members planned meetings regularly to discuss their findings and make proposals for project’s progress. Additionally, interviews or/and questionnaires were used to capture departmental knowledge of each process complemented with adequate and justifiable documentation provision. For the development of action plans benchmarking was used in five out of seven members with the following types: a) historical self-comparison of performance indicators (organizations MA, MB, M, R and H) and b) studying and adapting best practices (only organization H). Five out of seven members (organizations MA, MB, M, R and H) continued applying the CAF cycle, while the rest of them stopped in the report creation phase, without completing the After Action Review.

Regarding the organizational context that enabled and restricted the KM iterative process, a number of factors emerged through the interviews. CAF team members that applied it perpetually highlighted the following factors as process facilitators: strong leadership commitment, appropriate training, problem awareness and solving skills, team-building, trust, and compliance with legislation. For example, one team member stated that: “[project] success for me is the teambuilding and trust developed between team members that made those meetings joyful”, whereas another supported that: “leadership was a critical factor in scheduling and problem solving” and a third one claimed that “my training by EKDDA [Greek public sector body responsible for training public employees] was very useful in understanding the whole CAF process”. A forth member confirmed: “legislation compliance triggered the continuous
implementation of CAF”. Furthermore, there are various barriers limiting CAF KM-process iteration. For example, one team member claimed that: “it was politically decided to close down the organization”. Another team explained: “resources deficit (Human Resources, Time, and Money) paused CAF perpetual cycle” and complemented that: “…there was no leadership commitment but just a response to political requirements and political needs fulfilment”. Consequently, the abovementioned organizational factors influenced the KM-process continuation.

Discussion
According to interviewees, Greek public sector is currently characterized by bureaucracy, inflexibility, intensive legislative limitations, resource deficit, and change resistance. However, governments systematically try to modernize public organizations based on European standards. Therefore, they introduce tools, such as CAF either in a compulsory or motivational way. CAF implementation in our case synthesized context-specific dynamics where KM-tools were activated in each KM-process. From a KM-view the CAF’s basic goal is the transformation of tacit and explicit knowledge into new organizational explicit knowledge. This explicit Knowledge is the motive for the next KM-process through After Action Review (K-application), where members use their tacit and organization explicit knowledge to achieve the above-mentioned goal, iteratively. In our case, during the K-creation process, teams planned Meetings regularly, where tacit knowledge converted into explicit through minutes of meetings, Brainstorming, Interviews with peers, and Benchmarking. This explicit knowledge became the documentation used for the CAF report. In the phase of K-dissemination, tacit knowledge converted into tacit knowledge through informal Discussions, Teleconferences, and face-to-face meetings. This tacit knowledge was codified to explicit knowledge through minutes of meetings and Data Bases. E-mail, Formal Events and Notifications were communication tools that disseminated explicit knowledge to the organization. Presumably, figure 2 illustrates the “roadmap” of CAF mediated KM which public executives could utilize in their organizations.

With respect to Greek public sector culture, motives identified in this study could trigger under specific conditions different KM iteration results. For example, when CAF community focused on sole national legislation compliance, then the KM-process lost its spiral form and K-application was completed without After Action Review. In this case tacit and explicit knowledge was transformed into new explicit knowledge (CAF Report) that remained unused and unexploited within Data Bases or/and Minutes of Meetings. This motive was reinforced by weak leadership commitment and public sector restrictions (in people, time and money). In addition, when the motives of legislation compliance, Quality & Productivity Improvement and Quality Award winning coexisted, then KM was continuously implemented, resulting in citizen satisfaction and Quality Management interest. Finally, when the only motive was Quality & Productivity Improvement but political conditions changed the organization’s structure, then the KM-process was suspended. In sum, CAF community’s motives played a critical role in the KM spiral form, altering its result according to specific conditions.
**Conclusion**

Consequently, from a KM view, CAF aims in the continuous creation of new organizational explicit knowledge (CAF report) through the conversion of team’s tacit and explicit knowledge. In this framework KM-tools at each KM-process could be used in order to achieve the CAF goal (see Figure 2). Despite the fact that the abovementioned roadmap is a basic first point of KM, its critical factor is its processual iteration. Enablers of KM found in this study are: leadership commitment, teambuilding, trust, and training. However, barriers, such as daily workload, resource limitations and leadership commitment deficit, limited iteration. Therefore, taking into account internal and external conditions KM-tools used at each KM-process contributed differently in KM’s effectiveness.

This work is the first attempt to combine KM-tools with KM-processes in the public sector, and to provide a roadmap of CAF mediated KM that can be utilized from public sector executives. Case findings illustrate the richness of Greek public sector CAF community KM-process, but further research should be done to enhance theoretical generalizability within different public organizations around the world.

Abstract

This paper examines challenges faced by public sector organisations developing multi-agency working. Organisation A was tasked with engaging multiple User Organisations in collaborations designed to increase data accuracy, data standardisation, data quantity and data sharing, in order to improve decision making and service quality. The setting was UK police, fire and ambulance services, plus other agencies (such as social services, councils and charities), aiming to reduce harm and vulnerability in society. Multiple emergency and local services were involved in piloting data visualisation apps, designed and hosted by Organisation A, from which a number of challenges were noted.

Keywords: Multi-agency working; practice; performance measurement
Introduction

This research builds upon a body of work conducted by the AIMTech Research Centre at Leeds University Business School, investigating the use of information and technology across UK police forces (Allen et al, 2017), including three national surveys on police IT infrastructure and mobile information (Allen et al, 2018a; Allen et al 2018b; Allen et al, 2018c). Specifically, a Delphi study conducted in 2016-17 looked at digital transformation across the police and other emergency services over five – ten years (Shaw et al, 2017; Williams et al, 2017). The Delphi study engaged senior experts from four different domains: of ‘industry’, ‘policy’, ‘technology’ and ‘operations’. Findings were:

- Inter-agency working is considered a priority for transforming policing
- Making greater use of digitisation and standardising the use of that data is critical
- The leadership to do this, along with human resource implications are significant.

The research reported here builds upon findings from the Delphi study. An exploratory analysis was conducted of a flagship project designed to encourage and facilitate multi-agency working across UK emergency services and other agencies. The project’s aim was to develop data visualisation apps across a number of operational areas, offering a unique and innovative approach to traditional multi-agency collaboration. A number of interviews across the participating organisations identified some of the early successes, challenges and in some cases, misperceptions of the project outcomes.

Literature Review and Theoretical Context

In light of the continued impact of financial austerity in the UK public sector and increasing demand placed upon diminishing resources (Financial Times, 2015), this is an unprecedented time for managing resources across the UK public sector. The desire to work more effectively across multiple organisations - to aid decision making and utilise resources more effectively - and to work ‘smarter’ by adopting information technologies are commonplace.

It is readily acknowledged that sharing data can support solving not only high risk but also low risk cases (some of which can place significant demands on public services by their high frequency), by helping to identify individual cases earlier and allow more timely interventions (Wate & Boulton, 2015). However, this presents challenges.

Multi-agency working is not new however; Cheminais (2009) notes that late nineteenth century initiatives existed around health and social services working to reduce poverty, reduce social exclusion, community safety and in particular, in relation to children’s well-being through the Children’s Act 1989. Difficulties observed were:

- a lack of information sharing across different services and agencies
- duplication of needs assessments and subsequent provision
- poor levels of co-ordination integrating activities across different agencies
- inconsistencies in levels of service provision
- unclear accountability.
Technological advances over the past twenty years such as cloud computing and other IT platforms, coupled with austerity, have yielded renewed interest in the opportunities afforded through multi-agency working. The benefits of information technologies and mobile working in helping to increase efficiencies are well documented and increasingly, the application of this across multiple organizations is also gaining recognition (Dawes, 1996; Higgins et al, 2014). Yet the barriers to what is shared and how still remain. Wate & Boulton echo this sentiment: “For many years organisations that are or may become involved in safeguarding vulnerable people have found sharing information problematic to achieve.” (Wate & Boulton, 2015, p.194).

Yang & Maxwell (2011) provide a literature review of information sharing in public organisations both, interpersonally, intra-organisationally and inter-organisationally. Of primary interest here is the inter-organisational context, whereby information is shared between agencies. Their model was developed further by Karlsson et al (2017) as per Figure 1 below.

![Figure 1: Karlsson et al (2017) Inter-organisational information sharing in the public sector](image)

Karlsson et al (2017) suggest that it is often the complexity of information sharing across different organisations that causes such initiatives to fail. The numbers in the Figure above indicate the most frequent reasons for failure cited in their data. Hence, concerns of information misuse and lack of trust are primary barriers to overcome. When considering the context of this research, i.e. 1) emergency services including healthcare and 2) vulnerability, alongside 3) the recent implementation of GDPR (General Data Protection Regulation) it is hardly surprising that the relative risk-appetite for information sharing is sometimes quite cautious. A number of authors suggest that management of both the relationships between multiple agencies, and the nature of the information being shared, are required in order to facilitate rigour in the information sharing process (Karlsson et al., 2017; Higgins et al, 2014; Cuganesan et al 2017).
The case examined here investigates multi-agency working and the associated challenges, in the context of organisations with very different disciplines, historically very different ways of working, different technological infrastructures and organisational cultures, but all seeking similar aims.

For this research, a practice theory lens is adopted (Feldman & Worline, 2016; Gheradi, 2012), which considers entwinement (how people, actions, technologies are all inter-related), that practices are multi-faceted in nature (simultaneously social, discursive and material), contextual (where the practice is taking place and is embodied) and temporal (how practices develop and are improved over time) (Sandberg & Tsoukas, 2015). The research explores how practices change in the context of new opportunities to standardise and share data, and visualise this digitally to aid decision making.

Theories of practice “locate the source of significant new patterns in how conduct is enacted, performed or produced” (Gheradi, 2012, p. 77). Here, a practice theory lens is applied to Karlsson et al’s (2017) model against the five “reshaping relationships” (Karlsson et al, p. 573) indicated in Figure 1 above.

**Research context**

Organisation A describes itself as providing a ‘hub and spoke’ model of service delivery, whereby it provides centralised services to a number of organisations (referred to as Users), in the context of individual products. These products are apps, designed to help visualise shared data in a specific operational context.

Organisation A operates over a substantial geographic region within the UK, supporting police, fire and ambulance emergency services plus a range of associated agencies, from councils and social services, to welfare agencies and charities (i.e. multiple Users). Its goal is to collaborate with these multiple agencies in order to develop an agile and data-driven approach to sharing information (Interview, 2018).

Typically, organisations would collaborate within a specific operational context and identify a need and scope for information sharing. This would then be considered and evaluated by Organisation A and a formal data sharing agreement generated. Organisation A would then design the data visualisation app, which would then be piloted, refined and ultimately hosted by Organisation A as required by the Users.

Within the evaluation activity, Organisation A advises the Users on which information is appropriate (or not) to share, issues of GDPR, data quality and data standardisation. Finally, a successful outcome for Organisation A would be acceptance of the data sharing agreement by all Users. However, for the Users, a successful outcome would manifest much later depending upon the context i.e. once the app has been operational for a number of months, possibly years.

**Methodology**

Adopting the practice theory lens, researchers are “interested in understanding how [practices] are seen ‘from inside’, how conceptions and discussions form around the
mode of practising a set of activities” (Gherardi, 2012, pp.2-3). The practises in question took place within a range of different organisations.

The research design was that of a case study (Yin, 2014), whereby Organisation A’s work formed one individual ‘case’ (that of the hub, of the hub and spoke model) in order to ascertain the background, intentions and challenges to the project, and four further cases were identified by incident type. These cases were identified based upon how developed the data visualisation apps were and how embedded in practice they had become. They include: road safety; arson and anti-social behaviour; missing persons; knife crime (Figure 2).

A qualitative approach was taken in order to capture the diverse background and characteristics of each organisation. Data gathering took place primarily via semi-structured interviews, with two additional supporting focus groups. Some interviews were conducted face to face; others had to be conducted by telephone depending upon the availability of the interviewees. Interview questions were informed by a thorough review of the literature in each operational area and in accordance with a performance evaluation framework comprising forty-seven questions split into eight sections. This included:

i) background information
ii) relevant participants of the practice (i.e. those involved & their motivations)
iii) the work practices (mapping workflows and tasks, including division of labour)
iv) the motive(s) of the activity / outcomes of the practice
v) the resources utilised, e.g. technology
vi) implementation of the future app / improvement initiatives
vii) formal / informal conventions guiding behaviour and practice; and finally,
viii) multi-agency members with a shared interest in the outcome of the apps.

Interviews were conducted with domain experts within the Users and where possible, relevant staff within Organisation A too. A total of fifty-six individuals were identified, of which forty-eight interviews were completed. All data was audio recorded and transcribed. Dedoose software was utilised for coding, and a coding frame was developed between the researchers and in line with Government evaluation criteria to aid consistency of analysis. The coding frame identified categories of interest including:
Tensions and contradictions; Influence of the app technology on the area of work; and Benefits of use in terms of quantitative and qualitative outcomes. Both short term benefits (such as reductions in process time) and much longer term strategic changes to practice (such as long-term relationships developed between Users to facilitate wider collaborations) were included.

**Findings**

*Note: all interview quotes from Organisation A are simply listed as ‘interview, 2018’. Other interviews are simply quotations given the large number of interviews, from different people, in different organizations.*

After approximately one year, Organisation A had established 29 data sharing agreements (Interview, 2018). This was a significant, though non-cashable achievement and due in no small part to the project manager, who had spent months establishing relationships between Organisation A and key individuals within each of the agencies. The time to develop trust and openness necessary to establish the data sharing agreements depended upon the organisation, the individual within that organisation and their relative experience of working with multiple agencies and data sharing. Certain sectors, healthcare for example, “have a very different risk appetite” for data sharing (Interview, 2018) and historically do not share personal data which is considered private and confidential. In other instances, such as for knife crime where much less personal information needed to be shared, establishing data sharing agreements were much easier (Interview, 2018).

Organisation A considered its work as learning-by-doing, which “fits with that modern, agile, IT-based management style” (Interview, 2018), the Hub is “about pushing information to the right level in order for those people to act on that insight”, resulting in “intelligence-led policing” (Interview, 2018). With regard to data accuracy and quality, i.e. the information provided by the Users are beyond Organisation A’s control, one interviewee suggested that there is an atmosphere of “competition for data accuracy” which is part of a wider cultural context in which the apps are utilised.

The performance improvements, including time and cost savings, from this project were anticipated as multi-layered in terms of activity-based and organisation-based. The complexity derives from the fact that the Organisation A’s measures of success were more broadly around “have we delivered what we said we would?” (Interview, 2018), i.e. asking if the data visualisation apps enabled respective partners to share information in a way that aids service delivery. More extensive and longitudinal benefits are expected in line with the shorter-term gains. These comprised of individual operational process metrics such as processing times, through to Home Office measures of performance around target areas, such as reducing the number of road traffic accidents, and KPIs across individual partner organisations. Over time, the longer-term benefits will become much clearer. There were also additional unanticipated outcomes, such as the design of a data sharing agreement protocol, which would have benefit in being shared beyond this project to other multi-agency networks around the UK. A further outcome was the desire by other agencies across the UK to understand better what Organisation A was doing and to replicate its successes nationwide, share case studies and so on (Interview, 2018).
One interviewee expressed frustration at not being able to measure the impact and direct influence of the Hub inasmuch as the benefits realised by Organisation A were very different to the process improvements, cashable gains and net reductions in vulnerability experienced by User organisations. User’s benefits are more quantifiable, although each User also measured different elements of performance improvement depending upon their role, such as the police compared to a welfare agency. For the Organisation A, a direct benefit of its work across partner organisations include tangible and intangible performance indicators such as:

- Increased willingness to enter in to data sharing agreements [indicative of increases in trust, greater transparency of data sharing benefits]
- Number of partners actually signed up to data sharing initiatives [quantifiable measure of the breadth of engagement in data sharing]
- Number of times data sharing protocols have been shared [indicative of the transferability of Organisation A work to other settings]
- Levels of influence on information governance, in particular through standardisation of formats and processes [indicative of transferability of good practice in data sharing in existing and new contexts]

This list is not exhaustive but illustrates other performance metrics which impact the rate of establishing new data sharing agreements.

Road Safety

This app had been running for some time and was reasonably well established. Partners expressed a desire to support activity in the area of road safety, their current levels of engagement and strategic foci differed significantly. Local authority members recognised that collaboration and reliance upon data sharing was extremely valuable. However, interviews with ambulance services offered different opinions, whereby the need to analyse road safety data and share the data they owned themselves, was not perceived necessary. This was noticed by other agencies: “The one partner ... that never seems to be around the table, and it's not just an issue with the road traffic, is health”.

Fire service interviewees presented an alternative opinion: “from a fire service point of view, all it does is it provides ... statistical evidence of what is our gut feeling anyway.”

Arson and Anti-Social Behaviour

Challenges with this operational area centred around the variety of data surrounding incidents of arson and how they are captured by the different agencies. For example, one interviewee said: “Car fires are a problem. I think they're actually going up again at the minute, but the reasons why, you're going to look behind the reason; it's not just the incident, it's actually why, what was happening? Okay, so where was it? Was it easy to get into, what was broken into, what was stolen, what area was it in, where was it driven to when it was actually set on fire, for what reasons?”
One interviewee also had concerns about having to double check data, which resulted in increased processing time via duplication of effort: “Getting their information quicker and the rumours feeding into the same system would be fantastic. At the moment, I’m having to cross-reference our shelves to their shelves.” A number of interviewees expressed concerns about data potentially being misused:

“Depending on how they're going to gain the data protection .... Lots of data, somebody leaving, they can sell you the data, and not use it the correct way.”

“There could be resistance from other partners if they don’t want to share data. Then that causes other problems and it’s not useful at all to anybody.”

**Missing Persons**

Again, the context of missing persons cases offers high complexity, often significant vulnerability and a lot of personal data about each case. Equally, the diversity of terminology and associated data is very high. Given this, one interviewee expressed that: “Whatever is built has to be a very, very agile product or you have to convince five local authorities to use the same terminology.” With regard to illustrating complexity, another interviewee indicated that: “…we are seeing a lot more connections. Say, we’ve got 50 cases open in a month, I would say at least 20 of those are connected to each other. Boyfriend, girlfriend, family friend, uncle, cousin.”

Some frustration was also expressed with regard to the difficulty of accessing healthcare information regarding missing persons cases: “We’re entitled to that information because that's what we do. We look after people and we assess risk. We need that. Their job says, "You can't share it because it's confidential." There is a mechanism for sharing it, they just don't understand it.” An interesting observation was made by one interviewee, regarding the impact upon demand of people being reported as missing to the police: “If our data was more easily accessible across every agency and people understood some of the risk factors at certain points, it might not ever need to come to the police”, which is hugely significant in terms of the opacity of demand that missing persons cases place upon police forces nationally.

**Knife Crime**

This app was the most developed and had benefitted from different agencies already working together, hence the establishing of a data sharing agreement was relatively easy. The app itself helped Users visualise the vast amounts of data much more easily; previously a simple spreadsheet had been used. The project was quite focused in terms of what it was trying to achieve and as such, a greater number of benefits were observable.

Regarding the improvements facilitated by the app, one interviewee observed: “What the app has now allowed us to do is see everything in real time. If someone asked me “how many people on your database are open to social services? Under what categories is there a child protection?”, I will be able to see that at first glance. Whereas before, I would have to sit there and have to filter everyone who isn’t, everyone who is, and then
Another interviewee recognised the implications for practice directly, by noting: "this is where [the] data feeds into impact on practice. For me it’s not just about having the data, it’s really getting back to how we use it and I think there is not just an issue of providing data ... I think there’s going to be an educative part to this process that would say this is what the data is telling us, what do we need to do about it?"

**Discussion & Conclusion**

This work contributes to the literature on multi-agency working, particularly within the public sector supporting harm and vulnerability reductions to society. It has explored a large-scale example of the operational, information technology and organisational cultural challenges. A practice theory lens was adopted due to the complex inter-relationship between individuals, technology and data sharing practices across multiple organisational settings.

Organisation A’s work has the potential to positively influence data sharing for multi-agency working in a number of different ways. Within the current Organisation A project, the number of data sharing agreements put in place are clearly rising quickly. In addition, key outputs such as data sharing agreement protocols enable the rate of uptake of data sharing initiatives to increase beyond the Organisation A’s current remit to a national setting. The sharing of good practice around establishing trust between partners, data sharing agreements etc, is proposed as an ongoing initiative beyond the original scope of the Organisation A. Much of the findings clearly relate to practices, as influenced by the “reshaping relationships” identified by Karlsson et al (2017). For example, the ‘invisible’ work carried out by Organisation A to establish trust through relationship building within and between agencies. The Table below indicates this further:

**Table 1: Responses to Factors Inhibiting Inter-organisation data sharing**

<td>Trust</td>
<td>Significant time spent relationship building.</td>
</tr>
<tr>
<td>Different operation procedures, control mechanisms, work flows</td>
<td>Establishing standardised data formats, applying the same technology solution; creating a culture of data accuracy.</td>
</tr>
</tbody>
</table>

In summary, the scale and complexity of Organisation A’s work captured in this report should not be underestimated, i.e. the Organisation A are striving to achieve significant innovations that, to the best of our knowledge, have not successfully been undertaken at this scale before, often working with multiple organisations across very different disciplines with very different historical ways of working, both in terms of technological infrastructure and operational culture. Shared aims however provide a cross-cutting understanding to ease these divides and provide the motivation to ‘strive for
better together’, that is, to improve efficiency, maximise resources, and achieve greater effectiveness of outcomes.

For the work captured in this report, it shows that despite the challenges, significant progress has been made. It is hoped this paper will contribute towards a better understanding of the challenges and opportunities of the Organisation A’s work undertaken to date, and that this will support and contribute to the overall success of Organisation A’s project over the longer-term.

Demand and capacity management practices in austerity: A study across UK police forces

Paul Walley (paul.walley@open.ac.uk)  
The Open University, Milton Keynes, UK  
Matthew Adams  
The Open University, UK

Abstract

All public sector organisations within the UK have enduring a period of restricted finance. The UK’s police forces are no exception, despite changing patterns of demand. This paper provides fifteen case studies of how police forces have adapted demand and capacity management strategies as a consequence. The findings show there is no standard approach to managing demand, with wide diversity in system design. A distinctive feature of police forces, unlike most other organisations, is how they adjust thresholds for dealing with demand fluctuation. There are some promising ways in which demand can be reduced without compromising quality.

Keywords: Demand, Capacity, Police

Introduction

All public services sectors are under significant financial pressure, originating after the financial crisis from 2007. In a UK context, the Police Service has experienced similar financial pressures to other public services, with a steady real-terms cut in funding from 2015 and other changes to funding from 2009 (see Elliot-Davies et al., 2016). In the period 2009-2016 the number of full-time equivalent officers fell by 14% according to the Institute for Fiscal Studies (Disney and Simpson, 2017). At the same time the patterns of demand have been under considerable change, moving away from car theft, robbery and burglary towards “white-collar crime”, internet offences, sex crime and trafficking (Keene, 2012; Vinod Kumar, 2014; Boulton et al., 2017). This potentially changes the quantity and mix of skills required by forces. These problems have become more obvious in the last two year or so, leading to a series of comments in the 2017 “PEEL” review of UK policing by the Inspectorate of Constabulary (HMIC, 2018):

“[There are] major concerns that policing is under significant stress. On occasions, that stress stretches some forces to such an extent that they risk being unable to keep people safe in some very important areas of policing… About a quarter of forces are all too often overwhelmed by the demand they face, resulting in worrying backlogs of
emergency jobs, with officers not attending incidents promptly, including those involving vulnerable people.”

Source (HMIC, 2018)

In May 2015 the national Police Chief’s Council established the second phase of a project into demand management that reported back in November 2017. Amongst wide-ranging terms of reference there were the following objectives:

- To examine demand beyond recorded crime
- To examine the sources of demand data and how these could be recorded
- To identify ongoing professional good practice and set up a central repository
- To link demand to public value in terms of how the services add value
- To utilise demand forecasting models

The report contained a number of recommendations including the adoption of tools and techniques for assessing risk and prioritisation, emphasis on collaborative working, understanding internal processes to reduce waste and improve productivity and the better use of analytics.

Within the report attention was paid to defining demand, which was split into three types:

1. **Public demand** is equated with incidents reported by the public (but there is a need to factor in the actual resource consumption needed to meet this demand)
2. **Protective demand** comes from the need to provide policing cover for events, acting on intelligence or general protective patrols.
3. **Internal demand** is the demand for resources within policing organisations, including administrative tasks, processes and protocols.

The model that is produced to link this together is replicated in the figure below:

![Figure 1 The NPCC representation of demand](source: NPCC (2017))

One of the key themes of the report is to identify opportunities to reduce demand placed upon the service through a combination of selecting out demand that police do not need to attend and identifying those incidents that can be addressed through less resource
intensive solutions. An emphasis is also placed on attending incidents where those creating demand have some level of vulnerability (e.g. victims of domestic or sexual abuse).

**Existing literature**

In a previous paper (Walley & Jennison-Phillips, 2017) we drew attention to the perceived differences in the challenges of demand and capacity management between the public and private sectors. Literature from the private sector has long been established, with emphasis on the nature of demand in the service sector. Service demand is often instantaneous or unplanned, with seasonal and random variation (Lovelock 1992) making high utilisation a challenge. Many services also have degrees of variability that make responsiveness and flexibility necessary characteristics of service operations (Frei, 2006). The literature initially focuses on the capacity management aspects of the problem, with capacity adjustments to match demand a desirable practice (Sasser, 1976; Lovelock, 1992). Where capacity is not adjusted, demand management practices become more important. However, within the private sector there remains a desire to meet all profitable demand, so mechanisms such as price adjustments influence the timing of demand to quieter times, instead of always refusing demand when capacity limits are reached. Fitzsimmons and Fitzsimmons (2006) identify five types of demand management:

1. Reservation systems and overbooking
2. Offering complementary services that deflect demand from the core service
3. Segmenting demand so that level capacity can be better utilised by using it to deliver counter-cyclical services
4. Price incentives and price manipulation to influence the size and timing of peaks and troughs in demand
5. Promotion for off-peak times, to deflect demand away from the peak.

Within the public sector, increased demand is not usually met with an increase in revenues or resources unless there is some direct payment for service. This has significant consequences for the ways in which capacity is planned. In many cases capacity levels in the medium term are fixed and the system simply has to cope with whatever demand enters the system (Walley, 2012). Hence, public services adopt cost-centric rather than revenue-centric approaches to capacity management. Figure 2 shows how these approaches are manifested (Walley & Jennison-Phillips, 2017).

The literature on demand and capacity management within policing prior to the NPCC report (NPCC, 2017) is especially sparse. First, there are very few studies of demand for police services at all. One study (Boulton et al, 2017) highlighted the sheer diversity of the demand, with the single biggest identifiable category being concern for welfare (19% of incidents), with public nuisance (18%) and acquisitive crime (17%) also being significant. However, the biggest single category was “other” (28%), showing how the police have to deal with a wide range of rarely occurring situations. The latest crime figures from the Office for National Statistics (ONS) show that there were increases in homicides (14% increase), public order (24%) and robbery (17%). An 8% increase in knife crime has more recently become more of a topic for discussion, with a debate about the impact of the availability of police resources as a possible reason why this type of offence has become more prevalent. There is much discussion of emerging threats in policing (see Ransley and Mazerolle, 2009). The NPCC report cited previously identified 85 separate types of demand coming into police systems.
One study has previously looked at demand and capacity management practices inside one police force, focusing mainly on custody suites (Ritchie and Walley, 2015).

Table 1 Capacity Management Strategies Observed in policing

<table>
<thead>
<tr>
<th>Method</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chase demand</td>
<td>Assets (i.e. cells) are fixed, so in medium-term planning only adjustment of staff offers capacity change. There is limited focus on low utilization of cells, and to an extent staff. Therefore the attention to chasing demand is limited.</td>
</tr>
<tr>
<td>Increasing customer participation</td>
<td>In context of custody the arresting and investigating officers are the customer. The arresting officers have a specific influence on demand and throughput time. There has been awareness and engagement with arresting officers to complete all processing where possible in advance of entering the custody system.</td>
</tr>
<tr>
<td>Scheduling work shifts</td>
<td>A precedent has been set that although there are three shifts, these are consistent in their staffing. This is reflective of limited understanding of short term demand variability.</td>
</tr>
<tr>
<td>Creating adjustable capacity</td>
<td>Staff are paid both a shift and a rota allowance. However both through precedent and local affiliation the flexibility in staff assignment this is meant to provide the force is rarely used. Most of the flexibility is done through good-will agreements.</td>
</tr>
<tr>
<td>Sharing capacity</td>
<td>The rollout of super-custodies is meant to deliver shared capacity in terms of physical assets and staff. Further the use of ‘clusters’ (geographically close facilities) also provides some short-term capacity sharing. Hence capacity is shared across similar facilities more than switching resource from one type of service to another.</td>
</tr>
<tr>
<td>Using part-time staff</td>
<td>Part time staff have been in use for many years, and are inseparable from the full-time staff in their roles.</td>
</tr>

**Research Method**
Between October 2018 and February 2019 all forces that are members of the Centre for Policing Learning and Research at the Open University were invited to participate in a study of police demand and capacity management practices. Out of twenty forces and agencies, fifteen were able to participate on the study within the timescales set. In most cases forces have been anonymised in the research, with the exception of specific cases where permission to identify them has been given. Forces have been labelled by letter (A – O) where single examples are provided.

Each force was visited for at least one day by the research team to gather the basic information. The contact centre for each forced was observed and demand entering the system tracked to establish how work entered the system from 999 and 101 calls and then processed through to dispatch. Where more detailed cases were generated a considerable amount of follow-up information was obtained after visits, including samples of demand data, performance reports from contact centres and other reports of improvement or demand reduction work.

Information was also obtained through direct discussion in structured interviews where the opinions of force officers and staff were obtained to build up a view of the perceptions of staff responsible for aspects of demand and capacity management about the situation their force is in. In most cases, officers and staff from both operational and planning roles were seen, and this allowed contrasting views to be observed. Where permission was obtained, interviews were recorded with the condition that responses were anonymised both in terms of the force and interviewee.

Of relevance to this paper, questions were asked on the following themes:
1. How well do forces and agencies understand their levels of demand?
2. Have forces changed practices involving prioritisation and response as a consequence of demand/capacity imbalances?
3. Are forces trying to reduce demand?
4. What capacity and demand management practices have been adopted across forces?

**Findings**
In this section we summarise the key findings across the case studies.

**Demand Measurement and Forecasting**
Forces generally measured the volume of calls coming into their control centres and used this to measure demand. In all but one of the forces this data collection was carried out by a variety of human interventions and automated processes. One force that had fully automated the process through a bespoke piece of software but this was used primarily as a costing tool. It can work out the amount of demand placed on the force by an individual or business and highlight where costs are being incurred.

Forecasting of call volumes was used in all 15 forces to determine staffing levels for the control centre. These predictions had a variety of successes with one force (F) being an example of good practice in accurately predicting between 97-98% of future calls. Few forces translated this data into hard resource requirements outside of the control centre environment, especially officers needed to meet the demand and any other policing resource, such as investigative requirements. Force M was an exception as they have measured the demand across 30 different teams and created resource models to meet the demand. This has allowed force M to predict their future resource requirements. Generally forces lacked detailed understanding of demand once the call goes beyond the control room.
**Call Journeys**

Although there was some variation in the nature of demand across forces because some were rurally based and others were metropolitan, the basic task of meeting demand is largely the same in all forces. The call journey requires three basic steps:

1. Call handling, where calls are picked up by an operator and assessed for urgency and risk. The outcome is to reject or filter out those calls that do not need to be attended to and pass on all others graded by level of priority.
2. Dispatch, where work is allocated to available officers.
3. Attendance, where officers attend to an incident. More incidents are attended remotely now, e.g. by phone or email.

There was an unexpected amount of variation in the call journeys in each force. The variation mainly occurred through differences in the following aspects of the system design:

- The level of division or resource sharing between 999 (urgent), 101 calls (non-urgent) and dispatch.
- The number of filtering steps before dispatch, including whether or not a switchboard is used.
- The means used to assess the risk of each call.
- Thresholds for response decisions for common incident types, such as shoplifting.
- The levels of one-touch or call handler resolution.
- The levels of integration between call handling and dispatch.
- The points where demand is re-graded, e.g. by dispatch.
- The skill sets used within the contact centres (specialist staff, police officers etc.)
- The grading systems and response targets used.
- The levels of additional back office support, such as assessment units and mental health support.
- The types of response resources used, such as diary cars or booked appointments.

Figures 3 and 4 show the basic flow of calls at force A and Force B:

![Call Journey at Force A](image-url)
Prioritisation and Response

In all 15 forces the national decision making model was fundamental in making and justifying decisions across all ranks and departments. This changes slightly in the call centres where a method called THRIVE (threat, harm, risk, investigative opportunities, vulnerability and engagement) is predominately implemented. THRIVE has been adopted across 13 out of the 15 forces. There was evidence that all forces were simplifying their prioritisation systems, such as the number of levels of job grading, partly to improve the ways in which low-priority demand was dealt with quickly. There were clear trends towards remote resolution, where incidents would not be attended in person and would be classed as advice only. As such most forces now have just three main types of demand: urgent to be attended in person, attended soon and some form of bookable demand, such as diary car. All forces dispatched officers in a timely manner for the respective first priority category. Issues started to arise in the second category often called priority or prompt. The variety of different incidents in this category left it up to the individual dispatchers to reassess the vulnerability and risk before choosing which incidents should be dispatched to first. This problem was identified by force J, who decided to split the priority category into priority high and priority low. Hence the priority list in force J looks like this:

1. Immediate (15mins)
2. Prompt (1 hour)
3. Scheduled
4. Diary
5. Not Dealt with or closed

One of the issues that needed to be addressed in many forces was that of re-grading work where dispatch were unable to send officers within the target time. In many instances, across most forces, a call would be graded as a priority but there would not be the resource to immediately allocate to the work. There were many comments about the problem of the level of unresolved calls still being handled at any one time. In practice, once a response was going to be missed the dispatch team would re-grade the call, usually to a lower grade, including “not deal”. The actual frequency of this occurrence is difficult to objectively measure, partly as there was little desire to highlight this within the control systems.
Forces reported much demand that was unnecessary or was demand that should not be the responsibility of the police. There were common problems associated with demand associated with non-police matters such as noisy neighbours, inconsiderate parking, fly tipping and other civil matters. All forces had a concept of avoidable demand even if they didn’t use that specific term. The definition provided by forces was very similar. The general consensus was that avoidable demand was demand that the police shouldn’t be dealing with. This definition does differ from the formal definition of avoidable demand (demand arising from behaviours that can be changed). The lack of a consistent design archetype for control centres did mean that some failure demand was generated by some of the systems in place. For example, many forces had all 101 calls arrive at a switchboard before the work was passed to call handlers in the contact centre. However the role of the switchboard varied where some merely filtered out calls that were routine contact with office staff but others deflected demand that was deemed inappropriate or unnecessary. There was also significant variation in how work passed through from call handling to dispatch.

**Demand Reduction**

All 15 forces have taken steps to improve their ability to manage demand or indeed reduce demand. These practices have resulted in both success and failure but demonstrate that forces are striving for improvement.

Forces have set up protocols that identify types of demand that should not be dealt with by the police. The actual topics of these protocols varies considerably. These are often incidents such as fly tipping or noise complaints that can be dealt with by another agency in a more appropriate manner. It is not the case that forces are just refusing calls for service but they are educating the public and advising them to contact one of their partners. However, the way that forces have approached this varies between blanket polices that state that they will refuse to deal with a particular call. For example, force A refuse to deal with noisy parties and lost property. By contrast, most other forces will conduct a risk assessment on the call before deciding if they will refuse deployment or not. Some forces have taken this protocol and applied it to calls for service that included a crime. This was approached in two contrasting ways displayed by force A and force B. Force A have started to only respond to shoplifting if the value of the theft is over a stated value. Force B has taken a different approach and they assess the call based on solvability factors. If there are no solvability factors and no vulnerability or risk they will not investigate the crime. Forces have also moved towards increased use of telephone resolution to close an incident in the control room and therefore prevent an officer being dispatched.

Three forces had adopted comparatively sophisticated methods of reducing failure demand (Seddon 2009; Randle and Kippin, 2014). Gloucestershire Constabulary were one of the forces that conducted an in-depth study of their unnecessary demand. They studied a sample of non-urgent demand and discovered that, for every 100 calls that could have been resolved in one contact, the demand created was 160 actual contacts. The number of contacts per incident varied quite considerably, with up to seven extra unnecessary contacts on a single incident (see Walley and Jennison-Phillips, 2018).

**Capacity Strategies**

All forces were able to study demand profiles broken into short (say 15 minute) blocks of calls coming into the contact centres. This did allow them to make adjustments to centre staffing levels at any particular time of day or week. A key measure for these centres is the response time for emergency calls and systems were designed to maintain good
performance in this area. (Some forces did not regularly achieve the target response time of 10 seconds for emergency calls). Forces also made attempts to meet locally-set targets for response to non-emergency calls through capacity strategies. However, these strategies were not carried through as effectively in response functions due to the underlying demand-capacity mismatch. There were capacity adjustments to cope with weekly seasonal demand fluctuation, but as one officer put it “we need to choose when we are most short of capacity”. Demand management or demand deflection is still used to move demand, through the use of appointments. However, the most interesting aspect of current practice concerns the flexing of response thresholds to cope with demand at peak times. The threshold of what would be deemed a response call is adjusted, usually at dispatch, to maintain the balance between demand and resource availability. On a quieter day a less serious or urgent call may be attended. On a busy day an identical call might be graded as “not attend”, re-graded as less urgent than the original call handler grade or left in the system until the incident de-escalates.

Discussion
The findings support the idea that police demand and capacity management fits within the developing theory of cost-centric demand management practices. There is work to reduce the level of resource needed to meet demand through the elimination of failure demand and through attempts to streamline processes. However, this work was seen to be the most challenging to implement as it requires system and behavioural change for it to be effective. As a consequence it was only those forces that were developing high-level demand management strategies that were taking this approach.

It is also clear that changes to the service offering are happening, usually as an emergent strategy that finds ways to reduce resource commitment to some types of demand. In particular, remote resolution through telephone advice and recording only of incidents is happening more frequently. The most significant change is where demand will not be met if there is no policing benefit – such as if attendance will not result in catching a criminal.

Another difference to existing theory comes from how systems adapt to random and seasonal demand variation. Whereas they current theory points towards chase capacity strategies that flex capacity to meet demand, in the case of policing the threshold of what they are prepared to do flexes to limit demand to what they can cope with. There is also some flexing of capacity, but this is mainly limited to the most obvious seasonal peaks and troughs. The elements of chase adjustments are part of a formal plan whereas the threshold adjustments are unplanned but happen relatively consistently when demand exceeds capacity.

All forces declared strategies to move demand from themselves to other agencies, and there was probably some naivety in the belief that demand coming to them as the “wrong place” could easily be shifted elsewhere. In practice the problem is more complex, especially where incidents involve those who are vulnerable. In such cases demand can only be met in cooperation with partner agencies, sometimes having to both deal with an incident at the same time. There was no consistent pattern in how this was achieved, with a variety of initiatives that identified specific themes of partnership working.

At the present time, one of the responses to austerity is to limit demand by simply refusing to attend demand where these is a known capacity constraint. Most of the forces had made announcements about the type of demand that they were no longer willing to deal with, including some types of lesser crime.
Conclusion
This research suggests that police forces in the UK are in a state of continuing adaptation and change with regards to the management of demand and capacity. All forces appear to share the common problem that demand outstrips their current effective capacity to attend to all demand. All forces have had to adapt their demand and capacity management practices as a response to austerity, with more sophisticated approaches to both managing demand and making adjustments to capacity. Our main conclusion is that, however, there is no one single approach that has been adopted, consistent with operations management theory. At present there is instead a wide variety of solutions that are being developed across the forces, where the theory would normally predict a more consistent response.

Lean Supply Chain: the roles of SC partners in the Lean journey

Matteo Rossini (matteo.rossini@polimi.it)
Department of Management, Economics and Industrial Engineering, Politecnico di Milano

Alberto Portioli-Staudacher
Department of Management, Economics and Industrial Engineering, Politecnico di Milano

Abstract
Operations management literature presents a huge amount of successful cases of Lean implemented inside single organization boundaries, but few cases of Lean along supply chains. This research work aims at investigating possible reasons of why companies struggle with adopting Lean principles outside their organizations. Two potential reasons have been investigated through a simulation study: (i) unclear distribution of Lean implementation benefits along the chain and (ii) the necessity of involvement of all supply chain players for getting successful results. We focused on a sample of techniques belonging to Lean sphere: setup-time reduction, production batch size reduction and order size reduction.

Keywords: Lean supply chain, simulation

Introduction
Lean management is famous for its struggle against wastes and it has confirmed as one of the best and most profitable operations management approaches in modern era (Costa et al., 2018; Tortorella et al., 2018). Lean management has been wide implemented by organizations within their boundaries and great results have been achieved (Qing et al., 2015). However, companies cannot survive in the market focusing on its own system only: the destiny of a producer is strictly connected to events and performances of its suppliers and of its distributors (Barnes and Liao, 2012). Even though it is clearly recognized that the application of the Lean principles to the Supply Chain level can lead to further improvements, it seems that the both the study from a theoretical point of view and the practical application of the Lean at this scale is not so simple (Staudacher and Tantardini, 2012; Rossini and Portioli, 2018). Summarizing, the need of the adoption of the Lean practices in a Supply Chain scale is stimulated by the evolution of the competition, but there are few examples of lean approach applied in SCs those are composed by operations partners belonging to different departments/firms (Cabrál, Grilo and Cruz-Machado, 2012; Carvalho et al., 2017; Tortorella, Miorando and Marodin, 2017). This research work aims at bridging this gap, analysing the impact of adopting Lean Management in SCP planning and providing insights about potential criticalities that obstacle the implementation of Lean in SC context. In order to achieve that, a DES
simulation study has been carried out. The paper is organised as follows. The next section reviews the literature on Lean supply chain. In the following section, the paper explains the research methodology adopted for this preliminary study and the simulation model. Then, preliminary results of the research are presented. This article ends with concluding remarks, managerial implications of the study and future research steps in Section 5.

**Literature Review**

Jasti and Kodali (2015) defined the Supply Chain as a set of interconnected resources and processes, beginning from the raw material procurement and going on until the delivery of the final product to the consumer (Jasti and Kodali, 2015). According to them the Supply Chain Management is one of the most interesting research areas for both industry and academia. Academics made strong efforts to apply the Lean principles to a larger context, providing definitions and interpretation keys. Anand and Kodali (2008) defined the Lean Supply Chain as “an application of Lean Manufacturing principles to Supply Chain to integrate the activities of all the stakeholders involved in the Supply Chain network and provide value to the customers by eliminating wastes” (Anand and Kodali, 2008). Hence, the core thrust of lean in supply chain (LSC) is to reduce wastes in order to create a streamlined and highly efficient system that produces at customer demand pace (Shah and Ward, 2003). Differently from single firm planning, Lean in SC needs to consider that the different links are between points those belong to different legal organizations and may be far off each other (Arif-Uz-Zaman and Ahsan, 2014). Mungan et al (2010) studied the procurement, production and delivery over a finite planning horizon for companies characterized by continuous price decrease (Mungan, Yu and Sarker, 2010). Frequent deliveries and small lots are effective to reduce the overall cost of the supply chain. An optimal lot size for raw material and manufacturing batch is determined through an efficient algorithm. Other authors analysed the impact on SC performances of adopting Lean principles in SCP: in an interesting work, Swenseth and Olson simulated continuous improvement implementation in SCP and compared it with different SCP models. Results showed that pursuing continuous improvement principle in SCP model leads to better performances in long-term than other SCP models those appears more profitable in short-term (Swenseth and Olson, 2016). A similar simulation work carried out by Rossini and Portioli Staudacher, analysed in-depth the impact of implementing Pull and Flow principles in SCP and compared it with other SCP models in a single-product SC (Rossini and Portioli, 2018). However, there is not a clear understanding of the full potential of Lean SC model in improving SC performances that appears promising but struggle in its diffusion among industry (Tortorella, Miorando and Marodin, 2017). Regarding the practical application, according to Tortorella et al. (2017), the adaptation of Lean principles to the Supply Chain level is not a simple process for two main reasons: firstly, wastes are easier to be identified at shop floor level, while at SC level the task becomes harder; secondly, managers can easily control the manufacturing processes, while to keep the control on the entire SC a huge amount of information is required form both the suppliers and customers. This research focused on the latter point, in the sense of the relationship with SC partners, attempting to explain other possible causes that lead to difficulty in Lean SC implementation. According to that, two research question have been set:

(i) How are the improvements of LSC implementation distributed along the SC?

The aim of this research question is to highlight that benefits on adopting Lean practices along the SC are not directly corresponded to who invests efforts on implementing Lean practices;
How the adoption of LSC by the different members of the SC is affecting SC final results/performances?

The aim of this research question is to show that a pervasive adoption of Lean SCP along the SC is necessary for reaching great results: when only a SC member adopts Lean SCP good results are achieved, but the potential of Lean is not fully exploited; when more SC players adopt Lean, there is integration among SC partners and synergies in results are created and effectiveness of efforts increases.

Methodology

In order to answer the research questions, a simulation study has been set. During the years SC inventory management has been studied in several ways, and many research works find out that simulation is a perfect tool for analysing quantitatively the impact of SCP on SC performances (Terzi and Cavalieri, 2004). The experiments have been carried out through discrete-events-simulations run by using the Python programming language with a strong utilization of the module Simpy.

3.1 Supply chain model

The Supply Chain is a multi-product, three-echelons Supply Chain made. Every stage is in charge of providing items to the next customer (internal or external) to feed the next production departments downstream, when they demand it. The serial supply chain is composed by three production phases (M1, M2, M3) and four buffer stocks (B1, B2, B3, B4) as presented in the figure 1.

Production activities is activated by a pull mechanism and is triggered by the demand downstream. Every day, when the day starts, orders from final customers are collected. Each order demands a certain quantity of items of a product family. If the available stock is enough to fulfil the demand, the order is immediately processed and the quantity of items demanded are picked by the shipping department and delivered. Therefore, the inventory level in buffer is controlled starting from the first product family (Product 1): if the consume of stocks reached a batch size threshold, the production of a batch is then triggered. The algorithm that manages the production of batches is graphically represented in the figure 2.

3.3 Experimental variables
In this research, Lean SC is simulated through the implementation of batch size and setup time reductions. To verify that the effects of the Lean improvements do not show up just in particular cases, the batch and setup reductions have been applied at different reduction levels: 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%. Since now, the term “lean implementation” is used to indicate the batch size and setup time reduction. Moreover, one aim of the study is to test how the lean implementation of different SC players impacts on final results. Then, different levels of “participation” have been set: stage2, stage3, stage2 and stage3.

Preliminary Results
The performance is measured in terms of stock variance. This decision was driven by computational power limitations. Firstly, impact of single practice implementation has been evaluated, focusing on understanding how advantages of a practice are distributed.
among SC players. Figure 3 presents stock variance reduction while Lean is implemented in the second stage. Simulation results highlights that impacts of LSC practices are not concentrated in system where they are implemented: practices as setup time reduction and order batch size reduction do not lead for sure to positive impact on stock variance in the stage where they are implemented and presented a negative effect on upstream stage. Secondly, combined implementation of Lean have been simulated in order to understand potential synergies between LSCP practices in the results of SC performances. Figure 4 presents the sum of impacts of Lean implemented singularly in stage2 and Lean implemented singularly in stage3. Figure 5 presents the actual impacts of combined implementation of Lean in stage2 and stage3. Simulation results show the impact of implementing Lean in more stage is better than the sum of single implementations impacts.

![Fig. 3. Impact of Lean implementation in stage2](image)

![Fig. 4. Summed impact of single Lean implementation in stage2 and stage3](image)
Conclusions

The integration of the activities and the involvement of all players along the chain through long lasting relationships are required in order to reduce the wastes and increase the value for the customers. The research aims at investigating reasons and dynamics which could explain why Lean Supply Chain is not spread in industry as Lean inside single organizations.

It has been found that when a player implements Lean, it impacts also on other players, specifically the next one upstream. The batch reduction may lead to some misalignment in the production that could lead to negative effects on the variance of stock levels, counterbalancing the positive effects of batch reduction. This result should raise manager awareness on the potential impacts that could derive from lean implementation in a single stage of the Supply Chain. Indeed, it is necessary to take into account some trade-offs between the positive effects, resulting from the batch reduction, and the negative ones, arising from the batch misalignment. From the simulations it resulted that, for certain ranges of batch reductions (small reductions), the performances get worse compared to the initial situation. This means that if the company is not prepared or is not willing to make a significant effort, the lean implementation may conclude in a backlash.

In addition, combined Lean implementation of close players of the Supply Chain leads to synergies, compared to the single implementations, obtaining higher benefits in terms of stock variance reduction. In fact, in this case, there will not be misalignments in the production that lead to negative effects that worsen the variance. In addition, this result suggests that it is preferred to perform very small improvements along the whole chain instead of big improvements in a single point. However, if one or more players arrest the improvement process, the further efforts of the other players will be dampened, discouraging them and making them stop improving as well. Managers can learn that the involvement and the commitment of all the players in the Lean journey are necessary in order to reach positive results. Reaching necessary commitment is difficult, especially along a Supply Chain, where different organizations have different objectives and priorities. This could provide an insight on the reason why today, the Lean implementation at Supply Chain level is not implemented as inside single organizations.

These outcomes reflect the findings of the literature review, from which we learned that restricted applications, low understanding and low commitment (of managers or
personnel) are some of the causes that make the Lean implementation fail. Therefore, the research lends itself to represent a quantitative explanation to support the current theoretical literature.

Power plant preventive maintenance scheduling problem: a 0/1 mixed integer linear programming approach based on cost and reliability to establish and effective policy

Salvador Perez-Canto (spc@uma.es)
School of Industrial Engineering, University of Malaga, Spain

Abstract

This paper gives an approach to preventive maintenance scheduling of power plants in an electric system. This optimization problem has been formulated using a cost-based criterion. The main aim is to know which power plants must stop their production of electricity for periodic inspection over a time horizon. This activity has a considerable impact on power systems because an unforeseen failure in a power plant may cause a general breakdown and the demand of customers for electricity could be unsatisfied. A realistic applied example is included.

Keywords: Preventive maintenance scheduling, Power plant, Cost optimization

Introduction

The problem of power plant preventive maintenance scheduling is an important issue of the power industry. It is usually treated in the long-term exploitation of electric production systems and requires determining the period for which generating units of an electric power utility should be taken offline for planned preventive maintenance over a time horizon. The objective is to minimize the total operating cost while a set of constraints is satisfied (Besnard et al., 2011).

Preventive maintenance is an expensive activity for power generation companies. It requires shop facilities, skilled work force, replacement parts, keeping records, etc. However, the cost of avoidable outages may imply ten or more times the actual cost of repair. Thus, this high cost makes it imperative to economic operation that maintenance be scheduled into the operating schedule (Mohammadi et al., 2008).

A review of the recent literature shows that diverse methods have been proposed. These include: multiobjective optimization (Jafarian et al., 2012); mixed integer programming (Alam et al., 2017); decomposition methods (Canto, 2008); genetic algorithms (Giftson and Asir, 2012); heuristic techniques (Lee and El-Sharkawi, 2008); particle swarm optimization (Ekpenyong et al., 2012); meta heuristic-based hybrid approaches (Dahal and Chakpitak, 2007); neural networks (Mohammadi et al., 2008); harmony search (Fetanat and Shafipour, 2009); hybrid evolutionary approach (Reihani et al., 2010); ant colony (Fetanat and Shafipour, 2011); simulated annealing (Schlünz and Van Vuuren, 2013); and intelligent optimization techniques (El-Sharkh, 2014).
The main contribution of this work is to present a global approach to the problem under study, designing a model based on a cost perspective, and achieving an optimal solution. The research performed here encompasses a wide range of power plants: thermal, nuclear, hydroelectric, and wind power plants. In addition, a complete set of constraints is included to model the real world for power systems. The model analysed is representative of current energy production systems in many countries and regions.

**Problem definition**
The power plant preventive maintenance scheduling problem consists in disconnecting a power plant periodically to review its functioning and to detect potential failures. The planned maintenance is designed to lengthen the life of power plants and to maintain their safety. Since power plants are integrated into a global electric system, an unpredicted failure might hit the system by causing an undesirable interruption in the power supply and subsequent customer dissatisfaction. A double perspective can be distinguished: cost (Saraiva et al., 2011; Umamaheswari et al., 2017) and reliability (Giftson and Asir, 2012; Mollahassani-pour et al., 2015). Electric energy demand must be supplied at a convenient reliability level and the associated cost of shutdown of a power plants grid should be as low as possible.

This problem is categorized as a 0/1 mixed integer linear programming problem. Its complexity must be addressed and arises from the enormous size of the system to be modelled. A large number of variables are present in the formulation, especially considering the binary variables, which are the most difficult to handle.

The time planning horizon selected is 1 year (13 periods or 52 weeks). A time interval of 13 periods is the option for this study. The average maintenance lasts 4 weeks. The notation for periods of time will be 'k', varying from 1 to 13. Two parts are distinguished in each period of time, weekdays and weekends, according to the electric demand, with the larger demand occurring during weekdays. Each part is divided into three different subparts depending on the electric demand. The aforementioned subparts, from higher to lower demand are peak, shoulder, and valley. Thus, there are 6 subperiods with different durations. Its notation will be 'n', varying from 1 to 6. The previous distribution is repeated three times according to three possible electric demand scenarios, 's': high (s_h), medium (s_m), and low (s_l). This is a way to model the stochastic nature of the power demand. A probability of occurrence has been assigned to each scenario.

**Mathematical formulation of the problem**
In the following, the power plant preventive maintenance scheduling problem is formulated according to a mathematical model and an optimization perspective. Objectives such as cost minimization and consecution of a certain reliability level are proposed by imposing an objective function and satisfying a set of constraints (Jafarian et al., 2012; Lusby et al. 2013; Zhong et al., 2018).

The most relevant variable in this problem is the maintenance variable, whose notation is x_{i,k}. It is a binary variable (0/1) that indicates the following: x_{i,k} = 0: power plant i is not in maintenance during period k; x_{i,k} = 1: power plant i is in maintenance during period k.

Another 0/1 variable involved is c_{i,k}, which denotes the maintenance start-up and is indicated as follows: c_{i,k} = 0: maintenance of power plant i does not start at the beginning of period k; c_{i,k} = 1: maintenance of power plant i starts at the beginning of period k.
Costs are the objective function of the problem. They are divided into five types: fixed cost (it does not depend on the power production), start-up (cost of putting a power plant into operation), shutdown (cost of disconnecting a power plant), production (cost of producing a megawatt-hour), and maintenance (cost of putting a power plant into preventive maintenance). Fixed, shutdown and maintenance costs are negligible in comparison to start-up and production costs. The expression for the total cost is:

\[
\sum_{s \in S} \sum_{k \in K} \sum_{n \in N} q_s \left( f_i \cdot y_{i,s,k,n} + g_i \cdot p_{i,s,k,n} \cdot \tau_n \right) \quad (1)
\]

The first term refers to start-up cost and the second to production cost of power plant \(i,\) subperiod \(n,\) period \(k,\) scenario \(s\) (\$); \(I = \) index set for power plants; \(S = \) index set for demand scenarios; \(K = \) index set for periods in demand scenario; \(N = \) index set for subperiods in a period; \(q_s = \) probability of demand scenario \(s;\) \(f_i = \) start-up cost of power plant \(i\) (\$); \(y_{i,s,k,n} = \) start-up variable of power plant \(i,\) subperiod \(n,\) period \(k,\) scenario \(s;\) \(g_i = \) electric energy cost produced by power plant \(i\) (\$/MWh); \(p_{i,s,k,n} = \) output of power plant \(i,\) subperiod \(n,\) period \(k,\) scenario \(s\) (MW); and \(\tau_n = \) duration of subperiod \(n\) (h). \(y_{i,s,k,n}\) is a 0/1 variable whose value is given by the next criterion: \(y_{i,s,k,n} = 0: \) power plant \(i\) does not start at the beginning of subperiod \(n,\) period \(k,\) scenario \(s;\) \(y_{i,s,k,n} = 1: \) power plant \(i\) starts at the beginning of subperiod \(n,\) period \(k,\) scenario \(s.\)

The cost of the electric energy produced by a power plant is applicable only to thermal and nuclear power plants. Hydroelectric and wind power plants do not have production costs because the resources used are free. The start-up costs are also equal to zero.

The constraints of the problem are classified in five sets: maintenance, production operation, maintenance and connection, generating volume, and wind power constraints.

MAINTENANCE CONSTRAINTS

\(a)\) Maintenance window: the maintenance of the power plant \(i\) has a duration of \(\beta_i,\) periods.

\[
\sum_{k \in K} x_{i,k} = \beta_i \quad \forall i \in I \quad (2)
\]

\(b)\) Period: a maximum number of maintenance \(\psi_k\) is imposed in period \(k.\)

\[
\sum_{i \in I} x_{i,k} \leq \psi_k \quad \forall k \in K \quad (3)
\]

\(c)\) Maintenance continuity: when a power plant is removed from the electric production system for maintenance, it completes the maintenance with no interruption.

\[
x_{i,k} - x_{i,k-1} \leq c_{i,k} \quad \forall i \in I \quad \forall k \in K \quad (4) \quad \text{For } k=1, \text{ select } x_{i,0}=0.
\]

\(d)\) Precedence: this constraint ensures the order to follow in maintenance. If the maintenance for power plant \(i\) precedes the maintenance for power plant \(j,\) then
\[
\sum_{k=1}^{k} c_{i,k} - c_{j,k} \geq 0 \quad \forall k \in K \quad (5)
\]
\[
c_{i,k} + c_{j,k} \leq 1 \quad \forall k \in K
\]

**e) Exclusion:** power plants i and j cannot be in maintenance at the same time.

\[
x_{i,k} + x_{j,k} \leq 1 \quad \forall k \in K \quad (6)
\]

**f) Interval:** a number of ‘e’ periods are introduced between maintenances of power plants i and j. A sequence is provided. If \( \delta \) is the time horizon, then the formula is

\[
c_{i,k} = c_{j,k+\delta} \quad 1 \leq k \leq \delta - \beta_i - e
\]

\[
\sum_{k=1}^{k} (c_{i,k} + c_{j,k+\delta}) = 2
\]

**g) Overlap:** there is an overlap of ‘u’ periods between the maintenance of power plants i and j. Power plant i is the first plant out of service.

\[
c_{i,k} = c_{j,k+\delta - u} \quad 1 \leq k < \delta - \beta_i + u \quad (8)
\]

**h) One-time maintenance:** each power plant has only one outage for maintenance over the time horizon considered.

\[
\sum_{k \in K} c_{i,k} = 1 \quad \forall i \in I \quad (9)
\]

**i) Deadline:** the maintenance for power plant i must finish before the end of period \( T_i \).

\[
\sum_{k=\delta}^{T_i + \delta} c_{i,k} = 1 \quad \forall i \in I_d \quad (10)
\]

\( I_d \) is the set of power plants affected by this constraint.

**j) Crew availability:** the number of people required for preventive maintenance cannot exceed the available crew within each period of time.

\[
\sum_{i \in I} C_{N_i} \cdot x_{i,k} \leq C_{R_k} \quad \forall k \in K \quad (11)
\]

\( C_{N_i} \) is the number of people who are needed by unit i and \( C_{R_k} \) is the total number of people who are available at period k.

**k) Maintenance working hours:** the number of maintenance working hours used is less than the number of working hours available within each period of time.

\[
\sum_{i \in I} W_{H_{N_i}} \cdot x_{i,k} \leq W_{H_k} \quad \forall k \in K \quad (12)
\]
WHN\textsubscript{i} is the number of working hours needed for the maintenance of unit \textit{i} and WH\textsubscript{k} is the total number of working hours available at period \textit{k}.

\textit{l) Geographical location:} it enforces a maximum number of maintained wind farms, NPM\textsubscript{R}\textsuperscript{max}, in a region \textit{R} from a set of regions \textit{G}, to avoid the reduction of electric capacity during the time horizon.

\[
\sum_{i \in R} \sum_{k \in K} c_{i,k} \leq NPM_{R}^{\text{max}} \quad \forall i \in R \quad \forall R \in G
\]  

\textbf{PRODUCTION OPERATION CONSTRAINTS}

\textit{a) Production level bounds:} each power plant is designed to work between minimum and maximum power capacity (MW).

\[
v_{i,s,k,n} \leq \bar{p}_{i,s,k,n} \leq \bar{p}_{i} \quad \forall i \in I \quad \forall s \in S \quad \forall k \in K \quad \forall n \in N
\]  

\[
p_{i} = \text{nominal minimum power for power plant } i \text{ (MW)}; \quad \bar{p}_{i} = \text{nominal maximum power for power plant } i \text{ (MW)}; \quad \text{and } v_{i,s,k,n} = \text{connecting variable for power plant } i, \text{ subperiod } n, \text{ period } k, \text{ scenario } s. \quad v_{i,s,k,n} = 0: \text{ power plant } i \text{ is not connected in subperiod } n, \text{ period } k, \text{ scenario } s; \quad v_{i,s,k,n} = 1: \text{ power plant } i \text{ is connected in subperiod } n, \text{ period } k, \text{ scenario } s.

\textit{b) Demand supply:} power production in each subperiod must meet the electric demand, with a constant value in the considered subperiod of time.

\[
\sum_{s \in S} p_{i,s,k,n} = d_{s,k,n} \quad \forall s \in S \quad \forall k \in K \quad \forall n \in N
\]  

\[
d_{s,k,n} \text{ is the power demand in subperiod } n, \text{ of period } k, \text{ in scenario } s \text{ (MW)}.

\textit{c) Reserve:} the reserve is a margin of action if some eventuality occurs. If rr\textsubscript{s,k,n} (MW) is the reserve in subperiod \textit{n}, of period \textit{k}, in scenario \textit{s}, usually calculated as a percentage of the electric demand, then the results is as follows:

\[
\sum_{s \in S} v_{i,s,k,n} \bar{p}_{i} \geq d_{s,k,n} + rr_{s,k,n} \quad \forall s \in S \quad \forall k \in K \quad \forall n \in N
\]  

\textit{d) Start-up:} it establishes the start-up logic for thermal and nuclear power plants. The variable \(y_{i,s,k,n}\) must satisfy the following constraint to model the start-up costs:

\[
y_{i,s,k,n} \geq v_{i,s,k,n} - v_{i,s,k,n-1} \quad \forall i \in \{I-I_{2} - I_{4}\} \quad \forall s \in S \quad \forall k \in K \quad \forall n \in N
\]  

\(I_{2}\) is the index set for hydroelectric power plants and \(I_{4}\) for wind power plants. When \textit{n} is equal to 1, the applied contour condition is the condition that corresponds to the last subperiod of the previous period (when \textit{k} = 1, 0 is selected for the connecting variable).

\textbf{MAINTENANCE AND CONNECTION CONSTRAINT}

It models the correlation between \(x_{i,k}\) and \(v_{i,s,k,n}\).
For nuclear power plants, only equality exists because they are always connected, except when in maintenance. \( I_1 \) = index set for thermal units and \( I_3 \) = index set for nuclear units.

**GENERATING VOLUME CONSTRAINTS**

**a) Minimum volume:** it is related to a particular country and to coal thermal power plants. A minimum production using national coal is required to maintain jobs.

\[
\sum_{n \in N} p_{i_1, s, k} \tau_n \geq E_{i_1} (1 - x_{i_1, k}) \quad \forall i_1 \in I_1 \quad \forall s \in S \quad \forall k \in K \tag{19}
\]

\( E_{i_1} \) is the minimum energy (MWh) to be produced by power plant \( i_1 \). The parameter \( \tau_n \) is the duration of subperiod \( n \) (h).

**b) Maximum volume:** this is applied to thermal power plants. Legislation enforces a maximum limit of energy production to reduce the environmental impact.

\[
\sum_{n \in N} p_{i_2, s, k} \tau_n \leq \bar{E}_{i_1} (1 - x_{i_2, k}) \quad \forall i_2 \in I_2 \quad \forall s \in S \quad \forall k \in K \tag{20}
\]

\( \bar{E}_{i_1} \) is the maximum energy (MWh) to be produced by thermal power plant \( i_1 \).

**c) Water volume:** it is related to hydroelectric power plants. A basin water reserve cannot be used only to produce electricity because of human consumption and irrigation.

\[
\sum_{n \in N} p_{i_2, s, k} \tau_n = E_{i_2, s, k} (1 - x_{i_2, k}) \quad \forall i_2 \in I_2 \quad \forall s \in S \quad \forall k \in K \tag{21}
\]

\( E_{i_2, s, k} \) is the energy (MWh) to be produced by hydroelectric power plant \( i_2 \) in period \( k \) of scenario \( s \):

\[
E_{i_2, s, k} = 0.12 \frac{p_{i_2}}{p_{i_2}} \sum_{i_2 \in I_2} d_{s, k, n} \tau_n \quad \forall i_2 \in I_2 \quad \forall s \in S \quad \forall k \in K \tag{22}
\]

**WIND POWER GENERATION CONSTRAINTS**

**a) Maximum energy allowance:** when the electricity produced by a wind power plant reaches a certain level, it must be stopped because of the impossibility of disconnecting other power plants, such as nuclear power plants.

\[
\sum_{n \in N} p_{i_4, s, k} \tau_n \leq \bar{E}_{i_4, s, k} (1 - x_{i_4, k}) \quad \forall i_4 \in I_4 \quad \forall s \in S \quad \forall k \in K \tag{23}
\]

\( \bar{E}_{i_4, s, k} \) is the maximum energy (MWh) to be produced by wind power plant \( i_4 \) in period \( k \) of scenario \( s \).
b) Functioning hours: the number of hours that a wind power plant works is dependent on the wind regime of the geographical area considered. An average percent of the total number of hours in the time horizon is imposed.

\[
\sum_{k \in K} FH_{i_k,k} \cdot x_{i_k,k} \leq r_{i_k} \cdot TNH \quad \forall i_k \in I_k \quad (24)
\]

\( FH_{i_k,k} \) represents the working hours associated with wind power plant \( i_k \) during period \( k \).
\( TNH \) is the global number of hours of the time horizon, and \( r_{i_k} \) expresses the percentage applied according to the wind regime in the geographical area where \( i_k \) operates.

**Model and methodology for the problem**
The problem analysed is modelled as a 0/1 mixed integer linear programming problem because of its linearity and the inclusion of real and integer variables. The integer variables considered are binary. The model in this paper also includes real variables.

In compliance with the objective function and the constraints described in the previous section, the problem is modelled in the following form:

Minimize (1), subject to (2-24).

**Application example**
An application example based on a high-dimensioned realistic power system, similar to the Spanish one, was undertaken to validate the proposed analysis. The power system characterised has the following features: 100 power plants (50 thermal, 20 hydroelectric, 8 nuclear and 22 wind), 3 power demand scenarios, 13 periods, and 6 subperiods.

The entry data are: set of constraints, probabilities for power demand scenarios, power demand order for periods; peak, middle, and low duration in a period; fuel cost for thermal and nuclear power plants; power reserve; power demand, power plant capacity, nominal maximum power, etc. Owing to space limitations, the information is not detailed here.

After running the model for the application example using the industrial software GAMS, the findings are described below.

a) Objective function: The total cost of the system is $1,387.904 million.

b) Maintenance schedule: The time-plan is displayed on Table 1. The power plants labelled 1-50 are thermal, 51-70 hydroelectric, 71-78 nuclear, and 79-100 wind.

c) Power produced by four representative power plants for the medium demand scenario
Four graphics are provided that represent the average amount of power produced (MW) by an example of a thermal, a hydroelectric, a nuclear and a wind power plant in the three demand scenarios with respect to the total number of subperiods (78).

Figure 1 - Power by thermal power plant 20

Figure 2 - Power by hydro power plant 65

Figure 3 - Power by nuclear power plant 72

Figure 4 - Power by wind power plant 9
d) Cost associated with two representative power plants for the medium demand scenario

The following two graphics represent the average variation of cost (million $) for a thermal power plant and a nuclear power plant in the three demand scenarios with respect to the total number of subperiods (78). In line with the situation of no power produced, the total cost associated with the power plant under maintenance is zero. The global cost for hydroelectric power plants and wind power plants is also zero.

![Figure 5 - Cost for thermal power plant](image1)

![Figure 6 - Cost for nuclear power plant](image2)

The graphics for power and cost show a conventional way of functioning by the power plants considered.

**Conclusions**

This paper has explored the power plant preventive maintenance scheduling problem. In order to achieve a high quality service, its analysis stems from an essential need to maintain the electric supply of an electric grid. There are two main targets that address this problem: determining the periods of time to take down power plants for planned preventive maintenance over a certain time horizon and obtaining the specific power to be generated by every power plant and its cost according to a set of constraints imposed.

The problem under study is highly complex. The inclusion of topics related to maintenance, production operation, generating volume, and wind power, make this study quite detailed. The proposed solution provides insight into the problem using a cost perspective and after modelling a high number of constraints, providing a realistic frame.

The proposed model and methodology was applied to a large-sized and realistic electric production system to verify its efficiency. The results obtained are consistent and reflect the expected behaviour and effective performance of the electric system analysed. In addition to the specific maintenance schedule, findings obtained include the electric power produced by the power plants, as well as the associated costs, and demonstrate that the analysed methodology works correctly, in line with empirical situations.

The main contributions are: i) an integrated model for generator maintenance scheduling has been formulated for an adequate maintenance strategy; ii) several costs have been combined into a complex and general model for a power system to increase its efficiency; iii) different types of power plants were considered, including renewable energy in terms of hydroelectric and wind energy to obtain more sustainable power systems and to reduce the impact on the environment; iv) the model designed to analyse this complex problem uses a wide variety of variable and constraints; v) the results may well be an effective policy if they are applied to other realistic electric grid cases.

Measuring and visualizing delivery schedule variations in automotive supply chains

Patrik Jonsson, (patrik.jonsson@chalmers.se)
Chalmers University of Technology, Division of Supply and Operations Management,
Gothenburg, Sweden

J. Magnus Kjellberg
Chalmers University of Technology, Department of Computer Science and Engineering,
Gothenburg, Sweden

Abstract
The purpose of this paper is to describe and categorize inaccuracies in delivery schedules shared in European automotive supply chains, to relate types of inaccuracies to performance, and to propose how to measure and visualize inaccuracy types for value adding information access in suppliers’ planning processes. We first develop new measures of delivery schedule accuracy measurement and suggest how to process delivery schedule data for accuracy measurements. We then conclude the following from analyzing two years of delivery schedule data from five suppliers in European automotive supply chains: The value of information sharing is determined by the accuracy and visibility of the data. In automotive industry supply chains, measurement of late daily variations during, and schedule nervousness should complement traditional random and systematic accuracy measures. Weekly delivery schedules have very low accuracy on longer than 8 to 10 weeks horizon. A large proportion of schedule inaccuracies are due to schedule nervousness, and inaccuracies follows Pareto pattern based on customer and item groups, and escalate upstream supply chains.

Keywords: Big data, delivery schedule, Information sharing, performance measurement, supply chain management

Introduction
Numerous academic literature has studied variations, uncertainties and quality in demand information shared in supply chains. This study focuses on the measurement and visualization of delivery schedules, i.e. planned order information generated from MRP calculations and transferred to suppliers in supply chains – normally using daily EDI transactions. This is a common form of demand information sharing in, for example, the automotive industry. For several suppliers, this is the major, and sometimes only, demand information used as gross requirement in their production planning (Jonsson and Myrelid, 2016; Wang et al., 2016). Due to inaccuracies (i.e. schedule inaccuracy and bias) the information is not always used as intended (Jonsson and Myrelid, 2017) and/or results in unnecessary rescheduling, reworking, safety mechanisms, and/or backlogs (Myrelid, 2017). Schedule inaccuracies may escalate upstream supply chain tiers (Forslund and Jonsson, 2007), and the extent depends on item commonality, planning frequency, planning period, frozen periods, etc. (e.g. Myrelid, 2017).
Consequently, studies identify that delivery schedules are widely adopted in practice but that they are associated with inaccuracies. Still, no identified study has detailed and empirically analyzed the commonality or severance of different types of inaccuracies, or how to measure and visualize schedule variations to be managed in the suppliers’ planning processes. Such studies would, for example, be important in order to motivate and initiate studies on delivery schedule measurement, delivery schedule quality causes, and delivery schedule inaccuracy mitigation, and efficient and effective delivery schedule usage in supply chains.

The purpose of this paper is to describe and categorize inaccuracies in delivery schedules shared in European automotive supply chains. More specifically, problems and analysis relate to the following RQs:

RQ1: How could delivery schedule inaccuracies be measured and visualized for suppliers?
RQ2: What is the amount and type of delivery schedule inaccuracies in automotive supply chain delivery schedules?
RQ3: What is the performance effects of different types of delivery schedule inaccuracies?

Literature review

We leverage three streams of research in our work. The first area pertains to demand information visibility and utilization in supply chains. This literature moves beyond the importance of information sharing and focuses on the quality, and the extent to which the shared information is useful, easy to use and really used to generate value (Barratt and Oke, 2007; Jonsson and Myrelid, 2016; Viet et al., 2018). Information quality dimensions, such as, accuracy, timeliness and readily usable format determines the quality and visibility of shared information. EDI is a formal mode of information communication where data is communicated in standardized format and following a routinized time schedule (e.g. daily). The communication between sending and receiving actors can normally be fully integrated. The usefulness of the delivery schedule data can therefore to quite a large extent be expected to be a function of the accuracy.

The second area is plan/schedule stability and schedule accuracy measurement. The two major streams of schedule stability of relevance for this study are time fence management and MRP nervousness. Time fence management concerns the generation of stability in plans using time fences and specified planning policies or guidelines of restrictions for different time zones (e.g. Ho et al., 1995). The period corresponding to the throughput time of an order in the workshop normally constitutes a frozen time zone. Since orders within this time interval are already released, changed plans may result in increased production costs and decreased production efficiency and delivery service. Consequently, all types of delivery schedule variations within a frozen time zone can be expected to have negative performance impacts. Frequently changing planned order schedules is called MRP nervousness (e.g. Ho et al., 1995). Studies have presented measures of MRP nervousness and suggested solutions to reduce nervousness (e.g. Ho et al., 1995; Pujawan, 2004; Li and Disney, 2017). Schedule accuracy measurement is covered in detail in the forecast literature, but the literature calls for more empirical studies on its effects (Syntetos et al., 2015). Forecast accuracy is traditionally measured in terms of random and systematic deviations between actual and forecast values. Mean absolute percentage error (MAPE) and BIAS are commonly used forecast measures. Similar measures should be possible to use to measure delivery schedule accuracy. It is hard to say what is a good or a bad forecast accuracy performance – as it depends on planning bucket sizes and item aggregations, planning horizon and specificity of the item. A recommendation of the German automotive association VDA (2008) suggests that 90-95% schedule accuracy on item level corresponds to medium performance for weekly planning buckets on 3 to 8 weeks horizon (time lags). Less than 90% accuracy is a bad performance in
this recommendation. In a delivery schedule environment, schedule nervousness contributes to the schedule inaccuracies and it would therefore be relevant to distinguish between nervousness-generated inaccuracy and non-nervousness-generated inaccuracy.

The third area is literature about our empirical phenomenon, i.e. delivery schedules, schedule inaccuracy performances, and the automotive industry. This literature is more limited compared to the two first areas. It has been reported that measuring the impact of forecast errors is difficult (Kerkkänen et al., 2009), and various buffering and dampening approaches and performance effects of schedule inaccuracies is defined and used (e.g. Koh et al., 2000; Myrelid, 2017). Supply chain information sharing in the automotive industry has been studied with some different focuses, but common for the studies is that they indicate that EDI-based delivery schedule data sharing is associated with problems related schedule variations (Wang et al., 2016; Myrelid, 2017), lack of trust (Jonsson and Myrelid, 2016), lack of risk assessment (Simchi-Levi et al. 2015), and that there is a potential of applying advanced data analytics to improve the quality of data sharing in automotive supply chains (Hennelly et al., 2017). However, literature is almost absent from detailed empirical analyses.

Methodology
A multiple case research approach is used to analyse two years’ delivery schedule records received by five global suppliers in the automotive industry. The schedules are used as gross requirements in the suppliers’ demand management processes. The suppliers act as first-, second- and third-tier suppliers, so this set up allows us to conduct comparative analysis between schedules received from OEMs and suppliers. We apply a mixed-method approach combining quantitative analysis of a large set of delivery schedule data and qualitative data analysis of schedule usage at the respective supplier. To validate our findings, we have discussed the findings with representatives from three OEMs and the studied suppliers in interviews and two common workshops. Suppliers are chosen to be different in terms of types of items, manufacturing strategies and delivery patterns.

Quantitative data collection and preparation
Delivery schedule data from five suppliers were collected for years 2017 and 2018, and stored in a database. The following 11 variables were extracted from the delivery schedule database: (1) Customer number, (2) Item number, (3) Ship to gate address, (4) Order number, (5) Forecast indicator, (6) Demand date (The date on which the item should arrive at the shipping address), (7) Plan received date (The date when the plan is received), (8) Delivery schedule ID, (9) Quantity, (10) Demand bucket (This field indicates the time period covered by the demand in the delivery schedule. 1=daily demand, 2=weekly demand, 3=monthly demand, 4=yearly demand, 5=Biweekly demand). For each supplier a number of data preparation steps were performed to generate an analysis-ready data format:

(1) First a schedule grouping logic was defined. We choose to group schedules in groups of schedules with identical combinations of Customer number-Item number-Ship to gate address-Demand date or Customer number-Item number-Ship to gate address-Demand week, respectively, depending on whether daily or weekly aggregated data was being generated.

(2) The delivery schedule data contained multiple demand buckets (daily, weekly, bi-weekly and monthly) which had to be aggregated. First all schedules were converted into daily buckets, i.e. weekly, bi-weekly and monthly buckets where evenly split into daily demands. In cases where multiple schedules were received on a certain planning day, only the last schedule received was used. This generated daily data that was further processed.
(3) Weekly aggregated data was generated by taking the last daily demand for each week, i.e. only the last daily data for each planning week was used.

(4) As the data received only contained explicit updates to schedules we had to fill with implicit data: (a) For days when no update for a certain schedule group was received but any other schedule group for the Customer-Item-Address was updated the updated volume for the schedule group was set to zero. (b) If no updates for the Customer-Item-Address were received all schedule groups for that Customer-Item-Address were updated by copying the volume from the previous day. The same procedure was also followed on weekly data, however, data was copied from the previous week.

(5) For each schedule group we defined a reference volume, i.e. the volume that was most likely delivered to the customer. For weekly data we used the volume that week before the reference volume. For daily data, the analyses performed did not require any reference volume being defined.

Customer metadata, comprising of customer group (3 to 102 categories per supplier) and OEM/Tier1 mappings, was appended to the dataset. Similarly, item metadata, comprising of item group mappings (7 to 300 categories per supplier), was appended to the dataset. Table 1 summarizes some supplier characteristics.

Note: Weekly data

Quantitative data collection and analysis
Based on the literature review we define the following types of variations and measures to be measured and described in delivery schedule data:

(1) Late variations: We used daily planning buckets to measure the extent of late quantity changes (within two weeks from delivery). Any quantity change (no matter amount of change) was measured. Two weeks lag time was decided as this was the average frozen period at the suppliers.

(2) Random variation: We used the mean absolute percentage error (MAPE) to measure the random forecast error, on weekly planning buckets and planning horizons between 0 and 20 weeks. For each schedule the absolute percentage difference between the scheduled volume and the reference volume was calculated. As reference volumes could be zero and thus the percentage error is undefined, we set those errors as being 100 % if the scheduled volume was greater than zero. Following this we calculated the mean of the absolute errors.
for the schedules, possibly partitioned by a relevant categorical variable (customer groups, Tier/OEM, item group), was reported. We also calculated the fraction of plans that has an absolute percentage error less than 10, 20 or 40%, respectively.

(3) Systematic variation (BIAS): Systematic schedule variation was measured as systematic over- or under dimensioned weekly volumes on 1 to 20 weeks planning horizon.

(4) Schedule nervousness: We calculated the fraction of plans that changed from the current schedule until the week before the demand week. A modified version of this metric was used for determining the time-dependent variance, which we here use as a definition of schedule nervousness. We measure nervousness as being the fraction of schedule groups that are changed from the current schedule until the week before the demand week, and that change either to or from zero volume. We then report the fraction of variance accounted for by nervousness. Figure 1 shows an example of how changes to planned volumes of a Customer-Address-Item group shift over time. Black denotes planned volumes greater than zero. The x-axis represents demand weeks, and the y-axis represents schedule weeks.

(5) Backorder: We use backorder to measure performances/consequences of inaccurate schedule information. A backorder was defined based on the schedule data as schedule groups where demand date or demand week are prior to last non-zero volume update to the schedule group. We also filter backorders by only considering one- or two-week backorders. By this we avoided to include the limited set of schedules that are long-term backorders, most likely faulty added schedules or system errors.

Findings
Measuring and visualizing delivery schedule inaccuracy
MAPE – the ‘traditional’ forecast accuracy measure of random variations – is also a relevant measure to measure random delivery schedule variations. Measuring MAPE of delivery schedule data requires that a delivery schedule group database is created, and that bucket sizes (daily/weekly/monthly) are determined. In this study we have worked with daily and weekly buckets.

In our analysis (Figure 2 and Table 1) we identify that the average weekly item-level MAPE with 4 weeks of time lag for the five suppliers varies between 20 and 60%, and for 8-10 weeks lag it varies between 20 and 100%. MAPE measures continuously improve for shorter time lags. For longer than about 10 weeks time lag the average MAPE values are in general high in absolute values: 40 to 60% for three suppliers and lower for one and higher for one supplier. This indicates that the accuracy for weekly schedules on longer than 8 to 10 weeks time lags are associated with very high random variations (MAPE). The ‘Fraction of number of plans’ graph in Figure 2 indicates that Case C receives a larger fraction of the total number of schedules far in advance, which may explain why its MAPE-values are higher. The ‘Fraction of total volume’ graph further shows that the total volumes are lower the longer the
time lag is, especially for time lags longer than 8-10 weeks. These findings, consequently, question the value of sending schedules far in advance, with time lags longer than about 10 weeks – at least if using weekly time buckets.

Figure 2 – MAPE and fractions changed, number and volume of plans across cases on 1-20 weeks time lags

Figure 3 shows the fraction of schedules being 10%, 20% and 40%, respectively, inaccurate in terms of MAPE. 21-36% of the suppliers’ schedule groups have larger MAPE than 10% on 4 weeks lag, and 28-53% have larger MAPE than 10% on 8 weeks lag. Consequently, for all suppliers, we see a dramatic increase in the fraction of inaccurate plans during the last 4 weeks before delivery date, and for most suppliers this fraction decreases dramatically also when extending the time lag from 4 to 8 weeks. For some suppliers (B and D) it is about the same fraction of schedules that are 10%, 20% and 40% inaccurate, i.e. this indicates that those being inaccurate are very inaccurate. These suppliers use ATO manufacturing strategies and sequence deliveries, which may indicate that a limited amount of variant items may be more inaccurate. For suppliers A, C and E, however, there is quite smaller fractions of schedules being 20% or 40% inaccurate compared to those being 10% inaccurate. These suppliers make standard items to stock. Still, for all suppliers there is a large fraction of schedules (17-37%) being 40% inaccurate on 8 weeks time lag. Another observation is that Supplier A, but also Supplier E, which apply MTS strategies, have generally higher MAPE values than the other three suppliers. Table 2 shows that the fractions of items with late variations are 57%, 43%, 31%, 25% and 12%, respectively. Consequently, relatively large fractions of all items are associated with late schedule changes within frozen time zones. It is not clear to the suppliers if and how customers apply time fence management and frozen time zones. This, however, indicates that customers are not consistently using frozen plans.
Analyzing the distribution of MAPE across item groups and customer groups (Table 2) shows that for some suppliers (especially supplier D), a small proportion of customer/item groups stands for a large proportion of inaccurate schedules. This pattern is especially clear for late variations. We also compared MAPE and the fraction of late variations between schedules received from an OEM and from another supplier. For all suppliers having both OEMs and suppliers as customers, the fractions of late variations are (41 to 132%) higher for schedules from customers acting as a supplier in the supply chain. This pattern also exist but is not as significant for MAPE. For one of our suppliers the MAPE is much higher, and for one it is much lower, when schedules are received from OEMs and for two there are quite small differences. All in all, we confirm a bullwhip-type of effect where variations increase upstream the supply chain – mainly because of increasing late variations within suppliers’ frozen time zones. We have studies random and late variations separately, but we also see that there is a strong correlation between the size of random (MAPE) variation and fraction of late variations, which indicates that items with large random variation (MAPE) tend to end up in larger fractions of late variations, compared to items with low random variation.

Note: **p<.01

Figure 4 shows the ratio of schedule variations (and, thus, indirectly MAPE) that is caused by schedule shifts to and from zero quantities. These schedule variations are defined as nervousness. The nervousness ratio is relatively high for four of the five suppliers. On weekly basis, the nervousness stands for more than 70% of the variations on 10-20 weeks horizon, and for more than 50% of the variation on 2-9 weeks horizon. Only one of the five suppliers show very low nervousness ratio on weekly basis. On daily basis (days 1-14), no supplier shows very low nervousness ratio, with four suppliers having ratios about or above 40%. Consequently, these findings show that schedule nervousness is a key cause for schedule variations – both for weekly schedules and for daily schedules within the frozen zone. The
high daily nervousness ratios further indicate that several customer companies don’t have frozen plans.

Figure 4 - Schedule nervousness ratio

Performance effects of schedule inaccuracies
Performance effects were in this study measured as backorders, i.e. if a schedule group results in a delivery after the registered delivery date. Table 3 shows that 0.1 to 0.8% of all schedule groups result in backorders. This corresponds to 26 to 3904 backorders per supplier. Figure 5 compares the MAPE and BIAS between schedule groups resulting in backorders and schedule groups where the delivery is shipped on time. For four of five suppliers, the MAPE values with 1 to 8 weeks of time lags are much higher for schedule groups resulting in backorders. For three of five suppliers, the MAPE is higher during the entire measurement horizon (20 weeks). Regarding BIAS, we see that schedule volumes resulting in backorders are on average under-estimated, while they are on the average delivery quantity or slightly over-estimated for schedules delivered on time.

Table 3 shows that for Supplier A there are significantly more late changes in schedules resulting in backorders compared to those not resulting in back orders. Supplier A was the one where MAPE did not differ between backorder and non-backorder schedule groups. Consequently, all suppliers show higher random or late variations in schedules resulting in backorders compared to schedules not resulting in backorders. All suppliers show negative BIAS for schedule groups resulting in backorders.

Discussion and conclusions

How to measure and visualize inaccuracies

We proposed how to process and group delivery schedule data for accuracy measurement on different levels of aggregation. We also developed new measures of late schedule variations and schedule nervousness, and explored and measured five types of delivery schedule variation measures at five suppliers. These analyses suggest measuring and visualizing random, systematic and late delivery schedule variations with different time lags. Random and systematic variations correspond to common forecast accuracy measures, while measuring late variations is not as emphasized in the literature. Our findings suggest that daily planning buckets are used for measures within frozen time zones (here we have used two weeks as a standard length for a frozen zone), and weekly buckets are used for a planning horizon up to about 8-10 weeks. On longer horizons than 8-10 weeks the weekly schedule data shows high inaccuracies, so our study questions the value of weekly measurement for time lags larger than 8-10 weeks. We have not analyzed inaccuracies on monthly data, but perhaps the schedule data shows ‘good enough’ accuracy for longer time lags if using monthly buckets. Random and late variations are highly correlated, but their respective performance effects differ between suppliers so both types of measures need to be monitored. This requires that both daily and weekly delivery schedule databases are needed to be developed.

We identified clear Pareto patterns in the data, which indicate that different groups of customers may have different planning parameter settings/logics. Deeper comparative analysis of customers would be interesting. Findings also showed relatively larger schedule inaccuracies for customers acting as suppliers in a supply chain, compared to customers acting as OEMs. This verifies that schedule inaccuracies increase upstream supply chains (Forslund and Jonsson, 2017) and a bullwhip type of variation exists in the schedules (Syntetos et al., 2016). This is consequently one of the explanations for why schedule inaccuracies vary between customers. As large nervousness ratios were identified in the data, it is also motivated to track nervousness – both on daily and weekly schedule group data. These measures could identify customers with relatively high nervousness (e.g. because of lacking frozen time plans).

Amount and type of inaccuracies

In relation to target MAPE values suggested by VDA (2008), our analysis shows that the average random schedule inaccuracies are quite much larger than targets. About 40% of all schedule groups are more inaccurate than the 10% with 4 to 8 weeks of time lags, which is defined as ‘bad’ accuracy by VDA. We have not identified any target values for BIAS and late variations to compare with. We did not identify any large BIAS in any of the suppliers’ data, but the fraction of schedules with late variations is in absolute terms very high: 12-57% of all schedule groups at the analyzed suppliers. Conceptually, late daily variations should not exist if appropriate time fence management policies are applied, but this indicates that it is not the case in the industry, and the performance consequences are severe. The nervousness ratios
are also high for four of five suppliers (around or above 50% of all schedule changes are of nervousness type). This indicates that quite a large amount of the schedule inaccuracies perceived by suppliers in automotive supply chains (both weekly MAPE with 2-10 weeks of time lags and late daily variations) may be caused by parameter settings and planning logics in customer companies’ planning systems, rather than from end consumer demand uncertainties. I.e. variations are to large extent internally generated, rather than being caused by external demand.

Performance effects of inaccuracies
Many studies have analysed the relationship between information sharing and performance (e.g. Barratt and Oke, 2007). Our findings show that the performance of information sharing is not only a function of sharing information. Rather, and in accordance with Barratt and Oke (2007), Jonsson and Myrelid (2016), Viet al. (2018), our findings show that the accuracy, variation and corresponding visibility of shared information have direct performance effects, and consequently, need to be measured and visualized in value added information sharing. We empirically analyse the relationship between forecast errors and performances and extend previous research on supply chain information quality (Forslund and Jonsson, 2007) by measuring types of forecast inaccuracies with performance effects.

Operations Risk Management and Resilience
Risk and resilience in export sustainable supply chain management: a value chain approach

Luai Jraisat (Luai.Jraisat@northampton.ac.uk)
Faculty of Business and Law, University of Northampton, UK

Abstract

The study seeks to explore key drivers and barriers for building a system of risk and resilience for export Sustainable Supply Chain Management (SSCM). Scholars have proposed a number of risk and resilience models aimed at enhancing the sustainable performance for a single value chain actor. These models, however, lack the interrelationships of direct and indirect dyads. This is an abductive study and adopts a multi-case study strategy in the agri-food industry. 32 semi-structured interviews are conducted with managers in supply networks. The research identifies several types of drivers forming a sustainable management system of risk and resilience.

Keywords: Risk Management, Resilience, Export Supply Chain.

Introduction

Focal actors are often in control to sustainability-related misbehaviour in their supply chain by various stakeholders (Leat et al., 2013; Stone and Rahimifard, 2018). This chain charge effect places focal actors in responsibilities for building reputable systems of risk and resilience in order to manage misbehaviour that can happen beyond their direct control (Stone and Rahimifard, 2018). Yet, the present importance of export Sustainable Supply Chain Management (SSCM) is positioned on direct suppliers, which lead the focal firms to reconsider those direct and indirect relationships with other chain actors (Yan et al., 2015), that can be a positive source of sustainable value along the supply chain.

Previous scholars (e.g. Christopher and Helen, 2004; Pettit, 2011; Stone and Rahimifard, 2018) have called for analyzing export SSCM with the focus on the phenomenon of risk and resilience. Producers, exporters and importers as key chain actors collaborate to supply a wide range of products to the end-customers in export markets (Esfahbodi et al., 2016). Hence, there is a need to examine key drivers and barriers that have high effects on those actors for establishing their SSCM, especially their systems of risk and resilience in relation to their food chain losses and waste (Leat et al., 2013). These are related to the chain structure, resources and total value as economic of costs and return and non-economic of social and environmental issues. This will create a great sustainable business for actors and their dyadic relationships where innovation can also occur in SSCM (Fearne et al., 2012). Thus, the study seeks to explore key drivers for building a system of risk and resilience for export SSCM. Scholars have proposed a number of risk and resilience models aimed at enhancing the lead sustainable performance for a single
value chain actor. These models, however, lack the interrelationships of the existing direct and indirect dyads.

The present study applies abductive multiple case-studies to answer research questions below, following calls for theory development approaches in sustainable supply chains (e.g. Thiele, et al., 2011; Song et al., 2017). Accordingly, the use of Value Chain Analysis (VCA) perspective has been applied to response to several calls (e.g. Thiele, et al., 2011; Jraisat, et al., 2013) in order to surround the study’s findings by reflecting the perspective through its foundation when used for dyadic buyer-seller relationships in supply chains. This paper provides relevant views from managers in dyadic actors in the Jordanian agri-food network exporting products from Jordan to UK. The study poses the following research questions:

RQ1. How do focal actors in their network build a system of risk and resilience for their export SSCM?

RQ2. What contextual factors have an impact on these focal actors’ identifying of each driver for establishing their SSCM, especially their risk and resilience in relation to losses and waste in practice?

The structure of this paper is as follows. The theoretical background on export SSCM and risk and resilience is presented. Next, the research methodology is described. Then, key findings of case analyses are illustrated. Discussions on theoretical contributions and managerial implications is provided. Lastly, conclusions are provided with highlighted future research and limitations.

Theoretical Background
In food supply chains, there is a need to develop a new conceptual framework for export Sustainable Supply Chain Management (SSCM) with the focus on the phenomenon of risk and resilience. This framework can provide a protocol to analyze food chain losses, including waste for fresh fruit and vegetables (FFV) along the export supply chain. This is, in turn, to examine sustainability performance for the export SSCM with a focus on its drivers.

Producers, exporters, and importers as key chain actors collaborate to supply a wide range of FFV products in order to fill the demand in export markets. A large percentage of the FFV is produced in Jordan, due to the unique climate in the off-season, where Jordan Valley is the lowest point on Earth that enables production of FFV during winter for export markets. The UK market is one of the main importers for a number of FFV from Jordan, especially during the winter season. Hence, there is a need to examine key drivers that have high effects on those actors for establishing their SSCM (e.g. Esfahbodi, et al., 2016), especially their risks and resiliencies in relation to their food chain losses and waste (e.g. Leat, et al., 2013; Stone, et al., 2018). One of these key drivers should be examined is the structure of the food supply chain. A second factor is related to various resources, which are used by various actors for their activities along the export supply/value chain. These resources such as human, financial, information and physical components are key factors to make SSCM for food chain loss programmes. A third factor should be the total value as economic of costs and return and non-economic of social and environmental issues along the food supply chain. In fact, there are high potential for resilient sustainable approaches (Pettit, et al., 2011; Stone, et al., 2018) to minimize food chain losses and waste and at the same time perform efficiently in export markets. This will create a great sustainable business for all actors and their dyadic relationships where innovation can also occur in SSCM (Fearne, et al., 2012; Lewis, et al., 2014).
The failure of new food products such as FFV often comes due to not matching or designing to consumers’ needs or not producing efficiently (Jraisat, et al., 2013). On the other hand, several new technologies and innovations have been provided for food production over the past decades. As a result, food companies have struggled to select and apply the most efficient and effective procedures and technologies in order to develop new products. Thus, product development process has to be an effective and efficient by sending the information required to the suitable actor in the chain in order to meet or exceed expectations of consumer and then enhance its success rate. The kind of this information has to be markets and consumers’ demands, food losses and waste, and managerial and technological information exchange throughout the complete chain (Benner et al., 2003).

Food chain loss is defined as measurable qualitative and quantitative loss along export supply chains (Corradao, et al., 2017). This loss can occur either due to food waste such as human action or inaction such as expiry dates, extra size of needs, throwing away wilted produce or food loss such as inadvertent loss in food quantity because of infrastructure, logistics, markets, and management limitations of a given value chain (Donovan, et al., 2015). In a nutshell, food chain losses can either be the result of a direct quantitative loss or arise indirectly due to qualitative loss (Hodges et al., 2011). In many countries, the value chain faces losses and this current problem has not been analysed in detail by government nor private sectors (Satya, et al., 2017). According to reports of World Bank, Food Agricultural Organisation (FAO) and local organizations, an estimation of around 30% is identified as losses in many countries (Corradao, et al., 2017). However, the exact data of losses are unknown because of no exact know-how on doing analysis for export-food chain losses, lack of full analysis for this subsector, lack of understanding for the types of losses (i.e. quantitative and qualitative), and lack of required resources and available systems of food security.

The agri-food supply chain has experienced major risk caused by the increase levels of losses, wastes and innovation in the past years (Kamalahmadi et al., 2016). This has led to interconnectedness among various actors in the FFV supply chains (Jraisat, et al., 2013), which have dependency among entities in the supply chain thereby making the supply chain complex (Christopher et al., 2011). The dependency results in the effective running of the FFV chain in a stable business environment, but with great potential to risk and disruption in an unstable business environment. An risk in supply chains is defined as an uncertainty in the chain which leads to disruption (Ho et al., 2015). A further definition is given by Heckmann et al., (2015) as the potential loss for a supply chain in terms of its target values of efficiency and effectiveness evoked by uncertain developments of supply chain characteristics whose changes were caused by the occurrence of triggering-events (e.g. disturbance, disruption, disaster, hazard or crisis.). The interdependency between an organisation and its supply chain concludes that a risk indirectly affects the chain actors, especially the focal actors. Zhao et al., (2017) analysed specified risk source as antibiotic resistance, weather related risk and natural disasters, policy and institutional risk and unethical issues in agri-food supply chain. Figure 1 illustrates the risk sources for the agri-food supply chain and its actors.
In export SSCM, actors work to create resilient FFV supply chain which can be relied on adding value to their dyads for better sustainability. Christopher and Peck (2004) defines resilience as the ability of a supply chain to return to normal operating performance, within an acceptable period, after being disturbed. Ran et al., (2011) indicate resilience as the respond to risk which causes disruption in the business. Kamalahmadi and Parast (2016) provide phases of supply chain resilience to include anticipation, resistance and recovery and responses. The extent in which an organisation is said to be resilience depends on the capabilities and resources available. For a supply chain to be effective, it must have a resilience plan against disruption and unforeseen event (Brandon-jone et al., 2014). Organisation with a structured resilience framework can manage reputation and operational risk, operating cost reduced through resource management. Figure 2 illustrates resiliencies for the agri-food supply chain and its actors.
Figure 2. Resiliencies in agri-food chains
**Methodology**

This is a qualitative case study with an abductive approach. It seeks to provide a conceptual framework that can be developed from both existing literature and contextual field data (Eisenhardt, 1989). The cases are two from the context of FFV supply chains exporting products from Jordan to the UK. 32 Semi-structured interviews are conducted with different actors around the focal actors in both direct and indirect dyads. This research applies within case and cross-case analyses (Miles and Huberman, 1994). By exploring and explaining the several types of drivers forming a sustainable management system of risk and resilience, it became possible to develop the framework.

There are two case studies, including ten dyads of five direct and five indirect dyads, which have been selected on the basis of theoretical sampling in order to provide new insights into an emergent theory (Eisenhardt, 1989). These cases are identified as sustainable direct and indirect relationships by certified bodies and each actor should have systems of risk and resilience for FFV losses and wastes and drivers’ functions in FFV supply chains. This sampling selection is based on advanced research of the online directory of sustainable firms in Jordan and it included firms that have been working for at least five years with various dyadic firms in FFV supply chains. This led to a list of 80 firms, which were then shortlisted to 10 firms based on three steps: satisfactory achievement records, positive email responses and an initial interview. Then, each firm was asked to identify a dyadic collaborative firm to form the unit of analysis as a dyadic relationship. This is where two different FFV supply chains (Case: SC 1 and SC2) of different 10 dyads (unit of analysis) of two different focal actors (sub-unit of analysis) are examined. Each FFV supply chain is formed of a type1-retailer-importer (for dyads A1, A2), type 2-importer-exporter (for dyads B1, B2), type 3-retailer-distributor (for dyads C1, C2), type 4-distributor-wholesaler (for dyads D1, D2), type 5-wholesaler-importer (for dyads E1, E2) (Table 1). The basis for these studies was semi-structured interviews with six managers at each dyad. Managers as key informants were selected because they provide an overview of the topic. Jordan is one of the developing countries which has agreements and contracts across FFV chain actors, including collaborative dyads for the UK markets (Jraisat et al., 2013).

The interviews were conducted and recorded by the author in person, who were asked the same questions. The interviews were also transcribed and then sent to the managers for revisions. The approved interviews were used to develop the case studies, which were analysed through cross-case analyses (Miles and Huberman, 1994).

**Findings and Discussions**

Academic researchers have proposed definitions, frameworks and key findings to carry out development in export SSCM (e.g. Fearne, 1998; Burgress, 2006; Pang et al., 2012; Esfahbodi, et al., 2016). Their research studies are formed based on key underpinning concepts that can be termed the building blocks of assumptions and frameworks. However, a wider body of knowledge about dyads is needed to overcome overlapping concepts in order to generate consistent findings (Esfahbodi, et al., 2016). Thus, the intention of the present research is to contribute to the body of knowledge by providing new propositions for management of risk and resilience for direct and indirect dyads attached to better sustainability performance for the dyadic actors in FFV supply chains.

Both the literature review and cross-case findings support the suggestion that drivers of risk and resiliencies are the main key for adding value between dyadic actors that affect their sustainability performance, and this is also based on good control of losses and wastes for both actors and their export SSCM (Taylor and Fearne, 2006). Findings from cross cases highlighted how dyadic actors at both levels, chain and dyad, share...
drivers for a long term dyads, and this reflects a positive risk and resilience approach. The key findings have highlighted the fact that both dyadic actors in all relationships for direct and indirect dyads (A1, A2), (B1, B2), (C1, C2), (D1, D2), (E1, E2) generally identify high effects of the antecedents in drivers for better management of losses and wastes in FFV supply chains. See table 1 for the types of drivers of building risks and resiliencies for FFV supply chains.

Level of scoring from the perspective of dyadic actors: High (H), Medium (M), Low (L).

The value chain model (Porter, 1985) dominates as a tool for the strategic analysis of firm value creation and as a conceptual map for the description of activities actors perform in inter firm relations for risk and resilience. The working actor and the customer/consumer had distinct roles of production and consumption, respectively. In this perspective, the market, viewed either as a locus of exchange or as an aggregation of consumers, was separate from the value creation (Walters and Lancaster, 2000). However, the interactions between working actors and customers are not seen as a source of value creation (Normann and Ramirez, 1994; Wikstrom, 1996). In fact, the value chain for direct and indirect dyads amongst actors in an industry should be embedded in a larger stream of activities that we term the “value wheel” in the present research (Harland, 1996; Lambert and Cooper, 2000; Croom et al., 2000; Walters and Lancaster, 2000). The value
wheel includes the value chains of several working actors and focal actors under the explored topic (Berger et al., 2004; Pang et al., 2012; Barroso-Méndez et al., 2014). Motivated by this issue, we have proposed the conceptual framework for partnership in SAVC above.

Motivated by this issue, we have proposed the conceptual framework for partnership in SAVC above.

Figure 1 - Conceptual framework for drivers of risk and resilience in agri-food supply chain “Value Wheel”

Conclusion and Contributions
This research raises interesting areas of study. First, the conceptual framework indicates significant opportunities for future studies. A key opportunity exists at the direct and indirect levels which are developed within the FFV supply chain context. Prior research has highlighted that dyads (e.g. Porter and Millar, 1985; Bailey and Francis, 2008; Jraisat et al., 2013) and value creation (e.g. Prahalad and Ramaswamy, 2004; Francis, 2004; Xue et al., 2011) are needed at various levels of risks and resiliencies’ development and then improvement, raising questions about criteria for each level of development and improvement to support working actors (e.g. focal actor and other actors) form sustainable activities at each level. This study is qualitative in nature and the conceptual framework needs to be tested through further qualitative studies or quantitative studies involving large-scale surveys. The study considers only perspectives of local value chains and, therefore, future research should consider perspectives of export value chains.

Another potential area of study is the role of dyadic relationships (e.g. lack of ties among partners) in dyads from the perspective of both partners. When ties among value
chain members are direct about better relationship results between two actors, value creation will have a limited impact on sustainability performance. Alternatively, when such ties correspond to direct and indirect links with respect to other actors along the value chain activities, value creation will have a perfect, long-term impact on sustainability performance (e.g. Hsu et al., 2008; Amara et al., 2016). Therefore, it remains to be verified how drivers of risks and resiliencies and value creation influence sustainability development and chain actors’ performance especially in the field of agri-food (e.g. Martinez and Poole, 2004; Van-Der-Vorst et al., 2007; Mikkola, 2008; Pang et al., 2012). It also remains to be examined to what extent different country contexts influence these drivers in FFV supply chains.

How Does the Contingent Sustainability-Risk-Cost Relationship Affect the Viability of CSR? An Emerging Economy Perspective

Stanley E. Fawcett  
Weber State University

Abstract

Companies pursue sustainable operations for a variety of reasons, including to protect firm from reputational risk. However, sustainability may increase operational risks, disrupting supply chain performance. This contingent sustainability-risk-cost is poorly understood. To redress this gap, we conduct a multi-method study and document industry-specific risk profiles in an emerging economy setting. We interview 46 key informants in food, automotive, textile, white goods industries, and prioritize industry-specific risks by applying fuzzy analytical hierarchy process (Fuzzy AHP). Theoretically, we find that sustainability behaves as a limits-to-growth system. Sustainability initiatives engender different risk profiles across four industries for both social and environmental dimensions.

Keywords: Supply Chain Risk Management, Sustainability, Emerging Economies, Industrial Comparison, Fuzzy AHP

Introduction

Sustainability is increasingly a strategic imperative (Fawcett et al, 2015). Companies pursue sustainable operations for a variety of motivations. A small number of self-selecting companies, for instance, are true believers (Brockhaus et al, 2017). They pursue sustainability because it is the right thing to do. Investments are made regardless of cost. Most companies, by contrast, are motivated by a desire to improve corporate image or enhance operational efficiencies. That is, sustainability supports the companies’ competitive strategy by immunizing a firm from reputational risk and reducing operating costs (O’Callaghan, 2007; Ganesan et al., 2009; Siegel, 2016). Although these companies desire to protect or burnish their reputations, they are much more cost conscious. They must make the business case for sustainability, demonstrating a positive return on investment.
The sustainability-risk relationship may, however, be more nuanced. Anecdotal evidence, for instance, suggests that sustainability strategies may actually increase operational risks, disrupting both supply chain and organizational performance (Hofmann et al., 2013). Consider how glitches associated with sustainability-driven branding negatively affected operations at Chipotle and Volkswagen. Chipotle Mexican Grill built its identity on the popular notion of “Food with Integrity.” However, repeated supply shortages of eco-friendly inputs such as beef and pork required Chipotle to pull fast-selling products from its menu. Worse, food contamination caused E. coli and norovirus outbreaks, damaging Chipotle’s reputation and leading to a 29.7% drop in same store sales. For years, Volkswagen built its identity on high-performing, highly efficient clean diesel technology. The carbon-footprint reducing technology, however, didn’t actually exist. To perpetuate the clean-diesel narrative, software-driven “defeat devices” had been installed to cheat on emissions tests (Newman, 2015). Volkswagen was assessed an $18.2 billion fine. Worse, Volkswagen incurred billions more in lost sales.

These sustainability-induced behavioral and operational risks—and the subsequent operational disruptions—increase a variety of costs even as they expose the firm to a different kind of reputational risk. However, this contingent sustainability-risk-cost relationship is largely overlooked and remains poorly understood (Seuring and Müller, 2008).

This contingent sustainability-risk-cost sequence, however, is likely to have a more-pronounced adverse impact on sustainability efforts in emerging economies. To improve the long-term viability of sustainability initiatives in emerging markets, we elaborate theory on the sustainability-risk interaction across diverse industries. The goal: define the contingent sustainability-risk-cost relationship to help decision makers develop effective risk-management strategies, a process that begins by recognizing and prioritizing risks (Jüttner, 2005; Carter and Rogers, 2008; Zanoni and Zavanella, 2012). To do this, we pursued a multi-method research program. To gain insight into industry-specific risk profiles, we employed a Fuzzy AHP methodology with managers from the food, automotive, apparel, and white goods industries operating in Turkey, a leading emerging market. To contextualize the findings and better grasp why certain tradeoffs exist and how they are managed, we used semi-structured interviews.

**Theoretical Background: The Sustainability-Risk Relationship**

The extant research has long noted that sustainability and risk are related. In fact, Carter and Rogers (2008, p. 366) explicitly called sustainability “the ability of a firm to understand and manage its economic, environmental and social risks in the supply chain.” Even so, scholars acknowledge that our understanding of the sustainability-risk relationship is fragmented, meager and unsatisfactory (e.g., Seuring and Muller, 2008; Gouda and Saranga 2018). Despite the paucity of empirical research on the sustainability-risk relationship, research has, alluded to three pertinent points related to our research; sustainability is a response to stakeholder priorities (Hofmann et al., 2014); sustainability may engender risks (Anderson and Anderson, 2009); risk mitigation strategies may require customization (Giannakis and Papadopoulos, 2016).

These ideas, which are embedded in the sustainability literature, are neither explored in depth nor empirically tested by the extant research. This reality calls for 1) a brief review of risks identified by the supply chain literature as well as 2) an empirical exploration that considers the nuanced bi-directional sustainability-risk relationship.
Understanding Risk Profiles and Risk Mitigation

A firm’s sustainability efforts and supply chain risk are subject to influence from a combination of industry level dynamics and its institutional environment (e.g., Zsidisin and Ellram, 2003; Canzaniello et al., 2017). At the industry level, firm performance is generally determined by unique structural issues that influence the level and nature of competition (Porter, 1980; Dyer and Singh, 1998; Chen et al., 2007; Halebljan et al., 2012; Brockhaus et al., 2017). How a firm responds to these forces shapes its overall risk profile (Pratt, 1964; Thompson and Dean, 1996; Short et al., 2012; Goerlantd and Reniers, 2017). That is, firms may place different priorities on risk dimensions in reaction to characteristics unique to their industry.

On the other hand, institutional theory emphasizes homogeneity, isomorphism, and adaptive change as the three forms of pressure on firms to conform to their institutional environment. It suggests that commonly accepted policies and norms translate organizational members, their structures, and their processes into an isomorphic format (Eisenhardt, 1988). Following institutional theory, firms and their industries are assumed to converge on a shared approach, which could effectively reduce the costs of risk mitigation. Thus, when possible firms will attempt standardize their approach to risk prioritization and mitigation.

Methodology

This study employs a multi-method research design, which includes quantitative analysis and qualitative interviews. To begin to understand the sustainability-risk-cost sequence in emerging economies, we recruited 41 participants from five different Turkish food supply chains for interviews and on-site observations at 32 companies. This initial study identified five major risk categories and established the baseline for comparison as interviews were conducted in the automotive, apparel, and white goods industries. For sustainability to become mainstream practice, we must become more concerned with making sustainability practices viable in emerging economies (Evrendilek and Doygun, 2000). These industries attract significant investment, but manifest distinct industry structures (Seuring and Müller, 2008). Thus, we can expect diverse strategic priorities and unique supply chain practices. We purposefully recruited partnering-firms positioned at different points along the supply chain within each industry.

We first apply Fuzzy AHP analysis to inductively derive priorities for five dimensions of risk salient to environmental and social sustainability initiatives. We asked respondents to make qualitative evaluations of the risk dimensions and make pairwise comparisons with respect to environmental and social sustainability distinctively. Decision-making in multi-criteria problems becomes very challenging when some parameters are not in quantitative form. Analytical hierarchy process (AHP) overcomes this challenge, and offers an approach to incorporate qualitative assessment parameters, specifically for the cases where expressing preferences through exact numbers is very difficult (Chan and Kumar, 2007; Wang et al., 2012). Fuzzy AHP further extends this method by taking the fuzziness of decision-makers into account for valid cross-case comparison and consider potential uncertainty of responses (Zadeh, 1965; Deng, 1999). For each pair (e.g. behavioral versus opportunism), respondents rated their relative importance through a 9-point Likert scale ranging from equally preferred (1) to extremely preferred for the more important dimension (9). Each respondent rated all possible permutations of pair-wise comparisons, which are then used to determine a triangular fuzzy number (Saaty, 1980). Finally, each dimension’s triangular fuzzy
numbers are defuzzified using CFCS (Opricovic and Tzeng, 2003). We further conducted a series of in-depth interviews (Creswell, 2007) to understand the dynamics behind how environmental and social sustainability affects each dimension of risk in the Turkish economy.

**Findings**

We posited that the nature and prioritization of risks for each industry is influenced by both industry and institutional forces for environmental and social dimensions of sustainability. We used weights obtained through fuzzy AHP analysis to develop industry-specific risk profiles. Table 1 displays these risk weights and rankings for both environmental and social dimensions of sustainability.

Whereas differences in weights and rankings illustrate the trade-offs idiosyncratic to each industry’s competitive dynamic (Pratt, 1964; Porter, 1980; Chen et al., 2007), their commonalities support the idea that there are forces driving the four industries toward limited isomorphism (Scott and Meyer, 1982; DiMaggio and Powell, 1983; Scott, 1995). Next, we analyse each industry, highlighting distinctive characteristics of each industry’s risk profile.

For the automotive industry, high-priority sustainability-driven risk dimensions are different for environmental and social dimensions. Safety and traceability, organizational routines and behavioral risk dimensions are ranked with high impact on environmental sustainability, whereas behavioral and opportunism risk dimensions are found to be very critical for social dimension. Systems design is ranked very low in both environmental and social dimensions. Managers reported that rapidly advancing
production technologies require them “to implement new technologies to survive” in an industry that “has been turned into a computer model.” Organizational routines direct capital investments in advanced production technology to emphasize effective responses to “environmental pressures [that] are shrinking the market.” Despite the emphasis on technology adoption, key informants stressed that “[they] do all of [their] work with people,” who are tasked with ensuring environmental and quality standards. A lapse here threatens dire consequences. Hence, they use technology to control the behavior of people. Even though the company targets perfect performance, problems are generated at the time people execute the process, and thus occupational accidents are often human-induced. One reason is “save the day approach of employees”, having no motivation for environmental or social priorities. The industry lacks educated employees; employees are mostly self-educated. They mentioned that technology is critical to automotive industry to prepare the companies to their evolving future, but it doesn’t work without qualified employees.

In Turkish food industry, ranking of environmental and social dimensions are very similar; sustainability induces the greatest risks in the behavioral area. Specifically, a pervasive lack of awareness, knowledge, and care pertaining to sustainability permeates the food industry. Most firms have yet to widely recognize its importance. Managers pointed out that behavioral risks exacerbate organizational and opportunism risks. The low level of “awareness and knowledge” makes driving change difficult. Further, intense competition in the food industry makes profits razor-thin. As a result, investments in automation to reduce waste are often eschewed in favor of low capital investment and revenue-maximizing strategies. As one manager expressed, “I usually face [sustainability] problems with manual processes.” Profit pressures also motivate opportunism as decision makers cut corners to protect profits. For example, in the cold chain, managers explained that fish that “should be disposed of” is actually “frozen again to resell.” Managers in the food industry also place minimal priority on system design risks when considering environmental and social sustainability, but for the opposite reason. In contrast to the automotive industry’s adoption of systems established by long-term global partners, food industry members have no incentive invest in standardized systems to improve sustainability. Characteristic of a hypercompetitive industry (Jin et al., 2017), frequent entries and exits by partners in the food supply chain created a perception among managers that “subcontracting is risky in Turkey” and requires firms to pursue flexibility over a standardized system so as to maximize their ability to work with diverse suppliers and customers.

Organization routines risk dimension is ranked with greater impact on environmental and social dimensions of sustainability in apparel industry. Turkey’s apparel industry has low barriers to entry, is heavily reliant on labor and often generates hazardous waste (e.g., chemical dyes) that are loosely regulated and expensive to properly dispose. Managers thus isolate organizational routines as the most pervasive and potentially costly. Specifically, managers highlight the need for procedure-based rules to ensure that process standards are achieved. These rules must extend to worker conduct and waste disposal. Intense competition complicates the sustainability challenge because “anyone who buys a textile machine calls himself a textile manufacturer.” Cost is a primary differentiator. Business survival is possible with lower costs, and global customers require low margins and fast deadlines from the emerging countries like Turkey. However, implementing social and environmental needs investment. This raises the important dilemma in apparel industry; baring environmental and social cost to be eligible as the supplier, but not allowed to reflect that revised price to customers. As a
result, emphasis on near-term survival significantly hinders Turkish apparel makers from accumulating the necessary level of experience and sophistication to steadily improve organizational routines needed to promote greater sustainability.

The Turkish white goods industry is dominated by local brands rather than global producers. Hence, competition is fierce among local brands, all of which utilize a modular and labor-reliant production process of common components, resulting in goods that offer nearly identical performance and are thus mostly differentiated by cost or branding. To compete, decision makers at Turkish white goods firms are tempted to “cut corners” when it comes to promoting sustainability. In this case, behavioral and opportunism risks comingle, exacerbating each other. For instance, employees at the retail level turn to greenwashing or they mischaracterize sustainability performance to secure sales, relying on consumers’ ignorance and apathy regarding product sustainability. The tendency toward corner cutting is pervasive across the entire supply chain network. Managers thus described a need for stronger organizational routines to curb corner cutting and promote more legitimate efforts to enhance sustainability.

To summarize, whereas competitive intensity, capital intensity, and labor intensity induce tradeoffs among safety and traceability routines, opportunism, and behavioral risks, institutional forces guide the organizational routines and system design risks.

**Conclusion**

Our research empirically validated the nuanced view of the sustainability-risk interaction. Specifically, our research documented a contingent sustainability-risk-cost relationship, suggesting that the sustainability-risk relationship possesses the characteristics and behavior of a limits-to-growth systems archetype (Senge, 2006). Indeed, managers confirmed that sustainability initiatives cause or exacerbate a diverse set of risks, increasing the cost of operating sustainably. This reality makes it more difficult to cost-justify sustainability initiatives. The identification of distinct risk profiles provides a starting point for decision makers to understand the nature of risks their companies are likely to encounter.

By demonstrating the need for industry-specific risk mitigation strategies, we respond to Giannakis and Papadopoulos’ (2016) call for research on the nature of risk mitigation at the industry level. Ultimately, companies should seek to transfer best practices within an industry rather than across industries. However, institutional factors clearly apply isomorphic influence to all industries in our study. For instance, an overall lack of emphasis on system design illustrates the combination of inadequate regulatory framework and generally export-dependent industries. Although both industry-level idiosyncrasies and economy-level institutional forces guide an industry’s sustainability-risk interaction, the result is often that firms across all industries lack a holistic view on sustainability.

This study has some limitations, which offer further research opportunities in the area. First and foremost, the area of research, which integrates sustainability and risk specifically across different industrial settings, still needs to be explored deeply. A further examination of industries in different country settings would provide a rich discussion to compare the characteristics across industries as well as across different country settings.

Abstract

Drawing upon paradox theory, this paper conceptually proposes a dualism paradox framework for exploring the relationship between supply chain sustainability and resilience. Building basis from the literature which have collectively explored sustainability and resilience, we use and repurpose a dualism approach to paradox theory as a research lens for the SC context. We demonstrate the applicability of the framework to exploring the SC sustainability and resilience relationship. Our future research will test the proposed framework empirically.

Keywords: Sustainability, Resilience, Supply Chain

Introduction

Today’s supply chains (SCs) are increasingly complex, dynamic and interdependent (Gunasekaran et al., 2014; Levalle & Nof, 2015). In this context, SCs must ensure that organisational effectiveness is improved (Gunasekaran et al., 2001) and function is maintained whilst also to meeting the needs of changing and ever-increasing market and stakeholders demand (Sheffi & Rice, 2005). Uncertainty and volatility increase as SCs are more dispersed geographically and diverse, covering a wide variety of products, services and communities (Xiao & Wang 2014). SC collapse has devastating impacts (Burnard et al. 2018), potentially costing lives (Tukamuhabwa et al., 2017).

SC resilience concerns the SC ability to effectively respond to, and recover from, a disruption, preferably to a better state than before (Tukamuhabwa et al., 2015). Unpredictable human and natural events, of any scale, can occur at any point and at any time, disrupting the SC (Zineb et al., 2017); causing problems for dependant business and
stakeholders. Therefore, it is ever more important that SCs develop capabilities to handle unknown threats and function in disruption scenarios. SC sustainability is central to tackling global issues such as climate change, pollution, resource consumption, and social justice, associated with production, consumption and trade. Today, stakeholders and firms concerned about environmental and social issues within the SC are driving action on SC sustainability (Mani et al., 2018). Economic sustainability, underpinning SCs actions, are increasingly dependent on social and environmental SC performance (Carter & Rogers, 2008; Ortiz-de-Mandojana et al., 2016; DesJardine et al., 2017), so sustainable SCs are now increasingly framed as an investment, rather than a business cost; important for competitive advantage, and their survival (Katiyar et al., 2018).

There are three ways of exploring sustainability and resilience as disciplines: resilience as a component of sustainability, sustainability as a component of resilience, or resilience and sustainability as separate objectives (Marchese et al. 2018). These three distinctions in the literature highlight the complexity of joining resilience and sustainability approaches. Joining has so far been unclear (Pizzol, 2015), and in the context of SCs, relatively unexplored (Fahimnia & Jabbarzadeh, 2016; Zahiri et al., 2017). Sustainability and resilience approaches are different: “sustainability prioritizes outcomes, and resilience prioritizes process” (Redman, 2014). Sustainability and resilience share complementary characteristics, however adoption can also lead to conflict, such as sustainability reducing protective redundancies for resource use efficiency gains (Levalle & Nof, 2015). Both sustainability and resilience are important for SC survival and growth, and as a result, neither approach can be ignored in favour of the other.

There is a lack of literature incorporating the relationship between SC sustainability and resilience, which highlights a significant knowledge gap in our understanding of these two issues when taken together. SC managers deal with both sustainability and resilience, and an informed understanding of how those decisions are made and what is the impact on SC performance measures are important for them to know, so that both can be effectively optimised for SC performance. However, prior to this, the relationship between sustainability and resilience requires contextualising in a means that can explore how the relationships can be described. For this purpose, paradox theory has been explored and used for its suitability for application in sustainability research, its novelty for exploring complex relationships and because it has been posited as useful in SC research (Xiao et al., 2019).

**Literature Review**

There are only a few research papers which have considered sustainable or environmentally sustainable (green) and resilient SC collectively, with a few others also exploring these in the context of agile and lean SC. This review will explore those highlighted connections between sustainability (including green focused) and resilience in context of SC, demonstrating the research gap.

Some of the papers exploring elements of sustainability and resilience, also explore lean and sometimes agile aspects of supply chain management, and their relationship, whilst for the sustainability component, the environmental aspect is the emphasis. Govindan et al. (2014) proposed a conceptual model for implementation of lean, green and resilient practices, in focal, upstream and downstream contexts. In looking at the relationship resilience practices had on SC sustainability, ‘flexible transportation’ and ‘flexible sourcing’ did not have a significant impact. Green practices ‘ISO 14001 certification’ or ‘reverse logistics’ also did not have a significant impact. However, resilience practices ‘SC risk management’, ‘waste elimination’ and ‘cleaner production’...
did have a significant impact. This research considered only a small number of practices, and were categorised into upstream, focal and downstream components. This research, although recognising the existence of conflicting practices, did not consider them as part of the research. Govindan et al. (2015) explored the simultaneous implementation of lean, resilience and green paradigms for SC competitiveness, however, integration of these techniques and identifying issues related to these techniques remains problematic. When measuring for customer satisfaction, the practices deployed for improving performance do not interfere for this performance measure. Using this approach, it was possible to validate the practices which contribute most to competitive advantage. These are just-in-time (lean), flexible transportation (resilient) and environmentally friendly packaging (green). Azevedo et al. (2013) explored how green and resilience in combination can form an “eco-silence” measure for SC. Upstream green and resilience were united, with validity confirmed through a case study, however, this index weighs the two approaches without considering implications for their trade-offs, with no detractions for conflicting practices.

Carvalho et al. (2011) explored synergies and divergences between lean, agile, resilient and green paradigms and the effect of those paradigm practices on SC attributes. Between green and resilience aspects, there were divergences in context of capacity surplus, inventory level and replenishment frequency, but synergies in the level of integration and lead time. Cabral et al., (2012) builds on this work by developing an integrated analytical process to support decision making when making appropriate lean, agile, resilient and green practices, and KPIs to be implemented in a SC with a focus on SC competitiveness. The importance of the paradigms for their impact on SC competitiveness were ranked, with the most appropriate agile, followed by lean and resilient equally, and finally green. Green is the least important, as it is seen as an inconvenience by SC decision makers, and efforts usually go to minimum necessary requirements, however, many green initiatives are done so with the intention of reducing costs. The relationship between these different approaches were otherwise not discussed, with no conclusions drawn concerning green and resilience practices.

In recognising that research in SC sustainability and resilience is limited, Fahimnia & Jabbarzadeh (2016) conducted a trade-off analysis on how sustainability practices impacted the capacity for SCs to tolerate uncertain disruptions. With a multi-objective optimisation model, sustainability performance was assessed, and the model tested in a case study. The case study demonstrated that a SC designed to a business-as-usual sustainability scenario was unable to cope with disruptions and satisfy demand, whereas a resiliently-sustainable SC designed for disruption and business-as-usual scenario was able to meet demand at a slight increase in SC cost (Fahimnia & Jabbarzadeh, 2016). Whilst this paper explores the relationship between sustainability practice, as defined by the type of SC design adopted, and resilience performance, the findings cannot be generalised as their model needs further validation, further the model does not consider resilience practice.
Ivanov, (2017) through a simulation study, explored the interconnections between sustainability and resilience in SC. Disruption propagation and sustainability factors were analysed for creating a resilient SC which mitigated ripple effect and improved sustainability. If a disruption cannot be localised, a ripple effect occurs impacting SC performance. Sustainability factors such as sustainable sourcing enhances the ripple effect, whereas facility fortification mitigates it and improves sustainability. Storage facility reduction in downstream SC also improves sustainability but can cause the ripple effect. This paper highlights the relationship between event and outcome for both a measure of resilience and sustainability. However, this is just limited to three practices, and further practices need to be explored for broader managerial insight, particularly with resilience practices on sustainability.

Eltantawy (2016) argues that in supply management, for sustainability to be achieved, trade-offs between economic, environmental and social outcomes must be effective and ensure longevity for the firm. However, trade-offs are challenging because of tensions between divergent demands. In approaching resilience as a core component of sustainability, supply management ambidexterity, pursued through a paradox lens, is considered to describe two approaches for resilience, resisting damage from an event (exploitation) and quick recovery from that event (exploration). As the author considered resilience as a nested attribute of sustainability, the philosophical approach excludes considerations between sustainability and resilience. Supply management resilience framework for sustainable performance incorporates engineering resilience (through cultural and operational competency) and ecological resilience (through situational awareness, and access to keystone vulnerabilities). Popadopoulos et al. (2017) also considers resilience as a component of sustainability in exploring a framework which considers SC and infrastructure resilience as an important component of community and resource resilience. Using big data, it is argued that swift trust, public private partnership, and quality information sharing enable shaping SC resilience and critical infrastructure resilience.

A multi-objective decision-making model for designing a pharmaceutical SC was tested in a case study. The pharmaceutical industry is vulnerable to both internal and external disasters, and with stakeholder interest in environmental and social issues, objectives of minimising harm of disruption and to the society and environment were sought. The paper provides a series of optimisation and SC design recommendations (Zahiri et al. 2017). The approach to sustainability and resilience in SC for this paper focuses specifically on the characteristics of the SC design and the decision-making process in how to make optimisations and does not contribute in terms of practice or relationship to the research approach set out in this report, however the performance measures could be utilised.

Karutz et al. (2018), attempts to conceptually connect SSCM and RSCM through case study research in automotive SC. SSCM is prioritised over RSCM by SC managers. In their framework, connections are highlighted between SSCM and RSCM, with diversity and transparency enabling strategies of both approaches. This paper made some initial steps toward connecting SSCM and RSCM, proposing possible interconnections between objectives. However, the role of practices or strategies to performance is not yet considered and this paper requires expansion and further empirical analysis to validate and build upon their initial findings.

As highlighted in the literature review, there are several previous studies exploring interconnection between aspects of sustainability (or environmental sustainability) and resilience in SC context, but this research area is underdeveloped and the relationships
unexplored in context of how sustainability and resilience relate considering tensions and trade-offs among practices and particularly their collective impact on SC performance. Building upon the literature and to address this research gap, a framework for a sustainable-resilient SC is required.

**Theory and framework development**

In developing a sustainability and resilience relationship framework for SC context, their relationship was initially explored. Other literature has explored the relationship outside of SC context as a form of tension (Redman, 2014; Lizarralde et al., 2015). Conflicting interests generate tensions, and as the different goals of sustainability (outcome-oriented) and resilience (process-oriented) have conflicting interests, the tension literature is a suitable means for exploring this relationship. Lizarralde et al. (2015) highlights the nature of the tensions between sustainability and resilience (Table 1), informed from an urbanism perspective.

Tensions are described as conflicts between two factors and often explored in sustainability challenges. There are four approaches to sustainability tensions, these are: win-win, trade-off, integrative and paradox (Van der Byl & Slawinski, 2015; Brix-Asala et al., 2018). The win-win approach attempts to reconcile either the social and/or environmental performance with economic performance; trade-off accepts the goals as being in conflict, requiring that a choice is made; integrative approach attempts to ensure that all three approaches to sustainability are equally balanced; whilst paradox seeks to understand the nature of tensions along with how actors work with them, enabling the ability to view and evaluate complex sustainability issues and embrace them (Van der Byl & Slawinski, 2015; Brix-Asala et al., 2018). A paradox tension can be derived as having three main core components (Brix-Asala et al., 2018: 426):

1. Actors embrace the tensions between goals rather than resisting or avoiding tensions;
2. Actors attend to competing and interrelated demands simultaneously;
3. Paradoxes are dynamic demands which can be managed only by continuous cyclical responses in the form of practices.

Currently, research utilising paradox has been rarely applied in SSCM, despite its relevance (Matthews et al., 2016). Whilst most researchers utilise an instrumental perspective to explore conflict, Xiao et al. (2019) utilises a paradox perspective. Due to both complementing and contradicting components of the sustainability and resilience relationship, paradox theory is appropriate. A tension can be viewed in multiple ways, however, seeking to treat the issue as a paradox will enable solutions to these tensions beyond instrumental confines (Xiao et al., 2019). There are three kinds of paradox which
are highlighted in the literature, these are paradox (including duality), dilemma and dialectic (Smith & Lewis, 2011):

- Paradox consists of “contradictory yet interrelated elements that exist simultaneously and persist over time; such elements seem logical when considered in isolation, but irrational, inconsistent and absurd when juxtaposed”.
  - Dualities, two opposites which exist within a unified whole, have an internal boundary which highlights opposing elements, the external boundary demonstrates a synergy between them.
- Dilemmas are competing choices with advantages and disadvantages. This can become paradoxical when those choices contradict and interrelate in a way that choices between them are short lived and their tension resultanty resurfaces.
- Dialectic contradictions (of two propositions) are resolved through integration, which overtime will gain new opposition. This can become a paradox when elements are contradictory and interrelated. Combining elements promotes similarities, neglecting differences, resulting in temporary integration. The new formulation and opposition therefore maintain the core characteristics of the original contradictory elements.

The dilemma and dualism approaches to paradox are potentially particularly appropriate means of viewing the issues, with literature sought to explore those types of paradoxical relationships. Papers discussing practice-performance relationships in paradox context were explored. A paper exploring dualistic paradox in management science (Fajoun, 2010) offered a relevant framework in which sustainable and resilience SC management relationship with performance can be applied.

Fajoun (2010) explored stability and change as a duality paradox. Stability and change are interrelated, complementry practice and performance process and outcomes, whilst simultaneously capable of practice-performance contradictions. This relationship is highlighted in their duality framework which classifies stability and change relationships. This relationship highlights that stability, existing in opposition with change, matches the organisational paradox of exploitation vs. exploration, whereby firms utilise both to enable success, despite strategies also existing in tension (Andriopoulous & Lewis, 2009). Stability and change in these circumstances of exploitation/exploration exhibit different practices and outcomes, which do not complement. However, there are circumstances when stability and change are dependent on each other. Change can enable stability through managing variables which ensure that the performance goal is static around changing circumstances, whilst stability can enable change through provision of systems that are designed to manage elements of unpredictability or to encourage innovation (Fajoun, 2010).

Through the exploration of existing application of paradox theory on practice and performance relationships, a framework has been borrowed and applied to SC management in the context of sustainability and resilience approaches and their relationship to SC performance. As highlighted in other research exploring sustainability and resilience (Redman, 2014; Lizzaralde et al., 2015; Wilson, 2018), the relationship between sustainability and resilience exhibits synergistic and conflicting components, demonstrating tension across disciplines. Previous research utilises an instrumental perspective to explore tensions (Xiao et al., 2019), however, paradox is increasingly seen as a means, suitable to sustainability related issues, which can be used to manage tensions. Existing literature has informed how to frame the paradox relationship between sustainability and resilience. Smith & Lewis (2011) identified three kinds of paradox in their literature: dualism, dilemma and dialectic. A dualism framework from operations
management was located (Farjoun, 2010) and borrowed for SC context, replacing stability and change dualism with sustainability and resilience. Stability and change organisational practices are a dualistic paradox (Farjoun, 2010). Dualism explains a paradox as two components, which separately are conflicting, yet must exist together as they are co-dependent (Smith & Lewis, 2011). Sustainability and resilience align with the dualism of stability and change as sustainability and resilience share similar complementing and conflicting components. Whilst Farjoun (2010) explores stability and change as practices of exploitation (stability enabling stability) and exploration (change enabling change) respectively, and exploitation and exploration approaches can be applied to resilience through resistance (exploitation) or adaptation (exploration) (Eltantawy, 2016), this approach does not accurately describe the relationship between sustainability and resilience. Sustainability and resilience are best categorised in terms of success requirements: sustainability as structured (standards, quotas, KPIs) and resilience as adaptive (redundancy, flexibility, agility) (Redman, 2014; Lizarralde et al., 2015). Like exploitation and exploration, structured improvement and adaptive improvement reflect working with known (exploitation, structured improvement) and unknown (exploration, adaptive improvement) outcomes.

Whilst structured and adaptive processes are placed in opposition, the dualism aspect of this paradox emerges when considering how complementing approaches also apply. Resilience practices can enable sustainability (integration, communication), and sustainability practices can enable resilience (improving reputation, sustainability risk assessment). Using Farjoun’s (2010) framework as a template, these relationships are structured into four quadrants (Figure 1), which show oppositional elements (Q1 and Q4) and complementary elements (Q2 and Q3). Quadrants are summarised below.

Quadrant one, structured improvement: This focuses on how sustainability approaches can lead to sustainability outcomes, with attention focused around efficiency measures, commitment and maintaining standards.

Quadrant two, resilience enables sustainability: This quadrant focuses on how resilience approaches contributes to sustainability outcomes in process-oriented considerations, with the role of longevity in sustainability, integrating systems and communication highlights a core component of this section.

Quadrant three, sustainability enables resilience: This quadrant focuses on how sustainability approaches contribute to resilience outcomes in outcome-oriented considerations that have consequences for reputation, risk assessment and visibility.

Quadrant four, adaptive improvement: This focuses on how resilience approaches lead to resilience outcomes, with attention on agility, flexibility and redundancy.
**Next steps**

To develop this framework further and explore its potential contribution empirically, SC managers will be interviewed to thematically understand their experiences and knowledge with regards to SC sustainability and resilience practice implementation. This will be followed by quantitative analysis exploring practice implementation consequences.

Abstract

In recent years, various trends like outsourcing strategies have changed the way supply chains are managed and have increased the attention towards preventing supply chain disruptions. Therefore, supply chain risk management (SCRM) has gained growing awareness. In the literature, various authors call for further investigating the development of early warning risk management systems. To achieve this, predictive analytics can help organizations in deciding on adequate precautionary actions to minimize potential risks incurred. Therefore, the objective of this paper is to analyse the state of the art in supply chain and operations management regarding the application of predictive analytics in SCRM.

Keywords: Supply chain risk management, predictive analytics, literature review

Introduction

In todays globalized economy, sustainable success of businesses not only depends on successfully managing within the company’s boundaries—in fact, managing risks evolving from the supply chain seems crucial. Companies need to be aware of potential risks and be able to consider them in managerial decision-making. Thus, risk management in such complex environment requires continuous and dynamic approaches. Predictive analytics can help organizations in deciding on adequate precautionary actions to minimize potential risks incurred. Hence, this technology has the potential to refine SCRM as it supports organizations by informing them about possible future scenarios. Therefore, the objective of this paper is to analyse literature that aims to merge the two scientific domains predictive analytics and SCRM. The following research question can be derived for the present work: What is the state of the art regarding the application of predictive analytics in supply chain risk management? The rest of the paper is structured as follows. First, theoretical foundations of SCRM and predictive analytics are discussed shortly. The research methodology applied is then displayed and executed. Finally, the results are presented and discussed in order to derive prospective research directions.
Key concepts
Risk has been discussed extensively in the literature in a wide variety of domains such as insurance, engineering, and also finance and economics within the last 30-40 years (Romeike, 2018). The management of risk is an integral part of ensuring sustainable success of companies in a long-term perspective (Diederichs, 2013). Managing supply chain risks (SCR) has become more and more relevant in today’s complex and global supply networks (Wu, Blackhurst and Chidambaram, 2006). To date, no consensus has been reached in the scientific community on the definition of SCR (Ho et al., 2015). Heckmann, Comes and Nickel (2015) devote an article to filling the scientific gap by devising a suitable definition as well as describing essential features of SCR. This definition can be applied across all domains and covers both the consideration of potential sources of risk as well as their impact. Therefore, SCR in the context of this research can be defined as follows:

“Supply Chain Risk refers to uncertainty and severity of the events and consequences of any activity that adversely influence any part of a supply chain leading to potential loss in terms of its target values.” (Heckmann, Comes and Nickel, 2015)

Regarding a classification scheme of SCRs, there is also no consensus between various researchers. Ho et al. (2015) analyze existing classification schemes in their literature review and on this basis derive a comprehensive classification for SCRs as illustrated in Figure 1, generally distinguishing between macro and micro risks.

![Figure 1: Supply chain risk classification [own illustration according to (Ho et al., 2015)]](image)

Macro risks refer to those SCRs that reflect undesirable and relatively rare external events that could have a negative impact on the object under investigation. They can be further divided into natural risks (e.g., earthquakes) and man-made risks (e.g., wars). In contrast, micro-risks are those SCRs that are caused either by a company’s internal activities or by relationships with upstream and/or downstream companies in the supply chain. Furthermore, micro risks can be subclassified into four categories which are supply risks, manufacturing risks, demand risks and infrastructural risks. While supply risks refer to adverse events in conjunction with downstream partners, demand risks relate to undesirable events associated with the upstream companies in the corresponding supply chain. In addition, manufacturing risks are those unintended events within the company’s boundaries that relate directly to internal capabilities regarding the value creation process itself, its quality and its profitability. In order to ensure the sustainable functioning of a supply chain, it is also necessary to consider infrastructural risks. Managing these requires focusing on three subcategories: Information risks, transportation risks and financial risks. To each of these categories different risk factors can be assigned (Fan and Stevenson, 2018; Ho et al., 2015; Rao and Goldsby, 2009; Zsidisin and Henke, 2019). The discipline of SCRM is a relatively new research field and arose from the need to ensure business continuity in the presence of SCRs. The risk management framework, which has been adopted for managing SCR by many researchers, consists of four central phases: Risk identification, risk assessment, risk treatment and risk monitoring (Fiege,
The identification of potential risks constitutes the basis of the risk management process (Romeike, 2018). Thereupon, the identified risks are quantified and assessed in risk assessment (Fiege, 2006). This assessment is normally conducted according to two dimensions: The probability of occurrence and the potential impact of the considered risks (Diederichs, 2013; Fiege, 2006; Gleißner, 2011; Romeike, 2018). In addition, in the context of risk assessment it is also important to take into account the phenomenon of risk accumulation arising from existing dependencies between risks (Haimes, 2009). Once the risks have been assessed, companies should, after careful consideration by management, identify the resources required to manage the risks. Therefore, the objective of risk treatment is to keep the overall risk to which a company is exposed in an acceptable range (Pfohl, Gallus and Köhler, 2008). The fourth and final phase of the risk management process is risk monitoring. Risk monitoring verifies the effectiveness of the measures adopted as part of risk treatment. Target-actual comparisons are conducted to determine whether the company is operating within its individually defined risk limit (Reichling, 2003).

Over the last decades, digital technologies enabled a plethora of data and information being captured, analysed, shared and stored within different application areas (Choi, Wallace and Wang, 2018; Tiwari, Wee and Daryanto, 2018). Both researchers and practitioners agree that, by collecting and analysing this huge amount of data, also referred to as “big data”, essential improvements can be obtained, especially in the context of supply chain and operations management (Addo-Tenkorang and Helo, 2016). According to Tsai et al. (2015), business analytics illustrates the utilization of analytical techniques applied to a vast amount of data in order to create and extract valuable knowledge for data-driven decision making. Business analytics can generally be subdivided into the following three categories: Diagnostic Analytics, Predictive Analytics and Prescriptive Analytics (Ereth and Kemper, 2016). In the present work, the focus is on predictive analytics. Predictive analytics can be defined as the systematic analytical process of revealing meaningful patterns and underlying relationships of variables to turn data into strategic information and thereby improve decision-making (Abbott, 2014; Bose, 2009; Dinov, 2018). Though, it is important to mention that no statistical algorithm can predict future developments with hundred percent certainty. Over the past years, various methods for predictive analytics have been developed in order to, as the name already suggests, predict future outcomes built upon historical data (Gandomi and Haider, 2015). Lu (2017) distinguishes between offering numerical and categorical predictions. While the most common predictive analytics method for making numerical predictions are regression analyses, categorical predictions are mostly based on classification approaches (Abbott, 2014; Kuhn and Johnson, 2016). Regression analysis is a statistical technique used to model the relationship between dependent and independent variables. Build upon this relationship, predictions of unknown target variables are generated based on known predictors (independent variable). Regression analyses are the most widely used method for predictive modelling (Montgomery, Peck and Vining, 2012). Classification identifies which category a new observation belongs to grounded on given information from a training data set. Classification is counted as a supervised learning technique. Supervised learning means creating predictive models based on existing datasets. These so-called training datasets already contain the results that are to be predicted. Common classification algorithms are decision trees, Bayesian classification, support vector machines (SVM) or artificial neural networks (ANN) (Abbott, 2014; Eckerson, 2007; Lu, 2017; Rehman et al., 2016).
Research methodology
In order to answer the defined research question, a structured literature review is carried out. Structured literature reviews usually differ from a more narrative review in their methodical concept, establishing an in-depth description of the stages taken to select, examine and analyse relevant sources with the objective of minimizing biases and increasing transparency. The scientific approach of a structured literature review is adopted from Denyer and Tranfield and distinguishes four stages (Denyer and Tranfield, 2009). Each stage contains, according to the authors, more detailed specifications, which should be carried out in order to meet the requirements of the review (Denyer and Tranfield, 2009). Figure 2 summarizes the proposed methodology. This literature review provides an informative overview and focuses on the evaluation of the thoroughly selected literature.

Stage I has been completed already by phrasing the research question. The present sections include both stage II and stage III by subdividing them into five steps. First, the search terms are defined and relevant databases as well as further criteria of the search queries are determined. Thereupon, evaluation criteria for the selection of relevant studies are defined. The next step describes the process of searching the databases. Furthermore, an additional search based on citation reviews and within additional search engines is conducted. The section concludes by providing an overview of relevant literature. The last section of the paper summarises the results (Stage IV).

Definition of search terms and databases
Today, applying search queries in online databases is the prevailing method of identifying relevant literature aiming at collecting, structuring and synthesizing existing knowledge. Table 1 shows the keywords applied in the database search queries. The following major online databases were considered: Business Source Premier, EmeraldInsight, ScienceDirect, Taylor & Francis and Wiley. We used a combination of terms related to both research fields connected through an “AND”-operator (e.g., “predictive analytics” AND “supply chain risk management”).

Figure 2: Stages of a systematic literature review (Denyer and Tranfield, 2009)
Definition of evaluation criteria for study selection
The evaluation of relevant literature in the declared databases took place in February 2019. Studies, which were published in another language than English, were not included. No explicit starting point of the structured literature review has been chosen. Furthermore, based on the research question defined, the abstracts needed to show that the investigations apply methods from predictive analytics in SCRM as objective of the research. In some cases, the abstract did not clarify if the paper fulfilled these criteria. Those publications were kept for further analysis.

Search in databases
During the search process in distinct databases, publications must correspond to the defined evaluation criteria above while reading the abstract (1st check). Thereafter, the chosen publications have been examined within a deeper analysis to check if they match the mentioned criteria defined above (2nd check).

Additional searches based on citation review / additional search engines
To also consider articles published in non-scientific magazines or lower-ranked journals, search queries using the Google search engine have been performed. Furthermore, keyword searches in databases can be misleading because keywords are not used consistently across publications (Lecy and Beatty, 2012). Therefore, snowballing is applied to effectively expand the relevant literature for this review. Snowballing refers to using the reference list of a paper or the citations to identify additional papers. The evaluation criteria mentioned were also applied to the results of this additional search.

Screening and overview of relevant publications
In summary, by scanning the documents in line with the defined evaluation criteria, the search queries resulted in 24 articles (1st check). In the next step, an in-depth examination of the remaining papers was carried out. As a result, eight articles proved to have limited relevance in relation to the objective of the study. Thus, the final sample, after removing duplicates, consists of 16 articles. By the application of snowball sampling four more articles could be added, increasing the total number of publications to 20. The annual distribution of publications in the period from 2003 until 2018 is shown in Figure 3. In 2003, Bruzzone and Orsoni (2003) published the first article implementing predictive analytics in SCRM. With one exception in 2008, the remaining publications are limited to the period from 2010 to 2018. In the following section, the results of the literature review will be discussed in more detail.

Figure 3: Distribution of publications per year across the period studied

Reporting
The studies examined can be classified according to the framework by Ho et al. (2015). Seven of the twenty studies did not provide any information about which risk categories are examined. The remaining 13 publications include the investigation of micro risks,
four also examine macro risks. Regarding the further subdivision of micro-risks, it can be stated that ten studies include the consideration of infrastructural risk, seven studies consider supply risk, four studies manufacturing risk, and another four studies demand risk. A closer look at the ten publications that consider infrastructural risk reveals that seven publications examine transport risk, five studies information risk, and one study financial risk. Figure 4 illustrates this evaluation.

![Figure 4: Distribution of publications according to supply chain risk categories considered](image)

By analyzing the screened literature, it can be concluded that the application of predictive analytics is almost exclusively limited to risk assessment. Only one article focusses on the preceding phase of risk identification (Zage, Glass and Colbaugh, 2013). Within risk assessment either the probability of occurrence, the potential impact or the interdependencies between different risk factors is predicted (dependent variable). Ten studies focus exclusively on the prediction of the probability of occurrence of specific risk factors, four further studies focus on the potential impact. Two studies combine these parameters and try to predict both the probability of occurrence and the potential impact. One study is confined to the investigation of the potential impact in combination with existing interdependencies between individual risk factors. Moreover, two investigations consider all three parameters mentioned. To enable these predictions, independent variables are analyzed (“predictors”). Generally, the definition and discussion of these variables is often very limited or completely missing. This may be related to the fact that the quantification of risk using corresponding indicators has been named a major challenge within SCRM in the literature within the last years (Atwater et al., 2014; Heckmann, 2015; Rao and Goldsby, 2009; Tang and Nurmaya Musa, 2011). Table 2 provides an overview of the various dependent variables predicted as well as the number of independent variables on which the prediction is based.

In addition to the risk assessment phase, other process steps of SCRM are considered in some articles, in order to provide a comprehensive process model for the application of predictive analytics in SCRM. While Chen, Xia and Wang (2010), Wu, Chen and Tsau (2017) and Zhao and Yu (2011) additionally proposed strategies within risk treatment, Ye, Xiao and Zhu (2015) also considered the preceding risk identification phase. Emmenegger et al. (2012) and He et al. (2014) even broaden these considerations and include the complete SCRM process as described in the previous section. Nevertheless, based on the analyzed studies, it can be said that there is no harmonized approach in the literature of how to implement predictive analytics into SCRM. Only six of the articles provide further details by depicting a process model on which their investigations are based (Atwater et al., 2014; Emmenegger, Laurenzi and Thönssen, 2012; He et al., 2014; Jamshidi et al. 2018; Ye, Xiao and Zhu, 2015, Zhao and Yu, 2011). However, out of these six publications only Emmenegger, Laurenzi and Thönssen (2012) and He et al. (2014) present a holistic process model that considers all phases of the risk management process presented.
Furthermore, a distinction can be made regarding the predictive analytics method applied. As already mentioned, in predictive analytics regression- and classification-methods can be distinguished. 16 of the publications examined adopt classification methods. Only one publication implements exclusively regression analysis (Atwater et al., 2014). Furthermore, one paper combines both methods (Kumar, Narahari and Wright, 2014). As already stated, classification-methods identify which category a new observation belongs to, based on given information from a training dataset. Based on our literature analysis it can be stated that for predictive analyses of SCR often Bayesian classification (six publications) as well as ANN (six publications) are applied. SVM is used in three publications. One publication bases its prediction on the application of decision trees. Figure 5 shows both the general breakdown of the screened literature with regard to the predictive analytics method applied and the further proportional subdivision of classification methods.

Conclusion
This paper presents a structured literature review on the application of predictive analytics in SCRM. In general, it can be noted that there is not an extensive body of literature in this scientific field yet. This may be related to the fact that the quantification of risk factors using corresponding risk indicators has often been referred to as a major challenge of SCRM in literature within the last years (Atwater et al., 2014; Heckmann, 2015; Rao and Goldsby, 2009; Tang and Nurmay Musa, 2011). Nevertheless, our work has provided several insights into the topic of predictive analytics in SCRM. It was found that there has been a focus on both transportation risk and supply risk even if these were usually not considered exclusively in the different investigations. Furthermore, predictive analytics was almost solely applied in the risk assessment phase to either predict the probability of occurrence (74%), the potential impact (47%) or the interdependencies (16%) between different risk factors. For potential applications of predictive analytics in risk identification, risk treatment and risk monitoring additional research may be required. Regarding the independent variables on which the predictions are based it can be noted that there are major variations both in terms of the number and in terms of the object of quantification even within the same risk category. Therefore, further research is also required in this scientific area. Regarding the predictive analytics methods applied, 80 percent of the papers examined adopt classification approaches. The application of ANN and Bayesian classification is in the focus. Finally, it should be noted that within the screened literature a framework for the adoption of predictive analytics in SCRM is only provided in two cases. However, these do not cover the entire risk management process. For this reason, the need for further research can also be referred to here.

A network analysis of stakeholders at seaports: a case study of Hamburg

Ayman Nagi (ayman.nagi@tuhh.de)
Hamburg University of Technology

Wolfgang Kersten
Hamburg University of Technology

Abstract

A seaport is an essential central place of economic and cultural interchange with complex stakeholder structure. The stakeholders at seaports interact with each other using different communication means and devices. This research is using an interview study to analyse the stakeholders’ network at the Port of Hamburg along with the cooperation aspects related to risk management. The results indicate that there is no central stakeholder who coordinates the risk management activities. This work shows the potential cooperation has on the risk management process. Furthermore, this research will support the development of a conceptual framework for cooperative risk management in seaports.

Keywords: Network analysis, Risk management, Seaport

Introduction

More than 80% of global trading volume is transported by sea, making seaborne transport the most important transportation mode (UNCTAD, 2015). Seaports are essential logistics hubs, where different operations take place: the seaside, for loading and unloading vessels; the storage area, for storing and handling the different loads; and the landside, for distributing and collecting the freight by using several complementary transportation modes (Nagi et al. 2017). Seaports stakeholders interact with each other in different scenarios, with each seaport having a different network structure. These network structures reflect the complex operations that are carried out at seaports.

Seaports have been evolved in immediate proximity to residential areas exposing the population to various risk categories. For this reason, cooperative risk management can play an important role to efficiently mitigate different risk sources such as natural disasters, oil spills and explosion of dangerous goods at seaports. This paper focuses on analysing the network of stakeholders at the Port of Hamburg (Germany) with a particular
view on the field of risk management. The paper aims to analyse the network in order to understand the communication intensity, means and cooperation aspects related to risk management in the seaport. For this purpose, this work addresses two research questions:

(i) Which stakeholders exist in a seaport system?

(ii) How do seaport stakeholders interact with each other with respect to their risk management activities?

The rest of this paper is structured as follows. In a background section, an overview of seaports and main aspects of risk management and network structure are presented. Thereafter, the methodology selected to address the research questions is described. The results and analysis follow subsequently. The paper closes with a short conclusion and outlook for future research.

Background
This section delivers an overview of seaports in general and the relevant research areas combined in this paper: risk management and network structure. Relevant aspects, functions, and processes are briefly elaborated which serve as a theoretical foundation for the network analysis of stakeholders in seaports.

Seaports
Seaports have a complicated structure with different categories of stakeholders inside and outside the port. As an interface linking overland transportation and sea, seaports provide an integrated platform serving as a backbone for different operations and international trade, and as a key enabler for the economic growth of the hinterland (UNCTAD, 2015). Seaports need to carefully handle and process ships along with the different transhipment operations effectively and efficiently (Da Cruz et al., 2013).

Seaports play an essential role in the sector of exports, imports, transportations and travel; and therefore an important element of economic growth (Yoo, 2005). Transport integration is the core function of seaports, but at the same time, a seaport is an important source of employment as well as a powerful factor in national and regional development. Different cargo categories are processed by seaports, such as bulk, break bulk and liquids.

The different processes that occur at seaports including handling, transportation and storing require the involvement of numerous actors (Nagi et al., 2017). The stakeholders at seaports can be categorized into internal stakeholders such as port authorities, shipping companies and port operators as well as external stakeholders such as federal, state and local government (Notteboom and Winkelmans, 2002). The high number of actors increases the network complexity with the associated communication means. These communication means, such as radio devices and online platforms are essential to handle various sources of risks.

Risk management
A standard definition of the term risk in the discipline of management studies does not exist (Henschel, 2008). Damodaran (2007) defines risk as a “higher probability event where there is enough information to assess both the probability and the consequences” whereas Aven and Renn (2009) define risk as a consequence in a certain setting where the consequences are uncertain and might have considerable impacts on humans.
Olsson (2007) distinguish between risk and uncertainty based on the level of event probability. Uncertainty considers only an event and its probability is completely unknown. With risk, a sense of the relative level of event probability can be achieved.

The definition of risk management in this research is adapted from Normman and Lindroth (2004) definition of supply chain risk management (SCRM). Risk management in seaports is defined as the cooperation with partners within the network of seaport by applying risk management process tools to deal with risks and uncertainties that might have considerable impacts on the economy, the environment and/or the health and safety of people.

ISO (31000:2018) presents the risk management process that should take place within the risk management context of an organization. According to this standard, the risk management process should be integrated with management strategies, be embedded in the corporate culture, and be suitable for the business processes of the organization. The consultation and communication with external and internal stakeholders should take place at every phase of the risk management process in order to create the context for the identification, analysis, evaluation, management and monitoring of risks. These stakeholders, especially at seaports, form a network with complex relationships and activities.

Network structure

The network structure presents the number of actors, the relationships between them, and the heterogeneity and relative characteristics of their relationships (Afuah, 2013). Network analysis aims at examining relational systems in which actors exist and can determine how the structure of relationships affect behaviours (Rowley, 1997).

The core set of actors are located based on their prominent position in the studied system. Each actor is requested to indicate other actors who are also significant in the system (Burt 1980). One of the serious challenges that many network researchers face is the foundation of appropriate measures of the network structure such as network cohesiveness and centrality (Seidman, 1983; Rowley, 1997).

Network cohesiveness expresses how “tightly-knitted” and “loosely-knitted” networks are (Seidman, 1983). Centrality refers to the position of an actor in the network relative to the others. There are three types of centrality discussed in the social network literature. These are “degree”, “closeness” and “betweenness” centrality. The degree centrality defines the centrality of an actor by the number of connections an actor has with other actors in the network. Closeness centrality represents the actor ability to access all other actors in the network independently. Betweenness centrality considers as well access to other actors based on the existence of an intermediary actor that is located between other actors in the network. This can be represented as the level of control an intermediary actor has the access of other actors to different regions of the network (Rowley, 1997).

Concerning the development of knowledge networks, two categories can be distinguished. First, intentional knowledge networks, which are built up from scratch. Second, emergent knowledge networks exist already but should be refined in order to be highly productive (Seufert et al., 2004). The structure of knowledge network should be considered dynamically since knowledge is continuously updated and transferred.

In the case of seaports, the network of stakeholders comprises different clusters with each representing a unit of analysis. Examples include authorities, shipping companies and terminal operators. A problem, which represents the event of risk, can be decomposed
into sub-problems with each sub-problem being resolved by a specific actor. The cooperation among the actors is necessary to implement the required strategy to prevent the occurrence of certain risk sources or mitigate the risk’s consequences.

Methodology

This section presents the methodology of the paper that is based on the seaport of Hamburg as the main case study.

This research is using an explorative interview study within a single case study approach with multiple units of analysis in order to analyse the stakeholder network of at the Port of Hamburg along with the cooperation aspects related to the risk management activities.

Exploration studies might not have any propositions, but the research question can be explored using experiments, survey, interviews, or other research methods. Such studies should have a clear purpose and the person who is carrying out this explorative study should state this purpose along with criteria that will judge the success of the study (Yin, 2003).

A Single case study can represent a major contribution to theory and knowledge building. A rationale for a single case study is the representative or typical case (Yin, 2003). The case study of the Port of Hamburg can capture the different conditions and circumstances of the daily operations of a seaport. An embedded design of the case study involving multiple units of analysis is chosen in the Port of Hamburg since each stakeholder category represents a unit of analysis. A semi-structured interview study is used to explore the structure and interactions of stakeholders at the seaport.

Coding is an important approach to analyse and organise textual data. Data analysis is a challenging and crucial aspect of qualitative research. The coding process allows the researcher to connect and communicate with the data in order to generate explanations, develop clusters or generate a theory that is grounded in the data (Basit, 2003).

The 15 interviews were carried out with different stakeholder’s categories such as authorities, terminal operators and shipping companies, with an average duration of one hour per interview. These interviews were coded using the software MaxQDA (https://www.maxqda.com/). MaxQDA is a Computer Assisted Qualitative Data Analysis (CAQDAS) package that is specially developed for the qualitative analysis of qualitative data. Afterwards, a frequency analysis is carried out to determine the core cooperation aspects among stakeholders at the Port of Hamburg with a focus on activities related to risk management.

Three distinct approaches for qualitative content analysis can be used: conventional, directed, or summative. The conventional approach is very suitable for describing a certain phenomenon, especially when the existing literature and theories on the examined phenomenon are limited. For the analysis of interviews in this paper, coding categories are extracted directly from the text data using the conventional approach. These categories are then used to organize the set of codes and interpret the findings from the interviews (Hsieh and Shannon, 2005).

A thorough definition of the unit analysed is essential to enable proper decisions about what to be counted and analysed (Saeed and Kersten 2017). In this study, the interviewed stakeholder, as a subject, is selected as a unit of analysis for the frequency analysis of cooperation aspects.
Gephi software is used in this research to generate and analyse the network structure of stakeholder at seaports. It is a visualization and exploration software that is based on open-source code. The communication intensity values among stakeholders gathered during the interviews study serve as the main input for the software to generate the network graph. Figure 1 summarizes the overall approach of this research work.

**Results and discussion**

This section presents the results of the research based on the steps elaborated in the methodology. The first subsection presents the results of the network analysis using Gephi. Afterwards the cooperation aspects are elaborated with examples mentioned by the interviewed partners.

**Network structure**

The network of stakeholders in seaports is complicated since many information flows occur among different set of stakeholders in specific scenarios. The interview study contained a main part to analyse the intensity of communication among the stakeholders in the Port of Hamburg with regards to risk management. Each interviewee was requested to verify and fill out a communication intensity value (based on the frequency of warnings, disclosures and two-way communication) using a developed stakeholder map. The used ordinal scale has 5 values (0: no communication – 4: very high communication). These values were used as input to create a network and communication intensity map using Gephi to analyse the network structure. The position of each stakeholder in the network is based on the value generated by the software using Yifan Hu layout algorithm that is suitable for large networks. The thickness of each arrow represents the intensity of communication based on the defined ordinal scale. Each arrow is bidirectional, meaning that both partners in the network initiate the communication.

As it can be observed from Figure 2, terminal operators, shipping companies, fire brigades, waterway police as well as the authority for environment and energy play an important role in the communication with different stakeholders in the activities associated with risk management. The focus is specially concentrated on the reactive process and the emergency as well as evacuation plans. For instance, environmental risks, once identified, have a direct influence on initiating a communication channel between the authority for environment and energy with other relevant stakeholders, especially the waterway police and the fire brigade.
Figure 2 – Network graph of the stakeholders at the Port of Hamburg

The maximum centralization theoretically is the centralization that can be obtained in a perfectly centralized star-shaped network based on a central individual talking to everyone. The network centralization can be calculated as the sum of differences between the maximum and the other individual’s centrality values, with a normalization in the range from 0 to 1 using the division by the theoretical maximum centralization (Crowston and Howison, 2003). The ideal theoretical centralization of a network comprising 25 nodes (stakeholders) is 11.74 calculated using Gephi. The calculated centrality depends on the values of closeness centrality for each stakeholder (example is shown in Table 1).

Equation (1):
\[
\text{Network centralization} = \frac{\text{Calculated centrality of the overall network}}{\text{Ideal theoretical centrality}} = \frac{4.59}{11.74} = 39\%
\]

Equation (2):
calculated centrality of the overall network = \(\Sigma (1 – \text{Max (CC)})\)
where CC: closeness’s centrality

Equation (3):
Ideal theoretical centrality = \(\Sigma (1 – \text{Max (CC)})\) for star-shaped network
Table 1 – The top 10 closeness centrality values

<table>
<thead>
<tr>
<th>Label</th>
<th>Closeness centrality</th>
<th>Label</th>
<th>Closeness centrality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Waterway police</td>
<td>67%</td>
<td>Port authority</td>
<td>55%</td>
</tr>
<tr>
<td>Terminal operator</td>
<td>65%</td>
<td>Forwarding agent</td>
<td>53%</td>
</tr>
<tr>
<td>Authority for environment and energy</td>
<td>65%</td>
<td>Industrial injuries corporation</td>
<td>52%</td>

</tr>
</tbody>
</table>

The calculated centrality of the overall network as well as the ideal theoretical centrality can be extracted using equations 2 and 3, where N (number of stakeholders) = 25. The network centralization value indicates that there is no stakeholder who possesses a high number of connections with the other nodes in the network. This also validates one extracted aspect from the interview study, being the lack of a central actor who coordinates the activities related to risk management. Furthermore, it can be observed from the extracted values of closeness centrality (see Table 1) that the relative difference among the stakeholders, specially the top 4, is not significant, indicating the existence of a core set of actors that contribute to the management of different risk sources.

Cooperation aspects
This subsection complements the network analysis of stakeholders at the port of Hamburg. The stakeholders were asked to mention the cooperation aspects with the focus on activities related to risk management. Examples include handling of dangerous goods, proactive measures and risk specific response plans.

Figure 3 – Radar chart of the cooperation aspects for risk management at the port of Hamburg

Figure 3 presents the radar chart of the cooperation aspects mentioned by the interview partners with regards to risk management. The counting mechanism is based on a frequency count if the interview partner mentioned an activity related to that aspect. As can be observed, leadership and coordination as well as risk specific response plans are
the top cooperation aspects at the port of Hamburg based on the conducted interviews. In the following, several cooperation aspects are briefly explained.

Leadership and coordination
Leading a hazardous situation during the reactive risk management process is important in order to efficiently implement the required measures. As an example, the authority for environment and energy takes the lead with regards to environmental risks by assessing the situation and accordingly implementing the required measures. “Then the environmental authority comes as the competent authority and checks if the situation is cleanable or not cleanable and then orders the appropriate measures. If the authority is unavailable, we would be acting on a subsidiary basis and would work for the environmental authority” (#waterway police).

Risk specific response plan
An important cooperation aspect is the engagement in the reactive process. Examples include the emergency levels determined according to an initial assessment. Emergency management plays an important role to handle natural disasters such as flood or extreme winds. Responsible actors are carefully trained in each scenario in order to react efficiently using predefined measures. “If something happens, then we are no longer in risk management but in emergency management. For that case we completed a special training where we worked out everything that is reasonably imaginable with regards to the different scenarios” (#terminal operator).

Consultation and regular meetings
Stakeholders at the port of Hamburg stressed on the importance of regular meetings with authorities, terminal operators and shipping companies in order to get the latest updates on regulations, accidents, and other specific requirements. These regular meetings can also be organized for specific topics or sources of risks such as the handling of dangerous goods. “We have a dangerous goods circle, where we meet regularly and just talk without a tight agenda about the current hot topics. The circle comprises shipping companies, customs, police and also bulk career” (#shipping company).

Info / approval of dangerous goods
The aspect of dangerous goods was one of the most frequent aspects mentioned in the interview study. Many stakeholders cooperate to mitigate the negative effects of the risks associated with dangerous goods such as the wrong declaration of goods or the wrong handling leading to fires and explosions. “Normally we receive information on dangerous goods from the shipping companies or freight forwarders” (#terminal operator).

Definition of preventive measures
Defining the countermeasures in advance is important especially in emergency management to avoid the severe consequences of unexpected events such natural disasters. Examples include the cooperation between port authority and the terminal operators in the case of flood to protect the surrounding area and the citizens. “Waterway police help us to carry out a smooth process in order make sure that everything is planned correctly to avoid accidents such as the falling of containers” (#shipping company).

Exchange of data and information
Different stakeholders also cooperate in terms of data and information exchange to increase the efficiency of the knowledge management process. For instance, the exchange of data related to cargo accidents to carry out a root cause analysis. This in order to discover the root cause and prevent the occurrence of risk by defining suitable measures. “We exchange the data of cargo accidents to learn from each other in order not to have
the same accidents again. Based on that we carry out a root cause analysis” (#shipping company).

Post processing and follow up

Another important cooperation aspect is the post processing and follow up of the implemented measures during the risk treatment phase. The development of a damage report after mitigating the accident situation is an example of a follow-up process to document and improve the implemented measures and the communication process. “Every caller of us is obliged to write a damage report when he has completed a claim. It says in there: Who did I talk to, when did I talk, how long was I there, and what did I do” (#authority).

Each interviewed stakeholder cooperates only with his partners within a specific network cluster. This cooperation is not explicitly defined using specific knowledge and risk management process. Additionally, the aspects related to exchange of data and information, post-processing and definition of preventive measures were rarely mentioned, although they are essential for risk management, knowledge transfer and the continuous improvement process.

An efficient knowledge transfer process can be facilitated by the proper utilization of cooperation aspects among stakeholders in seaports. The definition of clear roles and responsibilities is required to coordinate the activities related to risk management. Additionally, the communication within stakeholders in a seaport is essential to coordinate and implement the treatment measures, especially in the case of emergencies (Nagi et al., 2018).

Conclusion

This paper aimed at analysing the network structure of stakeholders in the Port of Hamburg. The results of the network analyses are based on 15 semi-structured interviews with different categories of stakeholders. The analysis was carried out using Gephi software and its functions to generate the network structure of stakeholders at seaports. The cooperation aspects were extracted based on the coding analysis using MaxQDA. This work shows as well the potential a cooperation has on the risk management process. The definition of tasks and responsibilities as well as the mutual knowledge transfer among stakeholders can facilitate an efficient identification, assessment and handling of risks.

As it can be observed, there is no central stakeholder who manages or coordinates the activities related to risk management in seaports. The overall centrality of the network (39%) validates these results. The results also indicate that authorities represented by waterway police, fire brigades and rescue service as well as the authority for environment and energy together with shipping companies and terminal operator are primary actors when it comes to coordination, leadership roles and consultations related to the risk management activities, especially during the reactive risk management process.

Leadership and coordination and risk specific response plans are the most frequent cooperation aspects extracted from the interview study. These cooperation aspects are linked with natural disasters, environmental as well as operational risks associated with the handling of dangerous goods.

This work was limited to the interviews conducted at the port of Hamburg. 15 interviews were carried out to investigate and analyse the degree of cooperation for the activities related to risk management at the port of Hamburg. It is possible that certain
cooperation aspects were not mentioned during the interviews due to the nature and time frame assigned by each interviewee. Additionally, the coding mechanism might have omitted certain aspects that were mentioned by the interview partners. A survey study can validate and expand the results of the interview study. A larger set of stakeholders can be reached. Furthermore, the triangulation approach based on the interview and survey studies can increase the reliability of the results. Based on empirical study and the extracted requirements, a conceptual framework for cooperative risk management can be developed to utilize the cooperation aspects between the stakeholders and communications means based on the nature of covered risks. A conceptual model can be further extracted from the conceptual framework and validated using different scenarios with a set of stakeholders.

Abstract: This paper examines how companies manage the contingent uncertainty associated with geopolitical events. We gather data from 10 semi-structured interviews with managers dealing with Brexit. We find that small companies follow a passive strategy due to limited resource availability. Medium sized companies initially follow a wait-and-see strategy and then change to a reactive strategy. Large companies follow a worst-case scenario approach that includes aspects of wait-and-see, reactive and pro-active strategies. We contribute to contingency theory by identifying that companies faced with the same external environmental condition take very different approaches to managing contingent uncertainty, due to resource availability.

Key Words: Supply Chain Risk Management, contingency theory, contingent uncertainty,
Introduction

Today’s Operations Managers live in uncertain times. Trade disputes between the USA and China are prompting Operations Managers to reconsider their sourcing locations and target markets (Financial Times, 2019). Labour disputes such as the Gilets Jaunes strikes in Paris and political uprisings in Venezuela are impeding supply lines and disrupting distribution networks (The Economist, 2019). Operations Managers must decide how to manage the uncertainty that is created by these geopolitical events, otherwise, increased supply chain costs and delayed customer orders are inevitable.

Operations Management (OM) scholars have spent significant time exploring how firms manage supply chain risks using proactive, reactive, and passive risk mitigation strategies (Chopra and Sodhi, 2004; Grotsch et al., 2013; Ritchie and Brindley, 2007). Some scholars stress that firm size plays an important role in the type of risk mitigation strategy that a company will select (Ellegaard, 2008; Thun et al., 2011). For example, because large firms have greater amounts of resources in terms of time, money, and personnel, they can be proactive and make significant capital investments in flexible supply chain infrastructure to reduce the probability and severity of the risk event (Thun et al., 2011). Smaller firms do not have these slack resources and will tend to follow passive strategies reacting after the event has occurred (Ellegaard, 2008).

While the discourse surrounding how firms manage supply chain risk is detailed and extensive, little attention is paid to how firms manage the uncertainty created by geopolitical events. Risk describes decision situations in which probabilities are available to guide choice, while uncertainty describes decision situations in which information is too imprecise to be summarised by probabilities (Knight, 1921). Thus, risk applies to situations where we do not know the outcome of a given situation but can accurately measure the odds of the event occurring, while uncertainty applies to situations where we cannot know all of the information we need to set accurate odds in the first place (Knight, 1921). Risk is therefore a consequence of uncertainty and not a substitute (Figueira-de-Lemos et al., 2011). This means that supply chain risks result from uncertain situations. And, while the probability and severity of supply chain risks can be quantified and effectively managed, uncertainty in the supply chain is more difficult, if not impossible, for operations management to measure and address.

International Business scholars make an important distinction between two types of uncertainty that a firm may encounter (Clarke and Liesch, 2017; Figueira-de-Lemos et al., 2011). The first type is called ‘pure uncertainty’, which relates to the unpredictability of future events. Because the future cannot be known with complete certainty, pure uncertainty is impossible to reduce or eliminate (Figueira-de-Limos et al. 2011). The second type is called contingent uncertainty, which is knowledge-dependent and can be reduced as individuals learn more about a particular situation and develop contingency plans to manage the disruptive event (Figueira-de-Limos et al., 2011). In this paper, we are interested in how firms manage contingent uncertainty in their supply chain. We adopt the definition of contingent uncertainty provided by Clark and Liesch (2017) and apply it to the supply chain context as follows: Supply chain contingent uncertainty is defined as: “the extent to which the firm lacks knowledge about whether potentially significant and/or disappointing outcomes of its supply chain decisions will be realised” (adapted from Clarke and Liesch, 2017 p. 926)

The purpose of this paper is to answer the following questions: 1) what are the different strategies that firms deploy to manage the contingent uncertainty that arises from geopolitical events? And; 2) what is the role of firm size in the type of strategy that is deployed? Our research, using Contingency Theory, takes a theory building approach to explore these questions. Our context of study is Britain’s transition out of the European Union, or Brexit. Working longitudinally, we examine this geopolitical event as it unfolds; permitting real-time insights on the strategies that companies enact to cope with contingent uncertainty in the supply chain. While the firm acts as the unit of analysis, the UK’s pharmaceutical sector is selected as the unit of reference.
The UK’s pharmaceutical industry represents an extreme example of how supply chains can be directly affected by the uncertainty created by geopolitical decisions. Following the pro-Brexit vote in June 2016, the body responsible for approving and regulating the sale of pharmaceuticals in Europe (the European Medicines Agency), moved its Headquarters from London to Amsterdam creating uncertainty in new drug approvals for UK firms. Moreover, the UK government mandated that UK pharmaceutical companies stockpile a minimum of six weeks of all products to ensure that patients would not be left without lifesaving medications in the event of a no-deal Brexit (Reuters.com, 2018). We collect data using 10 interviews with managers at small, medium, and large pharmaceutical firms. The interview findings are corroborated through an analysis of primary documentation including policy documents, trade association briefs, and company strategy documents relating to Brexit. The findings from the primary data are further validated using secondary data sources gathered from databases including Factiva, Bloomberg, Financial Times/FT.com and ProQuest Archiver.

The remainder of the paper is organised in four sections. The next section reviews the pertinent literature to advance a conceptual model. Section three provides a justification of the research design and section four discusses the findings in relation to the literature to arrive at a framework of different strategies for managing the contingent uncertainty associated with geopolitical events. The paper concludes by outlining its theoretical and managerial contributions and highlighting potential fruitful areas for future research.

**Literature Review**

*Contingency Theory and contingent uncertainty*

Contingency theory asserts there is no single best way to organise and any method of organising will not be equally effective under all conditions (Galbraith, 1973). Central to contingency theory is the proposition that the structure, process, culture, and technology of an organisation must fit its external environmental if the organisation is to survive and be effective (Schoonhoven, 1981). One external factor that significantly influences how an organisation configures its structure and processes is the amount of uncertainty present in the external environment (Galbraith, 1973). Environmental uncertainty is defined as an inability to assign probabilities to the likelihood of future events (Knight, 1921) and is reflected by such factors as complexity, rate of change, and the availability and clarity of information (Galbraith, 1973).

By matching an organisation’s structures and processes to the external setting, a firm achieves fit with its external environment and, in turn, reduces the degree of perceived uncertainty (Burns and Stalker, 1961; Drazin and Van de Ven, 1985; Thompson, 1967).

Since these early writings, International Business scholars have categorized uncertainty into pure and contingent uncertainty (Clarke and Liesch, 2017; Figueira-de-Lemos et al., 2011). While pure uncertainty refers to future events that are impossible to know and plan for, contingent uncertainty implies that the more one learns, the more that individual can do to develop different contingency plans or alternatives (Figueira-de-Lemos et al., 2011; Jones, 2013). The more alternatives that an individual can identify, the more knowledge that is acquired and the less ignorant he or she becomes about the situation (Figueira-de-Lemos et al., 2011). Knowledge about an uncertain future event can be gained through tangible and intangible resource commitments (Hadjikhani, 1997). Tangible resource commitments are measurable; they relate to investments where it is possible to calculate both the input cost and financial outcomes, such as investments in supply chain infrastructure (i.e. production facilities, subsidiaries’ offices or transportation vehicles) (Hadjikhani, 1997). Intangible commitments are difficult to quantify; they are specific to relationships and are difficult to redeploy to another relationship (Figueira-de-Lemos et al., 2011; Hadjikhani, 1997). The purpose of intangible resource commitments is to learn about and predict environmental changes and include such things as forming new relationships to gather knowledge about a disruptive event. (Figueira-de-Lemos et al., 2011; Hadjikhani, 1997).
In stable environments, characterised by low levels of contingent uncertainty, managers are able to draw on their experience while acquiring context specific knowledge, giving them more confidence when deciding on future resource commitments (Figueira-de-Lemos and Hadjikhani, 2014; Petersen et al., 2010). However, in unstable environments, managers must compromise between knowledge and resource commitment decisions, as past knowledge cannot be entirely relied upon in volatile markets (Figueira-de-Lemos and Hadjikhani, 2014; Petersen and Pedersen, 1999). When contingent uncertainty is high, managers will be reluctant to make tangible resource commitments because there is too much at stake and tangible investments are difficult and costly to reverse (Figueira-de-Lemos and Hadjikhani, 2014). Instead, managers are more likely to make intangible resource commitments to gain more knowledge about the situation and to bring perceived uncertainty down to more tolerable levels – what is termed a ‘wait-and-see’ strategy (Hadjikhani, 1997; Sull, 2005). With a wait-and-see strategy the company aligns its strategic focus to the particular market context, and reacts according to the present situation as-is, be it an opportunity or threat (Clarke and Liesch, 2017; F Sull, 2005). We adapt the definition of a wait-and-see strategy provided by Clarke and Liesch (2017 p.924) and apply it in a supply chain context. Specifically, we define a wait-and-see strategy as: a measured decision to make intangible resource commitments in order to gather knowledge about a disruptive event and reduce contingent uncertainty. Interestingly, the SCRM literature reveals little acknowledgement of the wait-and-see approach and instead focuses on the tangible resource commitments that firms make to reduce the probability and/or the severity of supply chain risks.

Supply Chain Risk Management

SCRM strategies are generally categorised as passive, reactive, or proactive (Craighead et al., 2007; Grotsch et al., 2013; Kleindorfer and Saad, 2005). Passiveness is when firms do nothing and respond haphazardly to the risk event after it has occurred (Grotsch et al., 2013). Passive strategies imply that tangible resource commitments are only made after the event to minimise its impact on the supply chain. Reactive strategies focus on reducing the severity of the risk event, while proactive strategies focus on reducing the probability of the risk event (Grotsch et al., 2013). Reactive strategies may including making tangible resource commitments in the form of surplus capacity, excess inventory, and multiple sourcing contracts, to reduce the severity of the event’s impact on the supply chain (Sheffi and Rice, 2005; Thun and Hoenig, 2011). Proactive strategies are when companies plan ahead to eliminate the probability of the event occurring (Grotsch et al., 2013; Knemeyer et al., 2009; Mitroff and Alpaslan, 2003; Tang and Tomlin, 2008). Proactive strategies rely on tangible resource commitments in the form of control systems that help identify and assess supply chains risks (Chopra and Sodhi, 2004; Grotsch et al., 2013; Jüttner et al., 2003). If the risk cannot be avoided, proactive firms will embed flexibility in a firm’s supply chain by investing in multiple sourcing contracts and flexible manufacturing equipment to allow for an agile response to the risk event (Kleindorfer and Saad, 2005; Trkman and McCormack, 2009).

While SCRM scholars discuss passive, reactive and pro-active strategies they fail to examine the role of wait-and-see strategies when managing contingent uncertainty. A wait-and-see strategy is not proactive because tangible resource commitments are not made in advance to reduce the probability of the disruptive event occurring, nor is it reactive as tangible resources are not committed to reduce the severity of the event. Moreover, a wait and see strategy is not passive, as the firm does not stand idly by as the disruptive event occurs and reacts haphazardly after the fact. Instead, a wait-and-see strategy is the deliberate commitment of intangible resources to acquire knowledge about the disruptive event to reduce contingent uncertainty.

In the main, SCRM scholars study large multinational firms and their approach to managing supply chain risk. One exception is Thun et al. (2011) who surveyed 67 small, medium, and large enterprises to find that small and medium enterprises (SMEs) were more vulnerable to supply chain risks due to weaker cash flow and equity positions. They found that SMEs try to deal with supply chain risks by building up redundancies (safety stock, overcapacity) which
absorb the impact of the risk event, while large companies systematically attempt to eliminate or reduce the possibility that a risk comes into effect. Moreover, they find that large companies have greater resource availability to invest in capital-intensive instruments such as strategic supplier development or tracking and tracing (Thun et al., 2011). Another exception is Ellegaard (2008), who conducted eleven interviews with small company owners to find they use defensive risk management strategies based on local sourcing combined with seeking out responsive, dependable and like-minded suppliers. Unlike Thun et al. (2011), Ellegaard (2008) found that small company owners avoided multi-sourcing contracts and building redundancies because of resource and expertise restrictions. Small company owners were found to spend little time and resources actively acquiring knowledge about suppliers and supply markets (Ellegaard, 2008). To synthesize this discussion, we now advance a conceptual model of the different types of strategies used by small, medium, and large firms to manage the contingent uncertainty that arises from geopolitical events (See Figure 1).

![Conceptual Model: Strategies for managing contingent uncertainty in the supply chain](image)

**Research Design**

Our research design is based on an theory elaboration approach (Ketokivi and Choi, 2014). To elaborate on theory, we worked in an abductive manner (Josephson and Josephson, 1996; Niiniluoto, 1999; Suddaby, 2006), continuously moving between the empirical data and contingency theory. While guided by a priori theoretical considerations, we remained open to unanticipated findings and the possibility that the general theory required reformulation (Merton, 1968). We situationally grounded the study within the context of firm’s managing the contingent uncertainty resulting from the pro-Brexit vote. We conducted an in-depth investigation of the relationship amongst concepts including intangible and tangible resource commitments, contingent uncertainty and knowledge gathering. Throughout the study, we attempted to reconcile the idiosyncrasies of the data with existing theory and when unanticipated findings were identified we were able to elaborate on contingency theory (Ketokivi and Choi, 2014; Merton, 1968). Our context of study was Britain’s departure from the European Union (or Brexit), while the unit of analysis was pharmaceutical firms.

**Brexit and the Pharmaceutical Industry**

On June 23rd, 2016, the people of the United Kingdom voted on whether to remain in, or to leave, the European Union (EU). The vote went 51.9% in favour of Britain departing the EU, with the outcome creating a profound sense of surprise and shock on both sides of the debate (Wincott et al. 2017a). In the aftermath of the vote, Britain’s Prime Minister, David Cameron resigned and the Financial Times Stock Exchange (FTSE) 250 index fell by 13% (Rodionova,
Another major casualty was the value of the British pound which fell by 13% in relation to the Euro. Ten months after the vote, the pound was still trading around 15% lower compared to the U.S. dollar and 12% lower compared to the Euro than before the referendum (Bowers, 2017). More than 2,600 pharmaceutical products have some stage of manufacture in Britain and 45 million patient packs are supplied from the UK to other European countries each month, while another 37 million flow in the opposite direction (Reuters.com, 2018). UK pharmaceutical firms were advised by the UK government to implement no-deal plans by the end of 2017 and were told “to ensure they have a minimum of six weeks additional supply in the UK, over and above their business as usual operation buffer, by March 29th, 2019” (Reuters.com, 2018). In our study, we consider the period between the pro-Brexit vote (June 26th 2016) to the half way point when Britain was due to leave the EU (March 29th, 2019) as the longer-term. The medium term is considered to be the one year period between Nov 18th, 2017 to Nov 29th, 2018, when Theresa May returned from Brussels with a withdrawal deal for ratification by U.K. parliament. The short-term period is considered to be from Nov 30th to March 29th 2019, when Britain was initially scheduled to leave the EU.

Data Collection
Qualitative data was gathered using the key informant technique (Marshall, 1996; Tremblay, 1957). A key informant is an expert source of information (Marshall, 1996), that provide the researcher with insights into a matter and can initiate access to corroboratory or contrary sources of evidence (Yin, 2013). Moreover, key informants possess knowledge or can make assessments that are not available in the public domain; knowledge that is often considered confidential, sensitive or privileged (Christopoulos, 2010). We followed guidance provided by Carter and Jennings (2002) in assessing who meets the criteria of a key informant. First, we interviewed individuals at the manager level of higher, as these individuals tend to have detailed experience of the organization to give an informed opinion (Carter and Jennings, 2002; John and Reve, 1982). Second, we interviewed individuals with at least 3 years of experience at the organisation so they could provide insights on how the organisation functioned and responded to disruptive events (Carter and Jennings, 2002). Third, we only interviewed individuals who had a detailed understanding of the phenomenon under investigation (Carter and Jennings, 2002), or more specifically, individual’s whose day-to-day job role was directly affected by the Brexit process. Interview data was collected longitudinally, over a two year period from March 2017 to March 2019. Each interview lasted between 30 minutes and one hour and was transcribed verbatim for later coding and analysis. Firm size was determined by number of employees with >100 employees being categorized as small, 100-10,000 categorized as medium and 10,000+ categorized as large.

Table 2 – Interviewee organisation and positions (anonymised)
Data Analysis
To analyse the data, we followed the approach of Craighead et al. (2007) who used key informant interviews to study disruptive supply chain events. Specifically, we used thematic analysis techniques (Braun and Clarke, 2006) and followed the three-step process outlined by Miles and Huberman (1994). In step one, we performed first-level coding to summarize and describe the data. In step two, we performed patter matching techniques (Miles and Huberman, 1994; Yin, 2014) to group together similar codes together and then attach these codes to higher order themes. In step three, we formalized and systematized the findings into propositions that explain the different strategies that companies deploy to reduce the contingent uncertainty associated with geopolitical events. To enhance inter-rater reliability, the coding process was carried out independently by three members of the research team and the codes were later compared to reach consensus on the key themes (Armstrong et al., 1997).

Findings and Discussion
Small Firms and strategies for managing contingent uncertainty
Biological solutions is a small company of 30 employees based in Germany that produces probiotics for food. When the CEO of Biological Solutions was first interviewed in October 2017 she explained her company’s approach to Brexit as follows:

“As far as I see it we don't have any strategy [for Brexit]…. we might have to have more import regulations if we want to sell into the UK …but we have this for many other countries, like when we sell something in to US, so we are quite used to doing this.”

-CEO Biological Solutions –Oct 2017

This quote demonstrates that Biological Solutions was adopting a passive, or do nothing, approach to Brexit in the long term. The biggest anticipated impact was not being able to access research funding from the UK Government, as well as restricted access to highly skilled scientists in the UK. When she was interviewed again a year later (October 2018), her company’s strategy for managing Brexit had not changed and she explained that if there was a ‘hard’ Brexit, then her company would treat the UK like any other country outside of the EU in terms of customs declarations and duties and taxes. This finding is in-line with Ellegaard (2008), who argues that small firms will uphold the status quo, adopting a passive strategy of maintaining existing local sourcing contracts with dependable suppliers,. In addition, we found that this mall firm maintained its passive strategy over an extended period of time, even when the disruptive event drew closer. Our data suggests the primary reason for maintaining a passive strategy is resource constraints, in the form of insufficient human and financial resources. Biological Solutions did not have the resource slack to dedicate people to contingency planning, nor the financial slack to invest in buffer inventory. This leads us to posit that:

\[ P1: \text{Small firms will continue to follow a passive strategy over the long to medium term as they have insufficient resources to dedicate to reducing contingent uncertainty} \]

Medium sized firms and strategies for managing contingent uncertainty
UK Therapeutics is a medium-sized pharmaceutical company manufacturing sterile vaccines for allergy treatment at a single site in the UK. The interview conducted in September 2017 indicated the company was adopting a wait-and-see strategy in the long-term gathering information from trade associations to understand the implications of transportation delays, possible skill shortages and quality release planning, as explained by the Operations Director:

“As a company it's a wait-and-see… we're looking at what would be the implications of being a third country.”

– Operations Director-UK Therapeutics-Sept. 2017

When the second interview was conducted during October 2018 (medium term), UK therapeutics had moved to a reactive strategy as it made tangible resource commitments to cover what they called ‘no-regret actions’. This involved building a stock of licensed products at their
Spanish facility prior to the end of March 2019 and investing in resource for a UK Qualified Person responsible for Pharmacovigilance, or monitoring the effects of medical drugs after they have been licensed for use:

“We are not shifting manufacturing [from the UK], but we're aiming to build stock of our licensed products and ship them to the facility in Spain before the end of March '19… This avoids double testing” – Operations Director-UK Therapeutics-Oct 2018

Our study of UK Therapeutics revealed that the company adopted a wait-and-see strategy initially, gathering information from their departmental managers as well as from suppliers. UK Therapeutics also faced resource constraints and put tangible resource commitments on hold so they could gather more information on the future EU-UK relationship. This finding differs from Thun et al (2011) who suggests that SMEs will adopt a reactive strategy from the outset. Instead, we found that UK therapeutics followed a wait-and-see strategy in the long-term and when they acquired more information then moved to a reactive strategy based on building inventory as opposed to shifting production capacity of excess suppliers Therefore, we propose:

P2: In the longer term, medium sized firms will manage the contingent uncertainty associated with geopolitical events by adopting a wait-and-see strategy, making intangible resource commitments to gather information about the disruptive event

P3: In the medium term, medium sized firms will manage the contingent uncertainty associated with geopolitical events by adopting a reactive strategy, making tangible resource commitments in the form of buffer inventory

Large firms and strategies for managing contingent uncertainty

Unlike the small and medium sized firms, we found that the large pharma firms adopted a mix of wait-and-see, reactive and proactive strategies over the long to medium term. The Supply Chain Director from Large Pharma 1 explained the mind-set at her company:

“So all the way through we've taken a worst case assumption. So from day one we've assumed full WTO (World Trade Organization) conditions, we've assumed a full failure of the import-export simplifications that are currently available in the EU. We've assumed full customs and regulatory frictions on the way in, on the way through and on the way out of the EU.

- Supply Chain Director – Large Pharma 1

The worst-case scenario approach to managing the contingent uncertainty around Brexit was also seen at Large Pharma 3:

“We are planning for a worst case Brexit, what other people might call a 'hard Brexit', which is where we have no deal and we default to WTO terms and we default to having to retest all products coming in to the UK from the EU and vice-versa. We've responded very well in putting together all the right functions within the company to manage the workload and define and execute what we need to do, and we've made money available as well.”

- Supply Chain Director – Large Pharma 3

We found the worst-case scenario planning approach encompassed the information gathering aspects of a wait-and-see strategy, the redundancy building of a reactive strategy, and the shifting of supply chain infrastructure aspects of a proactive strategy. For example, the Supply Chain Director for Large Pharma 2 discussed how his company was providing supply chain information to policy makers to shape the outcome of Brexit:

“There are a number of areas where we tried to influence what the final shape (of Brexit) would be. Government is really trying to collect true hard data around the impact of an absolute hard Brexit. So we've had to submit a lot of data around inventory levels, physical location of inventory and import plans post-March (2019) next year.” - Supply Chain Director EMEA – Large Pharma 2
At the same time, the three large pharma firms followed aspects of a reactive strategy as they were building inventory and additional supplier capacity in their supply chains based on a worst-case outcome. While the UK Government had recommend that the large pharma companies hold a minimum of six weeks of stock, the three large pharma firms were building inventory over and above that requirement, as explained by the Supply Chain Director at Large Pharma 3:

“We have been asked by the government to build an extra six weeks’ worth of inventory. That's the way we mitigate risk of delays, by building more inventory in to the pipeline….anything that is lifesaving, we already have high stock levels of and we will probably build more. Anything that is revenue critical, we're probably trying to optimise the stock of.”

-Supply Chain Director – Large Pharma 3

In addition to building redundancies in the supply chain, the large pharma company’s strategy for managing contingent uncertainty also contained elements of pro-activeness. For example, from the long to medium term, the three Large Pharma firms were shifting production from their UK facilities to sites in Europe:

“From the end of this year we will have a warehouse setup in the UK within which we are going to store the product for UK patients. The French warehouse is going to lose the UK inventory, but what we're going to do in France is we're going to have to do sampling of product that is made in the UK and is destined for the EU 27.”

-Supply Chain Director- Large Pharma 1

These quotes demonstrate that the large pharma firms adopted a worst-case scenario planning strategy which is comprised of a mix of wait-and-see, reactive and proactive approaches. This finding differs from the predominant view of SCRM scholars, who argue that firms will follow either a passive, reactive or pro-active strategy (Grotsch et al., 2013). Instead, we find that large firms will follow all three strategies simultaneously, as they have the resource slack that allows them to do so. The three large pharma firms immediately established Brexit task forces and started contingency planning based on a worst-case scenario. They provided information to trade associations and policy makers to influence the future shape of the EU-UK relationship, whilst building up inventory and shifting production capacity to European facilities. We therefore propose that:

*P4: Large firms will manage the contingent uncertainty associated with geopolitical events by following a strategy of worst case scenario planning, which includes wait-and-see, reactive and proactive approaches.*

We now draw together these propositions to advance an empirical framework (see figure 2).
Contribution and Future Research Directions
This paper contributes to contingency theory by identifying that firms will react to their external environment in different ways based on internal resource availability. Small firms will maintain a passive approach because they cannot afford to make investments in information gathering, building redundancies or shifting production between facilities. In the longer term, when contingent uncertainty is high, medium sized firms will follow a wait-and-see approach. As the nature of the event becomes clearer they will then switch to a reactive approach and build redundancies. Large firms will follow a worst-case scenario planning approach which includes using slack resources to gather information and using this information to influence policy. At the same time, large firms will be reactive and build redundancies whilst proactively moving production volumes to other facilities. These findings show that resource availability can make firms act in different ways when facing the same degree of contingent uncertainty in the external environment. We provide managers with an empirically informed framework for managing contingent uncertainty. Our findings show that organizational size and resource availability will dictate which strategy a firm will pursue. We suggest that managers should gather information in the first instance before making costly to reverse resource commitments. We also suggest that managers can use newly acquired knowledge to influence the course of geopolitical events.

Abstract

This paper aims to add to the accumulative knowledge in the field through investigating the current situation of tourism industry in Egypt from a supply chain perspective, and how tourism businesses in Egypt understand the concept of resilience. Such investigation will help in achieving a deep and reflective understanding of current supply chain problems as issues affecting Egyptian tourism. Then identifying the main practices deployed by this sector to mitigate supply chain disruptions.

Keywords: Tourism Supply Chain, Tourism Resilience, Tourism Supply Chain Disruptions

Introduction

The tourism industry has become the world's preeminent industry, as it is one of the fastest growing economic sectors in the world. It plays an important role in the development of many countries. In 2017, it contributed USD 8,272.3bn to the global GDP (10.4%) and generated 313 million jobs in the world (World Travil and Tourism Coucil, 2018). The World Travel and Tourism Council estimates that by 2026, the value will increase to USD 10,986.5 billion, which would represent 10.8% of the world GDP (Szpilko, 2017). For tourism management, planning and assessing resilience is of growing concern since change processes and their interrelations have become more complex in an accelerated, globalized world, placing pressure on tourism to adopt and respond to various factors (Shinae, Hui, Beomcheol, & Chon, 2018).

In an era of growing political turmoil, socio-demographic, environmental changes, and volatility economy, the travel and tourism industry is facing a significant test. Political stability and safety are prerequisites for tourism, even the mere threat /risk of events such as civil war and terrorism can cause tourists to rethink their decision to visit a region (Dahles & Prabawa, 2015; Ghaderi, Hatamifar, & Khalilzadeh, 2018). In addition, to the previous challenges, the dynamic development of the tourism sector requires the enterprises, striving to maintain or achieve a competitive advantage, to take actions to meet the ever-increasing customer expectations.

Despite these challenges, less attention is given to what makes this sector succeed despite disaster. From the perspective of the tourism industry, this lack of research attention is somewhat surprising (Shinae et al., 2018). In addition, the industry needs to
be analyzed from an integrated perspective, that is, as a network of tourism supply chains (TSC) (Kim, Chen, & Linderman, 2015). As the processes involved in supply chain resilience (SCRES) such as adaptation and co-evolution are arguably difficult to understand by studying a single entity in the supply chain, they need to be examined across multiple related firms in a network (Kim et al., 2015; Rice & Caniato, 2003; Tukamuhabwa et al., 2017).

Egypt, as one of the developing countries, possesses one third of the world's known monuments. Egypt enjoys various fields of tourism attraction; the most important are archeological or cultural tourism that is one of the oldest types of tourism in Egypt. In addition to, beaches tourism, religious tourism, therapeutic tourism, eco-tourism, sports tourism, safari/desert tourism, maritime tourism, and finally conferences and festivals tourism (Rights, 2017). Tourism has long been a key contributor to Egypt's national economy along with the Suez Canal revenues and remittances from Egyptians living abroad. The total contribution of tourism industry to Egyptian GDP was EGP374.6bn (USD21.1bn), 11.0% of GDP in 2017. In 2017, the total contribution of tourism to employment, including jobs indirectly supported by the industry was 8.5% of total employment (2,425,500 jobs) (BMI, 2018). Tourism is a demand-driven activity largely influenced by visitors’ perceptions of the safety of travel and destinations. Erratic events affecting such perceptions are numerous including acts of terrorism, wars, political uncertainty, social unrest, economic crises, natural disasters, and health and environmental hazards; all of which strongly deter travel (Sakr & Massoud, 2003).

The survival of business in tourism industry depends on identifying and managing threats and risks. The focus of this study is on identifying the main disruptions, the practices deployed by this sector to mitigate supply chain disruptions and the impact of tourism disruptions on different TSC members in Egypt context.

**Tourism Supply Chain**

The tourism industry comprises a network of organizations (Figure 1) involved in a series of diverse tourism activities, ranging from providing an entire variety of components of tourism services/products, (such as flights, accommodation), and ending with the sale of tourism products in the tourism region, and involves a wide spectrum of participants in both the public and private sectors (Szpilko, 2017). This industry also involve many components: accommodation, transport, excursions, but also bars and restaurants, handicrafts, food production, waste disposal, and the infrastructure that supports tourism in destinations (Tapper & Font, 2004).
Supply Chain Resilience

It is noticeable an evolution through time on research for SC and Resilience, as a result of the negative consequences of SC disruptions, the academic and practitioner community emphasized the need to address the design of SCs that are efficient while resilient to disruptions in regions where the industry is more susceptible to risks (Kamalahmadi & Parast, 2016; Pires Ribeiro & Barbosa-Povoa, 2018). Fiksel, Polyviou, Croxton, & Pettit, (2015) argued that resilience is an important capability that complements the traditional risk management processes in many companies.

Resilience in SC context has been described in simpler and broader terms by several authors (Pires Ribeiro & Barbosa-Povoa, 2018) However, The commonly cited definition of SCRES in the literature is that of Ponomarov & Holcomb, (2009,p.131) “the adaptive capability of the supply chain to prepare for unexpected events, respond to disruptions and recover from them by maintaining continuity of operations at the desired level of connectedness and control over structure and function”. It can be stated that SCRES can hardly be considered as an isolated term, as it is a product of business and industry needs and evolution. For many researchers, it is important to address resilience in combination with uncertainty, complexity, and risk (Kamalahmadi & Parast, 2016).

Resilience of Tourism

The unprecedented rise in the number of crises and disasters affecting the worldwide tourism industry has brought forth the importance of building resilience in the industry of tourism. Recently, resilience in tourism has been explored in the context of disaster and risk management (Sheppard & Williams, 2016). UNWTO (2011) identifies five types of disruptions affecting the tourism sector at local, regional or national level. These are: (1) environmental crises, including geological, extreme weather, and human-induced events; (2) political and societal events; (3) health-related crises; (4) technological incidents or failures; and (5) economic events.
Resilience in tourism context, refers to the industry capacity to deal effectively with self-inflicted crisis and disasters in maintaining the stability of the sector while ensuring the diversity and flexibility essential for further development and innovation (Orchiston, Prayag & Brown, 2016). Daheles & Prabawa (2015) described three different attributes of resilient TSC: survival, adaptation and innovation. The core features of a resilient system in the context of tourism as Cochrane (2010) named “The sphere for tourism resilience” are the ability to connect and understand market forces, collaboration between participants to create strong networks, sufficient flexibility to adapt to change, and leadership normally provided by the public sector (COMCEC Coordination Office, 2017). A network structure supporting tourism resilience has to meet two fundamental criteria (Luthe & Wyss, 2014): preparing for disturbance by creating and maintaining diversity and responding to disturbance by creating and maintaining flexibility.

Tourism Disruptions in Egypt
Tourism in Egypt enjoyed a period of stable and continuous growth from the 1990s through the 2000s (Elshaer & Saad, 2017). However, this sector has been hammered since the uprising and what is known as Arab Spring in 2011 (Salman, Taw, Samy, & Artaltur, 2017). Egypt suffered a series of political events and clashes during 2011. After January 25th, 2011 Egypt witnessed social, economic and political instability leading to drastic consequences in the hospitality and tourism industry (Salman et al., 2017). The following table 1 shows the main disruptions that faces the tourism sector in Egypt.

<table>
<thead>
<tr>
<th>Disruption classification</th>
<th>Disruption</th>
</tr>
</thead>
<tbody>
<tr>
<td>Political</td>
<td>• Violent incidents and terrorists’ attacks (e.g., on January 25th, 2011 during the large demonstrations against the regime; in 2013 during the coverage of the coup against Islamist President Mohamed Mursi; in 2015 terrorists attacked the famous pharaonic temple (El Karnak), assassinated the Egyptian Attorney General and blew up the Italian consulate in downtown Cairo. Moreover, 12 Mexican tourists were mistakenly killed by military and security forces. The situation reached its peak in November 2015 after the crash of the Russian plane over Sinai causing the death of 224 passengers; in May 2016, EgyptAir MS804 crash into the Mediterranean Sea, killing all 56 passengers. Also, kidnapping and torture of Italian graduate student Giulio Regeni whose body was found in February 2016; in November 2017, the mosque attack in Northern Sinai which killed at least 235 people.</td>
</tr>
<tr>
<td>Economic (Saleh, 2010)</td>
<td>• Abrupt demand fluctuations due to: a. Global Financial Crisis (GFC) affected world tourism growth and hence the Egyptian tourism growth, the GFC leads to a sharp decline in the world growth rate of international tourists, average tourist expenditure, average length of stay, and a significant increase in the inter-travel period of international tourists. b. Income fluctuations, Accordingly, tourism demand notably responds to changing economic conditions in source countries. Risk exposure induces visitors to restructure their travel habits favoring a shorter duration of stay, closer and cheaper destinations, fewer tourist trips, and a tighter budget. (Sakr &amp; Massoud, 2003). c. the gradual depreciation of the Egyptian Pound against the US dollar affected the consumer prices in Egypt, this has led to increase in the hotel operating expenditure by more than 25% in 2015 (Anter &amp; Attia, 2017) Also, imposed restrictions on imports and increased tariffs on more than 300 products which affects food and beverage sourcing (Abdi, Counselor, El-habbal, Assistant, &amp; Tate, 2017)</td>
</tr>
</tbody>
</table>
### Environmental
- Traditional tourism management practices - which results in undesirable social and environmental impact, thus threatening the tourism industry's prospects for continued prosperity (Gouda, 2012). For example, the coastal development project Construction was done in a traditional and primitive ways without an environmental impact assessment, either before or during construction implementation or after operation.
- Frequent power outages - Egypt witnessed an energy crisis of unprecedented magnitude that caused endless lines at gas stations in various parts of the country, which leads to frequent power outages.

### Globalization
- News (speed of circulation of bad news) - local and international mass media outlets have significantly contributed to the issues faced by Egypt's tourism industry by exaggerating the circumstances surrounding the revolution and the current state of affairs in the nation. The news about the region has primarily focused on the unstable political situation, mass demonstrations, acts of violence and lack of sufficient police protection.
- Neighborhood political/security problems - Due to the proximity of Middle Eastern countries (i.e., Egypt, Syria, Jordan, Lebanon and the Gulf states), most foreign visitors consider them political and social complements rather than substitutes (Gouda, 2012).

### Social
- Criminality - unemployment has fueled rising levels of crime, particularly theft. Foreign workers and tourist visitors are particularly vulnerable to petty crimes such as purse snatching and pick pocketing. (Anter & Attia, 2017)

### Actions to Prepare/Recover from Disruptions.

#### Financial support actions taken by Egyptian Authorities:
- To deal with the tourism crisis, the Egyptian authorities agreed to allocate $5 million to support the sector (Anter & Attia, 2017).
- the Ministry of Tourism has been keen on supporting hotels and resorts through delaying loan payments, insurance and electricity bills in order to reduce operational costs (state information service, 2018).
- The government has delayed the collection of outstanding debt hotels (such as taxes and utilities bills) until 2018 in an attempt to prevent further hotel closures (BMI, 2017).

#### Political support actions taken by Egyptian Authorities:
- They agreed to launch a massive campaign to promote internal tourism (Ramzy, 2016), e.g., "Egypt in our Hearts" initiative that launched from 2015 and extended through 2016 encouraged domestic tourists in Egypt (Anter & Attia, 2017).
- Egypt fill the gap left by Americans and Europeans by relaxing visa restrictions on Chinese tourist groups (Rights, 2017).
- Minister of Egyptian tourism issued ‘Tourism Impact Plan’ which focuses on 6 main priorities to improve Egyptian tourism and is designed to deliver real and impactful results within 6 months: (Ali, 2019)
  - Working with international tourism partners to restore success;
  - Working in partnership with Egypt’s national carrier, EgyptAir, to develop new destinations, and to support charter and low-cost airline companies in bringing more tourists to Egypt;
• Enhance Egypt’s tourism infrastructure by supporting investors and innovating with new ideas;
• Meet the highest international standards through upgraded product and service levels at tourist facilities;
• Working to bring foreign direct investment to Egyptian tourism;
• Develop the growing trend in Egyptian tourism of sustainable eco-friendly accommodation, transportation, and activities.

Actions taken by other organizations:
• Cutting costs was the main applied strategy in tourism and hospitality companies (Elshaer & Saad, 2017). Most tourism and hospitality organizations have engaged in downsizing strategies that included labor reduction and flexible programs of using employees (e.g. part-time or temporary jobs). Thus, managers have reduced the salaries of staff or laid off a considerable percentage of their staff (Nassar, 2012);
• Launch of low cost packages for group tours for domestic tourists in Egypt (Anter & Attia, 2017a);
• Traditional travel agencies and destination management organizations use the new technologies in order to provide greater benefit to their clients. Increasing innovation activities enable travel agencies to provide travel arrangements tailored to each customer’s individual needs (Hadi, 2014).
• In terms of improving the image of its airports, Cairo hired the global security consultancy firm ‘Control Risk’ that specializes in assessing risk at airports, to obtain an internationally accredited by a neutral party safety certificate for its airports. The message they are trying to send is clear- Egyptian airports are safe.

Impact of Tourism Disruptions in Egypt
Egypt as a developing country affected by political unrest experience a decline in the number of international tourist arrivals and in tourism receipts from 15mn in 2010 to 5mn in 2016 (BMI, 2018). This resulted in a clear continuous decline in the total contribution of the tourism industry to the Egyptian GDP from approximately 450bn in 2010 to 250bn in 2016 (BMI, 2018). Table 2 illustrates the impact of tourism disruptions in Egypt on different TSC members.

Table 2: Impact of Tourism Disruptions on Different TSC members

<table>

</tr>
</thead>
</table>
| Political  | Accommodation | • Shortening of the duration of stay and tourist nights (BMI, 2018).
|            |            | • Reduction in hotel room occupancy rates, in 2015, overnight stays totaled 35.6 million, among which 19.6 million came from abroad, and 11.8 million from Europe. These three figures dropped respectively by 0.8%, 1.7%, and 9.3% over last years. The number of European overnight visitors reached its lowest level since 1958 (BMI, 2018).
|            |            | • The intensive decrease in the number of international tourist arrivals and hotel room occupancy rates has caused a sharp decline in cash flow and revenues of such organizations (Mohammad, Jones, Abdelbary, & Sayed, 2012).
<p>|            |            | • Due to the Russian plane crash travel to Sharm el-Sheikh has declined sharply and falls in occupancy rates led to over 50 hotels closing in 2016 (Rights, 2017) |</p>
<table>
<thead>
<tr>
<th>Category</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tour operators</td>
<td>• Occupancy rates have fallen by 90% in Sharm el Sheik and by 80% in Hurghada (Rights, 2017). A decrease in the number of international tourist arrivals (BMI, 2018). Many countries including the US, UK, Japan and Germany among other European States issued travel warnings and evacuated their citizens (Rights, 2017).</td>
</tr>
<tr>
<td>Travel agents</td>
<td>• Declining tourism revenues and increasing the percentage of unemployment (BMI, 2018). Halting the flights of airlines such as easyJet, Monarch, Thomson and British Airways to Sharm el-Sheikh. Many airlines suspending flights to Sharm el-Sheikh, which was the most popular resort destination for many European visitors (Mohammad et al., 2012). Cancelled business and the lack of new business have forced travel agencies in the nation to suffer extreme financial hardships and most have been forced to close (Nassar, 2012).</td>
</tr>
<tr>
<td>Transportation</td>
<td>• Many flights reservations were cancelled, UK flights to and from the resort were grounded and cemented the perception that Egyptian airports and Egypt in general is not a safe tourist destination, also flights from Russia to Egypt were suspended (Harb, 2013). Travel insurance premiums increased or did not cover travel to the country (Rights, 2017).</td>
</tr>
<tr>
<td>Attractions</td>
<td>• Popular attractions were left almost deserted. The revenue of ancient Egyptian monuments and cultural attractions that were down to just £ 10.5 million from £ 250 million in 2010 (Rights, 2017) Big price reductions lead to absence of revenues created by cultural tourism for example in Luxor complex, which normally attracts high spending visitors.</td>
</tr>
<tr>
<td>Handlers and inbound operators</td>
<td>• Hotels and tour operators reduced their workforce by at least 20% and in many hotels this percentage was much large 40 or even 60% (Abdi et al., 2017). Only 30% of workers on cruise ships remained on duty, however 50% were given unpaid vacations. As of the 400 cruise ships on the Nile only 40 were operating (Nasr, 2016).</td>
</tr>
<tr>
<td>Tourism business (shopping centers, craft producers)</td>
<td>• Souvenir shop owners and vendors along the base of the Great Pyramid and near King Tut’s tomb see only a few tourists patronizing their shops, so shop owners and vendors in business have been forced to close (Anter &amp; Attia, 2017). This has resulted in many layoffs adding to the total of job losses to the Egyptian tourism sector which has now reached 900,000 since the 2011 revolution (Nasr, 2016).</td>
</tr>
<tr>
<td>Food and beverage suppliers</td>
<td>• High taxes, e.g., Importation of alcohol has an import tariff of up to 250 percent on beers, 1,800 percent on wines, and 3,000 percent on spirits excluding a 14 percent sales tax (Abdi et al., 2017).</td>
</tr>
<tr>
<td>Tourist facilities providers (bars and restaurants)</td>
<td>• Restaurants that previously relied on the business of travelers have been forced to shut their doors as the rising food costs in the nation and steadily declining stream of customers has left restaurant owners with no other choice (Anter &amp; Attia, 2017)</td>
</tr>
<tr>
<td>Economic (the depreciation of the Egyptian Pound)</td>
<td>• With the devaluation, Egyptian consumers have seen high inflation rates, and Egyptian importers are facing increasing costs (El-Fiqi, 2014).</td>
</tr>
</tbody>
</table>
Environmental Energy and water supplies

- In the summer, with tourism at its peak, power outages became a problem and the energy shortage a looming threat (Lakhal, 2013).
- Water supplies to businesses were also disrupted, while the power outage also affected numerous state institutions including subway services, state television channels and radio stations, which could not air without electricity to run their facilities. (Lakhal, 2013)
- As there was no electricity and not enough fuel for adequate transportation, the supply of bread and food was also scarce. (Ibrahim, 2014)

Waste recycling and disposal

- Improper waste disposal from tourism facilities in the red sea
- Increasing levels of waste from construction and operation of tourism facilities (Gad & Rab, n.d.)
- The substantial garbage littering on the streets and desert threat the aesthetic beauty of the region, the sustainability of the tourism industry and the natural environment health (Ball & Taleb, 2011)

Challenges Facing TSC Management in Egypt

Driven by safety and security considerations, travelers shift to more secure destinations; above all, tourists value their personal safety and the ability to travel without threats to this safety. Therefore, if security is compromised in a particular region, it is not difficult for travelers to cancel bookings, postpone vacations or switch to other destinations.

Due to the proximity of Middle Eastern countries (i.e., Egypt, Syria, Jordan, Lebanon and the Gulf states), most foreign visitors consider them political and social complements rather than substitutes. As a result, all countries in the region suffer a decline in tourism due to an incident or instability in one country. For example, a wave of violence in the Palestinian territories is likely to have adverse impacts on tourism flows to Egypt (Gouda, 2012)

The vulnerability of the Egyptian tourism sector to external/internal shocks is further exacerbated by the high concentration of tourism traffic. The four largest tourism-generating countries, namely, Germany, Italy, France and the United Kingdom, account for nearly 50 percent of total arrivals to Egypt (BMI, 2018) Based on past records, these countries have proved to be highly sensitive to irregular events.

On the supply side, the tourism industry is highly competitive. It is well known that tourism is a perishable commodity as unsold hotel rooms or airline seats have no residual value. When events occur that expose visitors to personal risk, price competition becomes inevitable. To counter heightened safety risks, significant price discounts are often granted by business sectors (e.g., travel agencies, hotels). This practice stimulates low-price package tours at times of crisis, thereby curtailing the decline of tourist arrivals. The government administrative hierarchy and the lack of communication between stakeholders generate a significant slowdown of management (Ramzy, 2016). The major threats to the tourism industry in Egypt are political instability and socioeconomic problems, which in most cases lead to an increasing in the crime rates. The threat of terrorism remains as the current main disruption. It became clear that the tourism industry is highly susceptible to risk and that the list of risks and threats seem to be virtually without limit. There is also the impression that the Egypt’s tourism industry in general tends to be reactive rather than proactive in addressing risks and threats, producing many impact evaluations but few risk forecasts which emphasis the need for more studies concerning TSCRES.

Supply chain resilience: An analysis of Irish firm’s priorities in the wake of Brexit

Maurice Brady (maurice.brady@dit.ie)
Department of Transport Engineering, Environment and Planning
Technological University Dublin

Abstract

The modern trading environment exposes supply chains to a multitude and magnitude of risks and disruptions that affect the ability of firms to achieve the desired level of operational and financial performance. Supply chain resilience offers the opportunity to build a strong supply chain which will not only handle disruptions, but which can also learn and adapt in a more appropriate manner than competitors, thus attaining competitive advantage. This research will measure the key elements of supply chain resilience and their relative importance for Irish firms in light of the risks posed by Brexit.

Keywords: Supply chain resilience, Ireland, Brexit

Introduction

On the 23 June 2016, the UK public voted in favour of leaving the EU in a national referendum (Sampson, 2017). This decision has created a new Europe whereby the previous trading relationships, practices and protocols which have evolved since 1973 have become obsolete and redundant (Oliver, 2018). Whilst all member states across the EU are mindful of the potential negative impacts of a changed dynamic with the UK, Ireland is especially concerned as highlighted by the Irish government when they stated that, ‘Due to the close economic, highly integrated and concentrated nature of the trading relationship with the UK, amongst all Member States Ireland could be the most adversely affected by the UKs withdrawal from the EU’ (Government of Ireland, 2018, pp. 6).

Whilst Brexit brings an array of challenges for traders and in many respects is unparalleled, to many in supply chain management it is yet another example of a disruption that must be
managed (Saenz et al., 2018). Modern supply chains are exposed to an ever increasingly array of risks and obstacles that disrupt their ability to consistently operate at optimum performance expectations (Carvalho et al., 2012). Firms must manage external risks such as natural disasters and acts of terrorism as well as internal disruptions such as product life cycles, customer demand trends and supplier disruptions, and failure to adequately address these, in the event of their happening, can have catastrophic consequences for the firm (Ponomarov and Holcomb, 2009). Management teams must be mindful of the possible disruptions that could affect the planned performance levels of their supply chains and build an organisation with the appropriate culture and practices to proactively handle disruptions.

**Supply Chain Resilience**

Considering that supply chain management is now a key strategic management function, and one on which companies can utilise to leverage competitive advantage, any disruption to supply chain performance will negatively affect overall company performance (Christopher and Peck, 2004). Hitherto, risk management and risk mitigation were the management strategies and techniques commonly employed to minimise risks and disruptions that supply chain management teams deemed relevant to their firm from internal and external sources (Tang and Musa, 2011). The primary focus of risk management and mitigation is to create a robust supply chain which can forecast and withstand events outside of expected operational norms (Ho et al., 2015). Firms utilising a risk management strategy successfully, can expect a level of continuance in operations regardless of internal or external risks which have been identified and quantified. The onus is at the firm level to ensure that there is a comprehensive system for identifying, quantifying and reducing risk but Rao and Goldsby, 2009 found in their research that the level of risk identification within firms is ‘limited’ and without a solid foundation it is difficult for a firm to address risk in the fitting manner (Rao and Goldsby, 2009). Consequently, risk management positions itself within the scope of those activities and events that it can identify (Bak, 2018). These aspects of risk management have resulted in the practice relying on historical data for predictable events (Das, 2018). The nature and scope of supply chain results in risk management often time lacking the required ability and latitude to handle the vast array and magnitude of risks that apply to supply chain activities and actors (Pettit et al., 2010, Vroegindewey and Hodsb, 2018 and Kamalahmadi et al., 2016).

In order to mitigate against some of the deficiencies identified with the use of risk management, an increasing number of firms are turning to supply chain resilience (SCRES), as it is deemed a more holistic approach for the management of disruptions, (internally and externally), (Kochan and Nowicki, 2018 and Melnyk, et al, 2010) and if embedded correctly in a firm, can be used as an enabler of competitive advantage (Ponis and Koronis, 2012 and Sheffi, 2005). The growing emphasis on SCRES is attributable to the principle that not all risk is controllable and firms must be agile in order to engage in proactive and reactive management techniques and protocols should a disruption event occur (Wieland and Wallenburg, 2013). It is those firms who can navigate their way through the disruption event from start to finish, stronger and faster than competitors who will gain competitive advantage (Ponis and Koronis, 2012 and Sheffi, 2005). Whilst SCRES as a concept is growing in stature and importance within supply chain management, as demonstrated in Table 1, the definition varies amongst literature and authors (Abubaker et al., 2017, Fiksel, 2006, Ponis and Koronis, 2012 and Sheffi, 2005).

</tbody>
</table>

The primary differentiation between SCRES definition in literature relates to the end point of resilience with many authors determining recovery or the resumption of normal operations (pre-event) as being the culmination of SCRES. Numerous authors build upon this and include the ability to achieve a better performance level post disruption in comparison to pre-event levels and/or competition (Abubaker et al., 2017). Research by Abubaker et al. (2017) and Hohenstein et al. (2015), demonstrate the various viewpoints on SCRES with regard to the scope of SCRES through comprehensive systematic literature reviews. Following the review of previous research into SCRES, both research teams classified SCRES under 4 phases, namely; ready, respond, recover and growth. The two papers indicate that the primary focus of research thus far has been respond and recover, but there is an increasing level of attention on growth (Abubaker et al., 2017 and Hohenstein et al., 2015). Hohenstein et al. add that a common definition of SCRES “has to include all four phases” (Hohenstein et al., 2015, p. 101), and that the lack of clarity on the definition of SCRES has a major consequence for determining the key enablers or elements of a SCRES strategy.

Research into the enablers of SCRES at phase level has been limited without a standard and accepted definition of SCRES as much of the previous work has been focused on defining the concept (Mandal, 2014, Wieland and Wallenburg, 2013). Authors, such as Kamalahmadi and Parast, 2016, Hohenstein et al., 2015, Brusset and Teller, 2017, Christopher and Peck, 2004, Abubaker et al., 2017, Scholten et al., 2014, Pereira, 2009, to cite some examples, have all studied the antecedents of SCRES, but no one study has standardised the enablers which has led to further calls seeking to homogenise SCRES elements within each phase (Hohenstein et
This lack of consensus regarding SCRES enablers negatively impacts on the ability of a firm to identify priority elements and investment opportunities when embarking upon a resilience strategy (Mandal, 2014, Wieland and Wallenburg, 2013, Abubaker et al., 2017 and Manning and Soon, 2016).

In a recent study by Karl et al. the authors attempted to address this by reviewing previous research concerning SCRES elements, including those previously mentioned. In the study the authors reviewed 57 journal articles focused on enablers and elements of SCRES (Karl et al., 2018) in order to determine key elements for a SCRES strategy. Following the systematic literature review the paper concluded with a list of 13 key elements, as in table 2, pertinent to a resilience strategy (Karl et al., 2018).

The authors conclude with the insight that any coherent and successful resilient supply chain will exhibit the characteristics in table 2, with relative importance shifting as the firm moves through the pre-disruption phase through to post-disruption phase.

**Ireland and Brexit**

The Irish economy at the macro and micro level is largely connected to trade with and through the UK and any trade impediments in terms cost and/or time could have a major consequence for Ireland (PWC, 2018). Ireland exported €33.6 billion worth of goods and services to the UK in 2015 and imported €29.4 billion (CSO, 2016). Whilst other member states exported more in terms of monetary value the intensity of trade is lower (Department of Finance, 2017). The monetary value of Irish exports to the UK equated to approximately 15% of global trade in 2015 ex Ireland whereas countries such as Germany and France experience lower exposure with 8-9% of their exports destined for the UK market. The figure for countries such as Finland and Denmark is lower again at 5-7% (Department of Business, Enterprise and Innovation, 2018) indicating the high level of dependence on UK trade for Ireland.

At a sector level the concerns of Irish traders are magnified. Sectors such as agriculture (including food and live animals), chemicals, manufactured goods and minerals all exhibit a strong reliance on UK trade. In the beef market for example, 50% of Irish beef is exported to the UK, which accounts for 70% of the total imports of beef into the UK. 53% of Irish cheese is exported to the UK. Furthermore, over €80m or 90% of Irish grown mushrooms were exported to the UK in 2016 (Irish Farmers Association, 2019). Figures are similar for the chemical sector, whereby 26% of the total exports from Ireland to the UK in 2015 were chemicals with the machinery and transport equipment sector following with a rate of 17% (Department of Finance, 2017). The same report by the Department of Finance calculated that of the top 30 global products most exposed by the UK exiting the EU, Ireland had 17 positions, primarily in the agriculture and chemical sectors (Department of Finance, 2017).
However, not only is the UK an important trade partner for Ireland, but as a peripheral island nation, the UK serves as a key transit network for European market access. Irish traders have historically utilised the UK road network to transport their goods from Ireland to mainland Europe, essentially using the UK as a bridge (Vega et al., 2018). Transit time from Ireland to Europe can be 60 hours for LOLO services and 40 hours for direct RORO service, whereas vehicles can travel the same distance in less than 20 hours by using the UK road network (Breen et al., 2018). Given the nature of the products that Ireland is primarily exporting, i.e. agricultural products and chemicals, time sensitivity and security are major transport characteristics that must be addressed and it is for these reasons that an estimated 53% of global non-UK destined exports transit through the UK (Lawless and Morgenroth, 2017). The decision to leave the EU will result in greater customs control checks at the point of entry and exit of the UK, all of which could negatively affect the transit time, cost and administration burden for Irish traders.

**Problem Statement**

Whilst research has not settled on a discipline wide definition of resilience (Mandal, 2014), this research defines resilience in the supply chain as the “ability to cope with the consequences of unavoidable risk events in order to return to its original operations or move to a new, more desirable state after being disturbed”, (Juttner and Maklan, 2011, p.247). The research accepts Brexit as an unavoidable event that threatens major supply chain disruptions. The literature has shown that there is no consensus regarding the enablers of a resilient supply chain management strategy, and furthermore research is warranted in this area (Wieland and Wallenburg, 2013). This is all the more important in the light of Brexit and the potential disruption to Irish traders it brings, whether it be trading with or through the UK.

In order to address these concerns a research study was initiated in order to determine the key enabler(s) of SCRES within each of the four identified phases, as determined by Irish traders. Identifying the key enabler(s) in each phase will allow firms to proactively manage and invest in their resilience strategy and target key enablers for success.

**Methodology**

The study adopted a survey based research methodology whereby selected supply chain stakeholders were given the opportunity to rate the relative importance of the elements of resilience within each of the phases. The research followed studies such as those by Abubaker et al., 2017, Hohenstein et al., 2015, Adobor and McMullen, 2018 by deconstructing SCRES into four phases; ready, respond, recover and grow. The elements on which the respondents rated their relative importance were based upon the findings of Karl et al., 2018, specifically the 13 elements identified in their systematic literature review. Respondents were requested to rate the enablers as determined by Karl et al., on a five point Likert scale. Respondents were requested to complete this task for each of the four phases.

It was deemed prudent and reliable to request members of the supply chain workforce to complete the survey as it was in line with authors such as Brusset and Teller, 2017 who specify that it is the supply chain personnel who are key decision makers and informants regarding SCRES (Brusset and Teller, 2017). The online survey was distributed to 80 stakeholders in the supply chain sector in Ireland. The survey was emailed direct to the respondents along with a succinct explanation outlining the components of the survey in order to standardise respondent
understanding. The survey was open online for a period of 2 weeks and following email reminders, it was closed for public submission. The resultant response rate was 35%.

**Results and Analysis**

64% of respondents classified themselves as a senior manager or owner/director of the company they worked for. In addition, 61% of respondents had 16 years plus experience in the supply chain industry with a quarter of all respondents stating that they had over 20 years supply chain experience. No significant difference is seen when results are analysed within population groupings indicating a standard understanding of SCRES across industry experience, job level and industry sector.

In terms of phase averages, ready and grow were weighed 3.95 and 4.05 respectively, with respond and recover following with 3.85 and 3.91, signifying respondents placing a larger emphasis on the ready and grow phase of a resilient supply chain strategy, as opposed to respond and recover.

*Table 3 – SCRES Phase Score*

<table>
<thead>
<tr>
<th>Phase</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ready</td>

</tr>
<tr>
<td>Respond</td>
<td>3.85</td>
</tr>
<tr>
<td>Recover</td>
<td>3.91</td>
</tr>
<tr>
<td>Grow</td>
<td>4.05</td>
</tr>
</tbody>
</table>

In the overall context of enablers across the four phases, visibility, supply chain design and agility received the greatest weightings from respondents, with security and redundancy deemed the least important elements. As can be seen in table 4, respondent placed a large emphasis on the inherent strength of the supply chain architecture.

*Table 4 - Overall SCRES Element Score*

<table>
<thead>
<tr>
<th>Element</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visibility</td>
<td>4.22</td>
</tr>
<tr>
<td>Supply Chain Design</td>
<td>4.21</td>

<td>Robustness</td>
<td>3.92</td>
</tr>
<tr>
<td>Security</td>
<td>3.54</td>
</tr>
<tr>
<td>Redundancy</td>
<td>2.83</td>
</tr>
</tbody>
</table>

When the respondent’s data is disseminated into each phase of SCRES, commonality of importance is seen as opposed to standardisation, as shown in table 5. Aside from security and redundancy which are placed in 12th and 13th position respectively, no enabler has a consistent placing in the ranking across all four phases.

The results show that all elements, aside from risk management, fluctuate in terms of weighing between the various phases. In the case of risk management, respondents found it was most important in the ready phase and its relative importance declined throughout the four phases of SCRES, whereby its lowest score was to be found in the growth phase. Elements such as supply chain design, risk management and flexibility are deemed important at the early phases of SCRES but as a firm moves to the recovery and growth phase of SCRES supply chain managers are more concerned with enablers such as visibility and trust. The importance of the financial strength of the firm peaks in the recovery phase.

Figure 1 – SCRES Phase Analysis
The results show that the importance of the various enablers fluctuates in accordance to which phase they are embedded. Aside from risk management, all the enablers follow an oscillating path. In the case of risk management, it follows a constant trajectory in that it is deemed most important in the ready phase and loses prominence in the eye of the respondent to the point that its lowest rating is in the grow phase of SCRES. The fluctuating nature of the ratings indicate that the supply chain manager must ensure that SCRES enablers are aligned with phase placement.

**Discussion and Conclusion**

The research has shown that SCRES is a key enabler for a firm to gain or maintain competitive advantage when faced with adverse trading conditions, which can be exemplified by the possible difficulties faced by Irish traders as a result of Brexit. Additionally, the research and survey indicate that supply chain managers must be adaptive and agile when embarking on SCRES strategy as a myriad of SCRES elements are required, all with shifting levels of importance during the four phases of resilience. By utilising the four phases of SCRES, the research has been able to identify key stages of the resilience strategy and when coupled with the elements as acknowledged by Karl et al., 2018 in their systematic literature review, the research has been able to categorise the potential priorities of Irish supply chain managers at key points of their SCRES implementation and journey.

Whilst all elements received strong support from respondents, indicating validity in the research and the interconnectivity of SCRES elements, a strong supply chain design, is required at the outset of SCRES. A strong supply chain design creates a solid platform for the firm to be ready and respond to a disruption event and creates a solid footing on which to sit the elements that will bring the firm through recovery and onwards to growth. As the firm moves from ready through respond to recover and growth, supply chains should focus on their inherent visibility and agility to maximise the potential possibility derived from SCRES. Likewise, SCRES is predicated on a comprehensive risk management system that will create a strong foothold for recovery and growth.

It is incumbent on all supply chain managers to align phase position with element implementation in order to exploit SCRES to the fullest extent possible. Supply chain managers must ensure that the SCRES strategy evolves in line with the disruption event to ensure that the correct enablers and elements are employed and deployed at the opportune time.

On a cautionary note, Brexit at the time of research and writing, is a live event which thus far has been characterised by a lack of confirmation regarding the new trading environment, and the inherent protocols and systems, which will come as a result of the decision of the UK to leave the EU. At the time of writing traders are unaware of the exact expectations and consequences of this decision and as such respondents were asked to address an event devoid of all the details. With this in mind the author recommends that the results are taken as being preliminary in nature and recommends that further research is conducted when there are confirmed arrangements concerning the UK’s withdrawal from the EU.

Corporate Policy Antecedents of Supply Chain Disruptions – The case of Share Repurchases

Mario Vaupel (vaupel@time.rwth-aachen.de)
RWTH Aachen University

Abstract

Supply chain disruptions have detrimental effects on operating performance and shareholder value. To support corporates in their prevention, scholars developed sophisticated risk management and resilience concepts, all highly dependent on reliable funding. This paper argues that share repurchases, a popular use of cash reserves, consume essential resources required for operating stability. Matching SEC repurchase data with a novel set of disruption announcements for the S&P 500, we find evidence of the positive association of share repurchases with future disruptions, and the mitigating role of the COO. Results shed light on organizational dynamics and managerial short-term thinking preceding supply chain disruptions.

Keywords: Supply chain resilience, Supply chain disruptions, Resource allocation

Theory and purpose of study

Supply chain disruptions impose significant negative consequences on a firm’s short-term operations and long-term development (e.g., Hendricks and Singhal, 2005). Events such as delayed product introductions, delivery failures, or product recalls, diminish resources and eventually hurt the company’s market position. Besides immediate costs from lost business or repairs, disruptions can cause significant long-term harm, for example if products do not get developed or entire factories have to be foreclosed. Hendricks & Singhal (2005, 2014) in several studies found reduced stock price performance and increased equity risk in the years following disruptions. According to Hendricks & Singhal (2014), supply chain disruptions indicate a malfunctioning of one or several subsystems along the corporate value chain. As there is a multitude of different subsystems and processes, there are also many different types of disruptions, differing both in their antecedents and consequences. Following academic literature, disruptions can however be broadly categorized as either due to internal or external risks (Peck and Christopher, 2004; Wu, Blackhurst and O’Grady, 2007; Pettit, Fiksel and Croxton, 2010). Internal disruptions derive from “operational contingencies” (Kleindorfer and Saad, 2005, p. 54) and usually are the result of insufficient quality assurance and risk management (Wagner and Bode, 2009). External disruptions include natural disasters, terrorism, and any other kind of macro development that is difficult to anticipate (e.g., Braunscheidel and Suresh, 2009; Pettit, Fiksel and Croxton, 2010).
In order to prevent supply chain disruptions, companies can proactively identify critical processes and install effective risk management systems, thereby reducing vulnerability (e.g., Kleindorfer and Saad, 2005; Peck, 2005). Risk management includes identification and assessment of risks throughout the supply chain and subsequent development of effective capabilities to absorb them (Kleindorfer and Saad, 2005; Sodhi, Son and Tang, 2012). Operations management literature provides a comprehensive view on such capabilities, including quality management processes (Lee and Whang, 2005), functional integration, and frequent information sharing (Braunscheidel and Suresh, 2009). However, not all disruptions can be avoided (Craighead et al., 2007; Jüttner and Maklan, 2011), and especially macroeconomic events are difficult to predict. Firms therefore need to build up resilience to unavoidable disruptions to reduce their adverse impact (e.g., Pettit, Fiksel and Croxton, 2010; Ambulkar, Blackhurst and Grawe, 2015). As Craighead et al. (2007) show, the severity of a disruption is both related to supply chain characteristics and to a company’s mitigation capabilities. Building up those capabilities requires effective internal integration and training (Riley et al., 2016) and the agility to shift resources in case of need (Ambulkar, Blackhurst and Grawe, 2015).

Conceptual research on supply chain risk management and disruption mitigation has provided companies with effective tools and frameworks to protect their operations (e.g., Sodhi, Son and Tang, 2012; Ho et al., 2015; Kamalahmadi and Parast, 2016). Companies willing to build a robust supply chain need to ensure a stable resource base dedicated to operations (Pettit, Fiksel and Croxton, 2010; Zhao and Huchzermeier, 2015) by investing in technology and equipment, human resources, and intangible assets such as supplier and distributor relationships (e.g., Kleindorfer and Saad, 2005; Bakshi and Kleindorfer, 2009). Consequently, corporate policies that divert financial resources from operations will hurt the supply chain in the long run. Intuitively, investment in operations should be a corporate priority and enable companies to increase the robustness of their operations. However, vulnerability rises with the complexity of supply chains (Craighead et al., 2007) and disruptions remain prevalent (Germano, 2019; Sturcken, 2019). Existing literature demonstrated a failure of risk management systems in a variety of instances (e.g., Peck, 2005; Akkermans and Van Wassenhove, 2018; Scheibe and Blackhurst, 2018). While supply chain networks and partnerships have received wide attention (e.g., Bakshi and Kleindorfer, 2009; Cleeren, Dekimpe and van Heerde, 2017), there is a paucity of knowledge on internal decision mechanisms and trade-offs in budget allocation preceding disruptions (Wagner and Bode, 2009; Villena et al., 2018; Zhang, Zhao and Pang, 2018). Peck (2005) and Scheibe and Blackhurst (2018) emphasize the role of managerial incentives, explaining that a misalignment of managers’ goals and performance targets can create obstacles to risk management. Braunscheidel and Suresh (2009) point out that integrated supply chains are more agile, implying the need for effective “operations-finance” interfaces (Zhao and Huchzermeier, 2015), which ensure the deployment of sufficient financial resources for disruption prevention and resilience development. However, little is known empirically on the real-world effectiveness of this interface. Which corporate policies lead to a shortage of investment in operations? What roles do decision mechanisms and shareholder expectations play? Furthermore, what is the role of board power-balance? This study aims to fill this knowledge gap and focuses on share repurchases as an organizational antecedent of supply chain disruptions.

**The role of share repurchases in corporate development**

Share repurchases are a widespread instrument used in stock price management and corporate governance (e.g., Dittmar, 2000; Brav et al., 2005; Vermaelen, 2005) as they
allow to both steer shareholder satisfaction and reduce funding costs through the following main mechanisms: 1) By buying back their own stock, companies reduce shares outstanding and thus increase earnings per share (EPS) (Hribar, Jenkins and Johnson, 2006). Higher EPS increase the value per share and thus the value of investors’ holdings, facilitating investor-management agreement (Huang and Thakor, 2013). 2) repurchases signal positive operating prospects to the market, which leads to new investment being attracted (Comment and Jarrell, 1991). 3) Repurchases can reduce the cost of future capital raises as they correct pricing inefficiencies, reduce idiosyncratic risk (Busch and Obernberger, 2017), and increase liquidity (Hillert, Maug and Obernberger, 2016). Most traditional research on the operating effects of share repurchases focused on principal-agent problems (Akerlof, 1970) following the agency theory of free cash flow (Jensen, 1986): Through paying out funds in excess of those needed for operations, boards could avoid managerial overinvestment (Jensen and Meckling, 1976; Comment and Jarrell, 1991). However, recent evidence points to other motivators of share repurchases, which are effective regardless of productive uses of funds. First, managers may benefit from higher stock prices and EPS through stock options (Kahle, 2002; Bens et al., 2003), and EPS-based bonuses (Kim and Ng, 2018) and are thus incentivized to repurchase shares to maximize their personal payoff. Second, activist shareholders focusing on short-term returns can use their voting power to pressure board members for large-scale buybacks (Huang and Thakor, 2013; Autore, Clarke and Liu, 2018). In these cases, share repurchases are deployed solely to extract value from the company and may diminish resources required for long-term corporate development.

Several studies have associated share repurchases with subsequent reductions in operating metrics like R&D expenses, capital expenditures, employment, and cash reserves (Fos, Almeida and Kronlund, 2016; Iyer, Feng and Rao, 2017). However, little is known on the long-term operating effects of repurchases. Bendig et al. (2018) show that share repurchases positively relate to future product recalls, thus demonstrating adverse effects to operating robustness. Swift (2018) found negative effects for corporate innovativeness, manifesting in patent quality. These findings indicate a trade-off between payout and necessary investment in the operating business, with potentially enormous consequences for firm and customer value. We thus derive a clear mandate to bring share repurchases to the attention of operations literature and analyze whether they relate to increases in the likelihood and frequency of supply chain disruptions.

Figure 1: Research model
Hypotheses derivation
Figure 1 summarizes our research model. The risk of experiencing a supply chain disruption can be reduced through investment in physical, human, and intangible assets and robust processes (Pettit, Fiksel and Croxton, 2010; Zhao and Huchzermeier, 2015). While especially internal risks can be mitigated, companies further need to invest in proactive reduction of damage from externally caused disruptions (Craighead et al., 2007; Bakshi and Kleindorfer, 2009). A lack of funding hence increases the likelihood of a disruptive supply chain event. Such a lack of investment occurs when firms prioritize other uses of funds. Conflicts in budget allocation may arise when corporate divisions are incentivized towards different goals (Wu, Blackhurst and O’Grady, 2007; Scheibe and Blackhurst, 2018). The theory of bounded rationality helps to understand why individuals take decisions that are not in the best interest of their organization (Simon, 1955). Managers often face individual incentives, in the form of contingent compensation or performance targets (March and Shapira, 1987; Brandenburger and Polak, 1996), to allocate budget to alternative uses with more immediate benefits. Share repurchases represent an opportunity for managers to maximize their own payoff and increase investor support (Sanders and Carpenter, 2003). Furthermore, following opportunist motives and information asymmetry on operating needs (Akerlof, 1970), shareholders might be more interested in cash payouts instead of new investment. Share repurchases have been shown to deprive operations of critical resources such as R&D and Capex (Fos, Almeida and Kronlund, 2016; Bendig et al., 2018). If not aligned with operating investment needs, repurchases may thus impair firms in their supply chain risk management efforts.

Hypothesis 1a: A company’s share repurchase volume has a positive association with the likelihood of a subsequent internal supply chain disruption

Hypothesis 1b: A company’s share repurchase volume has a positive association with the frequency of subsequent internal supply chain disruptions

Data and methodology
Sampling and measures
Our sample consists of all companies constantly listed in the S&P 500 index from 2004 to 2016, as US-listed companies became obliged to publish share repurchase information in 2004 (Banyi, Dyl and Kahle, 2008). Excluding Financial Services (SIC codes 60-67), we arrive at a final set of 252 companies.
The dependent variables in this study are the occurrence and frequency of supply chain disruptions. Following the classification by Ho et al. (2015), we included all “micro” disruption events, i.e., disruptions resulting from risks internal to the supply chain. Supply chain disruption events were extracted from PR Newswire press announcements in the Nexis database using a supervised machine-learning algorithm. In a first step we trained the algorithm with 4,000 manually coded announcements. We then applied the optimized algorithm to a comprehensive set of ~475,000 announcements and received binary indications of fit for multiple disruption clusters. Subsequently, we manually reviewed all tagged announcements and accordingly validated or reclassified them.

We use the annual dollar volume of share repurchases as our independent variable. Share repurchase data are drawn from firms’ 10-K reports to the Security Exchange Commission (SEC), in which they reveal repurchase quantities, prices, and dollar volumes since 2004 (Banyi, Dyl and Kahle, 2008). According to Banyi, Dyl and Kahle (2008), SEC reports provide the highest measurement as they separate purchases of common stock, purchases of preferred stock and “non-cash” repurchases. As a result, SEC repurchase data have already widely replaced Compustat in finance literature (e.g., Busch and Obernberger, 2017). We manually extract repurchase data, cross-validate them and adjust for mergers and acquisitions during the observed period.

A binary indicator of COO presence is our moderator variable. We manually gathered COO data for all firms in our sample from 10K reports to ensure absolute measurement accuracy. Finally, we include several control variables driving supply chain disruptions. On firm-level, we include firm size, firm age, as well as several measures of operating performance and availability of funding: year-on-year sales growth and return on assets, financial slack, the leverage ratio, and Altman’s Z. To reflect the complexity and riskiness of operations we control for capital intensity and R&D intensity. On industry-level, using the Fama-French Industry12 classification, we control for competitive intensity through the Herfindahl-Hirschman-index (HHI), technological dynamism and the industry’s disruption intensity (average # of disruptions). Company and industry data are added from S&P’s Compustat. Our final set consists of 2,772 firm-year observations.

**Modeling**
Prior to modelling we review all independent and control variables for multicollinearity. Correlations are all below 0.4 and variance inflation factors below 2.8, indicating that multicollinearity will not influence regression results. To analyze the likelihood of a disruption following repurchases we use a probit regression, while for the frequency of disruptions we employ negative binomial regression, a commonly used method for analyzing overdispersed count variables (e.g., Kashmiri, Nicol and Arora, 2017). Following a Hausman test, we specify the negative binomial regression model with fixed effects to address unobserved heterogeneity in firms’ tendency to experience disruptions. The moderating effect of COO presence is tested for disruption frequency. Share repurchase volumes are log-transformed to correct for skewness. In addition to the above-mentioned controls, we account for time-fixed effects and winsorize repurchases and all continuous control variables to exclude outliers. As a lack of investment does not immediately manifest in operations, we forward-lag dependent variables by one and two periods, respectively. Finally, we include the lagged count of supply chain disruptions (in the previous year respective to our dependent variable), following Wowak et al. (2015), to reflect that disrupted operations increase the likelihood of further disruptions.
To ensure robustness or our findings we validate them with Compustat’s repurchase measure as an alternative independent variable. Furthermore, as it is possible that using the repurchase-heavy S&P500 created a self-selection bias as the index naturally includes well-performing firms, we include a Heckman correction term following Hendricks, Hora and Singhal (2015). The inverse Mills ratio is insignificant in all regressions, indicating that self-selection concerns in our model are minimal. We also use robust Huber-White standard errors in all models (White, 1982) to correct potential heteroskedasticity.

Discussion of findings
Table 1 presents regression results with standardized coefficients for our main regression and the moderation. Both the likelihood (β = 0.08, p<0.05) and frequency (β = 0.07, p<0.05) of supply chain disruptions are positively associated with share repurchases in the year after the repurchase. H1a and H1b are thus supported, implying that share repurchases reduce budget required for supply chain risk management and resilience development. Interestingly, the relationship disappears in the following years, indicating that the financial constraints resulting from repurchases manifest in operations already after a short time. Robustness tests using Compustat repurchases confirm results, but coefficients are less pronounced and significant. Our findings also confirm a significant
moderating role for COO presence on the relationship between share repurchases and disruption frequency. This moderating role is however only significant in the second year after repurchases (β = -0.13, p<0.1) and also renders the coefficient for share repurchases significant (β = 0.11, p<0.05). We infer that two years after repurchases, only companies without a COO face an increased number of disruptions, while in other companies the COO is able to mitigate an increase in supply chain risk. In the first year after repurchases, however, the COO does not exercise a significant influence in our model.

The regression results confirm our hypotheses and demonstrate that share repurchases indeed pose a threat to supply chain stability and thus corporate development. By distributing resources required for operating investments to shareholders, companies risk enormous consequences in terms of disruptions to their entire value chain. As investments are missed, companies fail to develop adequate risk management systems, and their vulnerability increases. However, having an operational expert on the board in the form of a COO can at least partially mitigate the consequences of repurchases, likely by ensuring that crucial supply chain investments are still made.

**Implications and contribution**

*Theoretical implications*

In this article we set out to unveil how corporate finance policies can impact operating stability and bring the topic of share repurchases to the attention of operations literature. Our results expose a trade-off between short-term shareholder appeasement (Brandenburger and Polak, 1996; Sanders and Carpenter, 2003) and long-term supply chain robustness. As literature showed, developing an effective supply chain risk management and resilient operating processes requires investment in the corporate resource pool (Bakshi and Kleindorfer, 2009; Pettit, Fiksel and Croxton, 2010; Zhao and Huchzermeier, 2015). Management decisions to distribute cash without alignment with operating needs can thus impair long-term corporate development. This article follows Zhang, Zhao and Pang (2018) in emphasizing corporate budget allocation mechanisms as a key tool to maintain the resource base required for supply chain robustness. Companies without effective operations-finance interfaces (Zhao and Huchzermeier, 2015) risk depriving the operating business of essential resources, and make their supply chains vulnerable to both internal and external risks. Operations literature thus needs to place a greater emphasis on functional interfaces and the role of corporate finance specifically.

In investigating corporate policies preceding supply chain disruptions, we focus on share repurchases and expose them as a driver of supply chain vulnerability. Share repurchases have long been largely positively view due to their financial market benefits (e.g., Dittmar and Field, 2015; Hillert, Maug and Obernberger, 2016), and thus received rather little attention in other literature streams (Sanders and Carpenter, 2003; Bendig *et al.*, 2018). This article builds up on recent contributions demonstrating negative operating effects of excessive buybacks (e.g., Fos, Almeida and Kronlund, 2016; Bendig *et al.*, 2018). In contrast to traditional theories of managerial overinvestment (Jensen, 1986), it appears that repurchases are frequently employed following motives that are not aligned with corporate long-term strategy (Sanders and Carpenter, 2003; Huang and Thakor, 2013). Motives like contingent manager compensation (Kahle, 2002; Kim and Ng, 2018) and investor activism (Brav *et al.*, 2008; Autore, Clarke and Liu, 2018) should be considered as potential antecedents of supply chain challenges. Companies conducting share repurchases at amounts beyond available excess cash risk severe disruptions of their
supply chain. Thus, this article introduces share repurchases to operations literature as a specific policy that may endanger supply chain robustness.

As budget allocation is determined within the TMT, we additionally ask whether a COO can mitigate adverse impacts from share repurchases. Literature demonstrated that the presence of a COO exerts a positive influence on financial performance (Hambrick and Cannella, 2004; Marcel, 2009) by ensuring that operations run smoothly and efficiently. Our results confirm that even when share repurchases curtail corporate investment budget, companies with a COO are partially able to attenuate the increased likelihood of supply chain disruptions. This study thus emphasizes the role of TMT structure in the context of resource allocation. As the moderating influence of the COO is only significant in the second year after repurchases, the question how far the COO’s power as a guardian of stable supply chains reaches remains valid and deserves further academic attention. What is more, we demonstrate the utility of machine-learning applications to increase the variety of supply chain disruptions covered and thus the generalizability of regression results. Machine-learning techniques, if applied in a supervised and reviewed process, can be used to create powerful data bases of firm events.

**Managerial implications**

To ensure that share repurchases do not happen at the expense of long-term operations, companies can make several provisions. First of all, companies need to control the amount of share repurchases to ensure that only excess funds are distributed. Detaching bonuses and earnings per share, as well as tying stock options to longer vesting periods, would reduce managerial incentives to repurchase when the business is in need of funds. Furthermore, companies should be more wary of giving large stakes to institutional investors, and ensure transparency when facing pressure to repurchase shares. Second, given incentives to repurchase, firms need to establish strong functional interfaces and decision mechanisms, for example through dedicated investment committees.

**Limitations**

Our study is not free from limitations. First, given the multitude of variables that may drive supply chain disruptions, we cannot derive causality for the relationship between share repurchases and disruptions. Moreover, our study might be influenced by survivor bias, as companies that remained in the S&P 500 are likely to have experienced fewer disruptions over the observed period. There is a clear opportunity to apply the analysis to smaller corporations. Another limitation is due to the limited degree of public information: we classified disruptions according to press announcements, which sometimes reveal the degree of economic damage, but mostly do not. Research able to analyze the effect of corporate policies on the magnitude of disruptions could shed additional light on the relationship between budget allocation and supply chain vulnerability. Finally, our model treats all disruptions as comparable, though in reality each disruption has unique features. Future research could analyze the effects of share repurchases on different types of supply chain disruptions.

Abstract

The purpose of this paper is to investigate Supply Chain Resilience (SCRES) with focus on supply, operations, and inbound and outbound logistics management capabilities. A model comprising of antecedents to the capabilities, their impact on SCRES, and the impact of SCRES on supply chain outcomes is developed and tested. Findings confirm the existence of the relationships between strategic focus, supply chain disruption orientation (SCDO), organizational capabilities and resilience outcomes, and confirm the established relationship between strategic focus and SCDO. This paper contributes to the literature by developing a theoretical model of SCRES and providing empirical support by testing it.

Keywords: Supply Chain Management, Supply Chain Resilience, Organizational Capabilities
Introduction
The complexity and global geographic spread of supply chains, their search for outsourcing and globalization options, and the increased volatility of demand have increased the types and frequency of disruptions experienced in supply chains. The damaging effects of disruptions such as natural disasters, government regulations, forecasting or supplier related issues can last for long if not addressed appropriately and instantly (Pettit et al., 2013). For example, a fire in a brake supplier facility that was supplying parts to Toyota caused a two-week closure of eighteen Toyota plants in Japan, and $195 million loss in revenues (Tomlin, 2006). Similarly, a key supplier failure to provide two critical parts caused Boeing Corporation to lose $2.6 billion (Blackhurst et al., 2005). Companies try to mitigate supply chain risk and disruptions by building resilient supply chains (Christopher and Peck, 2004; Ponomarov and Holcomb, 2009; Sheffi and Rice, 2005) that have the capability to prepare for unexpected events, respond to disruptions, and recover from them by maintaining continuity of operations.

Some supply chains demonstrate higher levels of resilience than others at the time of disruptions (Christopher and Peck, 2004). This research attempts to investigate some of the important antecedents of supply chain resilience. Specifically, the role of strategic focus (Sebastiao and Golonic, 2008), supply chain disruption orientation (Revilla and Saenz, 2017) and organizational capabilities (Ponomorov and Holcomb, 2009) are explored. Based on both traditional and emergent literature, we theorize and empirically test the hypothesis that organizations with higher capabilities are better at managing supply chain disruptions. Given the importance of organizational capabilities and supply chain resilience as competitive traits in dynamic and turbulent environments (Esper et al., 2010; Shore and Venkatachalam, 2003), it is somewhat surprising that the relationship between these constructs have not been empirically tested in the existing literature. This research attempts to bridge this gap.

The paper is structured as follows. First, the relevant theoretical background is described and the conceptual model is developed. Next, the methodology section described data collection, measurement, and validation. Next, the results of hypothesis testing are presented. Finally, we discuss our findings, and the theoretical and managerial implications.

Literature Review
Research in the area of supply chain resilience (SCRES) continues to grow (Melnyk et al., 2014), though much of it is theoretical. Specifically, the extant literature identifies a long list of capabilities necessary for improving SCRES (Pettit, Fiksel, and Croxton, 2010). However, given that all organizations are resource-constraint and can’t invest in all capabilities, there is need for research that: (a) identifies capabilities most relevant for different functions, and (b) links these identified capabilities with supply chain outcomes (Hohenstein et al., 2015; Kamalahmadi and Parast, 2016).

The purpose of this research is to identify capabilities specific to supply, operations, and inbound and outbound logistics management that have a strong impact on SCRES and link those capabilities to supply chain outcomes.

Capability is defined as a combination of activities and processes that enable an entity (such as an employee, department, or organization) to handle turbulent change caused by disruptions (Craighead et al., 2007). Five capabilities are investigated for this research, namely, process, communication and coordination, collaboration, human resources, and information technology (Grant, 1991; Day, 1994). These capabilities and other constructs (i.e., antecedents to and outcomes of capabilities) were chosen, based on extant research, for their strong relevance to resilience in supply, operations, and inbound and outbound
logistics functions (Pettit, Fiksel, and Croxton, 2010). The model (see figure 1) depicts the major constructs and relationships between them.

The supply chain strategy of an organization is the collection of objectives set for the supply chain and the policies and choices executed to support them. Supply chain strategy can be viewed as an umbrella for operations strategy (Perez-Franco et al., 2016). Accordingly, the strategic focus deals with the level of analysis, whether strategic, operational or tactical (Gunasekaran et al., 2001) and to allocate resources for either efficiency or responsiveness. We build upon Sebastiao and Golicić (2008) to define strategic focus as concentrating decision and directing efforts in a supply chain to balance cost and customer service outcomes. Focus on customer service and related outcomes is likely to lead to high resilience as compared to cost-focused outcomes.

In line with Bode et al. (2011), supply chain disruption orientation is defined as a firm's general awareness and consciousness of its environment and its openness to learn from supply chain disruptions. The stronger the firm's supply chain disruption orientation, the more importance is attached to the issue. This argument suggests that a strong supply chain disruption orientation leads to a stronger awareness, capability and motivation to act in case of a disruption.

Hypotheses Development
The conceptual model presented in Figure 1 illustrates the relationships between the constructs of interest. In this model, strategic focus and supply chain disruption orientation are linked with SCRES outcomes through organizational capabilities. All of the hypotheses presented below are developed out of the relevant literature. We hypothesize that as firms display greater strategic focus and supply chain disruption orientation; they will develop greater organizational capabilities and will be more readily equipped for establishing and maintaining supply chain resilience. As depicted in the model, the organizational capabilities will negatively influence the resilience outcomes but positively influence the financial outcomes. In addition, we argue that a higher strategic focus would result in a higher supply chain disruption orientation. We discuss
these relationships in detail in the following sections.

### Methodology

Since this research is aimed at theory testing of the proposed model, we used survey methodology. The survey was developed in stages as per accepted rigorous scale and survey development process (Dillman et al., 2014). This process included an extensive literature review, adoption of scales from extant literature (e.g. SCDO), iterative development of new measures, and review by knowledgeable managers and researchers.

A sampling of this study includes single informants whose primary job functions are logistics, supply chain, and operations management. In this research, the Amazon Mechanical Turk (Mturk) platform was used to find a suitable sample frame. Usage of Mturk to recruit respondents has been validated and found to yield results that are comparable to traditional surveys (Buhrmester et al., 2011). Also, Mturk is considered an adequate platform to reach participants with work experience in supply chain management, logistics, and operations management (Knemeyer and Naylor, 2011). Recruiting respondents from diverse backgrounds and locations, Mturk’s sample ensures greater generalizability (Buhrmester et al., 2011). To recruit respondents, we used the techniques of Schoenherr et al. (2015) to obtain valid responses. The results are provided in Table 1. Respondents were asked to indicate agreement with statements concerning
their firms’ supply chain logistics integration activities and processes based on a five-point scale where 1 = strongly disagree and 5 = strongly agree.

Screening questions were asked at the beginning of the survey to limit participation to those who hold a title of manager, supervisor, senior manager, senior director, or member of a management/executive board at firms. Sample respondents were also screened with questions about whether their job function is supply chain management, operations management, or logistics management. If respondents did not satisfy the screening criteria, the online survey was terminated. Additionally, only one response per one IP address was accepted. Participants who completed the survey received monetary compensation for completing the assigned task. Based on these screening questions (job function), out of 1709 attempts to participate the survey, 406 respondents were able to complete the survey. The sample demographics are presented in Table 2.

Item purification of the original measurement items was conducted through a qualitative assessment of nomological validity, that is, that the scale expresses the relationships shown to exist based upon previous research (Hair et al. 1998). This was followed by quantitative analysis consisting of correlation analysis, reliability evaluation (using item-to-total correlations as well as Cronbach’s alpha), and confirmatory factor analysis.
The scale items for measuring organizational capabilities and SCRES were first subjected to the exploratory factor analysis. The scale items were next subjected to confirmatory factor analysis and the nine-factor model was found to have good fit indices (CFI=0.95; IFI=0.95; RMSEA=0.04). All items included in the final research analysis are deemed reliable based upon Cronbach’s Alpha scores meeting or exceeding 0.70. Hypotheses were tested using structural equations modeling. The results are provided in Figure 2. For each path, two values are presented: (1) the hypothesis number, (2) the standard estimate for the path if it is supported.

We used the same fit indices for the structural model and overall; they similarly indicated a good fit to our model (Chi Square= 561.21, CFI=0.92; IFI=0.92; RMSEA=0.04).

General Discussion and Implications
The results confirm the existence of the relationships between strategic focus, supply chain disruption orientation, organizational capabilities and resilience outcomes. Firms that achieve higher organizational capabilities also appear to demonstrate high levels of resilience and better financial performance. The results also support the relationship between strategic focus and supply chain disruption orientation. However, interestingly, no relationship exists between human resources and resilience or financial outcomes. Similarly, no relationship exists between communication capabilities and financial outcomes but exists with resilience outcomes.

The lack of a relationship between human capabilities and outcomes can be explained by the illusion/perception that over relying on technology will overcome all problems we face. Another reason could be the lack of training and awareness of the human capital within the organizations. For communication capabilities, it makes sense that they will be critical during and after disruption recovery but we don’t necessarily see that translating into financial outcomes. Our study responds to the need for more empirical studies in the topic of SCRES (Ali et al., 2017) and confirm the results of Ponomorov and Holcomb (2009), Seville et.al (2015) and Brandon-Jones (2014), in establishing how organizational capabilities impact SCRES.

Relevance/Contribution
This research contributes to the body of knowledge for both academics and practitioners in several ways. First, a theoretical model of SCRES is developed comprising of antecedents, SCRES capabilities, and outcomes. Second, empirical testing of the relationships between the constructs expands the theory of SCRES. Empirical testing of the proposed model presented in this study advances our understanding of SCRES phenomenon and its antecedents in a comprehensive model. Also, valid and reliable scale items were developed for the constructs presented in the model through a literature review, interviews, and pilot studies. All scale items have been tested through confirmatory factor analysis for unidimensionality, convergent validity, construct reliability. All instruments are shown to meet the qualifications for validity and reliability. These items can therefore be used in future studies.

The results are also meaningful to supply chain managers. In general, the results demonstrate the importance of aligning strategy, orientation and capabilities to achieve higher resilience and better financial outcomes. More specifically, managers can invest in process, communication, coordination and IT capabilities to establish and maintain SCRES.

The first limitations of this research is data collection. Although the usage of Mturk has been validated (Buhrmester et al., 2011), the replication of this study employing non-panel participants would be a potential future research area to confirm and generalize the findings presented in this study. Secondly, the list of logistics capabilities is not all-inclusive. Future studies could incorporate additional capabilities and outcomes.

Abstract
In this study we look into factors that underlie the development of inter-functional glitch mitigation transactive memory systems by drawing on the Motivation-Opportunity-Ability framework. On the one hand, we find that organizational policies (role formalization, cooperation incentives and the use of project managers) positively influence the development of inter-functional glitch mitigation transactive memory systems. On the other, we show the extent to which they have had experience working in other departments of the firm are important determinants of the level of development of inter-functional glitch mitigation transactive memory systems.

Keywords: operational glitches, transactive memory systems, industrial equipment manufacturing

Introduction
Glitches that interrupt the normal operations of an organization and command immediate attention are commonly labeled “operational glitches” (Koufieros et al., 2010; Tenhiala and Salvador, 2014; Tenhiala et al., 2018). Every manufacturer has to contend with the reality of operational glitches. Suppliers may deliver components with quality defects. Customers ask for modifications in product requirements midway through the development process. Incorrect engineering specifications generate manufacturability failures. Functionality problems only reveal themselves during final assembly. In order to restore normal operations with minimal performance loss, manufacturers need to be able to design and implement adequate remedial actions to the occurrence of operational glitches. In other words, manufacturers have to develop the ability to effectively mitigate the performance impact of operational glitches (Craighead et al., 2007).

There is agreement on the fact that effective glitch mitigation entails collaboration across multiple organizational functions (Craighead et al., 2007; Hoopes and Postrel, 1999; Scholten et al., 2014; Zsidisin et al., 2005). This collaboration is needed to identify the nature of the glitch, understand its potential repercussions and develop adequate remedies. In particular, inter-functional collaboration is needed to develop and implement amendments to original order-fulfillment plans that integrate knowledge and information from different departments. Integrating knowledge and information from different
departments ensures the adequate amendment of production schedules, production volumes and, if necessary, product specifications (Konijnendijk, 1994).

Unfortunately, we still lack a full understanding of how organizations can stimulate inter-functional collaboration for the purposes of operational glitch mitigation (Scholten and Schilder, 2015). In this study, we address this gap in our understanding by investigating factors that underlie the development of inter-functional transactive memory systems (henceforth TMSs) for glitch mitigation. Glitch mitigation TMSs are defined as informal information and knowledge processing systems between personnel in the manufacturing department and individuals in other business functions based on their transactive memories about each other’s glitch mitigation expertise. We start from the assumption that the development of an inter-functional glitch mitigation TMS enables decision-makers in different functions to identify the particularities of each occurring glitch and to jointly develop remedial actions that simultaneously observe customer, design and manufacturing constraints.

In order to identify specific factors underlying the development of glitch mitigation TMSs, the chapter draws on the Motivation-Opportunity-Ability (MOA) framework (Blumberg and Pringle, 1982; Boudreau et al., 2003). This framework provides a conceptual basis for explaining knowledge sharing behaviors in work settings. We draw on this framework to identify specific organizational policies and managerial characteristics that are associated with more developed inter-functional glitch mitigation TMSs.

We employ the logic of the MOA framework to identify three organizational-level policies and three personal characteristics of managers heading the manufacturing department on the formation and development of inter-functional TMSs. We test our hypotheses using survey and archival data from 192 industrial equipment manufacturers in Europe.

**Background**

**Inter-functional TMSs**

Even though transactive memory research emerged through the study of romantic couples and small groups (e.g. Hollingshead, 1998; Lewis, 2004; Lewis et al., 2007), there have been multiple calls to extend it from the group into the organizational level of analysis. Differently from small groups though, organizations are partitioned into distinct formal structures, such as differentiated functional areas like R&D, sales, purchasing, product development or manufacturing. This aspect mandates a re-conceptualization of TMSs at this level of analysis (Klein and Kozlowski, 2000; Peltokorpi, 2012). We argue that the analysis of organizational level TMSs should be framed through the interactions among personnel located in different organizational functions. In this sense, we examine organizational-level TMSs by investigating the transactive memory processes that take place inter-functionally.

**The MOA framework**

The MOA framework has motivated several studies in the field of knowledge sharing in organizational settings (e.g. Argote et al., 2003; Siemsen et al., 2008). In line with its logic, we propose a conceptual model in which the formation and development of inter-functional glitch mitigation TMSs is a function of aspects that influence the motivation, opportunity and ability of multiple organizational actors to participate and encourage participation in one.

Motivation to engage in knowledge sharing refers to an individual’s willingness to communicate her knowledge to co-workers or to elicit their knowledge to be
communicated to her (Borgatti and Cross, 2003; Boudreau et al., 2003). Opportunity to communicate or retrieve knowledge from co-workers is understood as the set of contextual factors beyond an individual’s direct control that constrain or enable her behavior towards knowledge sharing. Finally, ability to communicate or retrieve knowledge from co-workers is about the capacity to transfer knowledge to or receive knowledge from co-workers. We use the logic of the MOA framework to identify organizational and individual antecedents to the development of inter-functional glitch mitigation TMSs.

**Hypotheses Development**

In order to influence the development of inter-functional glitch mitigation TMSs, organizational policies and Heads of Manufacturing must have an impact on encoding, storage or retrieval processes. We understand the development of an inter-functional glitch mitigation TMS to mean that personnel in the manufacturing department are aware of glitch mitigation knowledge and information possessed by members in other functions. It also implies that personnel in the manufacturing department lend credibility to glitch mitigation expertise located in other functions. It equally means that manufacturing personnel are able to coordinate the retrieval of inter-functional glitch-relevant knowledge exchanges effectively.

**Motivation**

Motivation is a critical component of the participation in knowledge exchange processes (Argote et al., 2003; Siemsen et al., 2008). Conveying information about one's expertise and making it available upon request involves costs that have to be outweighed by expected benefits (Argote et al., 2003; Borgati and Cross, 2003). The occurrence of glitches whose ownership spawns across distinct functions may generate resentment and engagement in blame games (Koufteros et al., 2010). In this sense, inter-functional relationships are liable to opportunistic behaviors that decrease the likelihood that manufacturing personnel will reach out to outside expertise during glitch mitigation efforts (Sitkin, 1992).

Cooperation incentives – defined as the extent to which individual rewards and compensation are tied to collective achievement – help to counteract these tendencies (Siemsen et al., 2007). In this sense, it is expected that the extent to which manufacturers implement compensation systems that reward overall goal attainment over departmental targets has a positive influence on inter-functional cooperative processes of encoding, storage and retrieval of glitch mitigation-relevant knowledge. Similarly, we expect the existence of inter-functional cooperation incentives to decrease the propensity of individuals and groups to restrict information searches in glitch mitigation situations.

Hence, we hypothesize that:

**H1**: The greater the level of inter-functional cooperation incentives within the firm, the more developed its inter-functional glitch mitigation transactive memory system is.

In order to understand the motivational antecedents of the engagement in inter-functional glitch mitigation TMSs processes, we also look at the Head of Manufacturing’s propensity to cooperate with others. The extent to which an individual has propensity to engage in interpersonal relationships and collaborate with others is called her teamwork orientation (Eby and Dobbins, 1997). In the context of inter-functional glitch mitigation TMS development, we expect managers with high teamwork orientation to motivate and inspire subordinates to engage in interactions with others in spite of the pressures engendered by the occurrence of operational glitches (Nevo et al., 2012; Peltokorpi and
Manka, 2008). In particular, we expect them to prompt subordinates to seek information from outside functions during glitch mitigation activities. This reasoning leads us to hypothesize that:

**H2:** The greater the level of teamwork orientation of the Head of Manufacturing, the greater the level of development of an inter-functional glitch mitigation transactive memory system.

**Opportunity**

Opportunity is a second fundamental aspect underlying engagement with inter-functional knowledge exchange processes during glitch mitigation. It encompasses the contextual aspects that influence the possibilities of organizational actors to engage in the knowledge exchanges reflective of a TMS connecting multiple functions. These aspects provide organizational actors with opportunities to learn who knows what in terms of expertise relevant for glitch mitigation. Considering such aspects is important, because the extent to which individuals seek information from each other in search for solutions to glitches is contingent on their mutual knowledge of each other’s domains of expertise (Borgatti and Cross, 2003).

In groups with few individual members, it is relatively easy to match expertise domains with specific individuals. In larger groups, such as organizations, there are many experts to keep in mind and much of their expertise is functionally differentiated. Thus, we expect an inter-functional glitch mitigation TMS in manufacturing firms to benefit from the existence of formal role definitions that assign responsibilities to specific individuals. Job descriptions and organizational charts help dispersed organizational actors to quickly identify what sort of expertise specific individuals are supposed to possess (Bechky, 2006). This enables the development of their knowledge of who knows what (Lewis et al., 2007). The formalization of roles within the organization also reduces ambiguity regarding the responsibility for particular tasks (Sine et al., 2006). This aspect facilitates transactive storage and retrieval processes by clarifying who can be expected to possess knowledge on what and what their usefulness might be in the context of particular glitches. Thus, role formalization should help individuals to construct a mental map that connects their own expertise to the expertise of others in the organization. In accordance with these conjectures, we hypothesize that:

**H3:** The greater the level of role formalization within the firm, the more developed its inter-functional glitch mitigation transactive memory system will be.

In order to understand the impact of contextual factors on the development of inter-functional glitch mitigation TMSs processes, we also examine the influence of the level of diversity in the functional background of Heads of Manufacturing. This level of diversity reflects the prior experience that individuals heading manufacturing departments have working in other functions (Bunderson and Sutcliffe, 2002). This level of diversity also reflects the opportunity these individuals have had in developing expertise pertinent to other functions than manufacturing and, thus, of granting subordinates with direct access to that expertise. While we expect traits such as teamwork orientation to positively influence the development of inter-functional glitch mitigation TMSs, we expect the level of diversity in the functional background to hinder it.

We expect this level of diversity of to be negatively associated with the inter-functional TMS development for two sets of reasons. Firstly, individuals with prior experience of working in other departments are more likely to possess broad expertise. Consequently, when approached by subordinates in search of information and knowledge from outside functional boundaries they are more likely to be in possession of such expertise. This
precludes them from directing subordinates to expertise holders from other departments. In addition, managers with experience in departments other than manufacturing may dismiss the need to engage in outside search and embolden the ‘not-invented-here’ syndrome (Alexiev et al., 2010; Odell and Grayson, 1998).

Secondly, subordinates who are supervised by individuals with high functional diversity in their background are less likely to engage in expertise search from outside functional boundaries. Research on advice seeking in organizations puts forward that there might be costs associated with admitting one’s ignorance on certain issues (Borgatti and Cross, 2003). If subordinates perceive their departmental head to possess broad cross-functional expertise they are more likely to turn to him rather than to engage in more time-consuming searches outside the manufacturing function (Singh et al., 2010).

Hence, we expect that:
**H4:** The higher the functional diversity in the Head of Manufacturing’s background, the lower the level of development of an inter-functional glitch mitigation transactive memory system.

**Ability**
Ability is another essential element underlying personnel engagement in inter-functional knowledge exchange processes. It refers to the general skills and information bases required to participate in the exchange of knowledge regarding glitch mitigation. One of the fundamental aptitudes to do so is to know who across distinct functions and hierarchical levels has relevant glitch mitigation knowledge and information. This entails being simultaneously aware of available glitch mitigation expertise and of who holds that expertise.

However, the ability to match information about multiple colleagues and their respective expertise domains is bounded by one’s cognitive limitations. Thus, it has been proposed that in large groups – such as organizations – individuals in boundary spanning positions can serve as directories of information about distant others (Burke et al., 2004, Peltokorpi, 2012). More recently, these types of positions have crystalized in the role of the project manager (Gittel, 2002, Hodgson, 2002), especially in product development contexts. Typically, manufacturers assign project manager roles to individuals who become temporarily responsible for integrating the work of several departments for the purposes of a specific order. One of the ways in which project managers accomplish this goal is by centralizing information on the skills and expertise possessed by people in different functions (Anantatmula, 2010; Hargadon and Sutton, 1997; Hargadon, 2002). This enables them to serve as brokers in connecting knowledge seekers to knowledge holders.

The frequency with which manufacturers deploy individuals to these roles influences their ability to amass information about functionally dispersed colleagues and, consequently, to facilitate the retrieval of relevant expertise. In the context of glitch mitigation activities, this becomes critical for expertise-seeking behaviors given the large number of individuals involved and the unviability of everyone being informed about everyone else’s mitigation-relevant expertise. Furthermore, in the context of glitch mitigation seeking and retrieving expertise has to occur swiftly and accurately. Project managers enable these processes by bringing forth their experience with past glitches and glitch mitigation solutions. In this sense, we hypothesize that:
**H5:** The more frequently a firm uses project manager roles, the more developed its inter-functional glitch mitigation TMS will be.
In our examination of the relationship between ability-related factors and the development of inter-functional glitch mitigation TMSs, we also study the role of managerial organizational connectedness. Organizational connectedness refers to the degree of direct contact a focal individual has with others in the organization, regardless of hierarchical position or departmental affiliation (Jaworski and Kohli, 1993). In other words, connectedness is about the network of contacts an individual has in the organization.

Connectedness provides individual organizational actors with the ability to access ideas from other actors with different backgrounds, disparate knowledge resources and diverse group memberships (Hansen 2002). Connected individuals also reduce the occurrence of inter-functional conflicts by engendering intimacy and trust among colleagues (Adler and Kwon 2002). Connected individuals also have more occasions to get to know multiple colleagues in-depth, including about the domain and extent of their expertise (Jansen et al., 2006; Jansen et al., 2009).

The more connected individuals are the more they are able to engage in effective cross-functional relations to access needed information resources (Tsai, 2002). In this sense, we argue that managers with high levels of organizational connectedness stimulate the development of inter-functional glitch mitigation TMSs.

Formally:

**H6**: The greater the level of organizational connectedness of the Head of Manufacturing, the greater the level of development of an inter-functional glitch mitigation transactive memory system.

**Methods**

**Sample and Data Collection**

The firms forming our sample come from the European industrial equipment manufacturing industry. We collected secondary data on financial performance, size, age, industrial domain and contact information. We collected primary data through four surveys per firm, customized to the Heads of the Sales, Design/Engineering, Manufacturing and Human Resources departments. We collected primary data on level of TMS development, cooperation incentives, role formalization, use of project managers and inter-functional interdependence. We also collected primary data on the Head of Manufacturing’s teamwork orientation, level of organizational connectedness, functional diversity and tenure in the firm. We received complete responses (i.e. 4 delivered surveys) from 60 companies in Italy and 132 in Spain, totaling 768 individual respondents.

**Measures**

Our dependent variable is the level of development of inter-functional glitch mitigation TMS (TMSgm). We measured it by adapting a scale developed in Lewis (2003) and used throughout most field research. The respondent for this scale is the Head of Manufacturing.

Our study employs six independent variables that correspond to the organizational and personal characteristics conjectured to influence the level of inter-functional glitch mitigation TMS development. We operationalized inter-functional cooperative incentives (CI) by adapting Campion’s et al (1993) scale for goal and reward interference. This variable captures the extent to which the goals and compensation of individual employees depend on the performance of the firm as a whole. Role formalization (RF) refers to the degree to which the firm employs formal definitions for job descriptions and reporting relationships. We operationalize this variable by using Patel’s (2011) three-item scale.
The extent of use of project managers (PM) is measured by a one-item question targeting the frequency of use of “liaison personnel with the job of coordinating the efforts of several departments for the purposes of a project” (Germain and Droge, 1997). The respondent for these three constructs was the Head of Human Resources. In terms of the personal characteristics of Heads of Manufacturing, we measured teamwork orientation (TOm) by adapting 4 items from Tangpong et al. (2010) and Zacharia et al. (2011). Organizational connectedness (OCm) captures the extent to which Heads of Manufacturing have personal contact to other organizational actors across departments and hierarchical levels. We operationalize this variable using a four-item scale found in Jansen et al. (2006) and Mom et al. (2009). The respondent for both measures was the Head of Human Resources. The level of functional diversity in the background of the Head of Manufacturing (FDm) is measured by directly asking these managers to designate all the departments in which they have worked in the firm. The variable is operationalized by counting the number of designated departments.

We also employ several control variables in order not to confound the relationship between the independent variables and the level of inter-functional glitch mitigation TMS development. We control for the level of inter-functional interdependence (IFI), firm age, and firm tenure of the Head of Manufacturing (Tenm).

In order to isolate country and industry specific effects, we also included dummy variables that reflect different countries and SIC codes.

**Results**

The results of the linear regressions are in Table 1. Model 1 includes all of the control variables expected to have a direct effect on the level of glitch mitigation TMS development. Model 2 adds to the control variables the hypothesized effects of inter-functional cooperation incentives (H1), role formalization (H3) and frequency of use of project managers (H5). The impact of each of these organizational policies on the level of inter-functional glitch mitigation TMS development is significant ($p < 0.01$, $p < 0.01$ and $p < 0.05$, respectively) and in the predicted direction ($\beta_{ci} = 0.16$, $\beta_{rf} = 0.14$ and $\beta_{pm} = 0.10$, respectively). Model 3 introduces the personal characteristics of individuals heading the manufacturing department hypothesized to impact the development of an inter-functional glitch mitigation TMS (H2, H4 and H6). Results show mixed support for the hypothesized effects. On the one hand, H2 is not supported, since the effect of teamwork orientation is not statistically significant ($p>0.05$). On the other hand, we find support for H4 and H6. Regarding H4, the effect of the diversity in functional background is negative ($FD_m = -0.10$) and significant ($p<0.01$). Regarding H6, the level of organizational connectedness is positively ($OC_m = 0.11$) and significantly ($p<0.01$) associated with a higher level of inter-functional glitch mitigation TMS development.

*Table 1: Regression Analysis*
Discussion and Conclusion

With this study, we have uncovered several aspects underlying the development of glitch mitigation capabilities in manufacturing firms. By studying the antecedents of inter-functional glitch mitigation TMSs, we have found that inter-functional cooperation incentives, the formalization of job descriptions and roles and the regular use of project managers enables the development of glitch mitigation capabilities. We have also found that certain characteristics of the Head of Manufacturing influence the development of glitch mitigation capabilities in manufacturing firms. More specifically, we found that the extent to which Heads of Manufacturing are networked with organizational actors independently of position or affiliation has a positive influence the development of a glitch mitigation TMS, whereas the degree of diversity in their functional background has a negative one. In what follows, we discuss the implications of these findings.

Previous research on glitch mitigation suggests that, in general, high levels of inter-departmental collaboration are required to address the operational challenges put forward by the occurrence of glitches (e.g. Hoopes and Postrel, 1999; Koufteros et al., 2010). Subsequent studies have evidenced that formal mechanisms such as periodic meetings (Tenhiala and Salvador, 2014) and the use of ERP systems (Tenhiala et al., 2018) are effective in achieving requisite levels of inter-functional coordination. Our study adds to this literature stream by examining organization and individual-level factors that are associated with the development of emergent and informal inter-functional coordination mechanisms in the form of glitch mitigation TMSs. These findings are important in that they provide firms with operative policies to develop an inter-functional glitch mitigation TMS and, in that way, enhance the resilience of their internal supply chains to operational glitches.

Our results regarding the characteristics of Heads of Manufacturing also address concerns about the conspicuous absence of human resource characteristics from the operations and supply chain management resilience literature (Ambulkar et al., 2016). By examining how personal characteristics of Heads of Manufacturing influence the development of inter-functional glitch mitigation TMSs, we offer insights on how managers in specific organizational positions relate to firm resilience to operational glitches.

Nevertheless, our results also confirm that some managerial characteristics can be detrimental to the development of inter-functional glitch mitigation TMSs. As conjectured, our results endorse that the variety in the Head of Manufacturing’s functional background has a negative relationship with the level of development of an inter-functional glitch mitigation TMS. In spite of the frequent occurrence of operational glitches, glitch mitigation constitutes a situation of exception that mandates the quick reconfiguration of order-fulfilment plans. During glitch mitigation activities, manufacturing personnel have to engage in the search of the knowledge and information required for devising and implementing adequate new plans. Given the typical urgency presented by the occurrence of operational glitches, the tendency will be to prefer proximate over distantly located expertise in the organization. In this sense, our findings illustrate how the perception of a functional head with high breadth of expertise—a perception that may or may not be warranted—discourages manufacturing personnel from engaging in systematic inter-functional knowledge exchange processes. This finding also supports the observation that glitch mitigation efforts tend to favor timeliness over comprehensiveness (Oliva and Sterman, 2001).

Finally, we note that we did not find support for the hypothesis that the Head of Manufacturing’s teamwork orientation has a positive influence on the development of inter-functional glitch mitigation TMSs. This result suggests that managers with high propensity towards cooperation are ineffective in motivating the behaviors conducive to inter-functional glitch mitigation TMS development. One possible explanation for this result is that managers’ intrinsic drive to cooperate is insufficient to influence the motivation of subordinate personnel to engage in knowledge exchanges across functional boundaries (Tierney et al., 1999). It could be that the Head of Manufacturing’s propensity towards teamwork stimulates cooperation within but not beyond the manufacturing function.

In summary, collectively these findings enhance our current understanding of glitch mitigation by exploring the neglected role of individual actors in the management of operational disruptions.

Abstract

Supply Chain Resilience (SCRES) is becoming increasingly important in the pharmaceutical industry, especially in the supply of drugs for cancer treatment, as cancer is one of the five most expensive diseases and new developments such as personalized medicine have led to changes in the pharmaceutical supply chain. The purpose of this paper is to elaborate the concept of dynamic capabilities for SCRES in the context of a pharmaceutical supply chain. For this purpose, a multiple embedded case study analysis of thirteen companies in the pharmaceutical industry spreading over Austria and Germany is undertaken.

Keywords: Supply Chain Resilience, Dynamic Capabilities, Pharmaceutical Industry

Introduction

While research in the area of SCRES has gained widespread attention (Jüttner and Maklan, 2011; Fiksel et al., 2015), and the body of knowledge continues to grow, further research is needed to validate existing and proposed SCRES constructs and relationships between them (Hohenstein et al., 2015; Kamalahmadi and Parast, 2016) and to investigate SCRES in the context of different industries (Hendry et al., 2018). In the pharmaceutical industry, SCRES is of increased importance as it has faced a number of disruptions in the past and issues specific to the industry. For example, damages to patient health and sickness due to counterfeit products, raw material shortages leading to scarcity of medicines and drugs, complexity of new drugs, dependence on off-shore manufacturers, waste elimination, product recalls, and diminishing protection provided by patents. These issues and their consequences translate into a need for higher resilience in the pharmaceutical supply chain as compared to the supply chains of other products, such as
consumer durables or office products. This need for higher resilience translates into requirements of near-perfect availability of supplies or ability to replace source if a disruption occurs, highly controlled storage conditions, and breach-proof transportation that assures the highest levels of integrity of the cargo (Bigdeli et al., 2013). Lack of resiliency in the pharmaceutical supply chain in dealing with disruptions can not only jeopardize the efficiency and effectiveness of the healthcare system, but also put patient health and life at risk (Moktadir et al., 2018).

Notably, over the past few years, researchers have addressed SCRES-related issues such as risk identification and assessment in the pharmaceutical industry (Breen, 2008; Enyinda et al., 2009; Ouabouch and Amri, 2013; Jaberidoost et al., 2015). However, a majority of these studies consider specific activities, such as outsourcing and off shoring, in isolation. Further, research in the specific context of the pharmaceutical industry is sparse. In sum, holistic research related to resilience in the pharmaceutical supply chain is limited (Aigbogun et al., 2014). Therefore, the purpose of this paper is to investigate how pharmaceutical companies build resilience into their supply chains. To do so, the theoretical context of dynamic capabilities, is adopted. Dynamic capabilities are the ability of a company to sense and adapt to changes in the external environment. For this research three categories of dynamic capabilities of sensing, seizing, and transforming (Teece, 2007) are used to guide this research.

The questions guiding this research are:

- How do pharmaceutical companies build resilience into their supply chains?
- How pharmaceutical companies prepare and respond to disruptions in their supply chains?
- What factors hinder and facilitate the process of building SCRES in pharmaceutical supply chains?
- How does SCRES help individual pharmaceutical companies improve supply chain performance?

The paper is structured as follows. First, the relevant theoretical background is described. Next, the methodology used in this research is presented followed by the preliminary findings. Finally, the main conclusions are presented and potential future research areas including the next steps are identified.

**Theoretical background**

This section provides a review of the literature relevant to understanding resilience in a pharmaceutical supply chain context. First, we define SCRES and identify the key findings from the extant literature. Next, we establish the uniqueness of the pharmaceutical supply chain to justify the context of this research. Finally, we review the literature on dynamic capabilities and explain why it is an appropriate theoretical lens for this research.

*Supply chain resilience*

SCRES in a broad sense refers to the ability of supply chains to prepare for, respond to and recover from disruption (Sheffi, 2005; Pettit et al., 2010), ideally leading to a phase of growth in order to emerge as stronger entities (Hohenstein et al., 2015). With growing volatility and uncertainty in supply chains, research in the area of SCRES has gained widespread attention (Jüttner and Maklan, 2011; Fiksel et al., 2015). Most studies investigate SCRES broadly (Hohenstein et al., 2015; Tukamuhabwa et al., 2015; Stone and Rahimifard, 2018). Consequently, the literature examining multiple tiers of a supply chain...
chain or network is rather sparse (Tukamuhabwa et al., 2015). Further, while there has been an emphasis on supply chain disruptions caused by catastrophic events such as earthquakes and terrorism, there is still a lack of research using in-depth studies that considers SCRES in the context of different industries (Hendry et al., 2018). One such industry is the pharmaceutical industry; research in this industry is currently underdeveloped and needs further exploration, especially by undertaking research that goes beyond a dyadic perspective (Seuring, 2008).

In recent years, researchers have focused on applying, testing and exploring diverse strategies and capabilities broadly (Stone and Rahimifard, 2018; Aboah et al., 2019), in order to increase supply chain resilience (Wieland and Wallenburg, 2013), as well as factors that reduce and improve supply chain resilience (Blackhurst et al., 2011). The three disruption phases readiness, response, and recovery have been generally suggested in the SCRES literature (Sheffi and Rice, 2005; Ponomarov and Holcomb, 2009). More recently, a fourth phase has been identified (Pettit et al., 2010; Blackhurst et al., 2011; Hohenstein et al., 2015; Adobor and McMullen, 2018).

One common theme across the entire SCRES literature is that of learning from previous experiences may shift the organization to a further state (Ponomarov and Holcomb, 2009; Pettit et al., 2010). Scholten et al. (2019), for example have focused on how organizations can learn and adapt their routines in order to build SCRES for non-routine events. Six learning mechanisms have been identified that explain how organizational decisions and actions intentionally and unintentionally facilitate the adaptation of routines to prepare, respond to and recover from supply chain disruptions. Further research could be adopted on how learning mechanisms could help a supply chain to return to an improved functional state after a disruption (Scholten et al., 2019).

Pharmaceutical supply chain
The pharmaceutical supply chain (PSC) is somewhat different from the supply chains of other industries or physical goods, because of its criticality, speciality and complexity (Breen, 2008; Bhakoo and Chan, 2011; Bigdeli et al., 2013; Nsamzinshuti et al., 2017). Criticality refers to the availability or non-availability of drugs, as any disturbances that occur in the pharmaceutical supply chain can affect the efficiency of the healthcare system and jeopardize the supply of medicines (Breen, 2008).

Speciality refers to numerous regulations to which the pharmaceutical industry is subject (Mossialos and Oliver, 2005; Parmata et al., 2016). Researchers and practitioners agree that the PSC is a special supply chain and “cannot be treated like other commodities”. The PSC underlies several regulatory requirements regarding the production, distribution, transportation and storage of pharmaceutical products (Bigdeli et al., 2013). Therefore, the management of both material and information flow in the pharmaceutical industry has become more important due to its complex and dynamic network structure (Jaberidoost et al., 2013). Complexity refers to the number of stakeholders in the supply chain (Nsamzinshuti et al., 2017). Numerous players in the pharmaceutical industry, such as pharmaceutical manufacturers, wholesalers, distributors, customers, information service providers and regulatory authorities, play a vital role in the provision and supply of medicines and save human lives (Bhakoo and Chan, 2011; Bigdeli et al., 2013).

Finally, the pharmaceutical industry is currently facing new challenges, as patents for medical products expires the economies of scale diminishes (PWC Report, 2007; Singh et al., 2016). The PWC Report (2007) points out, that the pharmaceutical manufacturers are already experiencing an underutilization of less than 50% at some sites. Lacking expertise of pharmaceutical companies causes the production of pharmaceuticals to be
handed over to contract manufacturers and an increase in cheap night courier services allows medicines to be delivered directly to pharmacies, reducing inventory levels and controlling product leaks more effectively (PWC Report, 2007).

To address these challenges related to criticality, speciality and complexity, SCRES is important, as pharmaceutical companies should understand how disruptions should be managed and how to become agile in order to deal with these situations (Mehralian et al., 2015). To meet these challenges a shift in this industry is imperative and therefore, pharmaceutical companies have to reduce costs and become agile (Singh et al., 2016).

More specifically, cancer is one of the five most costly conditions. New technologies such as personalized medicine are being used to treat cancer. This research is focused on the supply chain of medicines used for cancer treatments. Thus, it makes sense to initially focus on providing financial support for patients with this disease (PWC Report, 2007).

Personalized medicine as a new technology will eliminate redundant treatments, reduce side effects of drugs, prevent and predict diseases and previous intervention as well as reduce health care costs (Bakhiet, 2018). The manufacture of tailor-made drugs requires a different manufacturing strategy, which is why pharmaceutical manufacturers should no longer follow the lean manufacturing strategy, but rather produce "assembly-to-order" in order to create agility (PWC Report, 2007; Bogle, 2017).

Dynamic Capabilities

The concept of dynamic capabilities was introduced by Teece et al. (1997), and is the ability of a company to sense and adapt to changes in the external environment as a key for sustainability and competitiveness. Teece (2007) defined three categories of dynamic capabilities: sensing, seizing, and transforming. Sensing is the activity including scanning, creation, learning and interpretation. Seizing follows and includes the response to sensed opportunities and threats. Transforming as a third category involves the reconfiguration of intangible and tangible assets with the goal to enhance, combine or protect companies’ capabilities.

Dynamic capabilities are a competitive necessity in modern business as they help respond to environmental challenges (Ponomarov, 2012). This concept leads to evolutionary fitness by supporting the creation, extension and modification of a resource base and turning it into a long-term competitive advantage (Teece, 2007). This research focusses on the PSC and its evolutionary fitness, thereby making dynamic capabilities an appropriate theoretical lens. There are similarities between the concept of SCRES, including the phases of prepare, respond, recover and growth, and the dynamic capabilities categories. Sensing would ideally take place in the preparing phase, seizing in the respond, and transforming in the recover and growth phase. The categories of DC and the phases of SCRES informed our initial research model for this study (figure 1).
The dynamic capabilities theoretical lens helps to guide both the data collection process and the analysis of the findings. It helps to establish how the actors are “sensing” the current supply chain context, including developing an understanding of the disruption caused by supply chain risks, how they are “seizing” any associated opportunities, and finally, how they are “transforming” their businesses towards becoming more resilient.

**Methodology**
Not much is known about SCRES in the context of the pharmaceutical industry. Therefore, the case study approach was adopted to enable an in-depth investigation of the understanding of managers’ perceptions of and responses to supply chain disruptions and their strategies to improve SCRES. The case study method is appropriate as it allows researcher to collect data from multiple sources to make sense of and begin to build a theoretical model of managers’ perceptions and behaviours. The chosen approach facilitates extension of the existing dynamic capabilities theory, and the SCRES theory in the context of pharmaceutical industry, best described as a “theory elaboration” (Ketokivi and Choi, 2014).

In this research, a multiple embedded case study analysis of thirteen companies in the pharmaceutical industry spreading over Austria and Germany is undertaken. The pharmaceutical supply chain according to Carter et al. (2015), shown in figure 2, as the unit of analysis deals with a focal company, their suppliers, second tier suppliers, customers and carriers. The material flow goes from the supplier to the manufacturer via carriers to wholesalers and retailers or clinics/hospitals, which are also partly supplied directly by pharmaceutical manufacturers and wholesalers. In extant research, typically, the company type “retailer” includes hospitals, pharmacies and drug stores (Utami et al., 2009). In this work, a differentiation between retailer and clinics/hospitals has been made, as clinics and hospitals receive medical products directly from manufacturing companies. Drugs can be purchased from pharmaceutical retailer such as pharmacies and online-pharmacies (Gupta et al., 2012). In-person interviews and other data (e.g. archival data, documents, attending meetings, and secondary data) will be collected.
Data collection and analysis
Data will be analyzed, using NVivo 12, with a set of codes developed to identify themes around SCRES in the pharmaceutical industry. NVivo is a widely used tool in qualitative and mixed methods research with key strengths in the flexibility of reviewing and revising codes and search tools. This supports the iterative interaction between theory and data that is central to our approach. The applied iterative process in case research is based on what Dubois and Araujo (2007) drew from Ragin (1992) what is described as casing, a flexible, dynamic interaction between data and theory.

Preliminary Findings
The research team is in the process of finalizing the interview protocol. Interview protocol will include open ended questions around the concepts of dynamic capabilities and SCRES. So far, thirteen companies have agreed to participate, and eighteen interviews have been scheduled. We expect to have preliminary results of the study by mid of May 2019. We expect to report on the following: how pharmaceutical companies build resilience into their supply chains, respond to disruptions, factors that hinder and facilitate SCRES, and relationship SCRES to supply chain performance. Further, we will be able to identify similarities and differences related to building and maintaining SCRES between the pharmaceutical industry and other industries such as food industry (Hendry et al., 2018).

Sensing
We expect to find evidence for risks and challenges identified in the underlying supply chain from the cases. We will provide the evidence for each of these opportunities in a table including each category with quotes from the evidence and the related sources of the interviews.

Seizing
We expect to find in-depth insights of sensing opportunities and show the related categories in the pharmaceutical supply chain from the cases. We will show the evidence for each of these opportunities in a table including each category with quotes from the evidence and the related sources of the interviews.
Transforming
The third phase of transforming follows sensing the threats and seizing the opportunities in the underlying supply chain. Based on the cases we expect to find evidence of the transforming activities.

Relevance/contribution
This research contributes to the body of knowledge in several ways. First, this is one of the first empirical study seeking to investigate SCRES in pharmaceutical supply chains and includes both physical and support firms. It provides a comparison of the characteristics of the threats posed in the pharmaceutical industry with those in other industries. Further, it truly is a supply chain research as it includes multiple players across several levels in the supply chain. Second, depending upon the theoretical lens (for example, dynamic capabilities) that emerges as the most appropriate to study the phenomenon, the study is expected to contribute to that specific stream of research. Finally, SCRES implications for managers in the pharmaceutical industry will be discussed. The expected findings of this research are an elaboration of dynamic capabilities for SCRES in the context of a pharmaceutical supply chain.

Limitations and future research
This study has focused on the pharmaceutical industry. It could be interesting to conduct a study using dynamic capabilities as theoretical lens to study PSCs in other industries. Additionally, it would be beneficial to include companies from other countries than Austria and Germany that are part of the PSCs investigated in this research. An extension of this research into a longitudinal study would enable the companies to reflect on risks, opportunities and their impact, and provide greater insights into transformation part of SCRES.

Work-in-Progress Research
This research is still a work-in-progress project. We are currently finalizing the interview protocol and will start conducting the interviews in April of 2019. The next step in this research project is data collection. We expect to present initial findings from preliminary analysis during the conference.

Acknowledgement
The authors would like to thank the Austrian federal government and VDI in Germany for supporting and funding this research project “s4pt” as part of the research program FFG/Kiras in Austria.

Supply disruptions’ influence on internal operations and resilience: Balancing buffering and bridging

Mitchell J. van den Adel (m.van.den.adel@rug.nl)

Thomas A. de Vries
University of Groningen, the Netherlands

Dirk Pieter van Donk
University of Groningen, the Netherlands

Abstract

In this study, we explore the comparative effectiveness of two predominant strategies to deal with supply disruptions: buffering and bridging. Drawing from resource dependence theory, we propose that a buyer’s dependence on a disrupted supplier determines the effectiveness of the two strategies in preventing the disruption from resulting in internal production failures and, subsequently, in decreased resilience. We suggest that in high dependence situations, bridging actions – as opposed to buffering actions – can more effectively mitigate the impact of supply disruptions. We test these predictions using an extensive, four-year database on disruptions to more than 300 buyer-supplier relationships.

Keywords: Resilience, Disruptions, Resource Dependence Theory

Purpose

In 2018, over fifty percent of the disruptions that firms experienced emerged from their first-tier suppliers (Riglietti and Aguada, 2018). Extant supply chain research offers a wide range of strategies through which firms may mitigate such disruptions’ adverse consequences for their internal operations and performance (i.e., build resilience). Recent studies suggest that these strategies can be broadly distinguished into buffering and bridging actions (Bode et al., 2011; Mishra et al., 2016). Buffering actions, on the one hand, seek to minimize firms’ exposure to disruptions by, for example, establishing redundant inventory or identifying backup suppliers. Bridging actions, on the other hand, strive to increase firms’ influence over the exchange partner by acts such as intensifying information sharing or establishing personal relationships. Although these recent studies have provided valuable insights into intra- and inter-firm aspects that trigger buffering or bridging responses to disruptions, they offer no validation of the actual effectiveness of either strategy in preventing disruptions from causing internal production failures and performance issues for the buying firm. To address this
important omission, the purpose of the present research is to explore how and under which conditions buffering and bridging contribute to firms’ resilience.

To study the effectiveness of buffering and bridging across different situations and in relation to each other, we draw from resource dependence theory (RDT) as an important conceptual perspective on exchange relationships. According to RDT, firms’ susceptibility to adversity increases when they become more dependent on specific exchange partners for the provision of scarce resources (Pfeffer and Salancik, 1978). We therefore hypothesize that if the dependence of a buyer on a supplier increases, a disruption to that supplier is more likely to result in internal production failures and reduced resilience at the buyer. In doing so, we explore disruptions’ direct and indirect effects on firms’ performance (see Figure 1). RDT further suggests that the specificity of the scarce resources that characterize high dependence relationships makes the implementation of buffers extremely costly. In such situations, bridging is in the best interest of both the buyer and the supplier (Bode et al., 2011; Mishra et al., 2016). Consequently, we propose that the hypothesized adverse effects of dependence are more effectively mitigated when buyers engage in bridging as opposed to buffering.

Methodology
We will test our hypothesized relationships using an extensive database on disruptions to the more than 300 buyer-supplier relationships of an order-driven assembler of complex, highly technological products (Company A). This company is particularly appropriate for our research purposes because its suppliers deliver raw materials that range from standardized (low dependence) to highly customized (high dependence). Each year, Company A’s operations are disrupted more than 800 times due to, for example, production problems at these suppliers and subsequent delayed or cancelled deliveries of raw materials. In an ongoing collaboration with this firm, we have obtained access to Company A’s detailed records of the nature and impact of disruptions and ensuing actions toward suppliers for the past four years (2015-2018), complemented with internal reports and interviews.

From the obtained information, we will code our research variables. Records on supplier characteristics and production schedules enable us to respectively code levels of dependence and the occurrence of internal production failures. To operationalize buffering and bridging actions, we will build on the measures developed by Bode et al. (2011). Finally, we will gauge resilience for specific disruptions by determining the delivery reliability (in terms of on-time delivery and order accuracy) of Company A with respect to the customer orders affected by the disruption.
Because the disruptions are nested in both suppliers and time, we will conduct multilevel structural equation modelling (MSEM; Preacher et al., 2016) using Bayesian estimation to estimate model parameters. We will conduct these analyses in Mplus 8.1 (Muthén and Muthén, 1998-2017).

**Findings**
We have commenced coding the obtained information. In accord, the analysis of the data is at a preliminary stage, and we expect to finalize this at the end of April 2019.

**Contribution**
This study contributes to extant literature in several important ways. We relate the relative effectiveness of two important types of resilience strategies (buffering and bridging) to a buyer’s dependence on the disrupted supplier. In doing so, we extend prior research that focused on aspects that provoke buffering or bridging actions without assessing these actions’ subsequent effectiveness (cf. Bode et al., 2011; Mishra et al., 2016). Moreover, our approach to measuring disruptions’ adverse consequences for firms may have important implications for broader resilience research. Specifically, besides determining disruptions’ direct effect on firms’ performance, we additionally estimate their indirect effect by means of subsequent internal production failures. This approach provides valuable insights into the mechanisms through which disruptions affect firms’ resilience. Furthermore, we contribute to RDT by empirically illustrating how core notions of the theory manifest in a resilience context. More practically, our findings may guide firms in making better informed decisions about which mitigation strategy to pursue, thereby enabling them to more effectively mitigate disruptions’ impact.

Abstract
The purpose of this study is to understand the link between relational capital and disruption recovery performance and how its efficacy changes with the use of mediated power. Using buyer–supplier matched pair data from the US manufacturing industry, we explore the role of the buyer’s use of coercive and reward power in moderating the efficacy of relational capital in recovery performance. The results showed that while the buyer’s use of coercive power is insignificant in moderating the relationship between relational capital and recovery performance, reward power complements the ability of relational capital, thereby contributing to increasing recovery performance.

Keywords: Relational capital, Mediated power, Supply chain risk management

Introduction
While supply chain risk management studies have brought significant understanding to ways to mitigate supply chain disruption, relatively little attention has been devoted to the disruption recovery stage; that is, what to do after a disruption event (Sodhi et al., 2012). As it is impossible to completely prevent supply chain disruptions, being able to figure out ways to respond to and recover quickly from them is crucial (e.g., Krause et al., 2007; Sodhi et al., 2012). Therefore, understanding a firm’s successful disruption response/recovery approach is as important as understanding how to prevent disruption. However, the effectiveness of a collaborative buyer–supplier relationship in the disruption response and recovery stage is still unclear, and the impact of the dominant party’s use of mediated power to motivate the other party involved in collective action for the recovery process is rarely examined.

This study addresses this gap in the literature by using the theoretical lens of relational capital and power in the buyer–supplier relationship. By using matched pair data to capture both the buyer and the supplier’s perspectives, the results not only contribute to
understanding the dyadic nature of exchange relationships in the supply chain, but also contribute to understanding the buyer and the supplier’s perception asymmetry of the presence of the power in the relationship. Adopting a buyer–supplier dyadic perspective can also lessen the possibility of single rater bias, such as an exception fallacy (Roh et al., 2013).

Social capital theory offers a framework for understanding how organisations acquire resources that exist outside of their boundaries and access the benefits of developing closer ties with other partners (Inkpen and Tsang, 2005). In particular, relational capital offers the benefit of achieving successful recovery from a disruption by lessening the worry about the other party’s opportunism, thereby facilitating supply chain entities’ interactions to promote collective sensemaking and resource reconfiguration (e.g., Olcott and Oliver, 2011). Along with relational capital, power has been considered to be another important relational aspect that influences buyers and suppliers in developing and managing their relationships (Yeung et al., 2009). Coercive power and relational capital are opposing components of social behaviour, as coercive power deteriorates the ability to trust, and the willingness to continue the relationship thereby weakens the relationship and relational benefit. Conversely, reward power and relational capital are complementary components, as reward power enhances the ability of reciprocity and trust in the relationship, and promotes collaborative supply chain relationships (e.g., Ireland and Webb, 2007).

In this paper, we seek to shed light on this phenomenon by investigating the role of power (mediated power: coercive and reward power) in moderating the efficacy of relational capital in supply disruption response and recovery performance.

Literature review and hypotheses development
In a disruption situation, there is a necessity for appropriate recovery actions, such as the rapid mobilisation and reconfiguration of supply chain resources (e.g., Craighead et al., 2007; Olcott and Oliver, 2011). As these actions cannot be successful through a single firm’s effort, building collaborative relationships with partnering firms as a recovery enabler has been emphasised (Craighead et al., 2007).

Relational capital in the relationship permits privileged access to the key resources of others, promotes firms to engage in value creation (Lawson et al., 2008) and motivates the parties in the supply chain to take additional risks and cooperate even beyond contractual provision (Villena et al., 2011). One of the central roles of relational capital in the buyer–supplier relationship is reducing the expectation of opportunistic behaviour and transaction costs (Dyer and Singh, 1998). Therefore, the development of relational capital in the relationship has been suggested as not only a key mechanism that explains access to the other party’s resources and information (Krause et al., 2007), but also one that fosters a sense of openness and reciprocity (Coleman, 1990; Zaheer et al., 1998; Kale et al., 2000), and encourages more favourable attitudes and a stronger alignment of interests (Nyaga et al., 2013); thereby parties are more likely to act according to common agreement (Ireland and Webb, 2007). Thus, relational capital in the relationship helps to foster successful recovery from a disruption situation (e.g., Olcott and Oliver, 2011). Therefore,

Hypothesis 1. The buyer and its supplier’s accumulated relational capital that has been established prior to the disruption is positively related to their supply chain disruption recovery performance.
In addition to using relational capital, the buyer can use the influence mechanism based on their power–force compliance to motivate the supplier into going along with their wishes. Mediated power sources include coercive power and reward power (Zhao et al., 2008). In a disruption situation, by offering rewards when the supplier conforms to the buyer’s influence attempt (reward power) or punishing the supplier when failing to conform (coercive power), the buyer can produce the intended changes in the supplier’s behaviour to engage in collective action, thereby contributing to increasing recovery performance from the disruption.

When the buyer uses coercive power to motivate the supplier to be involved in collective action for the disruption recovery, the relational benefit from relational capital can be lessened. By forcing compliance on the supplier, the buyer may succeed in motivating it to rearrange and reconfigure its resources and engage in collective action. However, as many studies have indicated, there is a negative association of coercive power with a cooperative relationship (e.g., Maloni and Benton, 2000).

In particular, trust lies at the heart of relational capital (Johnson et al., 2013), and coercive power does not exist simultaneously in the relationships as they are opposing components of social behaviour (Ireland and Webb, 2007). When the dominant party uses coercive power, it decreases the efficacy of trust in the relationship (Yeung et al., 2009). This is because it signals that this party is not likely to maintain the relationship for the long term (Morgan and Hunt, 1994), and the target firm is also likely to take greater safeguards and seek mechanisms to reduce its vulnerability. This ultimately weakens the relationship, with an accompanying deterioration in relational benefit (Yeung et al., 2009; Nyaga et al., 2013).

The use of coercive power also lessens the ability of relational capital, which can reduce the fear of the other party’s opportunism in the exchange relationship (Nyaga et al., 2013). Use of coercive power makes the target firm realise that the coercing party is succeeding by taking advantage of its dependence. This is viewed as opportunism, with the buyer being seen as expecting to gain at the expense of the supplier (Nyaga et al., 2013). Hence, it reflects the dominant firm’s incompetence and thus reduces the ability of target firm’s trust (Leonidou et al., 2008). Additionally, the buyer’s reliance on coercive power implies that its supplier’s performance is not satisfactory (Zhao et al., 2008). It damages the supplier’s sense of competence and autonomy, which ultimately lowers motivation to continue the relationship with the buyer (Chae et al., 2017). Therefore,

*Hypothesis 2. The buyer’s use of coercive power towards its supplier during the disruption recovery/response stage negatively moderates the relationship between relational capital and disruption recovery performance.*

To influence its supplier to engage in collaborative action for response and recovery, a buyer can also use reward-based power, which motivates the supplier to go along with its wishes by offering rewards and benefits. The use of reward power helps to increase social and financial benefits, and provides numerous relational advantages; thereby collaborative supply chain relationships can be expected (e.g., Maloni and Benton, 2000; Ireland and Webb, 2007; Nyaga et al., 2013). Consistent with these views, it is held here that a buyer’s reward power complements the effect of relational capital in contributing to increasing recovery performance.
The use of reward power can lead to two parties to be bound to each other and raises costs for negligence or opportunism, thus fostering a relational contract and trust between the two (Ireland and Webb, 2007). Its usage is based on a firm’s ability to contribute resources to a relationship, which can also increase the ability of the target firm’s trust by providing the perception that the powerful party has the capability to fulfill the necessary obligations of a transaction (Ireland and Webb, 2007). Additionally, reward power helps to promote common interests and collective goals within the relationship, as well as engendering a constructive and friendly atmosphere (Leonidou et al., 2008). These positive aspects will subsequently lead to high levels of trust in the relationship. While the power source’s use of coercion and punitive action will most likely decrease relationship commitment, in contrast, when the customer uses reward power to meet the manufacturer’s expectation of reciprocity, commitment could well be further enhanced (Nyaga et al., 2013).

Additionally, the use of reward power is based on the idea that parties cooperate in relationships with the expectation of giving and receiving rewards, which supports the norm of reciprocity (Pulles et al., 2014). The notion of reciprocity embodied in relational capital suggests that firms feel obligated to reciprocate certain actions by the other party (e.g., Adler and Kwon, 2002). When reward power is used to influence the other party, both parties adjust their behaviour and actions toward their partner (e.g., Ireland and Webb, 2007). When this reciprocal action in a supply chain exchange is rewarded or produces benefits, both parties engage in it. The reward giver gets better results and the receiving party gets the reward promised (Nyaga et al., 2013; Pulles et al., 2014). Hence, by positively associating with reciprocity and trust in the buyer–supplier relationship, use of reward power will complement relational capital and its ability to coordinate resources and capabilities between the parties. Therefore,

*Hypothesis 3. The buyer’s use of reward power towards a supplier during the disruption recovery/response stage positively moderates the relationship between relational capital and disruption recovery performance.*

The proposed model investigates the moderating role of the buyer’s power (coercive and reward power) in the relationship between relational capital and disruption response and recovery performance. Figure 1 illustrates these relationships.

![Figure 1 – Conceptual Model](image-url)
Method

Survey administration and data collection

To test the proposed hypotheses, matched pair data (survey), from both the manufacturer (buyer) and its matched supplier, who had experienced the disruption, were utilised. Accordingly, matched pair questionnaires for the buyer and supplier were designed. For the buyer side, purchasing professionals who manage the procurement of direct materials across US manufacturing industries were targeted. Respondents were asked to recall a recently experienced (within two years) supply chain disruption that negatively impacted on their normal routine business or performance. To collect their matched supplier data, this first set of surveys for buyers included questions asking them to provide information about the disruption experienced and the contact details of the supplier involved. Subsequently, the named suppliers described in the main buyer survey were contacted. A total of 256 dyads were collected, with a response rate of 56.63% from the buyers, and 64.48% from the suppliers. 17 samples were excluded due to quality problems and missing data, leaving 239 valid dyads for statistical analysis.

Measurement instrument

The variables in the study were operationalised using previously tested and validated constructs. To collect matched pair data and capture the perspectives of both the buyer and their paired supplier, two different versions of the questionnaires are developed. For all the measurement items, a seven-point Likert scale was used. For the relational capital, 7 measurement items were adopted from Carey et al. (2011), Roh et al. (2013), Li et al., (2014) and Villena et al. (2011). To measure the disruption recovery performance, 7 items were adopted from Chowdhury and Quaddus (2016), Ambulkar et al. (2015), and Macdonald and Corsi, (2013), and modified to fit the context of the study. For the buyer’s coercive and reward power, 4 items and 3 items respectively were adopted from Maloni and Benton (2000), Zhao et al. (2008), and Pulles et al. (2014). To operationalise the buyer and supplier’s mutual perspective on the relational capital, the buyer’s coercive and reward power, and the disruption response and recovery performance, we followed Straub et al. (2004) and Klein et al. (2007); we used the average of the buyers and the suppliers to produce the degree (magnitude) of the dyad.

Bias Control

Non-response bias was followed through a comparison of early and late waves of returned surveys. To minimise recall bias, the respondents were asked to report on a recent supply chain disruption that they had experienced and were asked for the exact month of the disruption (Bode et al., 2011). To reduce the possibility of single rater bias, such as an exception fallacy (Roh et al., 2013), this study used samples from both buyer and their matched supplier. To assess the existence of the common method bias, Harman’s one-factor test and marker variable technique were conducted. Both the buyer and supplier model test results indicated that common method bias was not a problem in this study.

Control Variables

This study adopted several control variables: the size of the firm (measured by number of employees and firm sales); industry; the severity (impact size) of the disruption (measured
by financial loss; dependency on the exchange partner (measured by dependency on the other firm), and frequency of disruption (measured by the frequency of disruption occurred).

Analysis

Before examining the proposed hypotheses, we conducted confirmatory factor analysis (CFA) by use of Amos 14. Then, SPSS 21 was used for the moderated regression tests. Lastly, simple slope analysis was performed to assess the interaction effect. Table 1 presents the results of CFA. The average variance extracted (AVE) values are above the criterion of 0.50, and all of the composite reliabilities (CR) were well above the criterion of 0.70. Hence, it can be concluded that there is discriminant validity among the theoretical constructs. Additionally, none of the squared correlations were equal to or higher than the AVE for each individual construct in the model (see Table 2). The model fit indices results also showed good/acceptable fit. Taken together, these results indicate that the theoretical constructs exhibit good psychometric properties.

Moderation test: interaction effect of coercive and reward power and relational capital

The data were examined using moderated hierarchical OLS regression techniques, with the results being presented in Table 3. Model 1, a base model, includes only the control variables, while Model 2 adds buyer–supplier mutual perception of relational capital (MRC) as an independent variable. In Models 3 and 5, the main effects of mutual perception of relational capital and buyer’s use of coercive power (MCP) and of reward
power (MRP) are included, respectively. In Models 4 and 6, the variables for interactions between mutual perception of relational capital and buyer’s use of coercive power (MRCxMCP) and between mutual perception of relational capital and buyer’s use of reward power (MRCxMRP) are shown. From the results of moderated regression tests, support was found for H1 and H3, which indicates the positive impact of relational capital on disruption recovery performance (β = 0.758, p < 0.001), and the positive moderation effect of reward power on the relationship between relational capital and disruption recovery performance (β = 0.150, p<0.05) respectively. However, H2 was found to be not significant, thus providing evidence of no moderation effect of coercive power on the relationship between relational capital and disruption recovery performance (β = -0.230, n.s).

</table>
To probe these moderated effects further, interaction effects were plotted and found to be significant (H3) for high and low levels of reward power. High and low values have been defined as plus and minus one standard deviation from the mean (Cohen and Cohen, 1983), with Figure V illustrating these effects. First, high levels of mutual perceived reward power is shown to positively reinforce the relationship between mutual perception of relational capital and disruption recovery performance, as supported by a significant simple slope calculation ($\beta = 1.133, p < 0.001$). Low levels of reward power also have a significant effect ($\beta = 0.403, p < 0.05$). Hence, support is found for H3 relating to the positive moderating effect of a buyer’s reward power on the relationship between relational capital and disruption recovery performance.

![Figure 2 – Relational capital and disruption recovery performance by reward power](image)

**Conclusion**

This study explores the role of buyers’ use of coercive and reward power in moderating the efficacy of relational capital in disruption response and recovery performance. Our findings indicate that a buyer firm’s use of reward power towards a supplier has a positive interaction effect with relational capital on disruption recovery performance. However, a buyer firm’s use of coercive power was insignificant. That is, by mitigating the fear of opportunism in the relationship, reward-based power complements the ability of relational capital in a disruption situation, thereby motivating a supplier to engage more in resource reconfiguration and collective action in achieving timely disruption recovery. This finding is in line with the previous research on the complementary relationship promoting role of reward-based power (e.g., Ireland and Webb, 2007; Zhao et al., 2008). Conversely, a buyer’s punitive approach to influence a supplier to go along with its wishes...
is ineffective. This suggests that power should not be used exploitatively or coercively even in an urgent situation such as in a disruption situation, and indicates that reward-based power can complement the ability of relational capital in the disruption response and recovery context.

Our research can contribute to the body of supply chain management literature in three ways. First, this study captured both the buyer and the supplier’s perspectives. The use of matched pair data allows for more comprehensive insights into how timely response and recovery can be achieved through the use of the parties’ relationship and influence mechanism than is possible with a one-sided examination. Additionally, the results not only contribute to understanding the dyadic nature of exchange relationships in the supply chain, but this approach also reduces the possibility of single rater bias, such as an exception fallacy (Roh et al., 2013). Second, as it is impossible to completely prevent supply chain disruptions, paying attention to the disruption recovery phase is essential in supply chain risk management studies. However, relatively little attention has been devoted to this stage (Sodhi et al., 2012); not many studies have empirically examined how organisations can effectively recover from disruptions; and the speed of disruption response and recovery is rarely investigated. Hence, this empirical study can shed light on a relatively unexamined area. Lastly, our research is one of the first studies to examine the interaction effect of buyers’ coercive and reward power and relational capital in the context of supply chain disruption. Although a number of studies have suggested relational capital’s collective action and resource coordination promoting role in uncertain situations, such as a supply chain disruption situation, and it can be enhanced or lessened by the dominant party’s use of power, very few studies to date have investigated the application of power in relational capital. From this, this study can suggest an appropriate theoretical framing to understand this barely investigated area.

Abstract

This paper discusses the social risk supply chain management through a case study in a Brazilian company. We map the social risks and the main consequences of these risks tracked by the organization. By comparing the findings of the case study with the literature, the paper contributes to the academic studies with 2 new social risks, the main consequences of these risks, and the description of the company's strategy to manage its risks.

Keywords: Social Risk, Risk Management, Case Study.

Introduction

Academic researches in supply chain risk management (SCRM), in general, address the risks that occur due to interruption at some point in the chain, which later blocks the flow of materials, funds or information among the entities of the supply chain (Bode et al., 2011). Therefore, they approach the traditional view of SCRM, with the focus on avoiding interruptions along the chain to reduce financial losses that this disturbance can cause (Bode et al., 2011; Hofimann et al., 2014).

The risk management literature is diverse, but researches on financial risks have been studied for a longer time and have greater repercussion due to significant economic changes for organizations. However, this classical approach focused on financial performance does not consider the social view to be purely economic (Busse, 2016).

The social risks started to gain academic attention with the introduction of the concept of Triple Bottom Line (Elkington, 1994). Nevertheless, research on the social risks in which the supply chain of a company may be involved is still needed (Tang, 2018). Basta et al. (2018) also argue that when addressed, social risks are mostly
limited to labor rights and working conditions.

Therefore, the present paper aims to study the social risks in supply chains through a case study answering two research questions:

(i) The social risks and consequences found in academic literature are found / relevant also in a business enterprise?
(ii) What strategies does the company use to manage its social risks?

The case study considers a Brazilian company of Cosmetics, involved in the manufacture, industrialization, distribution and sale of cosmetics, fragrances and personal hygiene products. We compare and validate the results of the case with the list of 24 social risks and 13 consequences proposed by Cunha et al. (2019).

The remainder of the paper is organized as follows: Section 2 addresses the case study methodology. Section 3 presents the results and discussion of the case study, followed by a section presenting the concluding remarks and suggestions for future research.

Research Methodology

The present research adopted the case study methodology proposed by Yin (2013), composed of six steps: plan, project, preparation, collection, analysis, and sharing.

The plan aims to identify the relevant situation for the accomplishment of the case study in detriment to other research methods. Thus, the event to be studied within the context of real life is the management of social risks in supply chains.

We present a unique case as an exploratory study of a theme little covered by the literature. The present research considers common case study to capture the circumstances of a daily situation to provide processes related to some theoretical interest.

The project was carried out with a Brazilian company of Cosmetics recognized for its vision of sustainability, the principle of generating positive impacts on society and for being an organization that combines economic growth with the promotion of social and environmental well-being. The research question compares the social risks and the consequences that these risks can generate for a company covered by the academic literature with what is observed in a supply chains of a real company. The criteria for data interpretation to actual data that can reinforce, complement or contrast with the results derived from the academic literature to bring new insights to the strategies to mitigate these risks.

In the preparation stage, we developed the case study protocol, defining candidates, selecting the final case to be studied and synthesizing the initial definitions of the study.

Data was collected through documents made available by the company, interviews, and secondary documents from the internet. First, the professionals of the studied company answered an online questionnaire. This questionnaire was based on Cunha et al. (2019) and made available to respondents through the SurveyMonkey platform. Then, we conducted face-to-face interviews with open questions based on answers previously reported by company professionals. Finally, we compiled documents made available by the interviewees and secondary materials available on the website of the company studied.

The professionals considered in these interviews effectively deal with the risks of the company, and are: (i) the Supply Manager, responsible for Performance
Management and Relationship with Suppliers; (ii) the Audit Coordinator of Supply Management, and (iii) the Compliance Coordinator.

The data analysis considers the pattern matching technique, in which the theoretical reference is used as prognosis and compared with the results of the case study.

Finally, the sharing stage consists of the publication of the present paper.

**Results and Discussion**

The company's mission is to promote well-being through the mobilization of a network of people capable of integrating scientific knowledge and the sustainable use of the rich Brazilian botanical biodiversity, in order to deliver the cosmetics manufactured from natural elements of the Brazilian flora, processed, distributed and sold.

Through the online questionnaire, it was possible to understand that the company has three areas responsible for its risks, namely: (i) the Supply area, which deals with risks related to suppliers; (ii) the legal and Compliance area, an area concerned with issues related to labor laws, including the risks of corruption and bribery; (iii) the area of Corporate risks, encompassing other risks.

Through the interviews, it was possible to understand that the Brazilian cosmetic company has means of identifying social issues present in its supply chain through an audit carried out periodically by the company, through a complaint from one supplier over another (which has already occurred with a textile supplier), and through the media.

The interviewees stated that the company has a list of risks predefined by a multidisciplinary group (encompassing area of supplies, risk management, legal area and relationship with suppliers), which is reviewed every two years and serves as the basis for the supplier's audit checklist.

Among the 24 social risks found in Cunha et al. (2019) and listed for the interviewees, 11 of them are not on the list of pre-defined risks to be audited for the studied company, these being: unfair or low wages, although the same worries about workers' compensation however, it still cannot reach the level of detail of the amount paid by its suppliers to employees; access to drinking water; access to basic sanitation; unfair compensation; reallocation or rupture of indigenous peoples; exposure of communities near the end of activity; unavailability to public facilities; expropriation; exposure to unemployment; reallocations without explicit grounds and equality before the law.

Some of the social risks present in Cunha et al. (2019) do not fit directly with the area of cosmetics addressed. However, some risks such as low or unfair wages, exposure of communities close to the end activity and unavailability to public facilities are suggested as possible risks to be added to the list of social risks to be audited as they can cause significant damages to the company.

The respondents added two social risks to the list of Cunha et al. (2019): Corruption and Bribery and Compliance with Local Labor Legislation. Corruption and bribery should be added to the list presented in Cunha et al. (2019), as they may create critical social risks. For example, if the money destined to the aid of an Amazon community is diverted, the community will not receive the necessary assistance and may trigger various social risks. However, concerning local labor legislation, this risk applies to the cosmetics company studied because its suppliers
are within the Brazilian territory. If the company has suppliers located outside Brazil, the law to be followed should be the one proposed by the International Labor Organization (ILO, 2017).

Besides the company's identification of the social risks found in the academic literature, the developed questionnaire also addressed the consequences that these risks could bring to the company.

Regarding the consequences presented in Cunha et al. (2019), those that appear most frequently in the questionnaire are the damage of the company's reputation, the risk of operational stops, individual claims or collective action and payment of mandatory compensation by the court. The profit reduction consequence was mentioned only twice which demonstrates that the company has a social concern that goes beyond the financial consequence that these risks can cause.

In addition to the two respondent areas of the online questionnaire, the Audit Coordinator explained the process in more detail during the interviews. As strategy to manage the social risks that may be present in its supply chain, the company performs two types of audits, one related to the new suppliers and another related to the contracted suppliers of the company.

The main objectives of the Audit process for the company are to mitigate risk of shortages of products, to protect the company's image and the integrity of employees, contributing to the maintenance/obtaining of certifications and awards which guarantee brand value, and to integrate company beliefs and values into the supplier relationship network, ensuring the development of the value chain.

The audit process takes place through a checklist questionnaire answered by direct suppliers. According to the criticality of the supplier, audits take place at one-year intervals (most critical suppliers) to five years (less critical suppliers). The company studied has a partnership with eight different companies that perform around 300 audits per year with their suppliers. The companies to be audited are defined by the company studied, and the process of auditing the suppliers happens with a marked date, that is, without surprise for the suppliers.

The checklist is based on six pillars: Quality, Environment, Health and Safety at Work, Legal Requirements, Code of Conduct, and Social Responsibility. In this way, the supplier can be classified into three groups: (i) approved; (ii) approved with restrictions, where the supplier is still able to sell, but must adapt within 3 months with the requirements demand in a corrective action plan; (iii) Disapproved, where the supplier will not be able to supply. The corrective action plans are individual and depend on the responses of each supplier. Some items make suppliers automatically disapproved, such as: forced or compulsory labor, child labor, environmental requirements, legal noncompliance, non-compliance with benefit payment rules, non-compliance with health and safety standards, and corruption.

### Conclusion

The case study answered two research questions. The first one was answered as several social risks found in the literature coincide with the social risk monitored by the studied company. However, it became clear that social risks vary according to the area in which the company operates. Therefore, risks related to areas of construction, mining or oil and gas may or may not refer to the risks present in the area of cosmetics.

The second research question encompassed the strategy used by the company
to deal with its social risks. Cunha et al. (2019) presented the strategies in a general manner, whereas in the case study the process of supplier auditing was discussed as the strategy used by the company to manage social risk in its supply chain.

In this way, the main contribution of the paper to bring new insights to the academic literature through comparison between a real case and the results from Cunha et al. (2019). The social risks found by the academy may be included in the social supply chain management of the company. On the other hand, we demonstrate that the business environment brings updates back to the academy.

As future research, more case studies should investigate other supply chains, highlight disparities in relation to the private and public sector, and explore different types of organizations as well as different organizational areas, such as oil and gas, mining, construction, cosmetics, and textiles. Additional studies may also focus on the importance of stakeholders and their social risk management actions and other social risk management strategies.

Abstract

Our study examines supply chain resilience (SCRES) building stages and the role of supply chain integration (SCI) in relation to natural disasters. As such, two specific storms in the State of Queensland (QLD), Australia and their impact on eight supply chains (SCs) were studied. The findings explain the nature of practices exercised by the affected case companies, associated with each stage of the SCRES building. Correspondingly, we also elaborate on the SCI behaviour of these case companies. We, therefore, contribute to the SCRES theory and practice by unpacking the role of SCI in face of natural disasters and inductively capture additional practices that altered within SCRES building stages.

Keywords: Supply Chain Resilience, Natural Disaster, Supply Chain Integration

Introduction

Natural disasters are becoming more frequent and more severe (Ronnenberg et al., 2017). In addition to this, area affected by natural disasters is growing and financial damage they cause to businesses increased from approximately $50 billion (USD) loss during the 1980’s to $250 billion (USD) in losses in the last decade (UN, 2015). Moreover, 21st century natural disasters are recognised to be less predictive and more difficult to manage because of the cascading and prolonged effect (Corey & Deitch, 2011; Lawther, 2016; van der Vegt et al., 2015). For example, Tohoku earthquake and tsunami severely disrupted the automotive industry in 2011 (Matsuo, 2015) and superstorm Sandy caused breakdowns of infrastructure in multiple countries in 2012, with $75 billion of economic damage (Sales et al., 2012; WEF, 2015). In Australia, the most common natural disasters are tropical cyclones, floods and landslides, hailstorms, bushfires, heatwaves, and drought. These natural disasters have costed Australian economy $18.2 billion (AUD) annually in average, which represents 1.2% of average Australian Gross Domestic Product (GDP), and this cost is expected to increase and reach double value by 2040 (IAG, 2017; Handmer et al., 2018; Ronnenberg et al., 2017). With natural disasters
affecting organisations all over the world, resilience toward natural disasters is a subject of urgent research (van der Vegt et al., 2015).

Resilience has been defined as ability of company to bounce back after disruption to even improved state, and sustain operations during it (Tang, 2006). However, organisations do not operate independently, they function as part of SCs. Therefore, SCRES includes capability of SC to prepare for disruptive events, respond to it, and recover from it with continuity of operations maintained (Ponomarov & Holcomb, 2009). This definition recognises three SCRES building stages, namely Preparation, Initial Response, and Recovery, while later literature introduces a fourth stage i.e. Mitigation which relates to the identification and application of SCRES building processes and improvements (Scholten et al., 2014). However, there is limited research examining micro-foundations of SCRES building across the above-noted stages.

Consequently, we utilise structural contingency theory to examine SCRES building stages and SC practices that vary during these stages, drawing on findings from our investigation of two damaging storms in the State of QLD, Australia. In this regard, we focus on SCI practices of affected organisation and their SCs in sake of understanding their journey towards SCRES building. Our research design is based on multiple case studies drawing on semi-structured interviews and archival data. The paper is structured as follows: First, we review the literature on contingency theory, SCRES, and SCI; next, research methodology is presented, followed by research results and discussion; the paper finally summarises contributions and outlines future research.

**Literature Review**

**Contingency theory**

Contingency theory stands for custom made approach in management, depending on circumstances one SC faces (Lawrence & Lorsch, 1967). It also applies reductionist approach, where SC is built from different organisations, and each organisation is composed of different departments. Consequently, the environment in which SC operates will dictate structure of SC and organisations, and processes that take place between them.

Structural contingency approach explains that SC needs to align its goals to circumstances from the environment (Drazin & Van De Ven, 1985; Flynn et al., 2010; Sinha & Van de Ven, 2005). SC that faces natural disaster, will have to shift its goals and adjust its strategy. Goals will have to be changed from everyday profit increasing to reduction of financial losses, and from customer value creation to simple SCRES related goals, such as trying to keep operations ongoing, or try to re-establish operations. The alignment between changes in structure and processes and newly established goals in natural disaster environment are described as “fit” in work of Drazin and Van De Ven (1985). This indicates that SCs will seek for alterations in relationships and strategies in order to reach “fit” with newly occurred natural disaster as environment they operate in.

**SCRES building**

Nearly two decades of operations and supply chain management (OSCM) research resulted in multiple different frameworks of resilience building. Presence of different approaches in structuring SCRES building, different number of stages, and interchangeable utilization of terminology, indicates that additional research is needed in order to select or adapt one of existing setups (Pettit et al., 2010). Relying on structural contingency approach in this study, we recognised the common attribute of developed structures that consider natural disaster as contingency include stages before, during and after natural disaster, with additional stage of reflecting and improving, introduced by Scholten et al. (2014). Therefore, the present study applies SCRES building model, that includes four major stages, as follows: Preparation, Initial Response, Recovery and
Mitigation. Preparation stands for establishment of an emergency team, analytics of capabilities and potential hazards, and development and implementation of a safety, contingency and other plans (Henstra, 2010). Initial response is the first response after acknowledging immediate proximity of disaster, in the moment when disaster affects SC, or immediately before that moment. Safety is evaluated and security measures for life and property are applied (Henstra, 2010). The third step, Recovery, is applied after immediate danger of disaster has passed. Recovery plans are implemented, continuity of management ensured, and employee support is maintained. Mitigation is launched after recovery, and this stage includes identification of mitigation opportunities and continuous improvement plans. This step feeds Preparation step with necessary insights. However, practices conducted in these stages might differ depending on effect of natural disaster on specific company. While directly affected company will have to perform multiple safety related practices in Initial Response stage and invest additional effort in Recovery stage, just to be able to restart operations, indirectly affected company has no need to conduct emergency evacuation or safety plans, or rebuild.

SCI
SCI present strategical collaboration between organisations in SC and internally, in the organisation, with goal to provide maximum value to customers (Zhao et al. 2008). It consists processes that link SC organisations, including information exchange, integrated operations and strong relationships (Frohlich & Westbrook, 2001; Leuschner et al., 2013). However, one must wonder, what happens to SCI when the goal to maximise customer satisfaction or to facilitate connections between SC processes is changed? Does SCI differ when goal of profit-making is delayed on the priorities list and simple minimization of financial losses is prioritised, and goal of providing any product or service at all is prioritised over increasing customer satisfaction? This shift in final goal of SCI practices might alter practices completely.

In addition, structural nature of contingent approach is applied in terms of recognising different SCI orientation and SCI type. Contemporary OSCM literature distinguishes SCI into two broad clusters based on its orientation – internal SCI and external SCI (Das et al. 2006; Flynn et al. 2010; Schoenherr & Swink, 2012). While external SCI plays significant role in relations between companies and summarised effort invested in reducing spread of consequences of disruption on entire SC, internal SCI focuses on single company and questions how departments in that company functioned together while building SCRES. In addition, SCI with buyer and with supplier are distinguished as two separate orientations in external SCI and some other stakeholders SC’s operations depends on, might become important for recovery of SC.

Literature identifies three types of SCI, namely, informational, operational, and relational (Leuschner et al., 2013). Informational SCI consist of information exchange, knowledge sharing, and communication. Operational SCI comprise of creation of joint practices and work processes, sharing resources, coordination of teams, collaboration on joined goals, and all supporting processes needed for that operations to be successful. Relational SCI refers to strategic partnerships and long-term orientation, it requires higher level of trust between parties and includes social bonding, and genuine understanding between parties. If two companies have close relationship they will make joined decisions faster and coordinate their activities, to build SCRES in more efficient manner. In accordance with discussion above, the study focuses on following Research Questions:

RQ1: “How do practices of SCRES building stages differ across different companies, based on impact natural disaster has on specific company in the affected SC?”

RQ2a: “How SCI orientation and type vary during different SCRES building stages (with buyers, suppliers and internally)?”
RQ2b: “Which other stakeholders are important for SCs to build their SCRES?”

RQ3: “Are there any other practices that might simplify or proliferate SCRES, building, beside SCI?”

RQ4: “How will meaning and measurement of SCRES differ in SCs depending on disaster’s effect?”

Research methodology

The qualitative research design is used due to the complexity of the issue under investigation and exploratory nature study. Publicly available documents include reports and statements that contribute to the knowledge considering natural disasters’ effect on communities and government, and their experience and response. However, amount of data available on companies’ experiences and response is scarce. Therefore, the research is designed as multiple case study including direct interviews with SC managers. In addition, publicly available governmental, scientific and media reports are examined.

As part of a larger study examining resilient SCs, this paper examines two specific storms and their impact on eight SCs. Semi-structured interviews with SC managers of four different SCs per natural disaster are conducted. The industries varied from food production to transport and logistics (T&L)(Table 1). Secondary data examination is performed, including government documents, emergency services reports, satellite imagery, previously published research, news articles and audio-visual material. These were analysed to better understand the overall impact of disasters utilizing thematic analysis (Eisenhardt et al., 2016; Yin, 2009).

Interviews

With purpose to grasp companies’ experience with and response to natural disaster, this study used a purposive sampling method (Creswell, 2013). Only companies, members of SC that faced tropical cyclone (TC) Tasha and TC Marcia and their prolonged effects were selected. The unit of analysis is organization and its practices associated with SCRES, since this enables evaluation of SCRES as good practice on the one level of the SC replicated on the higher level (van der Vegt et al., 2015).

Total duration of all 8 interviews is 4 hours and 51 minutes. When saturation is reached, interviews were terminated (Hinkin, 1995; Lee, 1999). Interviews were conducted in person, using telephone, or skype conversation, from 21st August 2017 to 26th October 2017. All participants were male, currently holding middle or senior management position and performing a role of SC manager, in SCs during their response to effect of Tasha or Marcia. Transcripts were analysed using thematization process in excel and NVivo software. Table was generated for overview of all interviews with

Note: T&L = transportation and logistics

As part of a larger study examining resilient SCs, this paper examines two specific storms and their impact on eight SCs. Semi-structured interviews with SC managers of four different SCs per natural disaster are conducted. The industries varied from food production to transport and logistics (T&L)(Table 1). Secondary data examination is performed, including government documents, emergency services reports, satellite imagery, previously published research, news articles and audio-visual material. These were analysed to better understand the overall impact of disasters utilizing thematic analysis (Eisenhardt et al., 2016; Yin, 2009).
themes listed and codebook was developed following Lee’s (1999) and Van Manen’s (1990) guidelines. Overarching themes were identified, followed by underlying codes. Validity and reliability of data collection and analysis was evaluated relying on Yin (2009), Creswell (2013) and Bals and Tate (2018). For interviewing process specifically, Creswell (2013) was followed, all interviews were transcribed and enriched by notes, while increasing transferability. Guided by Kvale (1996, pp. 133-135) initial set of question included structured questions, as well as open-ended questions that were followed-up with additional questions when elaboration or confirmation of correct meaning capturing was needed. Additional sources, such as publicly available web sites of the companies, as well as interviewees’ Linked In profiles, were used to compare information (Yin, 2009).

Secondary data
Two natural disasters, TC Tasha and TC Marcia with their prolonged effects, were reconstructed in order to understand their overall impact and impact on SCs. In addition, secondary data was enriched by interviewees’ insights that referred to disaster description and impact. Collected secondary data was coded for overall description of natural disaster, and impact on QLD businesses and infrastructure. In total, 33 documents per each storm were included in analysis, documents referring to Tasha included interviews and statements from 25, and documents referring to Marcia included interviews and statements from 33 government officials, experts, and managers.

Discussion of findings
Natural disasters’ reconstruction and impact
TC Tasha was category 1 cyclone that formed on 24th December 2010 and dissipated 2 days later. It made landfall on early morning on Christmas Day 2010 (local time), near Cairns, QLD, about 1,400 km north from Brisbane. TC Marcia formed on 15th February 2015 and dissipated 14 days later. It was a category 5 superstorm, and it made landfall on the morning of 20th February 2015 (local time) in Shoalwater Bay near Yeppoon, QLD, about 500 km from Brisbane.

Although TC Tasha made landfall much further form QLD capital, affected the area with weaker winds and dissipated just 2 days later, the impact of this TC and its’ prolonged effects was more severe than TC Marcia’s impact. The reason for unexpectedly different effect of two storms lies in contingencies. Storms collided with additional events and had prolonged effects in terms of rain and floods. As a result of this TC Tasha directly affected QLD for 23 days and TC Marcia’s direct effect lasted just 4 days, when floodwaters withdraw, and Marcia went offshore and weakened. TC Tasha caused 35 deaths while there is no death related to Marcia. In addition, scope of TC Tasha was significantly larger than Marcia. Tasha directly affected 42 out of 77 local government areas in QLD, while Marcia affected less than half of that, only 17 local government areas (as presented on the Error! Reference source not found.). Consequently, over 10% of business in entire Australia were affected by TC Tasha, while TC Marcia had much smaller effect. Insurance Council Australia (ICA) published that commercial losses during Tasha reached $4 billion (AUD), while during Marcia they were $139 million (AUD). Infrastructure damage occurred in both storms, however, damage and power outages during TC Tasha were more significant. Tasha caused road damage on length over 19,000 km, and some roads were closed for 3 weeks, while TC Marcia caused road closure for 3 days and length of damage roads was 1,000 km. The contingencies that shaped disasters’ effect were not predictable, as well as duration or direction of storms. Since majority of natural disaster related attributes are not known before they occur, the
only approach to improve understanding of SCRES is through companies’ experience and response.

SCs response
The first step of interviews’ analysis was structural visualisation of SCs and effect of storms on them. Table 2 presents structure of SCs included in the analysis with directly affected part of SC marked with red circular shape, indirectly affected part marked with red arrow, and position of interviewed company in SC is marked with blue circular shape.

RQ1: “How do practices of SCRES building stages differ in different companies, based on impact natural disaster has on specific company in the SC affected?”
All SC managers except scT4 were able to describe Preparation stage in building SCRES and confirmed preparation plan has been developed and emergency team pre-established. The difference in this SCRES stage were spotted in terms of different management level of participants of emergency team and complexity level of preparation plan. Emergency teams in companies varied from purely local engagement with notification of upper management to inclusion and physical presence of top management on the location, such as: “We have a plan there for us that outlines the things that we need to do...” when interviewee indicated plan is outlined for local members of the team, and “That includes
sales people, includes SC people... Directors and heads of different divisions and
includes senior leaders...” Preparation plans varied from simple plan that instructed
stock amounts “It comes to planning, the buffering, understanding when those events
occur and planning for them” to complex risk evaluations and preparation plans, such as
“We have multiple emergency, safety and other plans developed. They are location and
natural disaster specific...”. In Initial Response phase opportunistic operations were detected, just before natural
disaster occurred “We continued shipping ... we tried to recognise as much revenue as
we could. [Even] when we stopped shipping we continued processing orders”. In
addition, directly affected scT1 supplier invested time to evaluate safety and conduct
emergency procures and evaluate strategies and damage later “The first reaction always
is the safety of the people involved. The second thing obviously is look at the crop
damage” while indirectly affected companies started evaluating strategies and potential
damage immediately “First reaction was” What is the level of cyclone?” ...then “Where
is it going to hit” ... we do an assessment of potential business impact... we decided to
continue to ship...”. ScT4 was not able to complete Recovery stage, and SC manager explained effect of
natural disaster being direct – in terms of partially flooded facilities and indirect in terms
of organisations in the same SC being unable to complete payments since they have
bankrupted “We were able to make deliveries but no one was ordering ... because their
stock was destroyed.... they just wouldn’t physically be able to pay”. All other companies
described cleaning and repairing in case they were directly affected and later on, re-
establishing operations and streaming towards full capacity of operations.
Mitigation stage was described in terms of learnings that bring upgrade to plans “You
get these events, execute them [plans], and then come back with the learning of those
events so that you improve upon each time.”. However, companies interviewed from scT3
ands scT4 were not able to identify any Mitigation activities. This may occur since scT4
has never recovered completely and scT3 manager’s position is in middle level
management, so he might be unaware of top management decisions and plans upgrade.

RQ2a: “Will SCI orientation and type differ during different SCRES building stages
(with buyers, suppliers and internally)?”
SCI was uniformly recognised as important enhancer of SCRES building. During
Preparation stage SC managers focused on communication in building preparation plans,
and communicating preparation plan among employees, indicating increased Internal
Informational SCI, “We already have mitigations in place, in terms of those risks. People
are aware of those plans. They are communicated.”. Managers highly emphasized
importance of Internal and buyer SCI, in terms of all three types, while describing Initial
Response stage. This included Informational SCI “Internal communication was critical.
Being able to have full visibility of all of our orders. ...”, Operational SCI “Each of
different teams can integrate. They can come together, as a working group very quickly,
formulate a plan and execute it...”, and Relational SCI “We communicated with
understanding... we know each other for 20 years... people are working together ...”. When describing Recovery stage, SC managers were again highly focused on Internal
and Buyer SCI in all three types of SCI, namely Informational “It’s about being seen and
having that [informational] transparency...”, then Operational “Bring extra capacity,
extra people, extra trucks.”, and Relational “Being able to work very closely with them,
very closely...”. In Mitigation stage, only Internal Informational SCI was emphasized
“You keep capturing that knowledge...you can use it year after year...”.

RQ2b: “Which other stakeholders are important for SCs to build their SCRES?”
SC managers described SCI practices with governmental organisations and community
as part of SCRES building. They emphasize importance of SCI with government and community especially during Initial response stage, such as “Basically, the approach was liaising with emergency services, liaising with bureau of meteorology to see which areas we need to focus on to put controls in place...”, or “We communicated with local communities in order to put clear instructions where to go...” and during Recovery stage “Government coordinated movement of goods [in affected area] and we were in constant contact with them in relation to that” and “We made sure local communities get supported in terms of us delivering sufficient quantities to local stores. People needed our support...”, where interviewee implicates comprehension of joint recovery of SC and community. In addition to this, multiple secondary data documents announced call for industry to conduct integrative practices during Preparation and Mitigation stages, such as Authority of the Senate (2015). Parliamentary debates - Senate Official Hansard., MacKenzie, I. S. (2015). 2015 Callide Creek Flood Review (T. S. o. Queensland Ed. Vol. 1). Brisbane, QLD: Office of the Inspector-General Emergency Management, and DILGP. (2015). Severe Tropical Cyclone Marcia. Brisbane, QLD: The State of Queensland - The Department of Infrastructure, Local Government and Planning, as well as many other reports after 2015. However, the matter of additional SCI orientation was inductively captured, therefore collected data did not allow further analysis.

RQ3: “Are there any other practices that might simplify or proliferate SCRES, building, beside SCI?”

Trust was inductively captured during Initial Response and Recovery stages. SC managers highly emphasized trust in relationships internally, within company “It’s the right thing to do, it comes back to values... Allow people to treat themselves as human, as part of a big mission, not just a number ...” and “We also need them [truck drivers] to trust us and we [managers in T&L company] trust them on reporting back...”, and in relationship with buyer “...put efforts and trust it will have the best outcome, to trust each other competencies and word.” Trust with T&L supplier was mentioned moderately in terms of its’ importance for SCRES building “... there's something to be said for developing long-term relationships with carriers who can obviously help you out during those events... You have to have that stronger bond.”, and in terms of luck of trust with T&L having negative outcomes for SCRES “I would call it scavenging nature of freight...”. 

RQ4: “How will meaning and measurement of SCRES differ in SCs depending on disaster’s effect?”

When speaking about SCRES in terms of direct effect of natural disaster, SC managers referred to re-establish operations as soon as possible as a primary goal. Only after operations restarted, SC managers explained their focus shifting to reach full capacity of operations, and after that, they paid attention on reduction of financial losses. In the times of natural disaster, financial concerns were not the first goal, however, when goals to operate and operate with full capacity were reached, financial issue was addressed. Eventually, when operations are established in full capacity and financial losses are minimised, companies return to everyday goals of profit and customer satisfaction. When describing indirect effect, managers described alterations in operations modes and capacity and primary goal to establish previous operations capacity, with minimisation of financial impact, together. In addition to this goal pattern seems to be shifted just before the impact of natural disaster. During preparation phase and even initial response stage, some SC managers did opportunistic shipping and producing, in order to generate more profit and recover faster, later on. However, as soon as disaster has impacted SC, this goal was shifted to reestablishment of full capacity operations and minimisation of financial losses.
Summary
The study finds practices conducted during SCRES stages differ between different companies. In addition, practices of SCI and trust in relationships are different in different SCRES stages. This indicates that importance of SCI and trust varies, with SCI importance for SCRES building differing in terms of orientation and type. The literature did not offer much on this topic, with only few studies examining overall importance of collaboration for SCRES (Fayezi, et al., 2010; Scholten et al., 2015; Van del Adel et al., 2018). Moreover, results indicate that trust might be influencing SCRES which was not previously linked with SCRES in OSCM literature.

In addition, findings indicate SCI practices should include governmental organisations and community, in addition to internal, buyer and supplier SCI, which is consistent with disaster management literature (Zhang, Lindell, & Prater, 2008), but haven’t yet been applied in OSCM literature.

In accordance with van der Vegt et al. (2015) implications, economic insights, and economical efficiency of building SCRES was important to SC managers, but only after operational gals. This indicates that immediate proximity of life-threatening situation for directly affected companies caused prioritisation of operational and delaying financial goals, while SC managers that haven’t faced immediate life and property threatening situations, kept finances in their mind as a goal. However, financial goals under natural disaster as environmental contingency were not oriented toward profit gaining, they were completely oriented toward reduction of losses.

Conclusions
We make a significant contribution to our understanding of SCRES through in-depth examination of SCRES building stages. In addition, application of structural contingency theory is broadened in the area of SCRES in relation to natural disasters, and the nature of traditional SC practices under natural disaster contingency.

This study also integrates two research areas namely OSCM and disaster management that have not been combined in this context before, with purpose to answers existing ambiguity in the body of literature, indicating that risk analysis and preparation plans might be insufficient for SCRES building, but additional alterations of SC practices must be performed.

Study inductively identified SCI with government and community as important enhancers of SCRES, as well as trust within company and between organisations in SC. Practical implications in following these suggestions could be established.

Future research
Future studies might build on the present study trough building and testing model that presents relation between trust, SCI, and SCRES in the context of natural disasters. That model can be tested in a quantitative study. In addition, some of the findings were captured inductively, such as SCI with government and community, and trust between companies and within company being important for SCRES building. Therefore, the deeper understanding is needed in future research. In addition, the sample of 4 SCs per natural disaster are not generalizable and generalizability is suggested for the future studies.

Abstract

The present paper explores the environmental risk supply chain management through multiple case studies conducted in three Brazilian companies. We compare the literature findings with the business reality, bringing insights on how environmental risks are managed by industries and their supply chains, what the potential losses perceived by companies are and the strategies adopted to hedge against them. The case studies’ findings show that most of the risks found in the literature were considered by the companies and that two environmental risks highlighted by one of the companies can be added to the academic list.

Keywords: Environmental Risk Management, Supply Chain Management, Multiple Case Study

Introduction

Risk management is one of the most significant challenges faced by supply chains (Torres-Ruiz and Ravindran, 2018). Risks occur due to an interruption at some point in the chain, which successively clogs the flow of materials, funds or information among the entities of the supply chain (Bode et al., 2011). Global competition and outsourcing render supply chains more exposed to disruptions caused by several factors, such as uncertain economic cycles, consumer demands, natural and man-made disasters (Torres-Ruiz and Ravindran, 2018) and adverse environmental impacts (Levner and Ptuskin, 2018). Furthermore, supply chains are more vulnerable to stakeholder scrutiny, which might generate vulnerability to reputation damage (Christopher et al., 2011; Hofmann et al., 2014; Valinejad and Rahmani, 2018), access to capital and to regulatory compliance (Torres-Ruiz and Ravindran, 2018).
This paper focuses on environmental risks and presents a multiple case study on the topic, since the increase of diversity and the grow of the supply chains sizes, highlighted the importance of the environmental concerns in supply chain risk management research (Levner and Puskin, 2018), and the literature on supply chain risk management has largely overlooked ecological and social issues in their operations (Hofmann et al., 2014).

As suggested by Oliveira et al. (2019), case studies should be conducted across different companies in order to strengthen the practical field of environmental supply chain risk management and form a basis for comparability between academia and practice. Thus, in order to compare, validate and add new evidence to the findings of Oliveira et al. (2019), the present research aims to explore the environmental risks, the stakeholder effects and the consequences to the companies, as well as the environmental strategies adopted, by conducting multiple case studies across three large companies located in Brazil. The companies, here designated as companies A, B and C, are respectively a petrochemical company, an air compressor manufacturer and an agrochemical biotechnology company. More specifically, this paper aims to address the following Research Question (RQ): Are the environmental risks, consequences and environmental strategies found in the academic literature also found/relevant in a business reality?

The following section outlines the case study methodology adopted for this study. The results achieved through the conducted case studies are presented and discussed in Section 3. Section 4 presents the concluding remarks and suggestions for future research directions.

Research Methodology

The present research adopts the case study methodology proposed by Yin (2001), composed of six steps: planning, project, preparation, data collection, data analysis and sharing.

The planning intends to evaluate the relevant situation for the development of the case study in contrast to other research methods, justifying the choice of the case study method. Yin (2001) clarifies that the case study intends to investigate a contemporary phenomenon within its real-life context, particularly when the boundaries between phenomenon and context are not clearly defined. Thus, the case study method meets the need of this research which is to analyse environmental risk management in supply chains, since it uses several sources of evidence, and does not have a clear definition of the boundaries between the phenomenon to be studied and the context of the real life in which it is inserted.

Hence, the phenomenon to be investigated within a real-life context is the management of environmental risks in supply chains, addressing the consequences that these risks may generate for the organisations and the strategies adopted to hedge against these risks.

The project aims to elaborate on the research question, define the case study project (single or multiple) and define the criteria for interpreting the findings (Yin, 2001). Therefore, the main question of this study is centered around comparing and validating the environmental risks, consequences, and strategies proposed by Oliveira et al. (2019), with the real-life situations, observed and applied in the supply chains of three large companies located in Brazil.

Cauchick and Souza (2012) elucidate that, in the single case study, it is
expected that there will be greater depth in the investigation and less capacity of
generalisation. On the other hand, in multiple case studies, there is a possibility of
greater generalisation, with perhaps less deepening in the evaluation of each case.
According to Herriott and Firestone (1983), the evidence resulting from multiple
cases is considered more convincing, and consequently, the study is considered
more robust. In order to provide greater robustness to the research, through the
analysis of several organisational realities and the cross-referencing of these
various cases, the present work undertakes a multiple case study.

The case studies were conducted in three large companies located in Brazil: a
petrochemical company, an air compressor manufacturer, and an agrochemical and
agricultural biotechnology company, chosen for being ones recognised for their
sustainability visions and principles of generating positive impacts on communities
and environment.

For the preparation, Yin (2001) proposes the development of a research
protocol, which is extremely important to increase the reliability of the work,
guiding the researcher in conducting data collection for cases. Thus, for this study,
the research protocols were developed in order to guide the researchers in
performing the collection of data from the multiple case studies.

Data collection considers multiple sources of evidence, such as: semi-
structured interviews, documents, file queries, physical artifacts and direct
observation (Yin, 2001). Yin (2001) recommends the use of several sources of
evidence, since these multiple sources allow for greater detail in the collection of
data. Considering the cases studies performed here, the data collection was
conducted in the same way with the three companies under analysis. This collection
took place in three different stages and used the following sources of data:
documents provided by the company, semi-structured interviews and secondary
documents sourced from corporate websites.

For data collection, a questionnaire was initially created based on a
systematic literature review (SLR) performed by Oliveira et al. (2019) and was sent
to the companies through the SurveyMonkey platform, in order to collect
background information about their management of environmental supply chain
risks. Then, three semi-structured interviews with different managers from the
companies were performed in October and November 2018. Open questions based
on feedback from the questionnaire were used in the interviews. Finally, the
documents provided by the interviewees and secondary materials available on the
companies’ websites were compiled and analysed.

The professionals considered in these interviews are specialised in dealing
with management of environmental risks, and are: (i) Environmental, Health and
Safety Engineer of Company A; (ii) Environmental Analyst of Company B; and
(iii) Environmental, Health and Safety Engineer of Company C.

The data analysis, according to Yin (2001), is concerned with the
examination, categorisation, tabulation, testing or recombing of evidence, in
order to produce discoveries based on empiricism. This step can be driven by four
different techniques: to construct validity, internal validity, external validity and
reliability (Yin, 2001). In this study, the technique adopted is the internal validity
by means of the adaptation to the standard, where the theoretical references of
systematic literature review are used as prognosis and compared with the results of
this empirical study, in order to reinforce the validity of the study (Yin, 2001).

The final step of the methodology, sharing, aims to transmit the relevant
information of the study through the presentation of the results (Yin, 2001). This
step is further presented in the following section.

**Results and Discussion**

This section presents the results and discussion of the case studies conducted in the three Brazilian companies. The online questionnaire and the interviews allowed for the evaluation of the environmental risks along the companies and their supply chains.

Firstly, through the online questionnaire and the interviews, it was possible to understand how the environmental risks and consequences were perceived and managed by the companies. Among the environmental risks listed for the interviewees, the ones considered for Company A were: greenhouse gas emissions (GHG) and ozone-depleting substances (ODS); industrial ash and soot emissions; chemicals and toxic effluents released into water or groundwater and oil; inefficient use of water; inefficient use of energy; and explosions, fires, chemical accidents. The most cited consequences that the risks may generate for the company were reputational consequences. Thus, the company realises that the losses go beyond the financial consequences that these risks can cause.

Company B considered the following environmental risks: greenhouse gas emissions (GHG) and ozone-depleting substances (ODS); chemicals and toxic effluents released into water or groundwater and oil; inefficient of raw materials; inefficient use of water; inefficient use of energy; non-compliance with sustainable laws and regulations; and explosions, fires, chemical accidents. For Company B, the most frequent consequence was the reputational consequence. The Company understands that damage to the companies’ reputation can cause it irreversible losses.

Company C considered the environmental risks already mentioned, except the environmental risk related to industrial ash and soot emissions, especially as it is not closely related to its activities. With regards to consequences, those that were most frequent were financial and reputational consequences.

Respondents from Company C added two risks that were not previously included in the list of environmental risks related to the systematic literature review, with these being: inadequate disposal of hazardous solid waste and a risk of loss of biodiversity. These new risks should be added to the SLR list presented in Oliveira et al. (2019), as they may create critical environmental issues. However, the risk of loss of biodiversity is a specific risk related to the activity of Company C, which perhaps will not fit into the list of risks of all company.

Finally, regarding the strategies to deal with the risks, among the strategies identified in the literature, the most frequent strategies cited by the three companies were: wastewater and solid waste management; carbon and water footprint monitoring; efficient consumption of natural resources; substitution, precaution, and reduction in the consumption of chemicals and toxic waste; introduction of carbon emission reduction initiatives and practices (e.g., use of renewable energy, filters, freight consolidation, driver efficiency, etc.; auditing, monitoring suppliers and the use of sustainable criteria for supplier selection, encouraging suppliers and partners to promote a sound environmental policy.

It was observed that the companies have a robust environmental policy to deal with their environmental risks, once they consider most of the strategies identified in the SLR of Oliveira et al. (2019).

Regarding the consequences, the respondents of the companies reported that,
nowadays, organisations are becoming more aware of ecological issues, especially due to stakeholder pressures, legal requirements and environmental regulations. Thus, the companies perceived reputational losses in the same light as financial consequences. Furthermore, it was also concluded from the interviews that all the consequences are closely related since damage to a company's image directly affects the company's profits. The legal consequences are also associated with financial losses since fines and legal penalties minimise the company’s profits.

Environmental risks caused by supplier irresponsibility and their failure to abide by environmental standards are still poorly addressed by the Companies. Only recently have the risks arising from the suppliers become a perceptible topic in the field of supply chain management, as mentioned by Torres-Ruiz and Ravindran (2018). For example, recently Company A has developed voluntary engagement actions of suppliers with a focus on sustainability, requesting them to report their greenhouse gas emissions and water consumption, as well as the risks, opportunities and strategies related to these specific issues.

Company C also pointed out that it seeks to engage with its suppliers, promoting workshops in order to influence and engage them into sustainable management practices. The workshops are also intended to encourage them to participate in the Reforestation Program which seeks to balance the emissions of greenhouse gases generated in their transport processes. Company B also emphasised that it is engaging with its suppliers regarding environmental issues, but did not mention specific actions or programmes adopted.

However, despite the engagement policies mentioned by the Companies, they did not have a well-structured matrix of the environmental risks from the suppliers. Companies A, B and C only audit the contracted service providers for the destination, treatment and transportation of their chemicals effluents and waste. Thus, it is found that the companies do not have well-structured management of environmental risks that exceed the borders of companies (environmental risks of the suppliers). Thus, due diligence, i.e. the co-responsibility and diligence of the counterparties, is a topic that needs to be addressed and further explored.

Conclusion

This paper explored the environmental risks in supply chains. This was accomplished through a multiple case study conducted in three Brazilian companies. From these cases studies, it was possible to identify the environmental risks, consequences, and strategies presented in the companies and its supply chains. The results achieved allow to provide an answer to the research question of this paper. The findings indicate that several environmental risks presented in the literature coincide with the environmental risk considered by the studied companies. However, it is relevant to highlight that although the types of adverse environmental impacts are universal, the risk types should be specified for every individual industrial enterprise (Levner and Ptuskin, 2018). For example, the risk of loss of biodiversity mentioned by Company C may not apply to another company.

The contribution of the present study for researchers was to perform a comparison and validation between the business reality and the academic findings from Oliveira et al. (2019), showing that the environmental risks found in the academic literature are in line with the environmental risks presented in a business environment. From the case studies, we realised that the environmental risks from
the suppliers are still poorly addressed by the companies, as opposed to the environmental internal risks of the companies.

Furthermore, our findings contribute to the supply chain risk management field as this paper introduces the environmental perspective and addresses the consequences that can be felt by the companies and environmental strategies from a practical business environment.

For future research, case studies should also consider different country perspectives to yield interesting insights from other cultures. Moreover, case studies conducted in different economic and climatic regions may result in different perceptions and effects of environmental risks. The region in which the company is located, the exposure to the risk, the intensity of stakeholder pressure and the legal requirements of the region will certainly influence the management of the environmental risks in the supply chain.

Abstract

Although studies discussing risk assessment are abundant, attention over supply chain risk perception is considerably lower. Moreover, papers regarding food safety risk perception from supply chain members’ perspective other than the consumer’s point of view are also limited. Therefore, this research aims to investigate: how does formal control and trust affect food safety risk perception in the milk chain? Results show formal control as a potential factor to reduce risk perception in four out of five measured risk events. Trust was also found as an antecedent that reduces risk perception in all events and as a moderator in specific settings.

Keywords: Risk Perception, Trust, Formal Control

Introduction

Supply chain risk management has become a consolidated field of research over the last years. Nowadays, a solid background can be found on many of the traditional SCRM topics, such as risk assessment and identification tools, supply chain risk modelling, as well as mitigation strategies, processes and practices (Sodhi et al., 2012, Ho et al., 2015, Fahimnia et al., 2015, Vishnu et al., 2019). However, little attention is being given to risk perception.

Risk perception is the general assessment conducted by one individual regarding an specific context in order to make decisions (Mitchell, 1995, Ellis et al., 2010, Kull et al., 2014). Most of current publication links risk perception to other managerial approaches but discards its relevance to supply chain risk management. The few papers that contributes directly to SCRM focuses mainly on consumers’ risk perceptions and its impact on supply (Van Kleef et al., 2007, De Krom et al., 2010, Bailey and Garforth, 2014) leaving a vast territory to explore (Vishnu et al., 2019).

Even if risk level as well as any other managerial information is properly assessed and provided, the final decision is a result of an individuals’ perception of environment, that suffers impact of many subjective variables (Sitkin and Weingart, 1995, Kull et al., 2014). Therefore, even if reliable and detailed information is available, a decision-maker can
consider other aspects or even reinterpret the scenario leading to different outcomes than expected.

In the supply chain, the perception of risk may cause different behavior regarding control (Das and Teng, 2001, Kull et al., 2014). From this perspective, previous occurrences lead to a perception about the specific likelihood of a repetition or related situation and this apprehension may cause the individual to assume a different position regarding future scenarios (e.g. increase control).

Since perception can not be explained only by objective data as it is a complex cognitive response (Mitchell, 1995, Simon et al., 1999, Kull et al., 2014), this study proposes to focus on the relationship between risk perception and two other relevant supply chain relationship constructs: trust and formal control.

Additionally, this research intends to associate the perception of risk in a specific context. Although quantitative SCRM models are abundant in literature, there is still a significant gap between theory and applicability in industry and therefore empirical studies are valuable research material (Vishnu et al., 2019).

Therefore, based on previous modelling on risk level and risk perception, this paper proposes to test the association of trust, formal control and the perception of food safety risk in order to understand their reciprocal implications.

Sector-specific research, especially in the food industry are still necessary, due to differences between regulations, policies and even industry maturity that demand further investigation (Roth et al., 2008, Sodhi and Tang, 2012, Van Asselt et al., 2017, Vishnu et al., 2019). The dairy sector stands out for the amount of risk types and high level of occurrences worldwide (Roth et al., 2008, Bailey and Garforth, 2014, Van Asselt et al., 2017).

In this perspective, this paper aims to answer the following research question: how does formal control and trust affect food safety risk perception in the milk chain? In order to answer this question, this paper addresses the first step of the process by understanding the producers’ point of view, since most of food safety risk still depends on proper production and handling protocols at the first stages of production (Fagnani et al., 2011, Van Asselt et al., 2017).

Brazil has recently faced a significant amount of investigations regarding multiple types of risk events in the dairy industry, involving mostly cases of fraud and chemical contamination (IGL, 2015, MPRS, 2019). Since it is also a country that lacks contextual and empirical research regarding SCRM (Ceryno et al., 2015) and the opportunity to study a current disturbance, this country was selected for delimitation.

**Theoretical Background**

As previously presented, risk perception is a personal assessment on a generic situation (Mitchell, 1995). On the SCRM perspective, previous occurrences – positive or negative – or situations that base risk perception are defined as risk events. Risk events are defined outcomes of risk (Manuj and Mentzer, 2008) or, in a simpler way, when something that was once risk becomes a concrete reality.

Risk events can provide foundation to assess risk probability, frequency, speed and impact (Sodhi and Tang, 2012). Also, they are critical to understand past situations and create mitigation strategies.

Formal control is the group of resource tools that are applied to verify if processes and outputs are complying with planned operations (Stouthuysen, 2012). As a part of risk mitigation and a continual improvement routine, formal control can affect agents’ behavior and reduce risk (Das and Teng, 2001, Ju et al., 2011, Kull et al., 2014). As a construct, formal control can be divided into performance or output control – that focused
on the final outcome of a process – and behavioral or process control, that will approach both objective and subjective elements of the process itself (Das and Teng, 2001, Ju et al., 2011, Stouthuysen, 2012).

Trust is often mentioned as a potential factor to reduce risk, although it is highly discussed if it should be used as a substitute of formal control (Villena et al., 2011, Skinner et al., 2014). Although its relationship with risk and control has been discussed significantly, trust is found as both antecedent of risk and moderator of control – risk relationship (Das and Teng, 2001, Ryu et al., 2008). Considering the wide use of risk variable rather than risk perception on research papers, it is not clear how these constructs would interact in specific environments.

Many studies address risk perception in general. Even so, a few models included formal control, trust and risk perception under the supply chain’s approach.

Das and Teng (2001) proposed a model that discussed the relationships between trust, control and risk perception that is one of the main references of this study. However, not only the original paper does not present empirical data, it does little to support further application, since the theoretical approach does not include scale or any data collection or analysis. Also, Das and Teng (2001) were focusing on strategic alliances when model was designed, which also reinforces the necessity to develop reviews, increment and data analysis of this constructs for the supply chain risk management perspective.

More applicable, Kull et al. (2014) presents a model about risk perception and perceived control as well as other cognitive and environmental aspects to understand supplier selection. The model presents relevant contributions of relationship proposals as well as scale testing. Yet, trust is only marginally discussed and does not participate as a construct on the model. Other models have as well partial connection to this proposal, but as observed in the main sources mentioned above, the construct relationship aims at a different direction than this article. To our knowledge, this papers’ approach has not been addressed until this moment.

The scarcity of publications is even bigger when food safety risk is observed. Theoretical literature is easily found and vast due to contribution of many fields (Roth et al., 2008, Van Klee et al., 2007, Bailey and Garforth, 2014), however, papers mainly focus on risk perception relation to demand, brand and other consumer-oriented constructs (De Krom et al., 2010, Bailey and Garforth, 2014, Van Asselt, 2017).

Food safety risks are also a wide range. In order to narrow perspective and provide a more accurate risk perception, as this construct is based on specific situations (Sitkin and Weingart, 1995), typical milk chain risk events were mapped in previous literature. As this data collection centers in the producer’s perspective, five of the ten main risk events were included in final model, described as follows: (a) microbial contamination of milk, (b) contamination of cattle feed, (c) chemical contamination of milk, (d) contamination of cattle due to medication and (e) milk fraud (Baars et al., 1992, Van Klee, 2007, Roth et al., 2008, Xu et al., 2010, Bailey and Garforth, 2014, Van Asselt, 2017).

Based on this scenario, three models were proposed considering, respectively, formal control as an antecedent of risk perception, trust as an antecedent of risk perception and trust as a moderator in ‘formal control – risk perception’ relationship, as presented in Figure 1.
Data collection and research design
As previously mentioned, Brazil was chosen for data collection due to recent risk events in the milk chain (IGL, 2015, MPRS, 2019). For this study, we considered the producers’ perspective due to the concentration of food safety risk events on the initial stages of the milk supply chain (Roth et al., 2008, Bailey and Garforth, 2014, Van Asselt et al., 2017). Also, Brazilian milk supply chains are typically formed by a large group of producers (around eighty thousand only in south region) selling to a limited group of manufacturers, a group of approximately 300 companies (IGL, 2017). Therefore, a sample of producers was more suitable to obtain in the specific context.

The questionnaire consisted of a total of five blocks, structured as follows: 'demographic data', 'risk perception', 'trust', 'formal control', and 'contextual aspects'. The fist block included general information regarding milk production, producer experience and qualifications, farm location and technological level of production.

Kull et al. (2014) and Sitkin and Wiengart (1995) scales were used to measure risk perception. A 7-point scale was used for the seven items generated from this combination. This block intended to measure objectively the different aspects of risk perception (as a threat, as a possibility, as potential situation, etc.) in order to understand how likely to occur is the risk event according to respondent’s assessment of the context. As risk perception is situation-based (Sitkin and Weingart, 1995, Kull et al., 2014) we replaced original scale risk events for via five specific conditions present in milk chains, according to literature: microbial contamination of milk (MICRO), cattle feed contamination (FEED), chemical contamination (CHE), cattle contamination by medication (MED) and fraud or adulteration of milk (FRA). The selection of risk events also considered the proximity of producers with the possible risk events, therefore final product occurrences
(e.g. package, retail storage, etc.) were not addressed. Also, since the risk perception is measured according to the specific scenario (Sitkin and Weingart, 1995), each risk event was measured as an independent construct.

The third block was built to measure how trustful the relationship between producer and manufacturer is according to the former’s perspective. Respondents were required to consider their main client when exclusivity was not established. For trust measures, Ryu et al. (2008) scale was replicated as a main reference and was complemented by Ju et al. (2011) for norm-based information exchange items. Eight items were considered in this construct, using a 7-point scale.

For formal control, previously validated scale items were also merged (Stouthuysen et al., 2012; Crosno et al., 2015). This block was designed to understand the level of control producers understood to be subjected to by manufacturers. It is formed by two subsections: performance control (five items, 7-point scale) and process or behaviour control (six items, 7-point scale).

The last block intended to measure contextual aspects of government regulation and food law as a control variable. The scales proposed by Sebata et al., (2016) were adapted, as it was used only 3 constructs: ‘food law and regulations’ (7 items, 7-point scale), ‘food control management and information flow’ (8 items, 7-point scale) and ‘analytical services’ (10 items, 7-point scale). Since data collection was conducted by local government agents, the construct ‘inspection services’ from original paper was not included in order to avoid bias. Considering results from this final block were out of the ordinary (a significant amount of responses was marked as neutral by respondents), it was removed from this paper analysis, pending further tests.

Original scales were translated from English to Portuguese and minor adjustments were made to preserve meaning. Final adapted and integrated scales assessed by specialists (academic and practitioners) and further small adjustments were conducted based on their review. A pilot test was also conducted to reinforce scale’s adequacy.

Data collection was conducted in loco by trained professionals from EMATER, a national government agency for agricultural development. Final count included 89 EMATER professionals involved in this data collection, occurring simultaneously in all 13 subregions of the Rio Grande do Sul state, south Brazil. A total of 265 valid cases was obtained and 23 cases were discarded for missing values or because they did not fit the sample description. Smart PLS version 3 and SPSS version 25 were used for data analysis and model testing.

**Measurement and Construct Validation**

In order to observe convergent validity, we conducted observations of the of the Average Variance Extracted - (AVEs). Initial results showed AVE > 0.50 for the variables representing risk perception in all five scenarios (MED, CHE, FRAUD, CATF and MICRO).

Therefore, variables with factorial loads of smaller values were removed according to threshold indicated in the literature (Hair et al., 2014). A total of 13 items was removed and although items were removed, observing that constructs integrity were maintained and still preserving more than three items each. As presented in Table 1, results after model adjustment presented satisfactory results (Hair et al., 2014; Ringle et al., 2014).

Subsequently, discriminant validity was tested and one more item was removed in order to provide model fit (variable ‘trust’). Final correlations are presented on Table 2. Convergent validity and reliability values were also reviewed and remained in the appropriate value range.

</table>

To assess significance of path coefficients, a bootstrapping analysis was processed on Smart PLS v. 2 (individual changes, 500 samples). For moderating effect, a multigroup analysis was conducted. Trust was recoded as dichotomous variable (‘high level of trust’ and ‘low level of trust’). Cases were assigned to one of the two conditions (130 on high level trust and 135 on low) and Student’s t-test was used to verify the significance of difference between groups. Both equal variances assumed and not assumed test were significant (p<0.000).

Findings

As presented on Table 3, regression analyses for the relationships between formal control and perception of risk events was found significant and negative in four occurrences: chemical and microbial contamination, fraud and contamination by cattle medicine. The ‘formal control-cattle feed contamination’ relationship, however, was not significant. Therefore, regarding Model 1, H1 is partially supported, since H1a, H1c, H1d and H1e were confirmed by data analyses but H1b did not hold significance to be considered validated.

The results indicate that producers perceive formal control as a factor to potentially reduce events that are directly related to their routine exchanges with manufacturers.
However, the lack of significance in the impact of formal control in cattle feed contamination may be linked to the fact that, in Brazilian context, manufacturers to not control this type of risk directly via laboratory and sample test analyses as conducted on the other four situations, but indirectly via producers reports, regulatory labels and licences and government monitoring of cattle feed production and storage (MAPA, 2006). In this scenario, results are coherent with context-specific formal control issues, as producers do not witness control processes for this risk type as part of the industry’s regular monitoring protocol. In previous literature, cattle feed contamination, although highly critical to the entire supply chain, becomes the focus of attention usually after a significant event (Baars et al., 1992, Xu et al., 2010, Fagnani et al., 2011).

Since recent events in the specific region of study were mostly related to fraud and chemical contamination (IGL, 2015), it is possible that producers are not in contact with this concern on their regular routines. Further studies in different contexts are necessary to enhance understanding regarding this aspect.

As for Model 2 - that considers solely the relationship between trust and the five studied risk perception constructs - all proposed paths were significant, supporting H2 (H2a, H2b, H2c, H2d and H2e). However, it is also appropriate to highlight that the ‘formal control-cattle feed contamination’ relationship was found less significant (p<0.05).

Finally, Model 3 considered trust as a moderator in the relationship between formal control and risk perceptions. As presented on Table 4, the moderating effect of trust was significant only in two of the five risk events: milk fraud and chemical contamination. Thus, H3 is only partially supported (due to significant values for H3c and H3e). Based on these results, it is possible to infer that when there is a high level of trust perceived by the producer, the negative relationship between formal control and risk perception of fraud and chemical contamination are more subtle. This output reinforces previous literature and can be interpreted as a positive use of trust in reducing potential risk and risk perception (Sitkin and Weingart, 1995, Simon et al., 1999, Das and Teng, 2002, Ryu et al., 2008) in milk supply chains but it also may present a liability due to the ‘illusion of trust’ effect and the possibility of opportunistic behavior (Ju et al., 2011, Villena et al., 2011, Skinner et al., 2014), especially regarding fraud occurrences.

Final considerations

Research findings contribute to current literature by: (a) bringing the discussion of risk perception perspective in the supply chain, a topic that still lack publication in the SCRM approach; (b) discussing food safety risk perception from the producers’ point of view, which can also be used for discussion in related fields, (c) proposing a model to understand the relationship between trust, formal control and food safety risk perception and (d) providing a scale adaptation for food safety risk perception that can be both replicated or adapted to other food-related contexts.

From a managerial point of view, this paper highlights the relevance of formal control in reducing risk perception on potential risk events in the milk supply chain. Also, as trust is also a factor that potentially reduces risk perception, it indicates that practitioners should be oriented to establish long-term partnerships in the supply chain. On the other hand, managers may as well remain observant, since findings exhibited that trust can also lead to the reduction of risk perception which can lead to a reduction of formal control, followed by the increase of risk levels.

Further analysis will consider demographic data, such as producer level of experience and technological production level to test detailed typical behavior. Also, SEM analysis will be conducted on SPSS AMOS to consolidate consistency of results. Data collection will as well be expanded to include manufacturers and other supply chain members via properly adapted surveys.

As for research next steps, it is our intention to replicate the study in a different context, measure government interference on supply chain internal controls and companies’ risk perceptions as well as the inclusion of comparative historical risk levels on the model.

Abstract

The well-established research on supply risk assessment has provided a strong theoretical basis allowing for a broad range of assessment methods to be proposed. However, the academic field lacks a similarly strong evidence base from the industry, mostly consisting of generic surveys offering a high-level feedback from practitioners. In collaboration with a multinational manufacturing company from the white goods industry, this paper proposes a novel survey methodology that deepens our understanding of supplier-buyer relationships and how each side perceives the process of risk assessment in different commodity families.

Keywords: Supply risk assessment, Survey, White goods

Introduction

Supply chain risk management (SCRM) became an extremely popular research subject ever since the advent of globalization and mass outsourcing (Gunasekaran & Ngai, 2012). Open markets and technological advances posed new challenges for companies to address, and the continuously growing complexity of supply chains has been calling for deeper analysis on identifying, assessing and managing potential risks.

The consistently increasing attention on SCRM has been motivating academics to frequently review the progression of the research field by conducting extensive literature reviews. The most notable literature review publications in recent years seem to be those by Colicchia & Strozzi (2012), Ho et al. (2015) and Fan & Stevenson (2018). These reviews offer a complete picture of the SCRM research field and provide a useful overview of the state of the art in terms of SCRM definitions, risk classifications and risk management methods.

In this paper, our focus lies on supply risk assessment (SRA) which involves analyzing and evaluating potential risks in the scope of supply management and sourcing. A summary of the most relevant background material can be found in the recent literature review by Tran et al. (2018).
Our research is mainly inspired by the theoretical work of Heckmann et al. (2015) which identifies three key characteristics of supply risk from the perspective of a company’s organization: 1) the importance of clarifying the objectives that will drive the risk assessment, 2) the attitude of the company’s management towards risk, and 3) the company’s exposure to potential risks that stem from the characteristics of the organization, the supply chain and the supply base. In reference to the defined objectives and risk tolerances deemed acceptable, a risk assessment exposes a company’s vulnerability to potential disturbances in its supply chain (Svensson, 2000; Peck, 2006).

Tran et al. (2018) classify previous publications on risk assessment in terms of their methodology and they make two notable observations. The first observation indicates an increasing attention towards quantitative methods, which can be explained by the extensive theoretical literature published in the past few decades, as well as our original note on the increasing complexity of the supply chain and the need for tools capable of analyzing it. The second observation connects the level of depth of the research analysis to the methodology, whereby qualitative methods tend to focus more on general supply chain risk concepts, while quantitative methods address specific risks.

Previous reviews (Ho et al., 2015) have commented on the limited availability of empirical SRA studies offering insight from the industry. This is understandable given the difficulty of academics to connect with practitioners, while companies also do not easily disclose information since exceptional knowledge or capabilities can give them a competitive advantage. Furthermore, empirical studies have not given enough attention to the supplier perspective (Fan & Stevenson, 2018), nor have they extended the scope to multiple tiers (Tran et al., 2018). Finally, case studies have been crowded on a few industries, such as the automotive sector, while context (e.g., industry, country, etc.) has been poorly addressed (Fan & Stevenson, 2018).

To address these research gaps, this paper proposes a deeper empirical study with the support of a case company in the industry. The research is carried out during a collaborative project with Electrolux, a multinational manufacturing company in the white goods industry. The proposed study consists of conducting interviews, using a structured questionnaire developed a priori, on a select group of suppliers and buyers. The intention is to collect insight from both supplier and buyer perspectives within the same relationship. We also seek to extend our reach beyond the first tier of supply by interviewing competing suppliers who share the same or similar sub-suppliers, or even by including sub-suppliers in the interview process.

While the interview process is ongoing, this paper seeks to make the case for this novel methodological approach in advance and to define the expected results. The remaining part of this paper is structured as follows: the next section briefly presents the profile of our partnering company, followed by a detailed explanation of the methodology proposed. Next, we describe the questionnaire structure and discuss the objectives and expectations from conducting this research. We close the paper with our conclusions and by outlining the next steps of this research.

Company profile
This research project is carried out in collaboration with Electrolux Appliances, and specifically, the central purchasing team responsible for the sourcing strategy of European production. This section briefly presents the company profile and the purchasing organization.

Electrolux is a leading global manufacturing company in the white goods market, with production facilities present in four continents and selling over 60 million products
annually. The company was founded in 1919 and is based in Stockholm, Sweden. It produces household ovens, refrigerators, washing machines and dishwashers (the four main product lines under Major Appliances), vacuum cleaners, air conditioners and other small domestic appliances (under Small Appliances), as well as commercial appliances (under Professional). More information on the general profile is available on the corporate webpage (http://www.electroluxgroup.com/en/electrolux-in-brief-492/).

The purchasing organization is separated according to direct material vs. indirect material vs. logistics. The direct material group (in scope here) is split between central and local purchasing. Central and local purchasing differ mainly in terms of responsibility. On one hand, central purchasing defines sourcing strategies, allocates business spend and manages the relational aspect with suppliers. On the other hand, local purchasing bears procurement responsibilities, such as ordering material from suppliers and managing material pricing records. Figure 1 shows the purchasing organization chart.

![Electrolux EU purchasing organization](image)

At the lower level of the purchasing organization, responsibility is split by commodity family. There is a wide range of families with two levels; for example, plastic is one such family, with the specific plastic material types forming the sub-families. Some commodities are common across multiple product lines (e.g., electronics and plastics), while others may be specific to one product line (e.g., refrigerator vacuum insulation panels).

The group’s objectives and key performance indicators (KPIs) are rather aligned with the industry and other manufacturing firms. The white goods market is generally considered a low-profitability and cost-oriented industry in comparison to markets such as automotive and telecom. In consequence, Electrolux has traditionally been strongly cost-oriented. In line with the historical evolution discussed in the literature review, the past 15 years have seen purchasing drilling down costs and maximizing LCC opportunities. However, in the last few years the mentality is changing, in line with the general trend in manufacturing industries and specifically the Electrolux company strategy, to balance cost reduction with quality performance, service level, innovation and sustainability. These aspects have always played an important role in the company’s strategy; for example, Electrolux continues to be recognized as “Industry Leader in the Household Durables category” in the Dow Jones Sustainability World Index for eleven years now (Electrolux, 2019). What is now spreading instead across the organization is a 360° holistic mentality that is driven by purchasing in the back-end of the company towards a sustainable supply base formed by strategic partnerships. Since this new sourcing strategy allocates more business and responsibility in the hands of a few suppliers, attention is rising on the need to assess potential risks. It is in this context that
we choose to conduct interviews with select suppliers and buyers in order to study their perceptions on risk assessment.

Methodology
In the existing literature we can find examples of empirical research that consisted of case studies in the form of surveys or questionnaires. For example, Zsidisin et al. (2004) contacted purchasing professionals of manufacturing companies via telephone or email to collect general information about their involvement in supply risk assessment. The study covered seven companies from highly technical industries (computer, aerospace, semiconductor, cellular phone) that were known for having a proactive supply management approach.

Another example is the questionnaire that Lavastre et al. (2012) conducted by interviewing 142 professionals in 50 French companies. The content of the questionnaire covered general concerns on risk management such as risk attitude and use of different risk reduction methods.

A third and more recent example is found in the work of Kotula et al. (2018) who conducted semi-structured interviews with professionals from 20 case companies from the construction and electronics industries based in Germany or the UK. The interview protocol is included in the publication and consists of general questions on supply risk management.

Similar examples can be found in papers by Ganguly (2013) and Sarker (2019); the former conducted interviews in six organizations while the latter interviewed 18 representatives from a single case company.

While the above list is not exhaustive, we notice a similar approach among these empirical studies in that they offer an extraction of general insight from the industry with regards to risk management. Whether focusing on a single company or comparing multiple organizations, and irrespective of the number of respondents, the premise is typically one of discussing general concepts of risk management in order to test the extant theoretical literature. These surveys are undoubtedly useful in qualitatively or quantitatively analyzing the industrial approach and perception on risk management.

Given our collaboration with Electrolux, our study seeks to take advantage of the author’s active participation in the company’s purchasing organization for a deeper understanding of risk assessment perceptions in the industry. Our intention in this paper is to formulate and propose a novel semi-structured interview-based empirical methodology that will address limitations of previous studies.

Research objectives
Prior to designing the methodology we must define the objectives of the research that we intend to carry out. The main purpose of our research is to extend the public knowledge and understanding of how practitioners experience and perceive their companies’ needs and challenges in assessing risks. As we progress in uncharted territory, we consider appropriate to use an explorative approach within our case company (Eisenhardt, 1989; Yin, 1994). Our work seeks to address four distinct aspects that have been identified as missing in previous studies:

1. the case of the white goods industry,
2. the perspective of suppliers,
3. the multiple-tiered nature of a supply base, and
4. putting suppliers in context according to their profile.

With respect to (1), in the previous section we already described the profile of our case company and how it relates to the topic of risk assessment. To the best of our
knowledge, there has been no previous publication on risk assessment (or risk management) using a case study from this industry (Fan & Stevenson, 2018). We believe the white goods industry is a valid addition to other manufacturing industries previously in scope and it is particularly interesting as its output is a product that combines components and technologies originating from a wide range of other industries and locations.

The above implies that by studying this company we gain access to a vast supply base with differing profiles that allows us to explore the perspective of suppliers (2) in contrast to what is mainly available in the literature (Fan & Stevenson, 2018). However, instead of choosing to approach a large number of suppliers that would force us to conduct a simpler, more general survey due to limited time availability, we prefer to focus on a few select groups of suppliers in order to study in depth the dynamics of some key commodities. In this way, we also have the possibility to approach both suppliers and buyers (i.e., commodity managers) in order to compare both sides of the relationship.

Furthermore, limiting the focus on a few competing suppliers within the same commodity offers the opportunity to investigate beyond the first tier of supply (3) (Tran et al., 2018). Suppliers can be questioned with regards to their own sub-suppliers which are likely to be similar in nature, in competition, or even common. If supplier-buyer relationships allow for it, we are likely to have the option of directly approaching sub-tier suppliers as well, which would offer a third perspective in a complex upstream supply chain.

The fourth and final aspect of our research focus is profiling suppliers in order to draw connections between their characteristics and their view or behaviour on risk assessment (Fan & Stevenson, 2018). Such differing characteristics, for example location, size or operational structure, are likely to affect their view as well as the buyer’s view on potential risks.

Based on these four key aspects, we can proceed in formulating our four resulting research questions:

**RQ1.** How is risk perceived and assessed in the white goods industry?

**RQ2.** What are the differences between supplier and buyer perspectives on risk assessment?

**RQ3.** What additional insight can be gained by extending the assessment to multiple tiers?

**RQ4.** How are supplier profile characteristics affecting the assessment of risks?

In the following sub-section we design the structure of our proposed methodology in such a way to be able to address these research questions.

*Research design*

For the most effective empirical exploration of the aforementioned aspects, we have selected a semi-structured interview-based survey. The survey is applied in two ways: a) internally, completed by members of the purchasing organization, and b) externally, completed by the suppliers of Electrolux. Commodities and suppliers of different profile, market, process and location are involved. These characteristics can form the independent variables to the questionnaire, as summarized in Figure 2.
The supply base potentially at our disposal for the external questionnaire consists of approximately 500 direct suppliers spanning several commodity families, such as electronics, motors, wiring, plastics, metal parts, glass, rubber and tapes. This supply base is significantly diverse in terms of technology and materials, as well as share of Electrolux spend. However, as mentioned previously, we prefer to select a few key commodities and to focus on a smaller group of suppliers and their corresponding buyers within those commodities. To achieve a good balance of diversity and comparability, we have chosen to conduct the survey on the commodities outlined in Table 1. For each of the commodities listed, we shall involve in the survey 3-4 suppliers and 3-4 buyers. The behavior and perception on risk assessment can be compared among these commodities in relation to their characteristics, such as geography, type of raw materials, process automation, product customization and complexity, etc.

</table>
We will conduct our survey with both suppliers and buyers in the form of face-to-face interviews that will be guided by the use of the appropriate questionnaire. This will allow for an easier explanation towards the interviewees and to ensure that questions are interpreted in the intended way. Moreover, interviews will facilitate a discussion in which to elaborate where deemed relevant and to ensure answers are appropriately matching the intention of the corresponding questions. Additional information or insight provided can be attached to the questionnaire.

**Questionnaire structure**

We have designed the survey in the form of an electronic questionnaire in excel, including a combination of open- and closed-form questions, many of which use the Likert scale. The survey is split in the following sections: i) profile, ii) market environment and company strategy, iii) risk of supply to Electrolux, iv) risk of (sub-tier) supply to Electrolux suppliers, and v) risk mitigation. Although the latter is not part of our focus, it is naturally linked to the assessment stage of SCRM and addresses the consequent business continuity aspect that is critical to the company’s strategy.

We start with the profile of the supplier or buyer that serves to place respondents in context. In the case of buyers we are interested in their experience in purchasing and on the specific commodities under their responsibility, while in the case of suppliers we report basic company information such as industry, product portfolio, ownership, organization size and location(s). Suppliers are also asked about their certifications to investigate whether a formally recognized level of quality or sustainability can positively influence the behaviour or perception on risk assessment.

In the second section of the questionnaire, we ask both buyers and suppliers their perspective on the dynamics of the market and commodity in scope. We are interested for example in the perceived level of competition and balance of bargaining power, as well as the importance given to various corporate strategies of suppliers and their performance on a selection of KPIs ranging from cost and quality to service and corporate social responsibility (CSR).

Sections (iii) and (iv) consist of the main part of the questionnaire relative to risk assessment. Here we include several questions starting from how the respondents define risk and what are their attitudes, objectives and behaviours in evaluating risks. Then we enquire about types of risks, assessment methods and processes for the given company and commodity. On these questions we use a closed-form approach to test what originates from the literature. However, we couple those with open-form questions to extract insight on individual experiences that could shed light to additional forms of risk or assessment methods, and also to distinguish the inherent challenges among the different cases.

The final section on risk mitigation addresses questions regarding contingency plans, emergency response teams and risk-reduction methods. The questionnaire closes by requesting suggestions on how the given supplier-buyer relationship could better manage business risks.
**Discussion**

We previously justified our proposed methodology by distinguishing our approach from other surveys in four distinct aspects. In this section, we discuss how this approach can address the four research questions defined and what results we expect to attain after completing the survey.

This survey is intended for a company in the white goods industry, which we consider to be a valid case in the scope of multinational manufacturing companies. White goods consist of technical products resulting from a complex manufacturing process. They are constructed by assembling a large set of diverse components that result from different chemical and electromechanical processes. A significant part of these components is purchased from a vast selection of suppliers belonging to different markets and geographically dispersed around the globe. In comparison to other industries investigated in the literature as mentioned earlier in this paper, it is more complex than the electronics industry since it is located one tier upstream in the supply chain. Its complexity or component diversity is more comparable to the automotive or aerospace sector. Production volume of appliances runs on a similar scale as automobile production, however, they are part of a continuous, stable manufacturing schedule in contrast to automobiles that can vary based on new product launches. Aerospace also runs on spot project orders and with significantly lower volumes. The construction industry, also of interest in the extant literature, differs significantly as it is project-based and operates under a slower pace.

These characteristics render the white goods industry a particularly interesting environment in which to study risk management in general. The industry offers a vast supply base spanning across many different sub-industries, which expands the scope of potential risks. The stable nature of the manufacturing output boosts the need for business continuity and for disruption avoidance to be an integrated part of the operational process and the supply chain. Moreover, the complexity of the product portfolio translates to an equivalent complexity spread amongst suppliers, creating additional challenges that increase exposure to risks. As a final note, cost plays a key role in the white goods industry and can, in some cases, increase exposure to risks and compromise the resilience of the supply chain in the event of disruption.

One of the arguments we make in favour of the white goods industry is the diversity of its supply base. With a wide selection to our disposal, we have opted for three commodities that we believe can offer valuable insight. First, we share a similar interest with fellow researchers on electronics due to its highly technical nature, fast rate of technological change and continuous market growth. In our case, we have the possibility to view a perspective from the receiving end of the buyer as well as from the viewpoint of electronics manufacturers supplying the white goods market. We expect electronics manufacturers to have a lower bargaining power with respect to the buyers, mainly due to a high level of competition, but also with respect to their suppliers who produce the electronic components that benefit from a generally strong market demand.

The second commodity selected is that of cables, which in the case of appliances consists of power cords and wire harnesses. These products typically use standard components, such as wires and connectors, but they are customized to fit the application, for example in terms of length and combination of connections. This leads to a high level of complexity, which, coupled with the relatively low product cost, tends to call for a localized supply. An interesting comparison can be done with electronics since the two commodities share some materials (mainly terminals and connectors) but differ in geographical sourcing strategy and complexity. Also the level of production...
automation can vary between types of cables, whilst electronics assembly lines tend to be highly automated.

The third and final commodity addressed in our survey consists of plastic parts. In this case, we move from electrical components to chemical raw materials and from a functional purpose to a more aesthetical one. Geography is strongly linked to the dimension of the parts; however, long-distance sourcing is unlikely, not only due to the impact of transport on cost but also due to plastic parts being by definition custom-made. In this commodity, the production process is rather simple (injection moulding) but performance is strongly dependent on the quality of the tooling.

In all three commodities, suppliers are likely to use similar or even common sub-suppliers. This provides an additional opportunity for our survey to extend beyond the first tier of supply. By interviewing competing suppliers, we expect to find matching statements in terms of risks in their market dynamics, but we also expect to find differences arising from differing strategies, operational structures, or even coincidental experiences. We also aim to directly interview tier-2 suppliers that can prove invaluable in providing a third perspective beyond the two-way supplier-buyer relationship. Essentially, a tier-2 supplier can offer a double perspective: on one side, in the role of supplier, thus placing the supplier of Electrolux in the role of buyer; on the other side, as a node closer to the source of the supply chain, where Electrolux buyers have limited visibility and control. As such, tier-2 suppliers can offer insight on potential risks that would not arise from interviewing Electrolux buyers or even Electrolux suppliers.

Our final research question addressed the correlation of supplier and commodity profiles with risk assessment. At this point, we highlight that throughout the discussion in this section we have considered supplier and commodity characteristics when arguing for their relevance to our study. These characteristics allow us to compare and contrast them from different perspectives, and, through this process, draw additional insight on behaviours and attitudes towards risk. Ultimately, we seek to increase the level of understanding and knowledge behind the risk assessment process, but we also suggest putting eventual theories and methods (as available in the literature) into perspective, considering that managing risks is subject to the given company’s strategy and attitude towards risk.

**Conclusion**

In this paper we have argued that the empirical side of risk assessment research would benefit from a deeper investigation in the industry. We have identified four main areas of improvement on these qualitative studies. First, we argue for the validity of the white goods industry as a fertile environment for studying risk assessment methods in the scope of multinational manufacturing firms and we note that it has not been addressed so far in the extant literature. Second, the nature of the white goods industry and its products offers a vast and diverse supply base with the potential to explore different behaviours, strategies and attitudes towards risk. Third, given our involvement in the case company’s purchasing organization and the dynamics of their supplier-buyer relationships, we have the opportunity to extend the survey beyond the first tier of supply in order to widen our perspective on the supply chain in scope and at the same time go deeper towards farther sources of risk. Fourth, we suggest exploiting the diversity of the supply base in scope in terms of profiling suppliers and commodities to explore the correlation between their characteristics and risk behaviours.

In the context of these four aspects, we propose a novel approach of conducting a qualitative survey. Our proposed methodology consists of conducting semi-structured interviews guided by a questionnaire provided a priori. Interviews are conducted on
both buyers and suppliers of the same commodities for a double perspective. We have designed two questionnaire versions to match the perspective of buyers and suppliers, referred to as “internal” and “external” questionnaire, respectively.

The next step of this research shall be to conduct the interviews, analyse the information collected from the respondents, and present findings that should contribute to our understanding of the industry’s approach to risk assessment.

We recognize that to focus on the key aspects presented in this paper we have also limited the connection of our work to further studies in the extant literature. It will be useful to collect additional publications with empirical research and compare in detail the respondent profiles as well as the content of the surveys. Further research in the white goods industry will prove invaluable to compare with our findings, whether done with the same case company or with competitors in the same industry. A detailed comparison among the various industries studied so far would also provide knowledge about general behaviours in different industries, but also the possibility to spread learning from one industry to another.

Abstract

Organisations are susceptible and vulnerable to crisis situations. These organisations have been able to exert resilience, and manage reputational damage, through crisis management protocols that include stakeholder engagement. However, given the rise of social media, a new cohort of stakeholders has emerged. Organisations are therefore faced with the task of managing new stakeholder relationships. This paper applies recent advancements in social media and crisis management discourse to investigate the prevalence of new, undiscovered stakeholders in crisis communications surrounding six prominent crisis situations. The results indicate that online stakeholders are becoming more powerful, urgent and legitimacy; thus shifting dynamics.

Keywords: Crisis Communication, Social Big Data, Stakeholder Salience

Introduction

Previous studies on crisis management have sought to identify effective methods and strategies for crisis communication. Crises can be unexpected and non-routine events or activities that interfere with an organisation’s normal business operations, jeopardise its public image and damage the bottom line (Faulkner, 2001). Managing crises is an important process to prevent or lessen such interference, repair images and disseminate the responding information. Therefore, ‘the communication following a crisis plays an integral role in this success’ (Ulmer, 2001, p592). According to Coombs (2015), crisis communication is ‘the collection, processing, and dissemination of information required to address a crisis situation’.

The recent prevalence of social media platforms has created a new and low-cost channel for
communication. These platforms have also changed the way that people search, publish and share information during crises (Oh et al., 2013). The use of new types of social interactions to report real-time crisis information somehow is more influential than the mainstream news. Given this, the main organisations are no longer the only influencer, rather, there are peripheral influencers that can gain legitimacy and become important stakeholders by creating and propagating crisis information. Hence, there is a new challenge for the main organisations to identify and engage with these emerging stakeholders to communicate crisis information.

In addition, the social media platform can encompass large amount of unverified information, including lies and false rumour (Oh et al., 2013), which can then easily spread anger, threats and aversion emotions to further worsen the crises (Jin et al., 2014). Assessing and scrutinising such information is therefore important for organisations to control crises, develop responses, and repair images. Previous studies in crisis management have identified an array of strategies for crisis communication and image repairing (e.g., Benoit, 2018). This study builds on the key lessons of from these studies, and builds on stakeholder theory and image repair theory to propose new solutions for crisis communication and stakeholder engagement via social media platforms.

Given the new role of social media platforms in crisis communication, scholars have put emphasis on the complex interconnectedness and centrality of emerging stakeholders in crises (e.g., Sedereviciute and Valentini, 2011). Using the stakeholder salience model (SSM) and social network analysis (SNA), this study aims to advance our understanding of the interface between image repair strategies and stakeholder salience. As such, this study aims to unbundle the critical W’s. These include: what is the conversation, who is framing the conversation, why do crisis-stricken organisations respond, and when they do.

To unbundle the W’s, this study is anchored in a research agenda to address:

RQ1: How do (emerging) stakeholders shape the conversation about crises using social media platforms?
RQ2: What topics of conversation, and which stakeholder groups, encourage crisis-stricken organisations to respond?
RQ3: Is stakeholder mapping an effective tool? And, can crisis-stricken organisations use stakeholder mapping to identify salient stakeholder groups?

**Literature review**

Grounded on traditional stakeholder theory, dominant logic in crisis communication discourse relates to the premise that: (i) a range of stakeholders will be involved in ex-ante and ex-post crisis communication (Wagner Mainardes et al., 2012), and (ii) organisations will attempt to communicate with certain stakeholder groups to manage the situation and reduce any reputational damage (Luoma-aho & Paloviita, 2010). To effectively manage crises, and reduce reputational risk (Benn et al., 2016), it is imperative for organisations to classify stakeholders and define dyadic stakeholder-organisation relationships. Parallel to the rise of social media platforms, however, interest and participation in crisis communication has become more accessible and fluid (Valentini & Kruckeberg, 2016), with organisations facing new challenges in stakeholder mapping procedures.

Traditionally, organisations could evaluate and categorise stakeholders with a scope to identify
the most salient stakeholder with prioritised stakeholder claims. Based on this evaluation process, an organisation could then respond directly to stakeholders with priori claims. Concomitant with the rise in social media, though, the evaluation of salience is becoming less static, with frequent changes in powerful, urgent, and legitimate stakeholders. What’s more, social media has also introduced a new environment in which ‘undiscovered’, ‘new’, and ‘unknown’ stakeholders can emerge (Himelboim et al., 2014).

The fundamental challenges for crisis-stricken organisations, therefore, are:

i. Requirements to grasp – and difficulties associated with grasping – the complex relationship between crisis situations and social media platforms;
ii. The emergence of new stakeholder groups, with Wan et al (2015) identifying new stakeholder labels, such as social media creators, social media followers, and social media inactives.

Addressing these challenges would make it possible for organisations to reconfigure their stakeholder maps, and thus recalculate salience calculations. Such possibilities could result in crisis-stricken organisations being better equipped to make optimal, rather than sub-optimal, crisis management decisions. An initial step toward providing a solution is provided by Sedereviciute and Valentini (2010). In their study, the author combined the Stakeholder Salience Model (SSM) and Social Network Analysis (SNA) to permit a mechanism to find and prioritise stakeholders on social media, with an emphasis on connectivity and content dimensions. The first dimension (i.e., connectivity), rooted in network theory, is based on connections between different online stakeholders on social media, as well as the dyadic connections between online stakeholders and the organisation. The core argument is that if an online stakeholder has a more prominent position in social media networks they will be viewed as more powerful. The second dimension (i.e., content), on the other hand, is preoccupied with the content and words propagated on social media platforms, such as Twitter, as well as the interest and relevance of this content for other online and offline stakeholders. Essentially, when an online stakeholder is seen as propagating interesting and relevant information on social media they will be deemed as urgent. When an online stakeholder is deemed both powerful (based on position) and urgent (based on content), they will be viewed as more legitimate by the crisis-stricken organisation, and thus will generally attract a response. As noted by Sedereviciute and Valentini (2010), these two dimensions will shift the traditional conceptualisation of powerful, urgent and legitimate stakeholders, and introduce new stakeholders into the mix, notably: unconcerned influencers (dormant stakeholders), concerned influencers (definitive stakeholders), unconcerned lurkers (non-stakeholder), and concerned lurkers (dependent stakeholders). This understanding will therefore be taken forward to assess who is important in crisis-related conversations on social media, and how they shape conversations on social platforms.

**Methodology**

*Data Collection*

This study develops a tweet analysing and stakeholder mapping tool to collect, extract and analyse the data from Twitter. The tool includes four analyses as illustrated in Figure 1: tweet word counts analysis (to classify trendy keywords); tweet cluster analysis (to identify dominant image repair strategies and prevalent crisis topics); tweet sentiment analysis (to identify the tweet sentiments and the pattern of information diffusion) and social network analysis (identify emerging emerging stakeholders).
The tweet datasets in this study are captured by a Twitter Application Programming Interface (i.e. QDA Miner and NodeXL), they contain seven recent crises and extreme events (Table 1). The software is selected based on their extensive features on exploring and analysing textual data.

Prior to the analyses, the Twitter datasets are normalised and tokenised (Liau and Tan, 2014) in the QDA Miner software package to stem and remove stop words. Other high frequency but pointless words (e.g., HTTP, HTTPS, RT, etc.) are also removed and common misspellings are corrected.

**Word Count Analysis**

For word count analysis, the QDA Miner is used to generate word count frequency (Table 2) and predict the popular topics from the textual data. The major characteristics are also extracted in the proximity plot (Figure 2) (Mostafa, 2013).

**Social Network Analysis**

The social network analysis (SNA) (Coombs, 2002) is performed to identify the key stakeholders who are accounted for the information distribution. NodeXL is employed to calculate the in-degree (the total mentions of a twitter account), eigenvector centrality (the total connections to other influential accounts) and betweenness centrality (the numbers of shortest connections with other non-neighbouring accounts) of each account in the network.
Table 5. The top 10 stakeholders based on in-degree, eigenvector centrality and betweenness centrality for the O2 UK Day-long Outage dataset

Results and implications
The word count frequency presented in Table 2 provides the basic tweet information on each dataset, the results help to construct key topics, identify main stakeholders, compare relationships between incidents and lay down the foundations for later sentiment analysis. In Table 2, the top keywords from each dataset are those mainly used to describe the crisis.
situations, the cause of the crisis and the public expectations. They form the main topics during the crises which link to the main stakeholders. For instance, the keywords used in the Fiat-Chrysler Dieselgate dataset are related to the RECALL due to the VEHICLES EMISSIONS CHEATING, and expecting SETTLEMENT PAY. In Figure 2, these keywords are compared against ‘DIESEL’ problem and the ‘DIESELGATE’ crisis. It can be noted that stakeholders have mentioned more about whether or not AGREES have been given to SETTLE the DIESEL problem, compare the stakeholder in the DIESELGATE who are more concerned with the cost in MN (millions) to SETTLE.

Table 3 highlights the important and related keywords and how they form popular topics. For instance, tweets to describe the crisis incidents, provide information about the impacts are affected areas, products are focal topic groups in every datasets. However, there are also tweets, although less, that form topics to offer suggestions and give feedback (to reduce the crisis impacts), asking questions (to fix the problem). In addition, there are also tweets represent groups to express jokes (schadenfreude) and sending disappointed messages (blame).

From the results of the SentiStrength classifier illustrated in Table 4, the overall average sentiment of all between the band distribution of circa -1/+1, which may indicate that some tweets are not very affective (Mostafa, 2013) and suggest a more detailed analysis to look into the sentiment score of each topic group/stakeholder group and at different timeframe for more meaningful explanations (Cao et al., 2018).

The results of the SNA to the O2 UK Day-long Outage dataset is illustrated in Figure 3 and explained in Table 10. Each of the three metrics used in this study indicate the influence of the tweeter users, such as a high in-degree indicates a high fluence of the account, a high eigenvector centrality represents a large number of connections with other influential accounts, and a high betweenness centrality shows an account with the most numbers of shortest connections with other non-neighbouring accounts. In this study, the key influential stakeholders are listed in Table 10. In particular, @sturdyAlex is the most influential stakeholder, as this account has the highest in-degree and eigenvector centrality, and a high betweenness centrality within the top 10 range. @2b_as and @EssexBuccaneer are two other important influential stakeholders.

**Conclusion and recommendations**

By adhering to Sedereviciute and Valentini’s (2010) holistic approach to stakeholder mapping, within the context of several novel and important crises, this research has uncovered a few important research notes. These are:

i. Concerned and definitive stakeholders have the capacity to shape crisis-related conversations based on their position within social media networks. For example, @sturdyAlex was seen to influence the narrative through a central position.

ii. Once categorised as non-powerful, non-urgent, and illegitimate, these undiscovered online stakeholders require responses from crisis-stricken organisations in order to control and mitigate reputational damage, as was seen in the O2 outage case.

iii. The combination of SSM and SNA facilitates the identification of new, undiscovered online stakeholders, which are integral in the narrative, tone, and longevity of crisis situations and their manageability.

To advance this research effort, and to generate managerial implications, the authors call for
further research on online stakeholders, especially those on Twitter, to identify the timeframe in which they are powerful, urgent, and legitimate. This can then be mapped against company response. Scholarship could also compare online stakeholders with offline counterparts to review salience across channels.

Operations Strategy
Understanding operating strategies for platforms and business ecosystems in Industry 4.0: Towards a conceptual framework

Sabine Baumann (sabine.baumann@jade-hs.de)
Jade University of Applied Sciences

Abstract

The Industry 4.0 concept proposes full flexibility of production environments to fulfil vastly individualized customer requests and requires increasingly digitized production settings. The future design and implementation of essential value-creation architectures will increasingly be based on standardized technological platforms. However, the operating strategies for the necessary platforms and multi-industry business ecosystems are not well understood. The purpose of this paper is to mitigate these limitations by introducing the emerging research stream on platforms and business ecosystems. It explicates the novelty and the usefulness of ecosystem-based approaches for production and operations management, to pave the way for a cumulative, interdisciplinary body of knowledge.

Keywords: Industry 4.0, platforms, business ecosystems

Introduction

The Industry 4.0 (I.4.0) concept aims at fulfilling extremely individualized customer requests and moves away from predetermined supply chains towards highly flexible production environments. This flexibility challenges the role of the focal firm as coordinator and central decision maker in a production and supply network. Besides implementing the best real-time combination of actors for each individual order (Holweg & Helo, 2014, Stein et al., 2014) focal firms face managerial problems. The actors that contribute to the focal offer’s value proposition increasingly operate via platforms and a growing number of complementary offers come from new partners outside the traditional industry settings (Gawer & Cusumano, 2014, Kapoor, 2018). These so-called business ecosystems bring their own set of rules and often ensuing loss of direct control for the focal firm over its production and supply network. In addition, the operating strategies for platforms and multi-industry business ecosystems are not well understood.

The purpose of this paper is to mitigate these limitations by introducing the emerging research stream on platforms and business ecosystems. It explicates the novelty and the usefulness of ecosystem-based approaches for production and operations management in order to pave the way for a cumulative, interdisciplinary body of knowledge. To achieve this purpose the author investigates the key tenets in research on platforms and business ecosystems in strategic management and in operations and production management literature and how they relate to established perspectives of value chains and of
production and supply networks. Based on this analysis the author proposes elements and constructs for a cumulative concept for operations and production management on platforms and business ecosystems for I4.0 settings.

The paper is organised as follows: the first section briefly describes the concept of I4.0. The following method section explicates information on the design and implementation of the literature review of operations and production management and strategic management research. The main part of the paper depicts the key tenets of the emerging research stream on platforms and business ecosystems and how they relate to established perspectives of value chains and of production and supply networks. Finally, the elements and constructs for a cumulative concept for operations and production management on platforms and business ecosystems are being derived for I4.0 settings. The paper closes with a conclusion and an outlook on future research.

The concept of industry 4.0
The term Industrie 4.0 (industry 4.0) was coined by the German government in their High-Tech Strategy Action Plan 2020 that addresses the increasing global competition on product quality and production costs faced by the German manufacturing industry. Nevertheless, even before the launch German manufacturing companies had started to exploit emerging technologies such as digitalization, the internet of things (IoT), internet of services (IoS) or cyber-physical systems (CPS) in search of new digital business models.

Although the concept Industry 4.0 is now widely discussed, neither academia nor practice has arrived at a generally accepted definition of what the concept comprises in terms of the actual objectives, the relevant technologies, or the applicability for different industrial sectors.

Following Baumann (2018) this paper defines industry 4.0 “as a concept in which companies, machines, devices and computers cooperate through digital technologies in horizontal and vertical networks to manufacture highly-individualized products. By connecting plants, equipment, machines, products and workpieces through information and communication technologies (ICT) into cyber-physical systems these networks continuously share information in real-time” (p. 2). The term smart manufacturing will be used interchangeably with I4.0 in this paper as it expresses the same ideas.

The I4.0 concept can be captured into four components: business models, enablers, information, and network management (see figure 1), which are briefly explained (see Baumann 2018 and the literature mentioned there for a more detailed description).

![Image of a diagram showing the four components of the Industry 4.0 and smart manufacturing concepts (Baumann 2018)](image)

*Figure 1: Components of the industry 4.0 and smart manufacturing concepts (Baumann 2018)*
**Business Models**

I4.0 business models either address cost reductions or capturing new business opportunities such as innovative products and services. The majority of new digital business models is based on data analytics, for example predictive maintenance. Extended models move to service offers where the customer pays for equipment use, but no longer buys the equipment. From a cost reduction perspective I4.0 increases production flexibility and adaptiveness, speeds up reaction times or improves overall effectiveness of manufacturing equipment.

**Network Management**

The best real-time combination of actors regarding objectives such as timing, cost, quality levels, etc. for each individual order can only be achieved through extended vertical, horizontal, and lateral collaborations. Actors face a trade-off between installing efficient production and supply networks for particular products while being flexible enough to be part of alternative networks for required product differentiations. Furthermore, the role of the focal firm as principal coordinator becomes increasingly decentralized in I4.0 settings (see also the discussion of business ecosystems below).

**Enablers**

I4.0 grounds in a variety of enablers, such as *Cyber-physical systems (CPS)*, *Internet of Things (IoT)*, *Internet of Services (IoS)*, and *Smart factory*. CPS connect computation with physical processes, so in manufacturing CPS refers to monitoring and controlling the processes via computer networks (through the use of multiple sensors, actuators, control processing units, and communication devices) and synchronising information related to the shop floor. Manufacturing execution systems (MES) link enterprise resource planning (ERP), production planning and control (PPC), and the actual shop floor to integrate all network participants. Thus, MES allow the shop-floor to become a marketplace where the allocation of capacity is self-coordinated with multi-agent systems. In *IoT* settings (physical) things connect to the internet with the use of RFID tags, sensors, actuators, or small computers. These “smart things” interact with each other and cooperate with their neighbouring ‘smart’ components in order to reach common goals. *IoS* makes services available through web technologies or software as a service (SaaS) and allows companies and consumers to access to the resources and service functions of another party. The idea of the *Smart factory* proposes a decentralised production network comprised of human beings, machines and resources. Digital connectivity enables an automated and self-optimised production and delivery free of human interventions or the customary central steering entity. Advanced data analytics derived from the operations of these connected systems provides decision support to both machines and humans.

**Information**

I4.0 grounds in extensive data collection, (big) data analytics and the implementation of efficient decision support and data-based self-coordination systems. The processes within the information processing chain in I4.0 systems also need to be evaluated from the perspective of value added by these processes, i.e. a detailed analysis of their accompanying value architectures in order to compare value propositions of competing I4.0 solutions (Wunck & Baumann, 2017).

**Design/methodology/approach**

IA content-analysis-based literature review is being completed, in which an inductive and multi-level coding procedure is applied on >120 articles on platforms and business...
ecosystems, spanning the literature in production and operations management and strategic management. The following section shares the key tenets in research on platforms and business ecosystems in strategic management and in operations and production management literature and how they relate to established perspectives of value chains and of production and supply networks.

**Cooperation and value creation scenarios**

The cooperation of companies, machines, and computers through digital technologies is central to the provision of individualised products and services in I4.0 settings. These collaborations are realized by integrating technical and organisational processes into order-based value creation architectures that include all actors that contribute to the focal offer’s user value proposition. Central elements of these value creation architectures are platforms and business ecosystems which are introduced in the following section.

**Platforms**

The concept of platforms is being discussed differently in economic (e.g., Rochet & Tirole, 2003 or Cennamo & Santalo, 2013) and engineering (e.g., Meyer et al., 1997 or Jiao, Simpson & Siddique, 2007) research. Economics investigates transactions on platform markets between different customer groups as well as the influence of network effects on competition. In contrast, engineering research regards platforms as technological designs that help firms generate modular product innovations (Brax et al., 2017; Gawer, 2014; Sköld & Karlsson, 2012).

Engineers interpret platforms as technological architectures that have been specifically developed (including their interfaces) so that their components can be utilised systematically across different products of a product family. Design and usage of these platforms allow for economies of scope in product development and production. Consequently, implemented platforms bear permanent structures while changes occur for newly developed or redeveloped modules, in order to achieve economies of scope through platform-based product development (Gawer, 2014; Jiao, Simpson & Siddique, 2007; Sköld & Karlsson, 2012).

In economic models platform competition is driven through the adoption of a platform through multiple user groups who themselves are being compelled through network effects. In the relevant literature network effects are distinguished into direct and indirect effects. Direct (or horizontal) network effects emerge through changes in the number of users of a platform (or a technology or a particular product): the higher the number of users, the higher the value for the users. Indirect (or vertical) network effects arise when the benefit of the platform (or technology or product) is not determined by the usage, but is determined by applications or complementary products that are based on or leveraged through the platform. Consequently, the influence on value is not determined by a direct relationship, but through a vertical network of interdependent complementary goods. It follows that it is not single products or components of the network that generate the value, but instead value is created through an inherent interdependency of the demand of two or more user groups. This mutual interdependency of two or more market sides in turn produces a self-supporting feedback loop (Hagiu & Wright, 2015; McIntyre & Srinivasan, 2017).

From the perspective of economic theory, value creation of platform relies on connecting user groups that would otherwise not be linked and could not transact with each other. The price settings of the platform operator coordinate these user groups. Developing the optimal price menu therefore is one of the central problems of platform management. Prices need to be set such that they motivate users from the relevant groups
to participate and transact on the platform. Specifically, attracting an increasing number of users from multiple user groups creates benefits for both the platform participants (increased value) and the platform operator (increased profits) because of the indirect network effects. This means that network effects are an essential attribute of platforms as they reflect the exogenous demand dependencies of different user groups and consequently shape platform competition. Thus, the economic perspective addresses the question under which conditions platforms could become dominant and or even drive out all other platforms in a „Winner-takes-all“ rivalry (Eisenmann, Parker & van Alstyne, 2006; Rochet & Tirole, 2003).

**Business ecosystems**

Digitization not only provides data to develop new data-driven business models, but also requires collaborations with companies that have not been part of the traditional supply chain of an industry. Through these collaborations so-called Business Ecosystems emerge, i.e. company networks that link incumbents from different industries and on horizontal, vertical, and/or vertical level. Simply put a business ecosystem comprises the set of partners that contribute to the value promise of the focal firm (focal offer). The focal offer can consist of a product and/or service that has been created with or without a platform-based architecture. The biological term ecosystem conveys the mutual interdependency of the partners that together operate as a combined system. In addition the analogy suggests that the partners in a business ecosystem may well come from different industries and that the system persistently changes over time: partners compete with each other, new partners join and others leave the system, connections between ecosystem partners change (Kapoor, 2018).

Business ecosystem participants mutually influence each other because of simultaneously existing independencies and complementarities. Interdependencies between partners arise through the combination of their offers within the system architecture in the production of the final product and/or service. Opposed to that complementarities emerge because the combination of the partners’ offers provides or increases value for the user/consumer. Economics investigates for how companies can survive competition in business ecosystems given these interdependencies and complementarities (e.g., Adner & Kapoor, 2010; Baldwin & Woodard, 2011; Hannah & Eisenhardt, 2017; Jacobides, Cennamo & Gawer, 2018 or Pierce, 2009).

The business ecosystems perspective differs from long-established concepts such as the value chain and the supply chain regarding focus and also the subject of investigation. Porter’s value chain centers on the focal firm and investigates how the focal firm can derive competitive advantage in a specific market through organising its value creation activities to achieve cost leadership or differentiation (Porter, 1996). Supply chain research studies the efficient design and coordination of object flows (goods, information, values) along all stages of a supply chain through which a product is manufactured and then distributed to the final customers (MacCarthy et al., 2016). In particular, it investigates coordination problems in buyer-supplier-relationships along the entire supply chain (Pullman & Dillard, 2010). As the supply chain typically involves different companies and supply chain research consequently extends its emphasis beyond the focal firm. Compared to business ecosystems supply chain investigations do not consider complementarities of demand and the structure of interdependencies (Kapoor, 2018; Kapoor & Lee, 2013).
Management of value creation architectures in industry 4.0
The management of value creation architectures in I4.0 comes with a number of challenges. Particularly relevant are the integration of technological platforms, coordinating partners in business ecosystems with complementary offers and dealing with bottlenecks.

Bottlenecks
Bottlenecks can occur in any system that consists of more than one component. They limit the performance of the entire system (dominance of the minimum sector). Accordingly, partners in business ecosystems can constrain the performance and growth of the focal firm’s offer due to their output, capacities or incurred costs. Similarly, interactions between components can be determined through the technological architecture such that improvements in the performance of one partner reduce or balance weaknesses of another partner and vice versa. Identifying and dealing with bottlenecks that result from technological innovations or business models therefore is one of the central problems of business ecosystem management. Besides developing value creation architectures with reduced bottleneck effects business ecosystem management concerns resource allocations between and mutual support of business ecosystem partners in order to resolve bottleneck situations (Adner & Kapoor, 2016; Kapoor, 2018).

Partners with complementary products and services
Providers of complementary products and services (complements) are central to business ecosystems, because they increase the value of the focal firm’s offer (e.g., smartphone apps or infrastructure for charging electric vehicles). The function of the complements differs depending on how they contribute to the focal offer. A strict complementarity between two goods exists, if the goods have no usage value without each other (e.g. razor and blade). A super-modular complementarity describes a relationship where an increase in complements (availability, performance) increases the value of the focal offer (e.g., smartphone and number of apps, or electric vehicles and charging stations). Furthermore, complements can be generic or specialised regarding the focal offer (Jacobides, Cennamo & Gawer, 2018).

Figure 2: Roles in business ecosystems: supplier vs. provider of complementary goods (based on Kapoor, 2018)
The interdependency between providers of complementary products and services differs from that between a focal firm and its suppliers in the context of a supply chain. The latter concerns a sequential supply-side interdependency determined by the focal firm who decides how the supplied product or service is integrated into the focal offer. In the case of a complementary product or service offer (at the market level) the users of the focal offer decide on the integration of complementary offers. Figure 2 visualises the difference.

Compared to managing traditional supplier relationships the focal firm faces much higher operational challenges in business ecosystems. Relationships with suppliers are typically steered via bilateral contract-based formal mechanisms that regulate amounts, timing, and prices of supplies. Opposed to that the relationship with providers of complements concerns establishing multi-lateral alignment of offers with all relevant partners in the business ecosystem. This alignment relationship is about ensuring successful joint value creation (e.g. standards of cooperation, roles in business models) and the consecutive value appropriation across the partners, including rules to resolve conflict. In addition, the function of the complementary offer (strict, super-modular) poses significant alignment challenges, in order for the focal firm’s value promise to be actually realised (Kapoor, 2018).

**Platforms**

Many value creation architectures organise the offer of complementary products and services via a central platform architecture. It is important to note that the management of product-based and platform-based business ecosystems differs considerably. Platform-based ecosystems are being orchestrated by the platform owner, who designs the platform architecture and determines the rules of participation. As such the platform owner also decides on the alignment structures with providers of complementary goods and services. In contrast, the rules in product-based business ecosystems are being determined jointly by the product company and the providers of complements.

In platform-based ecosystems the owner also defines the interface of the platform architecture through which providers of complements can access the platform as well as any changes over time (e.g., enhanced platform generation). Since every platform has its own specific interfaces providers of complements have to invest for their participation. They also have to decide in how many platform they want to participate (single- vs. multi-homing). Multi-homing provides them with a higher number of market opportunities, but increases costs through the necessary product adaptations for each platform. From the platform operator’s perspective increased multi-homing reduces the relative value of their platform compared to competitors (Eisenmann, Parker & van Alstyne, 2006; Kapoor, 2018).

Product-based business ecosystem contain a single-sided market transaction between the focal product firm and the user. Platform-based ecosystems, however, relate to two- or multi-sided markets, on which the platform company interacts with complement providers and users that influence each other’s platform benefits through mutual network effects (Rochet & Tirole, 2006). This multi-sided market interaction is a critical aspect of the necessary alignment structure, because it has to be designed such that it reinforces the platform value proposition through adequate price setting and subsidies (Rochet & Tirole, 2006, Rochet & Tirole, 2003; Eisenmann, Parker & van Alstyne, 2011).

In the context of I4.0 companies are expected to be able to develop and provide highly individualised products and service as participants of a value creation architecture. Depending on the order requirements the value creation architecture is assembled from a set of possible actors (Baumann, 2018). That means the architectures typically differ for
different orders. Ecosystem participants therefore have to take a number of strategic decisions. As focal firms they have to determine, for example, the structural design of the value creation architecture, the composition of the business ecosystem and which parts of the value creation they want to cover themselves (Kapoor, 2018; Pierce, 2009). Providers of complementary goods and services have different roles depending on whether they participate in product- or platform-based ecosystems. Their opportunities are limited by required technologies and necessary funds as well as their market position. Small and medium-sized enterprises (SME) in particular have to ensure that they are part of competitive value creation architectures, while competing successfully for orders in the business ecosystem. They face a trade-off between differentiation (unique selling proposition) and efficiency (e.g., cost minimisation, resource allocation). An increased degree of differentiation may allow for a higher share of value appropriation, but at the same time limits potential inclusion in a large number of value creation architectures. A higher standardisation improves connectivity, but with the danger of being easily replaceable (Baumann, Eulenstein & Wunck, 2017).

Conclusion
This paper elucidates the development and current state of platform and business ecosystems literature and synthesizes the strategic management and the operations and production management perspectives into a multifaceted view in I4.0 settings. A content-analysis-based literature review was completed on platforms and business ecosystems, spanning literature in production and operations management and strategic management. It was found that the number of studies in operations and production literature on business ecosystems is still low, while strategic management research is more advanced in their discussions. However, the latter often lacks the application perspective which is offered by the dynamic I4.0 settings. Exploring the ecosystem perspective in different research fields therefore helps to explain firms’ manufacturing and supply strategies and to assess outcomes in I4.0 settings through the lens of complementarities and interdependencies. By identifying and defining key elements and constructs the paper introduced a first draft for a platform and business ecosystem framework for extending future production and operations management research.

The cooperation of companies, machines, and computers through digital technologies is central to I4.0. These collaborations are realized through so-called business ecosystems, i.e. sets of actors that contribute to the focal offer’s user value proposition. The ecosystem perspective explicitly links supply-side and demand-side of focal offers and also considers contributions from multiple industries. It relates to traditional views of managing production and supply networks though investigating interdependencies between actors, because their offers are connected within a system-level architecture. In addition, it simultaneously considers complementarities between actors whose respective offers help to create or enhance the user value proposition. Consequently, interdependencies embody structural relationships between offers through their value contributions and the way changes in one offer affect the value contribution of other offers, whereas complementarities represent an economic value creation relationship between offers endorsed by the user.

However, business ecosystems come with a number of operational challenges. In the context of I4.0 the integration of technological platforms, coordinating partners in business ecosystems with complementary offers and dealing with bottlenecks are of particular relevance. These issues must be addressed on the level of the value creation activities, the perspectives of the different actors and the structure of the business ecosystem. Therefore additional research both in the production and operations
management and the strategic management fields is needed on three levels: the focal offer (innovation, technology), focal firm and the business ecosystem.

Abstract

Modularity has extended its application from product, process and organizational domains to newer ones such as services and business models. This growing literature has built up on the assumption that business models are complex systems and, as such, modularity could harness multiple benefits, such as business model innovation. In this sense, the aim of this article is to analyse the main theoretical insights towards the application of modularity principles to business model. Business model modularity is in exploratory phase, needing deeper theoretical refinements in order to identify main constructs and variables.

Keywords: Business model, Modularity, literature review

Introduction

Modularity, as a general systems concept, entails the “degree to which a system’s components can be separated and recombined” (Schilling, 2000, p. 312). In this sense, modularity is an attribute of complex systems (Campagnolo and Camuffo, 2010) and architecture in one important concept as it refers to the allocation of functions to components and, as for a product architecture, the allocation of functions to physical components and the specification of interfaces among components (Mikkola and Gassmann, 2003; Ulrich, 1995). Therefore, as a design principle, modularity allows for complex systems to decompose complex tasks into simpler ones (Frandsen, 2017; Mikkola and Gassmann, 2003) and standardizing interfaces among components in order to enhance greater substitutability of components within an architecture (Mikkola, 2006; Voss and Hsuan, 2009).

Although the concept of modularity has been discussed for quite a long time in the literature, its application in the management literature has been particularly focused on product modularity, production systems modularity and organizational modularity (Campagnolo and Camuffo, 2010). On the other hand, research has been recently
discussing modularity in other domains such as service modularity (Aas and Pedersen, 2013; Avlonitis and Hsuan, 2017; De Blok et al., 2014; Brax et al., 2017; Kuula et al., 2018; Pekkarinen and Ulkuniemi, 2008; Voss and Hsuan, 2009) and business model modularity (Abdelkafi et al., 2018; Aversa et al., 2015; Gärtnert and Schöen, 2016; Hellström, 2014; Scannella, 2015; Snihur and Tarzijan, 2018; Tsvetkova et al., 2015; Tsvetkova and Gustafsson, 2012).

Applying modularity principles to business models build up on the considerations that business models are complex systems (Aversa et al., 2015; Foss and Saebi, 2017a), which are treated as an architecture for value creation and delivery in which specific functions are assigned to modules (Foss and Saebi, 2017b). As such, modularization allows for the decomposition, recombinability and manipulation of modules within a business model (Abdelkafi et al., 2018; Aversa et al., 2015; Gärtnert and Schöen, 2016; Tsvetkova and Gustafsson, 2012). As a consequence, modularization of business models has the potential to deliver multiple benefits for firms, such as enhance business model innovation (Aversa et al., 2015; Foss and Saebi, 2017b; Gärtnert and Schöen, 2016; Minatogawa et al., 2018) through modular innovation (Foss and Saebi, 2017b; Gärtnert and Schöen, 2016) and provides firms with strategic flexibility and adaptability (Aversa et al., 2015; Gärtnert and Schöen, 2016; Tsvetkova and Gustafsson, 2012), extends and adds to firm’s value propositions (Hellström, 2014). Besides, modularity allows for cost reductions and smart use of resources (Abdelkafi et al., 2018) and also allows for the creation of platforms for solutions delivery (Cenamor et al., 2017; Kuula et al., 2018; Tsvetkova et al., 2015), specially in the cases of servitization, service-dominant logic or product-service systems (Brax et al., 2017; Cenamor et al., 2017; Kuula et al., 2018).

Despite the assumptions that modular business model are a mirror of modular product architectures (Najmaei, 2016), successful innovations of firms goes in parallel with business model innovation (Kodama, 2004). Although there has been a growing potential for future research opportunities in the business model modularity field, there is still a lack of fertilization between modularity and strategic concepts (Gärtnert and Schöen, 2016) and, due to its complex nature, there are number of several research possibilities (Aversa et al., 2015).

Therefore, the aim of this article is to analyse the main theoretical insights towards the application of modularity principles to business model field, looking to respond to the following research question (RQ): How are modularity principles being applied to business model in the literature? For answering this question, a literature review was performed, with an in-depth content analysis of 63 articles.

The article is structured in five sections. The first one corresponds to the introduction to the theme, highlighting the relevance of analysing this theme. The second section brings the research methods carried out in this research. The third section brings the main discussions and results of the systematic literature review. In sequence, the fourth section brings the main conclusions drawn from this research. Lastly, the references utilized are shown in section 5.

**Research Methodology**

The research design is a literature review applying qualitative content analysis. A codification scheme was developed and applied with the support of MaxQDA software. The sampling procedures comprised ISI Web of Science Core Collection (WoS) and Scopus databases. The following search query was utilized: “business model*” AND “modular*”. The keywords were selected to appear in the articles’ “title”, “abstract” and “keywords” in both databases. Additionally, the filter applied in both databases aimed to select only “articles”, “reviews” and “articles in press”. In total, 119 documents were
found in WoS and 202 in Scopus, resulting in 59 and 84 articles only after the abovementioned filter was applied with an overlapping of 42 articles. In Scopus, out of the 42 articles that were not overlapping with WoS, 4 were also found in this database but did not appear in the first research and included in the final sample. Finally, 63 articles composed the final sample from WoS. This database was selected as it is regarded as having a higher quality (Chadegani et al., 2013).

In order to perform the qualitative analyses, the research protocol followed the recommendations of Tranfield et al. (2003) which are (i) planning the review with research question, search strategy and coding, (ii) conducting the review and (iii) reporting the results. All articles were read and analysed, but only those articles discussing modularity in the business model domain were discussed in this article. This criterion was utilized in order to achieve the goal of this article which is to analyse the main theoretical insights towards the application of modularity principles to business model. In addition, the codification scheme was developed and applied in order to carry out the systematic literature review.

The codification was crafted mixing deductive approach based on theoretical background extracted from the analysis of articles identified in the co-citation and keywords networks generated for this database through bibliometric analysis. Codes were related to modularity features such as degree of coupling, decomposability and substitutability (Mikkola, 2006, 2007; Mikkola and Gassmann, 2003; Schilling, 2000; Schilling and Steensma, 2001), pre-requisites and catalysts such as labor intensity, competitive intensity, technological change and availability of standards (Schilling, 2000; Schilling and Steensma, 2001) as well as drivers such as balancing standardisation and customization and reduce system’s complexity. Also, business model building blocks proposed by Osterwalder (2004) were also used as codes, being (i) value proposition, (ii), target customer, (iii) distribution channel, (iv) relationship, (v) value configuration, (vi) capability, (vii) partnership, (viii) cost structure and (ix) revenue model. The codification was done using MaxQDA software, in which the codes we assigned to segments related to each topic and latter analysed in order to identify the main patterns and insights from this stream of literature.

Results and discussion
In the sample analysed, articles were discussing a diverse range of topics in which some of them, business model and modularity combined were not the object of study. In addition, in some studies, although modularity and modular approaches were proposed/applied, the theoretical elements of modularity were underspecified or missing or only mentioned in the article without proper theoretical backing. As such, these articles tend to assume modularity as a given, pre-conceived notion without specifying which features and elements of modularity were utilized.

On the other hand, a variety of articles discussed business model and modularity in a deeper and insightful manner (Aas and Pedersen, 2013; Aversa et al., 2015; Gärtnert and Schön, 2016; Hellström, 2014; Khan et al., 2018; Kodama, 2004; Kuula et al., 2018; Meier et al., 2011; Najmaei, 2016; Richter, 2013b, 2013a; Scannella, 2015; Snihur and Tarzijan, 2018; Spring and Araujo, 2009; Tsvetkova et al., 2015; Tsvetkova and Gustafsson, 2012).

Within the business model literature, business models are seen as the architecture for the value creation, delivery and capture of firms (Amit and Zott, 2001, 2015; Teece, 2010; Zott et al., 2011; Zott and Amit, 2007), composed of elements, modules or building blocks built together in an interdependent fashion (Demil and Lecocq, 2010). Thus, defining business model modularity is one necessary step so as to evolve in identifying the main
features around this stream of literature. Business model modularity is defined as “sets of choices about their (business model) elements, their combination and coordination through which value is created and captured” (Gärtner and Schön, 2016, p. 41) or, as highlighted by Aversa et al. (2015), since business models are composed of sub-categories and elements in an interconnected fashion, business model modularity consists of the ability to manipulate their components, facilitating changes in their design.

In treating business models as a set of interconnected modules and components, modularization, as a process, becomes one central aspect for business model modularity. In the work of Aversa et al. (2015), modularization is aimed to understand complex systems, such as business models, in simplified models of interconnected elements, drawing from modularity principles to achieve this purpose. Through this, Aversa et al. (2015) points out that understanding business model in a modular fashion should consider four cognitive steps, such as (i) identifying functionalities in a business model, (ii) assign functionalities do business model elements, (iii) prioritize which elements are focus of attention and (iv) decouple the interdependencies of these elements.

This modularization refers to conceiving complex systems as simplified models of interconnected elements (Aversa et al., 2015) in which the benefits of this process goes beyond its application to traditional domains such as product or technological systems (Gärtner and Schön, 2016). For Aversa et al. (2015), along with modularization as a process for business model modularity, manipulation and manipulability are key elements as manipulability allows for changes in business model design through the understanding of their components and their interdependencies. Recognizing business models as manipulable instruments (Aversa et al., 2015) refers to the need of conceiving and understanding business models in modular terms (Aversa et al., 2015; Gärtner and Schön, 2016).

For Aaversa et al. (2015), business models are manipulable instruments and manipulability is achieved through this modularization process and through understanding their components and their interdependencies. Manipulability, as a property of modular business models, relates to the changing of business model elements and their linkages (Aversa et al., 2015). Similarly, Tsvetkova and Gustafsson (2012) points out that manoeuvrability of business models for industrial ecosystems can be achieved through a modular approach. This ability to manipulate business model elements goes in line with the traditional feature of modularity of recombinability of components allowing for their mixing and matching (Schilling and Steensma, 2001).

Reducing and managing complexity is both an outcome and a driver to the modularization processes. In this sense, complexity surges as an important topic for the modularization of business models. According to Aversa et al. (2015), business models are viewed as complex systems and, as such, modularity is perceived as a problem-solving approach in order to decompose business models into components and elements to be further manipulated. Gärtner and Schön (2016) also highlights that firm’s business models are complex systems. In a different approach, Tsvetkova and Gustafsson (2012) and Tsvetkova et al. (2015) affirm that industrial ecosystems for biogas are complex and nearly-decomposable systems in which modularity serves as a way of managing and reducing complexity in which various business are considered modules in this ecosystem. Hellström (2014) discusses how a modularity-based solution business model contributed to manage the complexity in capital goods for power plant and shipbuilding cases. For Snihur and Tarzijan (2018), complexity is discussed in terms of managing multi-business models in a firm. In this sense, although the authors consider business model as complex systems, complexity is encountered within business model and between business models, entailing the complexity of managing various business models. As a result, modular
decentralization in organizational structure is necessary to manage low within complexity and between complexity as well as modular decentralization to manage high within and between complexities.

Within modularization of business models, balancing standardization and customization and the availability of standards within an industry surges as perceived drivers for business model modularity. In the industrial ecosystem approach for biogas, Tsvetkova and Gustafsson (2012) highlight that standardization in industrial ecosystem is necessary, but also needs to adapt to local business and material conditions, thus, customization is also required. It is noteworthy that Tsvetkova and Gustafsson (2012) propose a modular approach to business model for industrial ecosystem in which the modules corresponds to businesses and their functions in this ecosystem. In a subsequent article, Tsvetkova et al. (2015) argue that functions in industrial ecosystems are somewhat standardized, but requires degrees of customization to adapt to local conditions. In this sense, functional modularization in the business model for biogas industrial ecosystem may provide this balancing (Tsvetkova et al., 2015; Tsvetkova and Gustafsson, 2012) and also allows for the replicability of this business model (Tsvetkova et al., 2015).

Similarly, Hellström (2014) discussed the reasons behind modularization of two companies in the capital goods industry for integrated solutions business model based on functional modularity. In a power plant case, due to the high customization of each plant, economies of scale were not possible and, therefore, the company engendered modularity in order to standardize the content of sub-suppliers and manage demands for customization (Hellström, 2014). In terms of the availability of standards within an industry as pre-requisite/catalyst for modularity (Schilling and Steensma, 2001), Scannella (2015) highlights that sharing of standards reduces asset specificity and transaction costs, facilitating intra and inter firm transactions. In this sense, the author argues that standardization of information collection and processing acted as one very important driver for the vertical disintegration of the loan industry. Also, Scannella (2015) points out that modularity acted as a driver for new business models in the banking industry and allowed for the modularization of pricing strategies for information in the industry.

Through the analysed articles in the sample, it was evidenced that business model modularity may also entail a different level of analysis. On one hand, the modularization of business model building blocks was discussed in order to allow for their recombinability and flexibility (Aas and Pedersen, 2013; Abdelkafi et al., 2018; Aversa et al., 2015; Gärtnert and Schön, 2016; Richter, 2013a). Abdelkafi et al. (2018) discussed how modular business model (and modular value proposition) allowed for the updates of building blocks in education services, cost reductions and a balance between standardization and customization. Aversa et al. (2015) transfer six modular operators from technology domain to business model domain in order to allow for changes in the business model architecture through the manipulation its elements. Gärtnert and Schön (2016) discussed business model modularity based on five modular elements, such as (i) product and service modularity, (ii) channel modularity, (iii) pricing modularity, (iv) asset and capability modularity and (v) partner network modularity. In the case of German utilities, Richter (2013a) proposes a modular value for German utilities to overcome inhibiting factors to business model innovation and, therefore, seize a growing opportunity in solar photovoltaic energy. A modular value proposition enables bundling of product and services, enhances flexibility and allows for different combination of modules (Richter, 2013a). Finally, Aas and Pedersen (2013) describes that business modelling modularity in a specialized public service providers enhanced management control, service and client orientations and service innovation.
In addition, platform approach to businesses enabled by modularity were also a stream of analysis (Cenamor et al., 2017; Kuula et al., 2018; Tsvetkova et al., 2015). Interestingly, this discussion emphasized the use of platforms in systems composed of a bundling of products and services, such as servitization, product-service systems and service-dominant logic. In these domains, platform approach facilitates implementing services, enables efficient use of resources (Cenamor et al., 2017; Kuula et al., 2018), defines roles such as platform orchestrators and offering builders (Cenamor et al., 2017). In the biogas industrial ecosystem, platform approach allows for the replication of the business model (Tsvetkova et al., 2015).

Cenamor et al. (2017) highlight the role of platforms and information modularity in facilitating servitization through customized and flexible offerings in manufacturing firms. Kuula et al. (2018) discuss a solution platform consisting of different modules in co-creation of knowledge intensive business services. Lastly, in a different segment, Tsvetkova et al. (2015 and Tsvetkova and Gustafsson (2012) argues that modularity is an enabler to business model replication for biogas industry in which platforms are useful for this purpose.

**Conclusion**

The aim of this article is to analyse the main theoretical insights towards the application of modularity principles to business model field. This study contributed to understand the underlying theoretical insights behind the application of modularity principles to business model through the execution of a systematic literature review.

Current research has discussed business model as complex systems and how modularity can act as a tool for reducing this complexity, allowing for recombinability and manipulation of modules. In addition, different focus of analysis was also identified. While some discussions emphasized business models and their building blocks, other articles analyzed business model for industrial ecosystems in which other business acted as modules as well as the role of platforms (enabled by modularity) for the delivery of solutions in servitization, service-dominant logic and product-service systems domains. Widely accepted drivers for modularity in the literature, such as balancing standardization and customization and the availability of standards were also identified as driver for companies to pursue modularity in business models.

Business model modularity is a growing and recent research field with field research in its exploratory phase. In addition, deeper theoretical refinements are still needed, despite of the previous observable attempt to do it, in order to identify the main constructs and variables for business model modularity evolve and be consolidated as a research field. One of the main limitations of this research refers to the sampling process. It was considered only one database for analysis and, while being recognized as having better quality than other databases, interesting and insightful articles may be left out of analysis due to this sampling bias.

Abstract

Existing researches focus mainly on how Industry 4.0 technologies affect the existing Lean practices in companies. On the other hand, the opposite perspective, concerning the impact that Lean Production can have on the Industry 4.0 transformation, presents few and very narrowed studies. This work intends to provide a contribution to the analysis of such perspective, hypothesising that differences in companies’ Lean adoption level also reflect differences in the way they are transitioning to Industry 4.0. This research adopted a multiple-case study approach and several case studies have been conducted in companies operating in the low-volume high-variety metalworking sector.

Keywords: Industry 4.0, Lean, multiple Case-study

Introduction

The transition phase towards Industry 4.0 and the integration of new technologies are not free of interrogatives and doubts (Buer, et al., 2018). One of the most discussed issues is surely related to the mutual relationship and integration between Industry 4.0 and Lean Production, the most prominent paradigm in the existing industrial environment (Costa et al., 2019; Kundu and Portioli, 2018). Described as a technology independent approach, Lean Production can be generally considered as a complement to the technological perspective (Kolberg, et al., 2017). Indeed, some examples of successful integration between these two paradigms exist and are usually referred to the term Lean Automation (Kolberg, et al., 2017). However, it is still pending a clear definition about the mutual relationship and integration between Industry 4.0 and Lean Production (Buer, et al., 2018).

The aim of this research is to investigate the relationship between Lean Production and Industry 4.0. In doing so, particular attention is posed in the understanding of whether and how different Lean maturity level within companies can affect choices regarding the
introduction of Industry 4.0 technologies. This article presents the preliminary results of the research conducted by authors, obtained from multiple case studies conducted through the use of semi-structured interviews. All the companies involved in the study are based in Italy and operate in the production of either machinery or low-volumes, high variety metal products.

**Literature review**

A literature review has been performed, considering the framework from Buer at al. (2018) as a reference to classify studies. This framework identifies four different “theoretical lenses” through which it is possible to look at the relationship between Lean Manufacturing and Industry 4.0. Each study within this field of research concerns one (or more) of the following relationships:

- Industry 4.0 supports Lean Manufacturing;
- Lean Manufacturing supports Industry 4.0;
- The performance implications of an Industry 4.0 and Lean Manufacturing integration;
- The effect of environmental factors on an Industry 4.0 and Lean Manufacturing integration.

The first of the four perspectives is the only one that has already been assessed by a wide set of studies (69% of the sample). These researches investigate the possibilities, included in the Industry 4.0 paradigm, that may bring Lean tools and practices to a higher level. The application of Industry 4.0 technologies to Lean Manufacturing methods has been commonly defined as Lean Automation (Kolberg, et al., 2017). Analysing this set of papers, it is possible to find examples and models for the development, through Industry 4.0 technologies, of all the main Lean practices.

A small set of studies focuses on the opposite perspective, that is the support provided by Lean Manufacturing to Industry 4.0 implementation. Various experts believe that Lean can be considered a prerequisite or enabler for the introduction of Industry 4.0 (Dombrowski & Richter, 2018) (Prinz, et al., 2018) (Davies, et al., 2017), however, this statement is typically shortly analysed and motivated. A few studies have been performed on very specific aspects, such as the application of the 7 Muda paradigm in a digital context (Romero, et al., 2018) (Teixeira, et al., 2018). Only the research by Sony adopts a more comprehensive approach, though it bases on a narrative literature review and does not include empirical evidence (Sony, 2018).

The third set of studies evaluates the consequences, in terms of performance, of the integration between Lean Manufacturing and Industry 4.0. (Sanders, et al., 2016) point out that the combination of Lean Production and Industry 4.0 technologies may increase productivity, reduce waste and therefore reduce costs. (Kolberg & Zühlke, 2015) instead argue that smart modular working stations combined with SMED could strongly improve companies’ flexibility. (Wagner, et al., 2017) state that the introduction of CPS in a JIT system may enhance reliability as well as reduce the inventory level. The study conducted by Tortorella and Fettermann, by targeting Brazilian companies, analyses the correlation between Lean level, Industry 4.0 implementation and operational performances (Tortorella & Fettermann, 2018). Furthermore, the research from (Rossini, et al., 2019), adopting a similar methodology and focusing on European companies, obtains results in agreement with those related to Brazilian firms. Despite of few exceptions, for both the second and third group of papers, there is a large adoption of qualitative methods and the focus is often directed towards specific aspects.

Finally, even though some researchers are starting to propose questions related to this topic, to the best of the authors’ knowledge, no study entirely focuses on the effect of environmental factors on an Industry 4.0 and Lean Manufacturing integration.
The outcome of the literature review suggested that the research on the relationship between Lean Production and Industry 4.0 is not mature yet.

**Research methodology**

According to (Yin, 2014), the adoption of a specific research methodology over the others strongly depends on three main conditions: 1) the type of research question, 2) the researcher’s span of control over behavioural events, 3) the degree of focus on contemporary or historical events. Given the study context and the defined research questions, the multiple case study was therefore selected as the reference methodology.

Each of the performed case studies was mainly characterized by two sources of information and data. The first one consists of a quantitative survey based on the model developed by Shah and Ward (2007). This instrument allowed to assess the state of Lean Production practices implementation in companies’ plants and to group in clusters similar companies. The survey is composed of 41 questions evaluating, with a score ranging from one to five, the extent of implementation of Lean Production practices within a specific plant. The second source relates instead to the conduction of semi-structured interviews addressed to companies’ managers involved in both Lean and Industry 4.0 projects. The interviews were based on a set of questions covering aspects related to Industry 4.0 and its integration with Lean Production practices. This way of conducting interviews allows to blend closed- and open-ended questions, often combined with follow-up “how” and “why” questions (Adams, 2015). Given the intrinsic nature of the method, interviews were carried out in a way to leave respondents enough space to expose aspects and opinions considered as important. A set of questions was predetermined and used to guide the respondent across the entire interview. Questions within each interview were organized to cover four Industry 4.0 macro-areas of discussion: the investment decision, the adopted technologies, the impact of technologies on the company and the relationship with Lean Production paradigm.

The results gathered through surveys and interviews were then integrated and compared with information coming from direct observation during sites visits, secondary sources and companies’ publications. In performing the case study design, issues related to the final quality of the research were carefully considered. As suggested by Yin, the following four tests with the related tactics were performed during the whole development phase: construct validity, internal validity, external validity and reliability (Yin, 2014).

Companies taking part in the studies were accurately selected in a way to guarantee the highest possible homogeneity of the sample. The focus was directed towards Italian-based companies involved in the production and assembly of low-volumes high-variety metal products and machinery. A total of 85 e-mails were sent from December 2018 to March 2019, receiving the willingness to participate in the study from 19 of them. All these companies presented revenues from the previous years below 250 million Euros, with only one exception that was kept anyway in the sample due to not differentiating behaviours.

As suggested by (Eisenhardt, 1989), the data analysis was conducted following a two-step procedure: analysis within single case data and search for cross-case patterns.

Before starting analysing and synthesizing results across cases, a single-case perspective was adopted. Each of the transcribed interviews was analysed through the use of a two-cycle coding procedure (Saldaña, 2013). In order to analyse the pattern of data within cases, the results from the coded interviews were systematically organized in a standardized template. According to (Voss, et al., 2002), having information arranged in this way helps researchers to look for explanation and causality, and to reach valid conclusions on the single case. Furthermore, this way of conducting the analysis
determined the creation of a standardized case study protocol that increased and facilitated the comparability of all 19 cases.

The first action of the cross-case analysis consisted of the evaluation of the data gathered through the Shah and Ward’s survey (Shah & Ward, 2007). In this phase, companies sharing a comparable level of Lean Production practices implementation were grouped in two different clusters by means of a cluster analysis. Out of a total of 19 companies, 10 presented a high average adoption level of Lean Production practices and were therefore labelled as High Lean (HL). The remaining 9 companies presented instead a low average adoption of Lean Production practices and were labelled as Low Lean (LL).

The obtained clusters, together with the results from the single case study analysis, allowed at this point to perform a cross-case synthesis of the results. According to (Voss, et al., 2002), the simplest and most effective method for this, is to construct an array, pick a group and to search for similarities and differences within the group. For that reason, five different matrices were developed, one for each research question. The first dimension was filled with the observations and their related state of Lean implementation. The other dimension contained instead the variables describing the five research questions. By crossing observations and variables, the matrices were therefore completed leveraging the results from the single-case analysis. In that way, patterns across cases were systematically identified and examined, enhancing the generalizability of the conclusions.

**Preliminary Findings**

The cross-case analysis helped in highlighting some shared patterns among companies belonging to the research sample. Even though some hybrid behaviours can be identified, each of the two clusters presented some unique and differentiating features.

Low Lean companies consider Industry 4.0 as a stand-alone phenomenon. They leverage this wave of technological innovation as an opportunity to reach results that are not necessarily overlapped with the Lean Production ones. In particular, substituting outdated machines, coping with saturated production capacity and filling gaps in the data are the key drivers for investments. For that reason, the most discussed performance improvements refer to productivity and efficiency, as showed in figure 1. On the other hand, High Lean companies mainly interpret the fourth industrial revolution as an opportunity for further pushing Lean Production to a higher level, commonly referred to as Lean 4.0. For that reason, the drivers and performance improvement associated with this path are the ones typically considered by Lean Production, such as flexibility, efficiency and quality increase (figure 1).
Conclusions
In the authors’ view, this study could create a step forward in understanding the impact that Lean Production could have on the Industry 4.0 transformation, therefore enriching the framework by (Buer, et al., 2018). Behaviours and choices of companies with different Lean implementation levels were analysed and compared on five Industry 4.0 dimensions, highlighting common patterns and differences. In addition to the theoretical contribution, the obtained results can also represent a possible guide for companies involved in the Industry 4.0 transformation for performing benchmark analysis and directing their investments.

The main limitations of this research are three. Firstly, due to the selected research methodology, there is a lack of statistical generalization capacity. Secondly, other variables influencing the choices of companies in terms of Industry 4.0 might have been neglected, such as external market conditions, macro-economic situations or specific cost-benefit analyses. In this case, an attempt to reduce the impact of this limitation was made by trying to consider a set of similar companies in terms of products, locations, sectors and volumes. Thirdly, besides secondary information sources and direct observation on the field, no multiple points of view were considered in performing each case study.

Future researchers could replicate the same study to compare the results obtained in different countries or sectors. Moreover, the case study could be enriched by considering other characteristics of the companies’ behaviour in terms of Industry 4.0 transformation, such as quantitative information on the investments or a more disaggregated categorization of Industry 4.0 technologies.

Abstract

New formats of retail stores continue to emerge, in order to better meet the needs of consumers. In Brazil, the Cash & Carry format occupied a leading position due to the high growth in number of stores and billing volume. This research aimed to characterize the value chain of the Cash & Carry format in Brazil, in comparison to the traditional physical stores in search of the justification for this phenomenon. Through a documentary research, the ten largest retail chains of the country and their brands of physical stores and wholesale stores were analysed, in order to construct the presented models.

Keywords: Supply Chain Management; Cash & Carry; Value Chain

Introduction

Retail organizations are diverse and new forms continue to emerge so that consumers can now buy goods and services in a wide variety of stores (Da Conceição, 2018). The idea of cash & carry, better known as "Cash & Carry" in Brazil, came into being in Europe and was more developed in the United States from 1980 onwards. The idea came from the following understanding: having a store capable of bringing the desired product to small retailers or objective consumers, without offering any services but with a more robust mix of products (Napoleão, 2017).

According to Abad (2016) and Napoleão (2017), Brazilian families has preferred the "Cash & Carry" to the supermarket and hypermarket. This research aims to characterize the chain of values and the format Cash & Carry, demonstrating the main advantages obtained by this business model in comparison to the traditional physical retail that justify its recent rise and its impacts in the retail supply chain in Brazil. The contribution of the results obtained here derives from the example of this operation in an emerging country.
**Literature Review**

Chain of Values For an examination of the activities performed and the way they interact, for a broad approach and identification of the main process flows of the company, the chain of values can be introduced as a systematic tool for such an evaluation.

According to Porter (1990: 31): The value chain disaggregates a company into its strategically important activities so that it can understand cost behavior and existing and potential sources of differentiation. A company gains competitive advantage by performing these strategically important activities at a cheaper or better way than the competition.

The performance of the value chain represents a process of differentiation between companies and their processes and the establishment of competitive advantages. Figure 1 illustrates the value chain model proposed by Porter (1990).

![Value Chain Model, Porter (1990)](image)

*Figure 1 – Value Chain Model, Porter (1990)*

Primary activities are those involved in the physical creation of the product and its sale and transfer to the buyer, as well as after-sales service. In any company, primary activities can be divided into five generic categories: (1) internal logistics: the activities associated with the receipt, storage and distribution of inputs in the product, such as material handling, warehousing, inventory control, fleet scheduling, vehicles and return to suppliers; (2) operations: the activities associated with the transformation of the inputs into the final product, such as working with machines, packaging, assembly, equipment maintenance, testing, printing and production operations; (3) external logistics: the activities associated with the collection, storage and physical distribution of the product to buyers, such as storage of finished products, material handling, delivery vehicle operations, order processing and programming; (4) marketing and sales: these are the activities associated with providing a means by which buyers can buy the product and induce them to do so, such as advertising, promotion, sales force, quotation, channel selection, channel relationships and pricing; and (5) technical assistance: these are activities associated with the provision of service to enhance or maintain the value of the product, such as installation, repair, training, parts supply and product adjustment.

Support activities can be divided into four generic categories. Like the primary activities, each category of support activities can be divided into a series of activities of
value that are distinct and specific to a particular company. The generic categories of support activities are:

(1) acquisition: refers to the function of purchasing inputs used in the company's value chain, not to the purchased inputs themselves. Inputs purchased include raw materials, supplies and other consumer items, as well as assets such as machinery, laboratory equipment, office equipment and buildings. Although these acquired inputs are commonly associated with primary activities, they are present in each value activity, including supporting activities;

(2) technology development: it consists of several activities that can be broadly grouped together in efforts to perfect the product and process. The development of technology related to the product and its characteristics can support the entire production chain;

(3) human resource management: consists of activities involved in the recruitment, hiring, training, development and compensation of all types of personnel. Human resource management affects competitive advantage in any company, through its role in determining qualifications and the cost of hiring and training; and

(4) company infrastructure: consists of a number of activities, including general management, planning, finance, accounting, legal, government affairs and quality management. Infrastructure, unlike other support activities, generally supports the entire production chain and not just individual activities.

Porter (1990) relates an advantage to value creation, that is, the competitive advantage arises from the value that a company can create for its buyers and that exceeds the cost of manufacturing the company and provides the difference between a firm's offer and that of others.

From the evolution of Supply Chain to Cash & Carry

When looking to analyse the dynamics and structure of the chain of supermarkets, it is necessary, at first, to understand some basic concepts that guide the actions of the products and services that are in networks. The need to understand the performance scenario is fundamental for assertive and optimized decision making throughout the chain.

By understanding the organizations and the ways that these are instituted, it becomes perceptible to understand the dynamics and structure of the business and therefore outline the strategies needed to gain competitiveness. The understanding of economic reality requires interpretations that are based on a systemic environment, which involves not only the parts, but the whole and their interrelations (Capra & Jakobsen, 2017).

Antonialli et al. (2016) infer that it is emphasized as the importance of studies on productive chains requires evaluations of both economic and technical operations throughout the stages of production and consumption of goods, ranging from (organizational, institutional, consumer) environments that permeate the production chain, essential for the construction of the competitive advantage of the chain (Antonialli et al, 2016).

Although dynamics is different from that of the Supermarket Supply Chain, these studies converge to the same point, being applied to all sectors, which are the structures of their respective chains (Zylbersztajn, 2005). By using the concepts of chains, production systems and coordinated subsystems, the expansion of volumes of empirical research volumes, both national and international, was evident from the 1980s to the present day. Whether in agro-industrial systems or in any other organization, they all employ the concept of continuous production steps, from the raw material to the finished product, in order to guide their analysis (Andrade, 2015).
The supply chain, according to the Supply Chain Council (2002), infers that "the supply chain covers all efforts involved in the production and delivery of an end product from the vendor supplier to the customer's customer" (Machline, 2011). Thus, typical transactions and the influence of institutional and organizational environments (which are defined as determinants of competitiveness) are common to all chains, regardless of the theoretical conceptualization (Zylbersztajn, 2000).

This relationship between supplier, producer and client creates and models the organizational and institutional environment, from which it is intrinsically linked to the cultural environment and the consumer environment, as shown in figure 1. Thus, the Supply Chain can be understood as the "main cell" in all production dynamics of products or services goods, since each chain link is affected, directly or indirectly, by any actions that affect one of its agents.

When we turn the perspective to retailing in the dynamism of information and interpersonal relations, new approaches emerge not only in the academic environment, but also in the commercial relations and the Cash & Carry is one of those results coming from the modifications in the organizational and institutional environments, as mentioned above.

Cash & Carry
According to Oliveira, Lima-Filho and Watanabe (2013), it is understood as Cash & Carry being the format of store known in Brazil for being a mixed operation of wholesale and retail, of which its actions are intended to serve preferentially, purchase (Silva, 2017).

In addition, it is important to note that the quality of the food service is not limited to the food service sector. According to Broud (2016) and Levy (2000), Cash & Carry is understood to be: The "Cash & Carry" is a phenomenon nowadays, mainly in Brazil, this model joins features of wholesale retail and aims to provide products with lower prices to the client to offer good services. This model does not have a refined structure, the design is low cost and its focus is on "pay and carry" (Broud, 2016; Levy, 2000).

Napoleão (2017) advocates that over the years, the development of this type of business has brought from new purchasing systems to adoption of new practices, such as the agglomeration of additional services added to the physical structure of the store, and in this way, it is possible offer not only cheaper products, but also, better quality services whose situation ends up adding more value to the enterprise.

Methodology
This work, in terms of its concept, is characterized as qualitative, through documentary analysis as scientific articles, as well as reports of specialized journals in the field, descriptive-exploratory. This infers that this type of research seeks to understand a reality that has not yet been studied, in which one can describe how the phenomena related to it occur (Gomes, 2006; Reis, 2018).

Pimentel (2001), shows us that studies based on documents as primordial material, be they bibliographic reviews or historiographical research, extract from them all the analysis, organize them and interpret them according to the objectives of the proposed research, giving them the specific treatment in order to corroborate with the object of study (Pimentel, 2001). Garcia Gutierrez (1984) apud Junior, Medeiros & Augusta (2017), reflects on documentary analysis as "all recognition and study that is made of a document, requiring an identification of the physical characteristics, which would be the form, and the intellectuals, the content". These elements corroborate the establishment of the best method to organize all the "information" expressed in the document (JUNIOR, Medeiros & Augusta, 2017).
It was applied in this work the analysis of documents such as scientific articles, books and reports in magazines or nationally recognized electronic sites that dealt with the theme of evolution and modification in the structures and dynamics of the retail chain and seek to understand what the current panorama of the transition traditional market of the hyper and supermarkets for the recent cards.

As a study delimitation, we opted to work on the analysis with the top 10 retail chains in Brazil's supermarket or hypermarket sector, according to the Brazilian Retail and Consumer Society (Sbvc, 2017). From the list obtained, company flags were tabulated in a spreadsheet and classified according to their size and sales format (small retail, super / hypermarkets, cash backs, etc.). In order to obtain a broad analysis specifically of the cash cards, the analysis of the discount cards that make up the Brazilian Association of Wholesale Carriers (Abaas, 2017) was included in the analysis. Below, the table 1 presents the flags chosen for the analysis.

From the choice of the sample, the electronic websites and news related to the respective flags were searched and the data obtained were classified in a spreadsheet, so that the specific characteristics of each company were allocated according to each activity of the value chain. Then, the data collected and classified were submitted to content analysis according to Bardin (1977), and the content analysis categorization was based on Porter's value chain proposal (1990).

**Findings and Discussion**

In analyzing the Brazilian retail supply chain over the last decades, it is notorious to realize that there has been a restructuring between distribution channels both among internal and external agents and, therefore, shaping the structure and dynamics of the latter. With this, several consumers have migrated their shopping environment, but mostly inserted in the super / hyper format for the retail and small retail formats.

This fact can be evidenced when it is observed that the largest retail groups operating in Brazil started to enter this market more intensively over the years, especially in the
infrastructure and locality models of their stores. To better elucidate this phenomenon, the section will be presented in three stages. The first presents the comparisons of traditional retail value chains versus the retail value chain. Subsequently, the traditional structure of the Brazilian retail chain is presented, followed by the characterization of the chain after the rise.

The retail versus retail chain of value - Traditional structure of the retail chain in Brazil

The Cash & Carry in Brazil, although recent, presents a highly dynamic and increasingly comprehensive structure. The distribution channels between the suppliers of inputs, products or services to the final customer, generate impacts at all levels of the chain. The more complex and long the relationships between the agents that feed the chain, the more financial and managerial resources will be needed, and this is the dynamics of the traditional retail model in Brazil, where the acquisition, inventory, distribution and sale management of products of the supermarkets, presents in its great majority, like an extensive and pushed system. Figure 1 summarizes the distribution channels of the products in the traditional retail markets in Brazil.

Retail Chain - Previous View

![Figure 1 - Traditional structure of the retail chain in Brazil](image)

In this model, the product manufacturer presents itself not only as the one who produces a particular product, but also becomes a stockist (in this case, stockist would mean the manufacturer as being the maintainer of the products in its own physical structure for later distribution) and sometimes acts as a distributor to the wholesale or traditional retailer. The Wholesale in turn supplies the small retailers that make the products available to customers, replacing them from time to time. The same happens with traditional retail, where the products are stored at the disposal of the final customer. In this model, the interfaces between the links in the supply chain show an increase in the final cost of the product, since each agent must receive a value for transportation, inventory and / or resale of the products to final customers.

Losses, low optimization of inventory management and costs, is recurrent in this type of marketing. Sometimes this commonly used structure has certain barriers that raise costs throughout the chain, as explained above. Linked to this favor, chain coordination
becomes fragile because it has several links between agents, which, due to the complexity of coordination conditioned to the various factors, can generate countless losses due to the organizational environment that this chain is inserted.

In addition, the operational costs of the distribution operations mean that the products that reach the end of the chain have an additional level of intermediation and consequently an added value that ultimately increases the final price of the product to the final consumer.

Current structure of the retail chain in Brazil
At Cash & Carry sector, dynamics and coordination of the chain become leaner, with the optimization of the distribution and storage of products. In the meantime, it is worth stressing with the performance of the chain is more dynamic, both the product outputs and the search for these products by the end customer. This coordination of the chain reinforces the considerations of the Value Chain proposed by Porter (1990) and demonstrate the impacts that the operations both internal and external, modify the organizational and institutional environment of the retail chain as a whole.

Thus, stores denominated Cash & Carry become the link between the manufacturer and final consumer, presenting not only as a retail store, but also as a wholesale center and as a Distribution Center (CD - It would be inferred that it is a warehouse whose purpose is to manage the inventory of goods in the fixed distribution (Abralog, 2016; Do Nascimento et al., 2018).). This changes the whole structure of internal logistics, operations and supplier, vendor and consumer relations. In this sense, Cash & Carry is a protagonist in relation to the position in the supply chain, since it occupies in a concentrated and strategic way, a new location in the structure of the chain. Figure 2 demonstrates the Chain Supply Chain and its structural arrangement differentiated from the traditional chain.

Retail Chain - Current View

![Retail Chain - Current View](image)

*Figure 1 - Current structure of the retail chain in Brazil – By Authors*

Notorious is the concentration of the agents under a single player that are nets of Cash & Carry. These, in turn, have the following characteristics: 1) attacked; 2) Retail and 3)
Distribution Center for himself as well as the small and medium retailers of the surrounding region. This explains the growth of this type of commercialization in recent years in Brazil, since in addition to reducing the costs of maintenance, personnel and charges with CD’s, the cash cards provide a greater mix of products in a single structure and increase the capillarity of distribution of the products.

In addition to providing support to small retailers, the final consumer is also impacted by the quantity / price ratio, where more quantity, lower price than the cash cards provide and corroborates for the maintenance of small retail stores with quick purchases in small quantities and (which does not, on certain occasions, also exempt the consumer from purchasing small quantities in the card in certain situations or preferential).

This new arrangement solidifies the trend of the expansion of the Cash & Carry in Brazil, because it meets the assumptions of the Brazilian consumer (be it the final or internal consumer of the chain), which is the question of price. As the prices are better in the wholesale account, one can then refute, at first, that the card is a fad, but a new business model that emerges to consolidate over time.

**Delimitations and Suggestions**

This research was limited to a brief illustrative analysis of the structure and dynamics of the supply chain in Brazil, since the incipient studies are about this topic in depth and, thus, propose new perspectives and considerations about the Cash & Carry Brazilian. However, the limitation was only limited to some academic articles available and also focused on specialized magazines in Brazilian wholesale and retail.

As a suggestion for future research, it is the search for correlating international and national articles (if there is one) to understand the coordination of this chain and the economic, financial and social impacts that the attack provides to the region in which it is installed, such as employability, cost and inventory, logistic cost, among other determinants. Moreover, the authors of this work sought to demonstrate the Cash & Carry chain as a whole in its physical structure, but without neglecting or omitting, as shown in figures 2 and 3, the profound changes that online retailing causes and will cause in retail as a everything.

Thus, it is suggested that further studies are about what impacts online retailing can impact on the retail strategies, as well as, to understand the dynamics of Online Retail Supply Chain in the interfaces between supplier and buyer, restructuring the organizational and institutional environment of retail trade.

**Conclusions**

Cash & Carry, although widespread around the world for more than two decades, presents substantial growth in Brazil only from 2012 to the present day. However, the Brazilian retail sector is not in line with this expansion, since only large groups started to emerge for this new modality that is Cash & Carry. The perception of traditional retailers needs to be reviewed and, above all, studied and disseminated in their planning and management strategies so that there is no disappearance of traditional retails or even the bankruptcy of several of these, due to a strong and massive competition resulting from credit cards.

Since the Brazilian consumer is more closely linked to the prices of the products, the Cash & Carrys appear as an innovative and comprehensive business model, providing a more balanced inventory management between a push-pull management, since the latter occurs more strongly in the traditional retail. This leads to a reduction in the costs and concentration of the products in the own cards that not only replenish their stores in their gondolas, but also have their own stock at the same time, as well as serving as a CD for small retailers, that is, an anchor for other people in the chain.
This all leads to a reduction in costs and optimization of transactions across all interfaces, which today, is a matter of survival of most businesses. Thus, the exponential growth of Brazilian cash loans is more like a market trend than just fad or punctual actions of large corporations. The dynamics of the current relations are getting faster and faster and adapting to the new trends is and will be, in most cases, the threshold between the success or failure of the cash advance in Brazil.

**A NEW PRODUCT-PROCESS MATRIX:**
To explore why the ecosystem concepts are needed

Yongjiang Shi (ys@eng.cam.ac.uk)
Institute for Manufacturing, Cambridge University, Cambridge CB3 0FS, UK

**Abstract**
The Product-Process Matrix (P-PM) as a strategic manufacturing analytic tool has been with us for forty years since it was published in Harvard Business Review in 1979. The model has soon become not only one of the essential theoretical foundations for manufacturing strategy but also one of the core practical factory design tools. This paper seeks to develop a new version of P-PM by combining it with Ansoff’s corporate strategy model (1965) in order to demonstrate the new frontier of the discipline and the linkages of emerged and emerging industrial systems in the last forty years.

**Keywords:** Product-process matrix (P-PM), industrial systems, ecosystems, life cycle

**Introduction**
The Product-Process Matrix (P-PM) model scientifically synthesizes and systematically visualizes the compatible relationships between different types of products and various factory production systems (Hayes and Wheelwright, 1969). The model has soon become not only one of the essential theoretical foundations for manufacturing strategy but also one of the core practical factory design tools. Although the authors might not be the people firstly found the strategic compatible relationships between products and their production systems, the P-PM model was the first one systematically and concisely visualizes and details the relationships. The P-PM model has laid down a corner stone for the current production and operations management (P/OM) discipline, influencing basic textbook structures and knowledge organization. It even provides a strong hint guiding many followers to explore emerging types of industrial systems, such as international manufacturing networks, (global) supply chains, and global engineering networks.

However, the best way to celebrate an existing theory is to generate new vitality to it by extending it to new territories or linking it with emerging industrial systems. This paper seeks to develop a new version of P-PM based up the original one in order to demonstrate the new linkages of emerged and emerging industrial systems in the last forty years. Like the original P-PM, this paper is also keen to explore the deep science and various scenarios to design and govern the new industrial systems.

The original motivations to explore the new P-PM is inspired by three threads as the followings:
- In the last forty years, the industrial systems have been diversified and adapted from the traditional factory based system significantly and dramatically.
- In the last ten years, business ecosystem researches have emerged in many innovation and strategy related disciplines although the main stream of P/OM hasn’t response in a very significant way.
- Ansoff’s classical strategic management matrix (1965) has provided another key dimension in order to enrich the original P-PM model as innovation and strategic upgrading with different types of industrial systems.

These threads helped the paper set up its general research question as – “based on the original P-PM, could a new version of P-PM be developed in order to capture the main industrial systems and explore their product-process relationships?”

**Literature Review**

Classical Porter’s value chain (1985) is a firm based industrial system with value-added input-transformation-output process supported by other company functions. This industrial system provides an essential foundation to ensure the outputs (products and/or services) can be delivered effectively and efficiently. The whole POM body of knowledge is about how to design/construct, operate/deliver, and improve/adapt the industrial system (value chain) (Slack et al, 2013). The value chain is the core part of the POM, but it has been usually neglected because POM people pay more attentions to its subsystems rather than its totality.

During the last two decades, however, the business globalisation has transformed manufacturing industry and its industrial systems completely. Many POM researchers have involved in the explorations and theorisation. The Figure 1 demonstrates the value chain based industrial systems’ transformations, which diversifies linear input-output system into various types of networks. At this moment, the research scopes have been further extended into 3-dimensional space as illustrated in the Figure 2 as the manufacturing value chain has been considered.

![Figure 1: Manufacturing System Evolution Matrix and Key Drivers](image-url)

Global Value Chain (GVC) research work (Gereffi, Humphrey, and Sturgeon, 2005) explores and enriches the understandings of different types of international and inter-firm collaborative networks (Figure 3) illustrating a spectrum from traditionally vertical integrated firm towards classical free market. Interestingly, more and more emerging configurations of GVC appear between the extreme ends of the spectrum. The research highlights extended and adapted value chains during the globalisation. And cross-firm collaborated value chains are emerging as the powerful competitive industrial systems.
Business globalisation triggers developing countries catching-up. China has been an excellent example, particularly in mobile phone industry. Zhu and Shi as well as other scholars have explored the Shanzhai phenomenon in the Pearl River Delta region (2010). Their observations demonstrate more dynamic pictures about industrial system formation and dissolution according to fast changing technology and product. The dynamics of industrial systems and their quick reconfigurations have inspired people to pay more attentions not only to the value chain and its establishment but also to the behind enabling infrastructures that strategically function supporting system and nurtures emerging industrial systems. People give this new kind of supportive infrastructure a very imaginative terminology – business ecosystem. This term has further extended POM boundaries from industrial system towards its ecosystem or environment.

Business ecosystem concept was firstly suggested by Moore (1996). But, to certain degree, his vision as shown in the Figure 4 was not very far away from an extended supply chain model in POM. Even most recently, Adner and his colleagues seem to not strategically differentiate the fundamental distinction between supply networks and business ecosystems. Adner’s complementor consideration only provides minor improvements to the existing supply chain management theories. The main streams of
studies about business ecosystems fail to breakthrough the principal supply chain boundary and to exploit the conceptual potentials of business ecosystem.

In summary, the above brief literature reviews highlight the value chain or industrial system have been updating and transforming in the last thirty years. What are the implications of the manufacturing evolution to practitioners and academicians? Has the mission of value chain based industrial system been changed, or the value creation mechanisms and business principles changed? How many typical types of industrial systems are existing and can be identified to understand? One of the clear conclusions can be that there are many theoretical gaps in the new forms of value chains. We need to explore their evolutions and understand them more systematically.

Based on Ansoff’s corporate strategy model considering the relationship existing and emerging customers and firms’ products, the Figure 5 illustrates a new two-by-two matrix entitled with New Product-Process Matrix (NP-PM). The NP-PM horizontal dimension represents Products and their change from existing one (a certain state) towards a new one (usually an uncertain state). The vertical dimension represents Processes (in another term, an industrial systems) and their changes from existing towards a new. Both dimensions are quite similar to the Ansoff Model’s dimensions seeking to capture the business changes or innovations.

The New Product-Process Matrix can be understood as dynamic transformations from the original P-PM (product-factory) state when a company has its established products and processes towards three very different directions.

- At the original circumstance (the bottom-left quadrant) with existing products and processes, the company can completely follow the classical P-PM model as it is from a factory oriented situation as a starting point.

- Along the vertical dimension upwards towards the up-left quadrant, it is a circumstance that the company changes its industrial systems based on its established products. In this quadrant, many researches have explored many different types of new industrial systems including international manufacturing networks and inter-firm supply chains and/or both international and inter-firm value networks (Rudlberg and Olhager, 2003; Shi, 2004).
- Along the horizontal dimension changing towards the bottom-right quadrant, the circumstance is that the company seeks to develop new products based on existing industrial systems (factory). The established new product development approach of course can be adopted within this quadrant. However, new mass customization approach also can be adopted to enrich the company’s choices for competitive advantages (MacCarty, et al 2003).

- The final up-right quadrant has both serious challenges from product and process with new and uncertainty characteristics. For mainstream P/OM community, it hasn’t found any effective solution to cope with the challenges yet. However, is this the place for the new concept of business ecosystem that provides very interesting and inspiration to tackle the uncertainties?

Research Design: phenomenon capturing and analysis

In order to empirically explore the changes of value chain during the globalisation and inter-firm collaboration, a research programme was set up to address the following research question – “could the new version of P-PM illustrated in the Figure 5 be developed in order to capture the main industrial systems and explore their product-process relationships?”. The answer could be very obvious and positive. However, the general research question actually aims to achieve two strategic objectives. The first is to understand more about the adapted value chain or industrial system in order to systematically understand why, what and how the value chains have evolved. The second
is to strategically integrate and analyse our existing industrial data set developed in the last 15 years based on continuous observations in several industrial sectors in China.

Considering its exploratory characteristics of the research question, insightful case observation approach is seriously considered. The essential criteria for case selection are: (1) the targeted case should be fast changing or adapting itself, which can potentially help to identify, capture, and understand significant changes of the value chain; (2) the case studies had better to be a relatively narrow in terms of region and sector, which can be convenient to observe and follow; (3) the observed value chains had better to have a larger industrial impact, which demonstrates the new value chains have their significances in both practice and theory.

Based on the above criteria, the mobile phone industry in China, particularly in its Pearl River Delta (PRD) Region, was selected. A serial longitudinal, in-depth regional based, and multiple dimensional case observations have been adopted since the year 2000 in order to a holistic view about the value chains and their evolutions. The key units of the case studies include the following three different levels:

1. The Chinese regional evolutionary studies: Based on the mobile phone industry evolutions in China, the following four stages of industry development can be identified including:
   - Multinational corporations foreign direct investments in China, like Motorola operations in Tianjin TEDA from mid-1980s to mid-1990s;
   - Chinese domestic corporations catching-up, like Bird (BoDao) based in YRD from late-1990s to mid-2000s;
   - Chinese Shenzhen Shanzhai Phenomenon in PRD from 2007 to 2012; and
   - Xiaomi emergence from Zhongguancun High Tech Park after 2012;

2. The four representative development phases and flagship companies are taken as the unit of analysis to explore each phase’s key events and particularly the value chain statues and transformations;

3. Each phase and the related representative company’s key value chain partners and environmental supporting systems are also investigated in order to capture the comprehensive pictures of value chain formation and adaptations in an ecosystem context. The phases (2) and (3) form an ecosystem based holistic stories reflecting the value chain collaboration formation and adaptation in the phases.

By following the individual case and its value chain transformations as well as its regional and key organisational changes, a holistic picture about value chain transformations can be described and potentially further analysed. The four phase cross-case analyses along the time dimension can provide a longitudinal picture for better understanding the evolutionary journey of the value chain adaptations.

The detailed case descriptions and analysis have been deliberately omitted in order to concentrate on key findings and related discussions. The authors can be contacted for further information enquiries.

**Research Findings**

In the last 25 years, the global mobile phone industry has experienced three main transformations, and four different phases could be identified as shown Figure 6. Each phase has its very unique and dominant type of value chain:

**In the very early phase (1990 – 2000),** the global mobile phone industry was dominated by multinational corporations (MNCs) like Motorola and later Nokia and Samsung. Vertical integrated value chain model based on individual firm has been heavily adopted in the MNCs. Nokia as an emerging new star in the industry changed the traditional Motorola’s internal vertical integrated value chain and started to focus more on the
downstream of the value chain by adopting wider range of components and modules outsourcing.

**In the starting phase (2000 – 2005),** when Nokia demonstrated its highly variety of end products and very efficient supply chain against Motorola, Chinese mobile phone pioneer companies such as Bird and later Jinli still mainly tried to learn from Motorola by adopting the vertical integrated value chain. They tries to achieve the transformation from imitation to innovation (like the secondary innovation methodology). There are some breakthroughs but not very significant. But this phase was still very critical for China because it laid down a solid foundation including all kinds of components and assembly as well testing capabilities.

**In the middle phase (2007 – 2012),** Chinese Shan-Zhai phenomenon transformed the global mobile phone industry fundamentally (Zhu and Shi, 2010). The so-called “blank brand” or “white brand” phones, contract manufacturing service providers, and quickly formed networks forced people rethink about Porter’s value chain model. The Value Constellation Model (Normann and Ramirez, 1993) might be better for capturing the core of the emerging phenomenon.

**In the current phase (2012 – 2015),** it was very soon the industry moved to the smart phone or mobile computing age that nurtured more diversified business models and value chain patterns. Apple and Chinese similar version – Xiaomi – have pushed people’s attentions a wider range of business scope for not only the value chain operations but its designs and creations. Our observations on Xiaomi have helped us to notice both a new type of value chain including three key building blocks – supply parts, demand parts, and intermediaries – as well as the formation or evolution of the value chain from more fragmented social networks. We tend to call this extended value chain as a business ecosystem that continuously creates innovative ideas and nurtures new value chains (or industrial systems) to deliver highly efficient products and services.

Based on the four stages observations, three key transformation processes have been also identified in Figure 4. They are entitled with:

- Global Outsourcing (Globalization);
- Specialisation and Reconfiguration (Global-localization); and
- From Social Networks to Industrial Systems (Ecosystemization).

The third transformation can be illustrated in the following diagram (Figure 7). The diagram also presents the 4th phase of value chain highlighting the dynamics and transformation in a business ecosystem. The holistic model of business ecosystem in the diagram offers an integrated representation of value creation mechanism in the currently uncertain and quick-changing world.

The four case studies representing the four evolutionary phases in the mobile phone industry development in China have clearly demonstrated very different types of value chains or industrial systems. The different types of value chain organisations or governances have demonstrated very different strategic capabilities to cope with industrial innovation and customer demand changes.

The clear phenomenon of industrial systems adaptions and evolutions have inspired us to have better understandings about the value chains and their relationship with the ecosystems:

(1) There are many different types of industrial systems; but the most fundamental one can be represented as the value chain.

(2) During the globalisation, the value chain has also adapted itself to various types of forms, such as Figure 1, 2, 3, 4 and 5 illustrate; however, the core part of value chain is always an input-process-output such kind if industrial systems.
(3) The core part of POM discipline is to design/construct, operate, and improve an industrial system that can deliver product and/or service effectively and efficiently.

(4) The current challenges that POM discipline is facing are:
   1) Industrial systems emerge and evolve too many diversified forms. It is more critical to understand the new types of industrial systems than to better operate the classical ones, particularly from research perspective.
   2) The POM priorities have been changed from operations and deliver towards industrial system (re)design, (re)configuration, and (re)constructions in a much faster way.
   3) Therefore, the business ecosystem emerges as a more essential unit of analysis or attention focus to reconfigure the new industrial system.

(5) More attentions focusing on business ecosystems implies that POM should have new extended system boundaries – not only industrial systems but also their ecosystems.

Discussions

Relationship between Industrial Systems and Business Ecosystems

Based on the observations of manufacturing system evolutions, the new system boundaries for the ecosystems can be recognized in order to cope with the uncertainties of both product and manufacturing system. A new generation of “product-process matrix” (Hayes and Wheelwright, 1975) can be proposed as the Figure 5 demonstrated to capture the new requirements. The business ecosystem as a solution for the new challenges is discussed to call for more research and understanding in POM community. The new matrix explains the role of the ecosystems in the POM body of knowledge.

From the Figure 5 – the New Product-Process Matrix, the business ecosystems do have their clear boundaries distinguishing from the classical industrial systems or value chains. In the top-right corner, it illustrates the Figure 5 dynamic characteristics. Both diagrams conceptually offer a new definition and vision about business ecosystem – a business ecosystem is an interconnected and interactive community and continuously nurtures new industrial systems to create business value.
New Research Directions and Approaches for Studying Business Ecosystems

POM has established very robust methodology to deconstruct and analyze a system. The similar approach and tools can be used for the business ecosystems. A simplified framework from the 6C Model (Rong, et al, 2015) can be used to address the following issues of business ecosystems (BEs):

- Context of BE: the purpose and boundary of BE
- Configuration of BE: including constructs/building blocks of BE, archetypes of BE, and key dynamic mechanisms of BE
- Capability of BE: strategic functions, health status, and potential key performance indicators (KPIs) of BE
- Change of BE: the adaptation and evolution paths and mechanisms

The Framework provides a new target and logic relationship to systematically explore the emergence of business ecosystems.

New Priority of Production and Operations Management (POM)

Based on the case observations and business ecosystem emergence, the paper also suggests that POM research and education need to shift the priority from established industrial system operations toward new industrial system design and reconfiguration. Traditionally, POM pays too much attention to existing system running and continuous improvement. The industrial trends show the changes are so unpredictable the radical now, especially in the emerging industries and developing regions. POM people no longer to have the previous luxury time to build up an industrial system and rely on it for a few decades without any significant restructuring. Business ecosystem concept and vision actually hint to all of us that it is much more critical for operations managers to continuously monitor the environmental changes and very quickly redesign and configure internal and external resources to form a new industrial system in order to capture the opportunity, take advantage of emerging technology, and/or exploit accessible resources.

This will fundamentally change POM body of knowledge, putting strategic thinking and system design as well as construction or configuration into much higher priority. The operations managers need new types of capabilities to satisfy the requirements.

Conclusion

The paper explores the new forms of international manufacturing networks. It finds business ecosystems are emerging to cope with the dramatic industry changes. In order to introduce the new pattern of industrial systems, this paper also systematically review and study the evolving value chain patterns with four stages and three transformative process. Such process includes 1) Global Outsourcing; 2) Specialisation and Reconfiguration; and 3) From Social Networks to Industrial Systems. The paper argues the evolved types of value chains provides new theoretical challenges in POM discipline and the new researches on business ecosystems as a new type of value chain can contribute management studies fundamentally. Besides the suggested future research directions in terms of business ecosystem theories, the paper alert the POM community that operations management task priority should be shifted from existing system operations toward new system strategic design and fast reconstruction. The NP-PM extends and original P-PM, captures the dynamics of product-process, and demonstrates different types of industrial systems and their relationships.
Acknowledgement
The longitudinal industrial studies has involved many collaborative organisations in the last 15 years. I appreciate their co-operations and generous supports and sharing! Particularly I thank for EC-HVEN research programme (Grand No. PIRSES-GA-2011-295130) and Chinese NSF research grants (No 71232013 and No 71402051) to provide research resources enabling a longer term research and collaboration.

Bricolage – managing operations in a resource constrained environment.

Chris Voss (cvoss@london.edu)
Warwick Business School
University of Warwick

Abstract

Even with good supply chain risk assessment and management processes, short-term resource shortages are not uncommon. Bricolage is an approach to dealing with managing in resource shortage environments, and has been widely studied in innovation, but not in operations. Although approaches such as inventory build-up and capacity planning to deal with such problems, we explore how the experience of bricolage can be applied in such contexts and what are the potential contexts in which they may be applied.

Keywords: Resource constraints, Bricolage

Introduction

The uncertainties in the United Kingdom have highlighted the possibility of temporary or longer term resource availability for both industry and individuals. This is potentially a particular issue for those organisations that have well developed lean supply chains. At the time of writing, companies, public sector organisations such as hospitals are beginning to stockpile parts, raw materials medicines etc., and some individuals are stockpiling medicines and food. Whether this will be necessary is not yet known.

We argue that it is important to explore what may be effective policies is such situations. One approach that has been studied in resource-constrained situations is bricolage. To date it has mainly been studied in the context of innovation (Witell Gebauer, Jaakkola, Hammedi, Patricio, and Perks, 2017; Linna, 2013). In this paper we examine how it might be more broadly applicable.

Bricolage

Bricolage is a term derived from the French verb bricoler (meaning "to putter about") and related to bricoleur, the French name for a jack-of-all-trades or handyman. Bricolage made its way from French to English during the 1960s. The concept of bricolage originated with the philosopher, Levi-Strauss (1966). He contrasted Engineers with Bricoleurs. An engineer follows set procedures and have a list of specific tools to carry out their work, in contrast, a bricoleur by definition is someone who uses ‘whatever is at hand’ and this repertoire of resource elements can be odd and heterogeneous (Lina 2013. Baker and Nelson (2005) describe bricolage as making do by applying combinations of whatever resources at hand to new problems and opportunities.
Bricolage is typically not a strategy that is chosen from alternatives, but one that is forced upon the organisation when there is constrained access or uncertain access to resources. Resources can include physical elements such as products, raw material, people and capability. There has been substantial research on the use and impact of bricolage in innovation. It has been argued that when confronted by resource scarcity, individuals can be more creative leading to innovation. Bricolage can enable the adaptive design process by making solutions to problems more achievable, by making critical resources more obtainable and by reducing costs (Vanevenhoven, Winkel, Malewicki, Dougan and Bronson, 2011). Baker and Nelson (2005) found that it explained many of the behaviours observed in small firms that were able to create something from nothing by exploiting physical, social, or institutional inputs that other firms rejected or ignored.

Contextual implications

Research on the impact of bricolage has focused on two main contexts. First, smaller firms who lack access to resource. Guo, Zhang and Guo (2018) argue that that medium-sized firms benefit less from bricolage than SMEs because they are more formalized and can afford standardized resources. If they rely too heavily on bricolage, they can fail to adopt the optimal solutions for the exploitation of recognizable opportunities. The second context is at the country level where there are inherent shortages of resources, in particular less developed countries. It has been argued that a selective bricolage approach can break through resource constraints while also establishing a base for firm growth. Instead of deploying bricolage capabilities consistently and repeatedly across multiple service innovation projects and entire NSD processes, organizations should use it selectively (Baker & Nelson, 2005, Witell et al. 2017).

In operations, the risk of resource shortages can occur from two sources, (1) risks arising from the problems of coordinating supply and demand, and (2) risks arising from disruptions to normal activities (Kleindorfer and Saad, 2009). A particular problem in recent years has been the risk associated with financial crises (Blome and Schoenherr, 2011). With increased amounts of outsourcing, a financial crisis can lead to supplier failure leading to higher risks of resource shortage.

There has been substantial study of supply chain risk in multiple contexts. Much of this has been focused on risk identification and risk management. There are a number of ways of categorising risk, for example, they can be known risks or unknown risks. Known risks may include supplier problems, quality failures, industrial action, factory process problems etc. Unknown risks such as natural disasters are those that are very difficult foresee. Short-term and non-forecast disruptions are often known as Glitches. “A supply chain disruption is an unintended, untoward situation, which leads to supply chain risk. For the affected firms, it is an exceptional and anomalous situation in comparison to every-day business. Depending on its severity other terms might be applied, e.g. glitch, disturbance, or crisis. It is triggered by an underlying disruptive event (or a series of such events). Since the resulting detriment is usually a function of time, supply chain disruptions involve time pressure implying that decisions for mitigation must be made swiftly” (Wagner and Bode, 2006 p303).

Supply chain risk assessment and risk management approaches would seem to be able to address and mitigate much of the potential resource shortages that could result. Bricolage approaches would seem to be most applicable when resource shortages are unexpected, and
difficult to mitigate. In operations this consistent with what has been described as glitches and where risk mitigation has failed and there are still severe resource shortages.

**Bricolage in operations**

Despite the wide research in innovation, bricolage has been neglected in operations. I first encountered a bricolage approach to operations many years ago in a presentation by a senior Hungarian expert during the communist era. He argued that at that time, there were shortages and uncertainties as to what would be available and that rather use sophisticated production planning systems, production was scheduled based on what was available. With hindsight, this was a bricolage approach.

Dealing with temporary or long-term resource constraints is likely to be a problem that many organisations will experience. Dealing with short-term resource shortages in operations has been studied by Morrison (2015). As he points out, resource constraint is commonplace in organizations, but resourceful and dedicated people find ways to do with what is available. He argues that, due to resource shortages, pressure on the person increases to find a way of accomplishing more tasks in the same amount of time, and their way of responding is through workarounds. Maybe surprisingly, this works in the short term. However, Morrison (2015) found that this can have severe negative consequences. Workers generating way of working round constraints such as resource shortages signals to management that more personnel are not needed and counteract requests for more resource, locking the organisation into a continued contexts of resource shortage and over time potentially leading to an enduring regime of poor performance. This behaviour is clearly one aspect of a bricolage approach. It also illustrates in an operations context the strengths and weaknesses that have been found in innovation – it works in the short-term but can lead to sub-optimal solutions.

“Manufacturers can reduce the occurrence of glitches in their operations by building capabilities to prevent them, yet mitigation capabilities are also needed to contain the effects of the glitches that will still inevitably occur every now and then” (Tenhiälä and Salvador, 2014 p437). They point out that “operational glitches constitute a major concern for manufacturing managers: minor glitches like late raw material deliveries or machine breakdowns are fairly common in most manufacturing environments yet they have potential to transform into big disruptions, unless they are mitigated effectively” (op.cit. p 438).

Although approaches such as inventory build-up can in part deal with such problems, Tenhiälä and Salvador (2014) examine interorganisational communication routines as a key glitch mitigation capability. They argue that although, consistent with Morrison’s (2015) work on workarounds, glitches should be dealt with as near as possible to their and point of origin, at the lowest possible level in the organisation, a local solution to a glitch is not always possible. Without effective communication of messages concerning the glitch it may not be possible to rapidly deal with it. They find that the use of formal communication channels mitigates the impact of glitches and this is supported by informal communication channels. This is consistent with one of the capabilities required for bricolage, networking with external partners, put forward by Witell et al. (2017).

**Discussion**

A useful analogy for bricolage in supply chains is supermarket delivery and cooking. Increasingly, many order from supermarkets for direct delivery to home. However, not
infrequently the items ordered are not in stock, so the supermarket substitutes something else or notifies the buyer that the item cannot be delivered. The result can be that plans for meals to be cooked have to be adjusted rapidly to reflect the actual supplies available. Alternatively other routes to supply could be sought such as visiting a different shop or just asking the next-door neighbour whether they have some of what is needed. This can be seen as a bricolage approach in the context of an unexpected supply failure.

Our review of Bricolage approaches and research on mitigation of short-term resource shortage shows a strong similarity between the two. This raises two questions, what can our knowledge of bricolage approaches add to what is already known about mitigating short-term resource shortage and second in what contexts should it be used.

**Bricolage capabilities**

Witell et al. (2017) argue that successful exploitation of bricolage in service innovation requires development of four capabilities: (i) actively addressing resource scarcity, (ii) making do with what is available, (iii) improvising when recombining resources, and (iv) networking with external partners (Baker & Nelson, 2005; Fisher, 2012; Linna, 2013). Morrison’s (2015) work provides additional insights into what bricolage activities and outcomes can be in an operational environment, in particular the positive and negative outcomes associated with workarounds. Having these capabilities will enable superior performance to others operating with the same resource constraints. We argue that these capabilities apply equally to the management of short-term operational resource shortages and glitches. Capabilities (ii) and (iii) are most easy to implement in a make to order or make to stock context, but may be very difficult in high volume lean production contexts. They require capabilities of production planning and control systems to re-programme schedules based on what is available.

However, Seynard, Baker, Seffens and Davidson (2014) point out that bricolage is frequently associated with outcomes that leave a lot to be desired such as second best solutions, maladaptation, inefficiency and slowness, and as Morrison (2015) points out, approaches such as workarounds work, but lead to sub-optimal solutions.

In conclusion, bricolage approaches should not a strategy that is chosen from alternatives, but one that is forced upon the organisation when there is constrained access or uncertain access to resources. The outcomes of their use can be sub-optimal. Unfortunately, short-term resource shortages are common occurrences in organisations. Thus, organisations may have to resort to bricolage approaches in such circumstances. Thus although such problems may fall into the supply chain risk category of unknowns, it is important that an organisation should have the capabilities outlined above to so as to be able to deal with resource shortages effectively.

This area, mitigating short term unexpected resource capabilities is one that requires further research and in particular the capabilities needed in different operational contexts. Study of how firms in the UK are dealing with the current uncertainty and risk may provide interesting insights.

Abstract

Slack and Lewis (2017) conceptualize Operations Strategy (OS) as reconciliation – i.e. recognizing the prima facie significance of both, the market- and the resource-perspective on strategy and aiming at harmonizing implications from the two. However, there is no study providing empirical data to understand if and how companies practically approach the goal of reconciliation in their strategy-process. This is both a practical as well as a theoretical problem. Addressing this deficit, in a first step this paper reports on the development of a scale for measuring the reconciliation process.

Keywords: Operations Strategy Process, Empirical Research in Operations Management

Introduction

Slack and Lewis (2017) conceptualize Operations Strategy (OS) as recognizing the prima facie significance of both, the market- and the resource-perspective on strategy and aiming at harmonizing implications from the two. They refer to their concept as reconciliation. From a practical point of view, reconciliation seems plausible since there is arguably no need for strategists, to strictly opt for only one approach to OS: a pure market- or pure resource-based perspective. Thun (2008) finds so-called hybrid strategy-types (i.e. strategies showing market- and resource-based characteristics) in the HPM-Database. Hence there is at least some empirical basis for the existence of reconciliation. The lack of insight on how to formulate a strategy that harmonizes the market- and resource-approach, however, is both a research deficit as well as a practical problem. This is in line with the general lack of a broad theoretical understanding for strategy processes (Chatha and Butt, 2015). In particular, there is no study, providing empirical data to understand if and how companies practically carry out reconciliation. Addressing this deficit in a first step this paper reports on the development of a scale for operationalizing the strategy process, particularly measuring the reconciliation process as conceptualized by Slack and Lewis (2017). Our main research question is: based on the existing OS process literature, how can the process of reconciliation be measured in a survey?

Literature Review
The body of OS literature is commonly divided into content (“what”) and process (“how”) studies (Dangayach and Deshmukh, 2001) (Chatha and Butt, 2015). Slack and Lewis (2017) prescriptive concept of a reconciling strategy approach refers to the goal of the content of strategy. Simply put, firms should make decisions in a way that best exploits the interplay between their competitive resources and the fulfillment of market requirements, leading to a sustainable performance advantage. This paper focuses on the question if there is also a process element to reconciliation, i.e. how companies try to approach this goal of a reconciled strategy. We refer to this as the process of reconciliation. The following review therefore focusses on relevant process contributions to the OS literature. Compared to the content literature, which is methodologically rich and split into many broadly discussed subthemes (da Silveria and Sousa, 2010), the theoretical foundations of the process theme are far less developed. In the latest review of OS articles in major journals, Chatha and Butt (2015) find that merely 15% of contributions deal with process topics. Barnes (2001) argues that the OS process literature tends to be prescriptive in nature, thus conceptually speaking about what should be done rather than empirically studying what companies do. Due to the generally increased use of quantitative and qualitative empirical studies in recent years (Chatha et al., 2018), the lack of descriptive studies has been addressed. However, there is still a lack of purely descriptive, empirical insights in the process literature (Jagoda and Kiridena, 2015) and especially regarding the specific concept of reconciliation. This presents a problem for theory building since practical issues and procedures are not considered, which, in turn, weakens academic relevance and input for practitioners. The specific aspect of the OS process we want to examine is strategy formulation, i.e. gathering and understanding information to come to a common understanding of a strategy. A large part of strategy formulation is constituted by research on alignment Chatha and Butt, (2015). Alignment comprises the sub-themes of aligning OS with business strategy (Joshi et al., 2003), aligning OS with other functional strategies (Weir et al., 2000) as well as alignment within the operations function, i.e. aligning strategic goal with operative actions (Choudhari et al., 2013). The rationale of all three alignment-concepts is that a harmonization between OS and the afore-mentioned elements leads to a sustainably improved business and manufacturing performance. We argue that Slack & Lewis (2017) reconciliation process differs from alignment in two dimensions. 1) the first two types of alignment refer to a harmonization between strategies (business strategy and other functional strategies respectively) and the third type to a harmonization of different levels of action (strategic versus operative). In contrast, reconciliation covers the harmonization of different approaches to strategy (market- and resource-based) within the same level of action (OS as functional strategy). 2) Particularly the first type of alignment implies directionality, i.e. OS is meant to align with business strategy, not vice versa. Reconciliation is balanced in that both strategy-approaches are initially equal and a focus on one or the other is only the potential outcome of the reconciliation process. Having stated these differences, the underlying rationale of harmonization is akin to both concepts. For operationalizing the reconciliation process we therefore draw on insights from alignment. The underlying rationale of harmonization is akin to both concepts. For operationalizing the reconciliation process we therefore draw on insights from alignment.

The positive effect of alignment on performance seems to be a commonly shared notion. (Anderson et al., 1991) (Weir et al., 2000) (Joshi et al., 2003) (Olhager et al., 2008). However, firms seem to struggle in reaching high overall levels of alignment reflecting the general difficulty of the strategy process as mentioned in the introduction of this paper. Weir et al., (2000), Sun and Hong (2002)and Hausman et al. (2002) show
that inter-functional harmony between OS and marketing strategy is caused by intensive communication between representatives from both functions as well the intensity of cooperation during their strategy process. Similarly, Weir et al., (2000) indicate the importance of inter-functional communication and cooperation to exploit benefits of alignment. Cheng and Musaphier (1996) out that reaching alignment is an iterative process of reviewing and validating information to come to conclusions regarding desirable strategic actions. We argue that the importance of communication and collaboration is that it fosters a learning process and facilitates that the access to information. This notion is supported by other contributions to OS (Berry et al., 1999) as well as older contributions to the management literature (Hambrick and Mason, 1984). To conclude, literature for serving as a basis for operationalizing the reconciliation process is scant. However, contributions to the field alignment yield preliminary insights into steps taken to harmonize different perspectives: i) communication with various information sources (to gather and validate information) and ii) cross-functional collaboration/decision-making (also to gather and validate information and create legitimacy for the potential strategy outcome). Referring to Slack & Lewis (2017) concept of reconciliation, we hypothesize that a process-element to reconciliation could materialize through gathering market- and resource-information (regarding an OS decisions problem) and validating this information with market- and resource-sources.

**Methodology**

Research Design Scale Development

Sound measurement development is critical for good survey-based science and is associated with numerous challenges (Forza, 2002). Addressing this, we follow an adapted, rigorous scale development approach designed by Menor and Roth (2007). As illustrated in figure 1, they report on a two-stage approach, with the ‘front-end’ designed to ensure face validity and inter-rater reliability and the ‘back-end’ leading to construct valid and reliable scales. The two stages are linked as face validity is a prerequisite of construct validity (Forza, 2002).

![Figure 1 – scale-development process adapted from Menor & Roth (2007)](image-url)
Just as with hypothesis testing, the basis for scale development is an analysis of the existing literature as discussed in the previous section. On this basis, we conducted expert interviews with five strategy professionals from three different manufacturing companies in Germany. We specifically asked them what their approach to the OS process has been in the past and how they carried out the steps they mentioned. According to the interviewees, the formation of OS is initiated by problem scoping (i.e. precisely describing the decision situation) followed by defining alternative courses of action (i.e. defining alternate scenarios) and finally by assessing the various scenarios. Problem scoping strongly relies on gathering and processing relevant qualitative and quantitative data on the strategic issue at hand. Defining and assessing scenarios is characterized as a highly communicative process, were stakeholders from various functions are involved to validate the data gathered in the first step. The experts’ descriptions of OS formulation is similar to the simple illustration of Slack & Lewis (2017). Further, communication flows across functions and cross-functional collaboration were stressed by experts corresponding to the rationale of the alignment literature presented above. The expert’s evaluation complemented these by adding the importance broad information from various sources. In sum, this led us to an operational definition of the reconciliation process: The balance of gathering and processing information on both, operations resources and market requirements to cross-functionally develop an understanding of the desired interplay between the two. Note that we combined the concept of alignment and harmonization with the concepts of market- and resource-based-strategies. Consequently, we hypothesize the reconciliation process to be measurable using six constructs:

- **Market-Information**: The significance of information regarding market requirements
- **Resource-Information**: The significance of information regarding operations capabilities
- **Market-Source**: The significance of market-related information sources
- **Resource-Source**: The significance of resource-related information sources
- **Functional Collaboration**: The extent of functional collaboration
- **Cross-Functional Collaboration**: The extent of cross-functional collaboration

**Front-End (Prior to Data Collection)**

Having defined our constructs, we generated items based on literature and expert interviews. Following Menor & Roth (2007) last ‘front-end’ step, we employed a modified Q-sort-method (McKeown and Thomas, 1988) to purify our items prior to sending out the questionnaire. In three rounds of item-sorting exercises we asked two subject-matter-experts (SMEs) in separate interviews to categorize a randomized list of items (Hinkin, 1998) based on their fit with the constructs. This led to nominal item-to-construct-mappings. Item-sorting allows for a quantitative measure of interrater reliability and face validity and has been advocated as a critical quality factor of survey research (Hardesty and Bearden, 2004). We interviewed representatives from academia in the first round and OS and supply chain professionals in round two and three. After each round, we calculated scores and based on these, refine definition, explanation or example of the items. First, we assess interrater reliability, i.e. the extent to which two SMEs agree on the classification of a specific item. Table 1 shows the results of our scores over all three rounds.
The interjudge agreement percentage is the ratio of pairwise agreements to the total number of pairwise judgements in one round. There is no established standard for this simple score, however a low percentage indicates confusion about the item. Cohen’s $k$ addresses the element of chance in the interrater agreement and Moore and Benbasat, (1991) note that a $k$-value greater than 0.65 is considered acceptable. Finally, Perrault and Leigh’s $I_r$ calculates with the number of categories an item was possibly mapped into. Here a value of 0.7 in exploratory designs is acceptable. As can be seen in table 1 threshold values are met after the second round of item-sorting. Note that values in all scores are comparably high, which is explained by item-sorting being carried out as an interview. Secondly, we checked for face validity on item-level (or substantive validity) (Anderson and Gerbing, 1991). We calculated the proportion of substantive agreement ($P_{sa}$) as well as the coefficient of substantive validity ($C_{sv}$). $P_{sa}$ is the proportion of experts that have correctly mapped the items to the designated construct with 1 being the maximum proportion of agreement. $C_{sv}$ additionally considers experts that have assigned the item to another construct, taking on values between -1 and 1. Each item not complying with threshold of values of 0.7 ($P_{sa}$) and 0.41 ($C_{sv}$) respectively were eliminated from the questionnaire. Finally, our initial pool of 42 items was reduced to 33 items representing the six constructs measuring the reconciliation process.

Using these items, we designed an online-questionnaire using freeonlinesurveys (https://freeonlinesurveys.com), containing not only our own items, but items inquiring about characteristics of the surveyed company, its contextual variables, its performance measures as well as its OS content. All these items are adapted from previous surveys, mainly the IMSS- or the HPM-survey, to ensure validity. Our unit of analysis is a manufacturing unit that has the autonomy to decide on strategy and, on an empirical level, a manufacturing plant. We sent out the questionnaire based on a convenience sample of 163 representatives of manufacturing plants involved in strategy-making, with a focus on the machine tooling- and automotive-sector. Each participant received a personalized e-mail along with a link to a survey that was open for eight weeks. We received 52 usable responses (32% response rate). We excluded three cases answering for non-German companies to avoid a country-bias and five cases due to sector (non-manufacturing), ending up with 44 cases. Three cases showed missing values which we estimated based on averages (Kaufman, 1985). 27 respondents represent the engineering sector (mainly machine tooling and automotive), 16 respondents other manufacturing companies (e.g. electronical devices) and 1 respondent is unclassified. Concerning positions of the respondents, 22 hold board executive positions (e.g. CEOs), 20 work in strategy-related positions (either as executive or task lead) and 2 are unclassified. The time a respondent is associated with the company she represents is on average 11 years and the time in the position indicated on average 8.6 years. One can therefore assume respondents to be experienced and knowledgeable about the surveyed content. 55% of responding companies have less and 45% more than 500 employees, making the sample

Back-End

Following Menor and Roth (2007) we analyzed the factor structure of our scale in an Exploratory Factor Analysis (EFA) and verified its internal consistency. EFA is an approach to structure data-sets through identifying groups of variables which are highly correlated with each other (Backhaus et al., 2018). Note that the precondition of both conventional EFA and Confirmatory Factor Analysis (CFA) is a reflective model. Following Backhaus et al. (2018), this means that the latent variable (e.g. market-information) influences the indicator variables (e.g. significance of customer requirements), rather than vice versa. Changes in the hypothesized construct thus also lead to changes in the measurement variables. For instance, the construct market-information is defined as the significance of market information during a strategy project. A firm values market-information because it (deliberately or not) addresses this information in its strategy process. Hence, this significance also drives the extent to which market-information is gathered. We therefore argue our model to be reflective.

As discussed below, the high correlation among indicator variables empirically supports our rationale. We entered item sets per question (i.e. three models with 2 hypothesized constructs respectively) and explored the factor structure using SPSS 24. As example, results for the EFA of the first model are summarized in table 2.
